**Bits 23:16 – CLKDIV[7:0]** LCD Controller Clock Divider

8-bit width clock divider for pixel clock (LCDPCLK). The pixel clock period formula is:

$$\text{LCDPCLK} = \text{source clock} / (\text{CLKDIV} + 2)$$

where source clock is the system clock when CLKSEL is written to '0', and 2x system\_clock when CLKSEL is written to '1'.

**Bit 13 – CGDISPP** Clock Gating Disable Control for the Post Processing Layer

| Value | Description  |
|-------|--|
| 0     | Automatic Clock Gating is enabled for the Post Processing Layer. |
| 1     | Clock is running continuously.                                   |

**Bit 11 – CGDISHEO** Clock Gating Disable Control for the High-End Overlay

| Value | Description   |
|-------|---|
| 0     | Automatic Clock Gating is enabled for the High-End Overlay Layer. |
| 1     | Clock is running continuously.                                    |

**Bit 10 – CGDISOVR2** Clock Gating Disable Control for the Overlay 2 Layer

| Value | Description  |
|-------|--|
| 0     | Automatic Clock Gating is enabled for the Overlay 2 Layer. |
| 1     | Clock is running continuously.                             |

**Bit 9 – CGDISOVR1** Clock Gating Disable Control for the Overlay 1 Layer

| Value | Description  |
|-------|--|
| 0     | Automatic Clock Gating is enabled for the Overlay 1 Layer. |
| 1     | Clock is running continuously.                             |

**Bit 8 – CGDISBASE** Clock Gating Disable Control for the Base Layer

| Value | Description   |
|-------|---|
| 0     | Automatic Clock Gating is enabled for the Base Layer. |
| 1     | Clock is running continuously.                        |

**Bit 3 – CLKPWMSEL** LCD Controller PWM Clock Source Selection

| Value | Description  |
|-------|--|
| 0     | The slow clock is selected and feeds the PWM module.   |
| 1     | The system clock is selected and feeds the PWM module. |

**Bit 2 – CLKSEL** LCD Controller Clock Source Selection

| Value | Description  |
|-------|--|
| 0     | The asynchronous output stage of the LCD controller is fed by the System Clock.    |
| 1     | The asynchronous output state of the LCD controller is fed by the 2x System Clock. |

**Bit 0 – CLKPOL** LCD Controller Clock Polarity

| Value | Description   |
|-------|---|
| 0     | Data/Control signals are launched on the rising edge of the pixel clock.  |
| 1     | Data/Control signals are launched on the falling edge of the pixel clock. |

### 38.7.2 LCD Controller Configuration Register 1

**Name:** LCDC\_LCDCFG1  
**Offset:** 0x04  
**Reset:** 0x00000000  
**Property:** Read/Write

| Access | R/W       | R/W | R/W | R/W | R/W | R/W | R/W       | R/W |
| Reset  | 0         | 0   | 0   | 0   | 0   | 0   | 0         | 0   |

**Bits 25:16 – VSPW[9:0]** Vertical Synchronization Pulse Width  
 Width of the LCDVSYNC pulse, given in number of lines. Width is (VSPW+1) lines.

**Bits 9:0 – HSPW[9:0]** Horizontal Synchronization Pulse Width  
 Width of the LCDHSYNC pulse, given in pixel clock cycles. Width is (HSPW+1) LCDPCLK cycles.

### 38.7.3 LCD Controller Configuration Register 2

**Bits 25:16 – VBPW[9:0]** Vertical Back Porch Width

This field indicates the number of lines at the beginning of the Frame. The blanking interval is equal to VBPW lines.

**Bits 9:0 – VFPW[9:0]** Vertical Front Porch Width

This field indicates the number of lines at the end of the Frame. The blanking interval is equal to (VFPW +1) lines.

### 38.7.4 LCD Controller Configuration Register 3

**Name:** LCDC\_LCDCFG3  
**Offset:** 0x0C  
**Reset:** 0x00000000  
**Property:** Read/Write

| Reset  | 0        | 0   | 0   | 0   | 0   | 0   | 0         | 0   |

**Bits 26:16 – RPF[10:0]** Number of Active Row Per Frame

Number of active lines in the frame. The frame height is equal to (RPF+1) lines.

**Bits 10:0 – PPL[10:0]** Number of Pixels Per Line

Number of pixels in the frame. The number of active pixels in the frame is equal to (PPL+1) pixels.

### 38.7.6 LCD Controller Configuration Register 5

**Name:** LCDC\_LCDCFG5  
**Offset:** 0x14  
**Reset:** 0x00000000  
**Property:** Read/Write

|        | DISPDLY        | DITHER |       |       | DISPPOL | VSPDLYE | VSPDLYS | VSPOL     |
| Access | R/W            | R/W    |       |       | R/W     | R/W     | R/W     | R/W       |
| Reset  | 0              | 0      |       |       | 0       | 0       | 0       | 0         |

**Bits 23:16 – GUARDTIME[7:0]** LCD DISPLAY Guard Time  
 Number of frames inserted during startup before LCDDISP assertion.  
 Number of frames inserted after LCDDISP reset.

**Bit 13 – VSPHO** LCD Controller Vertical synchronization Pulse Hold Configuration

| Value | Description   |
|-------|---|
| 0     | The vertical synchronization pulse is asserted synchronously with horizontal pulse edge.            |
| 1     | The vertical synchronization pulse is held active one pixel clock cycle after the horizontal pulse. |

**Bit 12 – VSPSU** LCD Controller Vertical synchronization Pulse Setup Configuration

| Value | Description   |
|-------|---|
| 0     | The vertical synchronization pulse is asserted synchronously with horizontal pulse edge.          |
| 1     | The vertical synchronization pulse is asserted one pixel clock cycle before the horizontal pulse. |

**Bit 10 – PP** Post Processing Enable

| Value | Description                                       |
|-------|---|
| 0     | The blended pixel is pushed into the output FIFO. |

| Value | Description  |
|-------|--|
| 1     | The blended pixel is written back to memory, the post-processing stage is enabled. |

### Bits 9:8 – MODE[1:0] LCD Controller Output Mode

| Value | Name         | Description                                 |
|-------|--------------|---|
| 0     | OUTPUT_12BPP | LCD Output mode is set to 12 bits per pixel |
| 1     | OUTPUT_16BPP | LCD Output mode is set to 16 bits per pixel |
| 2     | OUTPUT_18BPP | LCD Output mode is set to 18 bits per pixel |
| 3     | OUTPUT_24BPP | LCD Output mode is set to 24 bits per pixel |

### Bit 7 – DISPDLY LCD Controller Display Power Signal Synchronization

| Value | Description   |
|-------|---|
| 0     | The LCDDISP signal is asserted synchronously with the second active edge of the horizontal pulse. |
| 1     | The LCDDISP signal is asserted asynchronously with both edges of the horizontal pulse.            |

### Bit 6 – DITHER LCD Controller Dithering

| Value | Description                         |
|-------|-------------------------------------|
| 0     | Dithering logical unit is disabled  |
| 1     | Dithering logical unit is activated |

### Bit 4 – DISPPOL Display Signal Polarity

| Value | Description |
|-------|-------------|
| 0     | Active High |
| 1     | Active Low  |

### Bit 3 – VSPDLYE Vertical Synchronization Pulse End

| Value | Description   |
|-------|---|
| 0     | The second active edge of the Vertical synchronization pulse is synchronous with the second edge of the horizontal pulse. |
| 1     | The second active edge of the Vertical synchronization pulse is synchronous with the first edge of the horizontal pulse.  |

### Bit 2 – VSPDLYS Vertical Synchronization Pulse Start

| Value | Description  |
|-------|--|
| 0     | The first active edge of the Vertical synchronization pulse is synchronous with the second edge of the horizontal pulse. |
| 1     | The first active edge of the Vertical synchronization pulse is synchronous with the first edge of the horizontal pulse.  |

### Bit 1 – VSPOL Vertical Synchronization Pulse Polarity

| Value | Description |
|-------|-------------|
| 0     | Active High |
| 1     | Active Low  |

---

---

**Bit 0 – HSPOL** Horizontal Synchronization Pulse Polarity

| <b>Value</b> | <b>Description</b> |
|--------------|--------------------|
| 0            | Active High        |
| 1            | Active Low         |

### 38.7.7 LCD Controller Configuration Register 6

**Name:** LCDC\_LCDCFG6  
**Offset:** 0x18  
**Reset:** 0x00000000  
**Property:** Read/Write

|        |              |     |     |     |        |           |     |     |
|--------|--------------|-----|-----|-----|--------|-----------|-----|-----|
| Bit    | 31           | 30  | 29  | 28  | 27     | 26        | 25  | 24  |
|        |              |     |     |     |        |           |     |     |

|        | PVMCVAL[7:0] |     |     |     |        |           |     |     |
| Access | R/W          | R/W | R/W | R/W | R/W    | R/W       | R/W | R/W |
| Reset  | 0            | 0   | 0   | 0   | 0      | 0         | 0   | 0   |
| Bit    | 7            | 6   | 5   | 4   | 3      | 2         | 1   | 0   |
|        |              |     |     |     | PWMPOL | PWMP[2:0] |     |     |
| Access |              |     |     |     | R/W    | R/W       | R/W | R/W |
| Reset  |              |     |     |     | 0      | 0         | 0   | 0   |

**Bits 15:8 – PVMCVAL[7:0]** LCD Controller PWM Compare Value

PWM compare value. Used to adjust the analog value obtained after an external filter to control the contrast of the display.

**Bit 4 – PWMPOL** LCD Controller PWM Signal Polarity

This bit defines the polarity of the PWM output signal.

| Value | Description  |
|-------|--|
| 0     | The output pulses are low level.   |
| 1     | The output pulses are high level (the output is high whenever the value in the counter is less than value CVAL). |

**Bits 2:0 – PWMP[2:0]** PWM Clock Prescaler

Selects the configuration of the counter prescaler module.

| Value | Name   | Description   |
|-------|--------|---|
| 000   | DIV_1  | The counter advances at a rate of $f_{\text{COUNTER}} = f_{\text{PWM\_SELECTED\_CLOCK}}$    |
| 001   | DIV_2  | The counter advances at a rate of $f_{\text{COUNTER}} = f_{\text{PWM\_SELECTED\_CLOCK}}/2$  |
| 010   | DIV_4  | The counter advances at a rate of $f_{\text{COUNTER}} = f_{\text{PWM\_SELECTED\_CLOCK}}/4$  |
| 011   | DIV_8  | The counter advances at a rate of $f_{\text{COUNTER}} = f_{\text{PWM\_SELECTED\_CLOCK}}/8$  |
| 100   | DIV_16 | The counter advances at a rate of $f_{\text{COUNTER}} = f_{\text{PWM\_SELECTED\_CLOCK}}/16$ |
| 101   | DIV_32 | The counter advances at a of rate $f_{\text{COUNTER}} = f_{\text{PWM\_SELECTED\_CLOCK}}/32$ |

# SAMA5D2 Series

## LCD Controller (LCDC)

---

---

| Value | Name   | Description   |
|-------|--------|---|
| 110   | DIV_64 | The counter advances at a of rate $f_{\text{COUNTER}} = f_{\text{PWM\_SELECTED\_CLOCK}}/64$ |

### 38.7.8 LCD Controller Enable Register

**Name:** LCDC\_LCDEN  
**Offset:** 0x20  
**Reset:** –  
**Property:** Write-only

#### Bit 3 – PWMEN LCD Controller Pulse Width Modulation Enable

| Value | Description     |
|-------|-----------------|
| 0     | No effect       |
| 1     | PWM is enabled. |

#### Bit 2 – DISPEN LCD Controller DISP Signal Enable

| Value | Description                  |
|-------|------------------------------|
| 0     | No effect                    |
| 1     | LCDDISP signal is generated. |

#### Bit 1 – SYNCEN LCD Controller Horizontal and Vertical Synchronization Enable

| Value | Description   |
|-------|---|
| 0     | No effect   |
| 1     | Both horizontal and vertical synchronization (LCDVSYNC and LCDHSYNC) signals are generated. |

#### Bit 0 – CLKEN LCD Controller Pixel Clock Enable

| Value | Description |
|-------|-------------|
| 0     | No effect   |

# SAMA5D2 Series

## LCD Controller (LCDC)

---

---

| Value | Description                            |
|-------|--|
| 1     | Pixel clock logical unit is activated. |

### 38.7.9 LCD Controller Disable Register

**Name:** LCDC\_LCDDIS  
**Offset:** 0x24  
**Reset:** –  
**Property:** Write-only

|        |    |    |    |    |        |         |         |        |

#### Bit 11 – PWMRST LCD Controller PWM Reset

| Value | Description  |
|-------|--|
| 0     | No effect.   |
| 1     | Resets the PWM module. The duty cycle may be violated. |

#### Bit 10 – DISPRST LCD Controller DISP Signal Reset

| Value | Description             |
|-------|-------------------------|
| 0     | No effect.              |
| 1     | Resets the DISP signal. |

#### Bit 9 – SYNCRST LCD Controller Horizontal and Vertical Synchronization Reset

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | Resets the timing engine. The horizontal and vertical pulse widths are both violated. |

#### Bit 8 – CLKRST LCD Controller Clock Reset

| Value | Description  |
|-------|--|
| 0     | No effect.   |
| 1     | Resets the pixel clock generator module. The pixel clock duty cycle may be violated. |

---

**Bit 3 – PWMDIS** LCD Controller Pulse Width Modulation Disable

| Value | Description                                 |
|-------|---|
| 0     | No effect.                                  |
| 1     | Disables the pulse width modulation signal. |

**Bit 2 – DISPDIS** LCD Controller DISP Signal Disable

| Value | Description               |
|-------|---------------------------|
| 0     | No effect.                |
| 1     | Disables the DISP signal. |

**Bit 1 – SYNCDIS** LCD Controller Horizontal and Vertical Synchronization Disable

| Value | Description  |
|-------|--|
| 0     | No effect.   |
| 1     | Disables the synchronization signals after the end of the frame. |

**Bit 0 – CLKDIS** LCD Controller Pixel Clock Disable

| Value | Description               |
|-------|---------------------------|
| 0     | No effect.                |
| 1     | Disables the pixel clock. |

### 38.7.10 LCD Controller Status Register

**Name:** LCDC\_LCDSR  
**Offset:** 0x28  
**Reset:** 0x00000000  
**Property:** Read-only

|        |    |    |    |        |        |         |        |        |
|--------|----|----|----|--------|--------|---------|--------|--------|

|        |    |    |    |        |        |         |        |        |
| Bit    | 23 | 22 | 21 | 20     | 19     | 18      | 17     | 16     |
|        |    |    |    |        |        |         |        |        |
| Access |    |    |    |        |        |         |        |        |
| Reset  |    |    |    |        |        |         |        |        |
|        |    |    |    |        |        |         |        |        |
| Bit    | 15 | 14 | 13 | 12     | 11     | 10      | 9      | 8      |
|        |    |    |    |        |        |         |        |        |
| Access |    |    |    |        |        |         |        |        |
| Reset  |    |    |    |        |        |         |        |        |
|        |    |    |    |        |        |         |        |        |
| Bit    | 7  | 6  | 5  | 4      | 3      | 2       | 1      | 0      |
|        |    |    |    | SIPSTS | PWMSTS | DISPSTS | LCDSTS | CLKSTS |
| Access |    |    |    | R      | R      | R       | R      | R      |
| Reset  |    |    |    | 0      | 0      | 0       | 0      | 0      |

#### Bit 4 – SIPSTS Synchronization In Progress

| Value | Description   |
|-------|---|
| 0     | Clock domain synchronization is terminated.   |
| 1     | Synchronization is in progress. Access to the registers LCDC_LCDCCFG[0..6], LCDC_LCDEN and LCDC_LCDDIS has no effect. |

#### Bit 3 – PWMSTS LCD Controller PWM Signal Status

| Value | Description              |
|-------|--------------------------|
| 0     | PWM is disabled.         |
| 1     | PWM signal is activated. |

#### Bit 2 – DISPSTS LCD Controller DISP Signal Status

| Value | Description               |
|-------|---------------------------|
| 0     | DISP is disabled.         |
| 1     | DISP signal is activated. |

#### Bit 1 – LCDSTS LCD Controller Synchronization status

| Value | Description                |
|-------|----------------------------|
| 0     | Timing engine is disabled. |

# SAMA5D2 Series

## LCD Controller (LCDC)

---

---

| Value | Description               |
|-------|---------------------------|
| 1     | Timing engine is running. |

### Bit 0 – CLKSTS Clock Status

| Value | Description              |
|-------|--------------------------|
| 0     | Pixel clock is disabled. |
| 1     | Pixel clock is running.  |

### 38.7.11 LCD Controller Interrupt Enable Register

**Name:** LCDC\_LCDIER  
**Offset:** 0x2C  
**Reset:** –  
**Property:** Write-only

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Enables the corresponding interrupt.

|        |    |    |      |           |    |       |        |        |        |
|--------|----|----|------|-----------|----|-------|--------|--------|--------|
| Bit    | 31 | 30 | 29   | 28        | 27 | 26    | 25     | 24     |        |
|        |    |    |      |           |    |       |        |        |        |
| Access |    |    |      |           |    |       |        |        |        |
| Reset  |    |    |      |           |    |       |        |        |        |
|        |    |    |      |           |    |       |        |        |        |
| Bit    | 23 | 22 | 21   | 20        | 19 | 18    | 17     | 16     |        |
|        |    |    |      |           |    |       |        |        |        |
| Access |    |    |      |           |    |       |        |        |        |
| Reset  |    |    |      |           |    |       |        |        |        |
|        |    |    |      |           |    |       |        |        |        |
| Bit    | 15 | 14 | 13   | 12        | 11 | 10    | 9      | 8      |        |
|        |    |    | PPIE |           |    | HEOIE | OVR2IE | OVR1IE | BASEIE |
| Access |    |    | W    |           |    | W     | W      | W      | W      |
| Reset  |    |    | –    |           |    | –     | –      | –      | –      |
|        |    |    |      |           |    |       |        |        |        |
| Bit    | 7  | 6  | 5    | 4         | 3  | 2     | 1      | 0      |        |

| Access |    |    |      | W         |    |       | W      | W      | W      |
| Reset  |    |    |      | –         |    |       | –      | –      | –      |

**Bit 13 – PPIE** Post Processing Interrupt Enable

**Bit 11 – HEOIE** High-End Overlay Interrupt Enable

**Bit 10 – OVR2IE** Overlay 2 Interrupt Enable

**Bit 9 – OVR1IE** Overlay 1 Interrupt Enable

**Bit 8 – BASEIE** Base Layer Interrupt Enable

**Bit 4 – FIFOERRIE** Output FIFO Error Interrupt Enable

**Bit 2 – DISPIE** Powerup/Powerdown Sequence Terminated Interrupt Enable

**Bit 1 – DISIE** LCD Disable Interrupt Enable

**Bit 0 – SOFIE** Start of Frame Interrupt Enable

### 38.7.12 LCD Controller Interrupt Disable Register

**Name:** LCDC\_LCDIDR  
**Offset:** 0x30  
**Reset:** –  
**Property:** Write-only

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Disables the corresponding interrupt.

|        |    |    |      |           |    |       |        |        |        |
|--------|----|----|------|-----------|----|-------|--------|--------|--------|
| Bit    | 31 | 30 | 29   | 28        | 27 | 26    | 25     | 24     |        |
|        |    |    |      |           |    |       |        |        |        |
| Access |    |    |      |           |    |       |        |        |        |
| Reset  |    |    |      |           |    |       |        |        |        |
|        |    |    |      |           |    |       |        |        |        |
| Bit    | 23 | 22 | 21   | 20        | 19 | 18    | 17     | 16     |        |

**Bit 13 – PPID** Post Processing Interrupt Disable

**Bit 11 – HEOID** High-End Overlay Interrupt Disable

**Bit 10 – OVR2ID** Overlay 2 Interrupt Disable

**Bit 9 – OVR1ID** Overlay 1 Interrupt Disable

**Bit 8 – BASEID** Base Layer Interrupt Disable

**Bit 4 – FIFOERRID** Output FIFO Error Interrupt Disable

**Bit 2 – DISPID** Powerup/Powerdown Sequence Terminated Interrupt Disable

**Bit 1 – DISID** LCD Disable Interrupt Disable

**Bit 0 – SOFID** Start of Frame Interrupt Disable

### 38.7.13 LCD Controller Interrupt Mask Register

**Name:** LCDC\_LCDIMR  
**Offset:** 0x34  
**Reset:** 0x00000000  
**Property:** Read-only

The following configuration values are valid for all listed bit names of this register:

0: The corresponding interrupt is disabled.

1: The corresponding interrupt is enabled.

|        |    |    |      |           |       |        |        |        |   |   |
|--------|----|----|------|-----------|-------|--------|--------|--------|---|---|
| Bit    | 31 | 30 | 29   | 28        | 27    | 26     | 25     | 24     |   |   |
|        |    |    |      |           |       |        |        |        |   |   |
| Access |    |    |      |           |       |        |        |        |   |   |
| Reset  |    |    |      |           |       |        |        |        |   |   |

#### Bit 13 – PP Post Processing Raw Interrupt Status

| Value | Description  |
|-------|--|
| 0     | No Post Processing interrupt detected since last read of LCDC_PPISR  |
| 1     | Indicates that Post Processing interrupt is pending. This flag is reset as soon as the LCDC_PPISR is read. |

#### Bit 11 – HEO High-End Overlay Raw Interrupt Status

| Value | Description  |
|-------|--|
| 0     | No High-End layer interrupt detected since last read of LCDC_HEOISR.   |
| 1     | Indicates that a High-End layer interrupt is pending. This flag is reset as soon as the LCDC_HEOISR is read. |

#### Bit 10 – OVR2 Overlay 2 Raw Interrupt Status

| Value | Description   |
|-------|---|
| 0     | No Overlay 2 layer interrupt detected since last read of LCDC_OVR2ISR.  |
| 1     | Indicates that an Overlay 2 layer interrupt is pending. This flag is reset as soon as the LCDC_OVR2ISR is read. |

#### Bit 9 – OVR1 Overlay 1 Raw Interrupt Status

| Value | Description   |
|-------|---|
| 0     | No Overlay 1 layer interrupt detected since last read of LCDC_OVR1ISR.  |
| 1     | Indicates that an Overlay 1 layer interrupt is pending. This flag is reset as soon as the LCDC_OVR1ISR is read. |

**Bit 8 – BASE** Base Layer Raw Interrupt Status

| Value | Description   |
|-------|---|
| 0     | No base layer interrupt detected since last read of LCDC_BASEISR.   |
| 1     | Indicates that a base layer interrupt is pending. This flag is reset as soon as the LCDC_BASEISR is read. |

**Bit 4 – FIFOERR** Output FIFO Error

| Value | Description   |
|-------|---|
| 0     | No underflow has occurred in the output FIFO since last read of LCDC_LCDISR.                            |
| 1     | Indicates that an underflow has occurred in the output FIFO. This flag is reset after a read operation. |

**Bit 2 – DISP** Powerup/Powerdown Sequence Terminated Interrupt Status

| Value | Description   |
|-------|---|
| 0     | Powerup sequence or powerdown sequence has not yet terminated.  |
| 1     | Indicates the powerup sequence or powerdown sequence has terminated. This flag is reset after a read operation. |

**Bit 1 – DIS** LCD Disable Interrupt Status

| Value | Description   |
|-------|---|
| 0     | Horizontal and vertical timing generator has not yet been disabled.   |
| 1     | Indicates that the horizontal and vertical timing generator has been disabled. This flag is reset after a read operation. |

**Bit 0 – SOF** Start of Frame Interrupt Status

| Value | Description   |
|-------|---|
| 0     | No detection since last read of LCDC_LCDISR.  |
| 1     | Indicates that a start of frame event has been detected. This flag is reset after a read operation. |

### 38.7.15 LCD Controller Attribute Register

**Name:** LCDC\_ATTR  
**Offset:** 0x3C  
**Reset:** –  
**Property:** Write-only

#### Bit 13 – PPA2Q Post-Processing Update Add To Queue

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | Add the descriptor pointed to by the LCDC_PPHEAD register to the descriptor list. |

#### Bit 11 – HEOA2Q High-End Overlay Update Add To Queue

| Value | Description  |
|-------|--|
| 0     | No effect.   |
| 1     | Add the descriptor pointed to by the LCDC_HEOHEAD register to the descriptor list. |

#### Bit 10 – OVR2A2Q Overlay 2 Update Add to Queue

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | Add the descriptor pointed to by the LCDC_OVR2HEAD register to the descriptor list. |

#### Bit 9 – OVR1A2Q Overlay 1 Update Add To Queue

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | Add the descriptor pointed to by the LCDC_OVR1HEAD register to the descriptor list. |

**Bit 8 – BASEA2Q** Base Layer Update Add To Queue

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | Add the descriptor pointed to by the LCDC_BASEHEAD register to the descriptor list. |

**Bit 5 – PP** Post-Processing Update Attribute

| Value | Description                     |
|-------|---------------------------------|
| 0     | No effect.                      |
| 1     | Update the PP window attribute. |

**Bit 3 – HEO** High-End Overlay Update Attribute

| Value | Description                      |
|-------|----------------------------------|
| 0     | No effect.                       |
| 1     | Update the HEO window attribute. |

**Bit 2 – OVR2** Overlay 2 Update Attribute

| Value | Description                       |
|-------|-----------------------------------|
| 0     | No effect.                        |
| 1     | Update the OVR2 window attribute. |

**Bit 1 – OVR1** Overlay 1 Update Attribute

| Value | Description                       |
|-------|-----------------------------------|
| 0     | No effect.                        |
| 1     | Update the OVR1 window attribute. |

**Bit 0 – BASE** Base Layer Update Attribute

| Value | Description                        |
|-------|------------------------------------|
| 0     | No effect.                         |
| 1     | Update the BASE window attributes. |

### 38.7.16 Base Layer Channel Enable Register

**Name:** LCDC\_BASECHER  
**Offset:** 0x00000040  
**Reset:** –  
**Property:** Write-only

#### Bit 2 – A2QEN Add To Queue Enable

| Value | Description   |
|-------|---|
| 0     | No effect   |
| 1     | Indicates that a valid descriptor has been written to memory, its memory location should be written to the DMA head pointer. The A2QSR status bit is set to one, and it is reset by hardware as soon as the descriptor pointed to by the DMA head pointer is added to the list. |

#### Bit 1 – UPDATEEN Update Overlay Attributes Enable

| Value | Description  |
|-------|--|
| 0     | No effect  |
| 1     | Updates windows attributes on the next start of frame. |

#### Bit 0 – CHEN Channel Enable

| Value | Description             |
|-------|-------------------------|
| 0     | No effect               |
| 1     | Enables the DMA channel |

**38.7.17 Base Layer Channel Disable Register**

**Name:** LCDC\_BASECHDR  
**Offset:** 0x00000040  
**Reset:** –  
**Property:** Write-only

**Bit 8 – CHRST** Channel Reset

| Value | Description   |
|-------|---|
| 0     | No effect   |
| 1     | Resets the layer immediately. The frame is aborted. |

**Bit 0 – CHDIS** Channel Disable

| Value | Description   |
|-------|---|
| 0     | No effect   |
| 1     | Disables the layer at the end of the current frame. The frame is completed. |

### 38.7.18 Base Layer Channel Status Register

**Name:** LCDC\_BASECHSR  
**Offset:** 0x00000048  
**Reset:** 0x00000000  
**Property:** Read-only

#### Bit 2 – A2QSR Add To Queue Status

| Value | Description              |
|-------|--------------------------|
| 0     | Add to queue not pending |
| 1     | Add to queue pending     |

#### Bit 1 – UPDATESR Update Overlay Attributes In Progress Status

| Value | Description  |
|-------|--|
| 0     | No update pending                                    |
| 1     | Overlay attributes will be updated on the next frame |

#### Bit 0 – CHSR Channel Status

| Value | Description    |
|-------|----------------|
| 0     | Layer disabled |
| 1     | Layer enabled  |

**38.7.19 Base Layer Interrupt Enable Register**

**Name:** LCDC\_BASEIER  
**Offset:** 0x0000004C  
**Reset:** –  
**Property:** Write-only

The following configuration values are valid for all listed bit names of this register:  
0: No effect.

1: Enables the corresponding interrupt.

|        |                            |     |      |     |      |     |    |    |
|--------|----------------------------|-----|------|-----|------|-----|----|----|
| Bit    | 31                         | 30  | 29   | 28  | 27   | 26  | 25 | 24 |
|        | [Greyed out register bits] |     |      |     |      |     |    |    |
| Access |                            |     |      |     |      |     |    |    |
| Reset  |                            |     |      |     |      |     |    |    |
| Bit    | 23                         | 22  | 21   | 20  | 19   | 18  | 17 | 16 |

| Reset  |                            | –   | –    | –   | –    | –   |    |    |

**Bit 6 – OVR** Overflow Interrupt Enable

**Bit 5 – DONE** End of List Interrupt Enable

**Bit 4 – ADD** Head Descriptor Loaded Interrupt Enable

**Bit 3 – DSCR** Descriptor Loaded Interrupt Enable

**Bit 2 – DMA** End of DMA Transfer Interrupt Enable

### 38.7.20 Base Layer Interrupt Disable Register

**Name:** LCDC\_BASEIDR  
**Offset:** 0x00000050  
**Reset:** –  
**Property:** Write-only

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Disables the corresponding interrupt.

|        |    |     |      |     |      |     |    |    |
|--------|----|-----|------|-----|------|-----|----|----|

**Bit 2 – DMA** End of DMA Transfer Interrupt Mask

### 38.7.22 Base Layer Interrupt Status Register

**Name:** LCDC\_BASEISR  
**Offset:** 0x00000058  
**Reset:** 0x00000000  
**Property:** Read-only

|        |    |     |      |     |      |     |    |    |
|--------|----|-----|------|-----|------|-----|----|----|
| Bit    | 31 | 30  | 29   | 28  | 27   | 26  | 25 | 24 |
|        |    |     |      |     |      |     |    |    |
| Access |    |     |      |     |      |     |    |    |
| Reset  |    |     |      |     |      |     |    |    |
| Bit    | 23 | 22  | 21   | 20  | 19   | 18  | 17 | 16 |
|        |    |     |      |     |      |     |    |    |
| Access |    |     |      |     |      |     |    |    |
| Reset  |    |     |      |     |      |     |    |    |
| Bit    | 15 | 14  | 13   | 12  | 11   | 10  | 9  | 8  |
|        |    |     |      |     |      |     |    |    |
| Access |    |     |      |     |      |     |    |    |
| Reset  |    |     |      |     |      |     |    |    |
| Bit    | 7  | 6   | 5    | 4   | 3    | 2   | 1  | 0  |
|        |    | OVR | DONE | ADD | DSCR | DMA |    |    |
| Access |    | R   | R    | R   | R    | R   |    |    |
| Reset  |    | 0   | 0    | 0   | 0    | 0   |    |    |

#### Bit 6 – OVR Overflow Detected

| Value | Description  |
|-------|--|
| 0     | No overflow occurred since last read of LCDC_BASEISR             |
| 1     | An overflow occurred. This flag is reset after a read operation. |

#### Bit 5 – DONE End of List Detected

| Value | Description  |
|-------|--|
| 0     | No End of List condition occurred since last read of LCDC_BASEISR              |
| 1     | End of List condition has occurred. This flag is reset after a read operation. |

#### Bit 4 – ADD Head Descriptor Loaded

| Value | Description  |
|-------|--|
| 0     | No descriptor has been loaded since last read of LCDC_BASEISR  |
| 1     | The descriptor pointed to by the LCDC_BASEHEAD register has been loaded successfully. This flag is reset after a read operation. |

#### Bit 3 – DSCR DMA Descriptor Loaded

| Value | Description   |
|-------|---|
| 0     | No descriptor has been loaded since last read of LCDC_BASEISR |

---

---

| Value | Description   |
|-------|---|
| 1     | A descriptor has been loaded successfully. This flag is reset after a read operation. |

**Bit 2 – DMA End of DMA Transfer**

| Value | Description   |
|-------|---|
| 0     | No end of DMA transfer has been detected since last read of LCDC_BASEISR      |
| 1     | End of Transfer has been detected. This flag is reset after a read operation. |

### 38.7.23 Base DMA Head Register

**Name:** LCDC\_BASEHEAD  
**Offset:** 0x0000005C  
**Reset:** 0x00000000  
**Property:** Read/Write

|             |     |     |     |     |     |     |     |     |
|-------------|-----|-----|-----|-----|-----|-----|-----|-----|
| Bit         | 31  | 30  | 29  | 28  | 27  | 26  | 25  | 24  |
| HEAD[29:22] |     |     |     |     |     |     |     |     |
| Access      | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset       | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit         | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
| HEAD[21:14] |     |     |     |     |     |     |     |     |
| Access      | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset       | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit         | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   |
| HEAD[13:6]  |     |     |     |     |     |     |     |     |
| Access      | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset       | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit         | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
| HEAD[5:0]   |     |     |     |     |     |     |     |     |
| Access      | R/W | R/W | R/W | R/W | R/W | R/W |     |     |
| Reset       | 0   | 0   | 0   | 0   | 0   | 0   |     |     |

**Bits 31:2 – HEAD[29:0] DMA Head Pointer**  
 The Head Pointer points to a new descriptor.

### 38.7.24 Base DMA Address Register

**Name:** LCDC\_BASEADDR  
**Offset:** 0x00000060  
**Reset:** 0x00000000  
**Property:** Read/Write

|             |     |     |     |     |     |     |     |     |
|-------------|-----|-----|-----|-----|-----|-----|-----|-----|
| Bit         | 31  | 30  | 29  | 28  | 27  | 26  | 25  | 24  |
| ADDR[31:24] |     |     |     |     |     |     |     |     |

| Reset       | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

**Bits 31:0 – ADDR[31:0]** DMA Transfer Start Address  
 Frame buffer base address

### 38.7.25 Base DMA Control Register

**Name:** LCDC\_BASECTRL  
**Offset:** 0x00000064  
**Reset:** 0x00000000  
**Property:** Read/Write

|        |    |    |         |        |         |        |        |        |
|--------|----|----|---------|--------|---------|--------|--------|--------|
| Bit    | 31 | 30 | 29      | 28     | 27      | 26     | 25     | 24     |
|        |    |    |         |        |         |        |        |        |
| Access |    |    |         |        |         |        |        |        |
| Reset  |    |    |         |        |         |        |        |        |
|        |    |    |         |        |         |        |        |        |
| Bit    | 23 | 22 | 21      | 20     | 19      | 18     | 17     | 16     |
|        |    |    |         |        |         |        |        |        |
| Access |    |    |         |        |         |        |        |        |
| Reset  |    |    |         |        |         |        |        |        |
|        |    |    |         |        |         |        |        |        |
| Bit    | 15 | 14 | 13      | 12     | 11      | 10     | 9      | 8      |
|        |    |    |         |        |         |        |        |        |
| Access |    |    |         |        |         |        |        |        |
| Reset  |    |    |         |        |         |        |        |        |
|        |    |    |         |        |         |        |        |        |
| Bit    | 7  | 6  | 5       | 4      | 3       | 2      | 1      | 0      |
|        |    |    | DONEIEN | ADDIEN | DSCRIEN | DMAIEN | LFETCH | DFETCH |
| Access |    |    | R/W     | R/W    | R/W     | R/W    | R/W    | R/W    |
| Reset  |    |    | 0       | 0      | 0       | 0      | 0      | 0      |

#### Bit 5 – DONEIEN End of List Interrupt Enable

| Value | Description                       |
|-------|-----------------------------------|
| 0     | End of list interrupt is disabled |
| 1     | End of list interrupt is enabled  |

#### Bit 4 – ADDIEN Add Head Descriptor to Queue Interrupt Enable

| Value | Description  |
|-------|--|
| 0     | Transfer descriptor added to queue interrupt is enabled  |
| 1     | Transfer descriptor added to queue interrupt is disabled |

#### Bit 3 – DSCRIEN Descriptor Loaded Interrupt Enable

| Value | Description                                      |
|-------|--|
| 0     | Transfer descriptor loaded interrupt is enabled  |
| 1     | Transfer descriptor loaded interrupt is disabled |

#### Bit 2 – DMAIEN End of DMA Transfer Interrupt Enable

| Value | Description                                  |
|-------|--|
| 0     | DMA transfer completed interrupt is enabled  |
| 1     | DMA transfer completed interrupt is disabled |

**Bit 1 – LFETCH** Lookup Table Fetch Enable

| Value | Description                        |
|-------|------------------------------------|
| 0     | Lookup Table DMA fetch is disabled |
| 1     | Lookup Table DMA fetch is enabled  |

**Bit 0 – DFETCH** Transfer Descriptor Fetch Enable

| Value | Description                           |
|-------|---------------------------------------|
| 0     | Transfer Descriptor fetch is disabled |
| 1     | Transfer Descriptor fetch is enabled  |

### 38.7.26 Base DMA Next Register

**Name:** LCDC\_BASENEXT  
**Offset:** 0x00000068  
**Reset:** 0x00000000  
**Property:** Read/Write

|             |     |     |     |     |     |     |     |     |
|-------------|-----|-----|-----|-----|-----|-----|-----|-----|
| Bit         | 31  | 30  | 29  | 28  | 27  | 26  | 25  | 24  |
| NEXT[31:24] |     |     |     |     |     |     |     |     |
| Access      | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset       | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
|             |     |     |     |     |     |     |     |     |
| Bit         | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
| NEXT[23:16] |     |     |     |     |     |     |     |     |
| Access      | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset       | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
|             |     |     |     |     |     |     |     |     |
| Bit         | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   |
| NEXT[15:8]  |     |     |     |     |     |     |     |     |
| Access      | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

|             |     |     |     |     |     |     |     |     |
| Bit         | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
| NEXT[7:0]   |     |     |     |     |     |     |     |     |
| Access      | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset       | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

**Bits 31:0 – NEXT[31:0]** DMA Descriptor Next Address  
 The transfer descriptor address must be aligned on a 64-bit boundary.

### 38.7.27 Base Layer Configuration Register 0

**Name:** LCDC\_BASECFG0  
**Offset:** 0x0000006C  
**Reset:** 0x00000000  
**Property:** Read/Write

**Bit 8 – DLBO** Defined Length Burst Only For Channel Bus Transaction

| Value | Description  |
|-------|--|
| 0     | Undefined length INCR burst is used for a burst of 2 and 3 beats.    |
| 1     | Only Defined Length burst is used (SINGLE, INCR4, INCR8 and INCR16). |

**Bits 5:4 – BLEN[1:0]** AHB Burst Length

| Value | Name       | Description   |
|-------|------------|---|
| 0     | AHB_SINGLE | AHB Access is started as soon as there is enough space in the FIFO to store one data. SINGLE, INCR, INCR4, INCR8 and INCR16 bursts are used. INCR is used for a burst of 2 and 3 beats.                                     |
| 1     | AHB_INCR4  | AHB Access is started as soon as there is enough space in the FIFO to store a total amount of 4 data. An AHB INCR4 Burst is used. SINGLE, INCR and INCR4 bursts are used. INCR is used for a burst of 2 and 3 beats.        |
| 2     | AHB_INCR8  | AHB Access is started as soon as there is enough space in the FIFO to store a total amount of 8 data. An AHB INCR8 Burst is used. SINGLE, INCR, INCR4 and INCR8 bursts are used. INCR is used for a burst of 2 and 3 beats. |

# SAMA5D2 Series

## LCD Controller (LCDC)

| Value | Name       | Description   |
|-------|------------|---|
| 3     | AHB_INCR16 | AHB Access is started as soon as there is enough space in the FIFO to store a total amount of 16 data. An AHB INCR16 Burst is used. SINGLE, INCR, INCR4, INCR8 and INCR16 bursts are used. INCR is used for a burst of 2 and 3 beats. |

### Bit 0 – SIF Source Interface

| Value | Description   |
|-------|---|
| 0     | Base Layer data is retrieved through AHB interface 0. |
| 1     | Base Layer data is retrieved through AHB interface 1. |

### 38.7.28 Base Layer Configuration Register 1

**Name:** LCDC\_BASECFG1  
**Offset:** 0x00000070  
**Reset:** 0x00000000  
**Property:** Read/Write

#### Bits 9:8 – CLUTMODE[1:0] Color Lookup Table Mode Input Selection

| Value | Name      | Description                                     |
|-------|-----------|---|
| 0     | CLUT_1BPP | Color Lookup Table mode set to 1 bit per pixel  |
| 1     | CLUT_2BPP | Color Lookup Table mode set to 2 bits per pixel |
| 2     | CLUT_4BPP | Color Lookup Table mode set to 4 bits per pixel |
| 3     | CLUT_8BPP | Color Lookup Table mode set to 8 bits per pixel |

#### Bits 7:4 – RGBMODE[3:0] RGB Mode Input Selection

| Value | Name                | Description             |
|-------|---------------------|-------------------------|
| 0     | 12BPP_RGB_444       | 12 bpp RGB 444          |
| 1     | 16BPP_ARGB_4444     | 16 bpp ARGB 4444        |
| 2     | 16BPP_RGBA_4444     | 16 bpp RGBA 4444        |
| 3     | 16BPP_RGB_565       | 16 bpp RGB 565          |
| 4     | 16BPP_TRGB_1555     | 16 bpp TRGB 1555        |
| 5     | 18BPP_RGB_666       | 18 bpp RGB 666          |
| 6     | 18BPP_RGB_666PACKED | 18 bpp RGB 666 PACKED   |
| 7     | 19BPP_TRGB_1666     | 19 bpp TRGB 1666        |
| 8     | 19BPP_TRGB_PACKED   | 19 bpp TRGB 1666 PACKED |
| 9     | 24BPP_RGB_888       | 24 bpp RGB 888          |

# SAMA5D2 Series

## LCD Controller (LCDC)

| Value | Name                 | Description           |
|-------|----------------------|-----------------------|
| 10    | 24BPP_RGB_888_PACKED | 24 bpp RGB 888 PACKED |
| 11    | 25BPP_TRGB_1888      | 25 bpp TRGB 1888      |

**Bits 23:16 – RDEF[7:0]** Red Default  
 Default Red color when the Base DMA channel is disabled

**Bits 15:8 – GDEF[7:0]** Green Default  
 Default Green color when the Base DMA channel is disabled

**Bits 7:0 – BDEF[7:0]** Blue Default  
 Default Blue color when the Base DMA channel is disabled

### 38.7.31 Base Layer Configuration Register 4

**Name:** LCDC\_BASECFG4  
**Offset:** 0x0000007C  
**Reset:** 0x00000000  
**Property:** Read/Write

**Bit 11 – DISCEN** Discard Area Enable

| Value | Description  |
|-------|--|
| 0     | The whole frame is retrieved from memory.  |
| 1     | The DMA channel discards the area located at screen coordinate {DISCXPOS, DISCYPOS}. |

**Bit 9 – REP** Use Replication logic to expand RGB color to 24 bits

| Value | Description  |
|-------|--|
| 0     | When the selected pixel depth is less than 24 bpp the pixel is shifted and least significant bits are set to 0.          |
| 1     | When the selected pixel depth is less than 24 bpp the pixel is shifted and the least significant bit replicates the msb. |

**Bit 8 – DMA** Use DMA Data Path

| Value | Description  |
|-------|--|
| 0     | The default color is used on the Base Layer.                 |
| 1     | The DMA channel retrieves the pixels stream from the memory. |

**38.7.32 Base Layer Configuration Register 5**

**Name:** LCDC\_BASECFG5  
**Offset:** 0x00000080  
**Reset:** 0x00000000  
**Property:** Read/Write

|        |               |     |     |     |     |                |     |     |
|--------|---------------|-----|-----|-----|-----|----------------|-----|-----|

**Bits 26:16 – DISCYSIZE[10:0]** Discard Area Vertical Size

Discard Vertical size in pixels. The Discard size is set to (DISCYSIZE + 1) pixels vertically.

**Bits 10:0 – DISCXSIZ[10:0]** Discard Area Horizontal Size

Discard Horizontal size in pixels. The Discard size is set to (DISCXSIZ + 1) pixels horizontally.

### 38.7.34 Overlay 1 Channel Enable Register

**Name:** LCDC\_OVR1CHER  
**Offset:** 0x00000140  
**Reset:** –  
**Property:** Write-only

#### Bit 2 – A2QEN Add To Queue Enable

| Value | Description   |
|-------|---|
| 0     | No effect   |
| 1     | Indicates that a valid descriptor has been written to memory, its memory location should be written to the DMA head pointer. The A2QSR status bit is set to one, and it is reset by hardware as soon as the descriptor pointed to by the DMA head pointer is added to the list. |

#### Bit 1 – UPDATEEN Update Overlay Attributes Enable

| Value | Description  |
|-------|--|
| 0     | No effect  |
| 1     | Updates window attributes (size, alpha blending, etc.) on the next start of frame. |

#### Bit 0 – CHEN Channel Enable

| Value | Description             |
|-------|-------------------------|
| 0     | No effect               |
| 1     | Enables the DMA channel |

**38.7.35 Overlay 1 Channel Disable Register**

**Name:** LCDC\_OVR1CHDR  
**Offset:** 0x00000144  
**Reset:** –  
**Property:** Write-only

**Bit 8 – CHRST** Channel Reset

| Value | Description   |
|-------|---|
| 0     | No effect   |
| 1     | Resets the layer immediately. The frame is aborted. |

**Bit 0 – CHDIS** Channel Disable

| Value | Description   |
|-------|---|
| 0     | No effect   |
| 1     | Disables the layer at the end of the current frame. The frame is completed. |

### 38.7.36 Overlay 1 Channel Status Register

**Name:** LCDC\_OVR1CHSR  
**Offset:** 0x00000148  
**Reset:** 0x00000000  
**Property:** Read-only

#### Bit 2 – A2QSR Add To Queue Status

| Value | Description              |
|-------|--------------------------|
| 0     | Add to queue not pending |
| 1     | Add to queue pending     |

#### Bit 1 – UPDATESR Update Overlay Attributes In Progress Status

| Value | Description  |
|-------|--|
| 0     | No update pending                                    |
| 1     | Overlay attributes will be updated on the next frame |

#### Bit 0 – CHSR Channel Status

| Value | Description    |
|-------|----------------|
| 0     | Layer disabled |
| 1     | Layer enabled  |

### 38.7.37 Overlay 1 Interrupt Enable Register

**Name:** LCDC\_OVR1IER  
**Offset:** 0x0000014C  
**Reset:** –  
**Property:** Write-only

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Enables the corresponding interrupt.

|        |    |     |      |     |      |     |    |    |
|--------|----|-----|------|-----|------|-----|----|----|
| Bit    | 31 | 30  | 29   | 28  | 27   | 26  | 25 | 24 |
|        |    |     |      |     |      |     |    |    |
| Access |    |     |      |     |      |     |    |    |
| Reset  |    |     |      |     |      |     |    |    |
|        |    |     |      |     |      |     |    |    |
| Bit    | 23 | 22  | 21   | 20  | 19   | 18  | 17 | 16 |
|        |    |     |      |     |      |     |    |    |
| Access |    |     |      |     |      |     |    |    |
| Reset  |    |     |      |     |      |     |    |    |
|        |    |     |      |     |      |     |    |    |
| Bit    | 15 | 14  | 13   | 12  | 11   | 10  | 9  | 8  |
|        |    |     |      |     |      |     |    |    |
| Access |    |     |      |     |      |     |    |    |
| Reset  |    |     |      |     |      |     |    |    |
|        |    |     |      |     |      |     |    |    |
| Bit    | 7  | 6   | 5    | 4   | 3    | 2   | 1  | 0  |
|        |    | OVR | DONE | ADD | DSCR | DMA |    |    |
| Access |    | W   | W    | W   | W    | W   |    |    |
| Reset  |    | –   | –    | –   | –    | –   |    |    |

**Bit 6 – OVR** Overflow Interrupt Enable

**Bit 5 – DONE** End of List Interrupt Enable

**Bit 4 – ADD** Head Descriptor Loaded Interrupt Enable

**Bit 3 – DSCR** Descriptor Loaded Interrupt Enable

**Bit 2 – DMA** End of DMA Transfer Interrupt Enable

### 38.7.38 Overlay 1 Interrupt Disable Register

**Name:** LCDC\_OVR1IDR  
**Offset:** 0x00000150  
**Reset:** –  
**Property:** Write-only

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Disables the corresponding interrupt.

|        |    |     |      |     |      |     |    |    |
|--------|----|-----|------|-----|------|-----|----|----|
| Bit    | 31 | 30  | 29   | 28  | 27   | 26  | 25 | 24 |

### 38.7.39 Overlay 1 Interrupt Mask Register

**Name:** LCDC\_OVR1IMR  
**Offset:** 0x00000154  
**Reset:** 0x00000000  
**Property:** Read-only

The following configuration values are valid for all listed bit names of this register:

0: The corresponding interrupt is disabled.

1: The corresponding interrupt is enabled.

|        |    |     |      |     |      |     |    |    |

| Reset  |    | 0   | 0    | 0   | 0    | 0   |    |    |

#### Bit 6 – OVR Overflow Detected

| Value | Description  |
|-------|--|
| 0     | No overflow occurred since last read of LCDC_OVR1ISR             |
| 1     | An overflow occurred. This flag is reset after a read operation. |

#### Bit 5 – DONE End of List Detected

| Value | Description  |
|-------|--|
| 0     | No End of List condition has occurred since last read of LCDC_OVR1ISR          |
| 1     | End of List condition has occurred. This flag is reset after a read operation. |

#### Bit 4 – ADD Head Descriptor Loaded

| Value | Description  |
|-------|--|
| 0     | No descriptor has been loaded since last read of LCDC_OVR1ISR  |
| 1     | The descriptor pointed to by the LCDC_OVR1HEAD register has been loaded successfully. This flag is reset after a read operation. |

#### Bit 3 – DSCR DMA Descriptor Loaded

| Value | Description   |
|-------|---|
| 0     | No descriptor has been loaded since last read of LCDC_OVR1ISR |

# SAMA5D2 Series

## LCD Controller (LCDC)

---

---

| Value | Description   |
|-------|---|
| 1     | A descriptor has been loaded successfully. This flag is reset after a read operation. |

### Bit 2 – DMA End of DMA Transfer

| Value | Description   |
|-------|---|
| 0     | No End of Transfer has been detected since last read of LCDC_OVR1ISR          |
| 1     | End of Transfer has been detected. This flag is reset after a read operation. |

**38.7.41 Overlay 1 Head Register**

**Name:** LCDC\_OVR1HEAD

**Bit 13 – LOCKDIS** Hardware Rotation Lock Disable

| Value | Description   |
|-------|---|
| 0     | AHB lock signal is asserted when a rotation is performed. |
| 1     | AHB lock signal is cleared when a rotation is performed.  |

**Bit 12 – ROTDIS** Hardware Rotation Optimization Disable

| Value | Description                        |
|-------|------------------------------------|
| 0     | Rotation optimization is enabled.  |
| 1     | Rotation optimization is disabled. |

**Bit 8 – DLBO** Defined Length Burst Only for Channel Bus Transaction

| Value | Description  |
|-------|--|
| 0     | Undefined length INCR burst is used for a burst of 2 and 3 beats.    |
| 1     | Only Defined Length burst is used (SINGLE, INCR4, INCR8 and INCR16). |

**Bits 5:4 – BLEN[1:0]** AHB Burst Length

# SAMA5D2 Series

## LCD Controller (LCDC)

| Value | Name            | Description   |
|-------|-----------------|---|
| 0     | AHB_BLEN_SINGLE | AHB Access is started as soon as there is enough space in the FIFO to store one data. SINGLE, INCR, INCR4, INCR8 and INCR16 bursts are used. INCR is used for a burst of 2 and 3 beats.   |
| 1     | AHB_BLEN_INCR4  | AHB Access is started as soon as there is enough space in the FIFO to store a total amount of 4 data. An AHB INCR4 Burst is used. SINGLE, INCR and INCR4 bursts are used. INCR is used for a burst of 2 and 3 beats.                  |
| 2     | AHB_BLEN_INCR8  | AHB Access is started as soon as there is enough space in the FIFO to store a total amount of 8 data. An AHB INCR8 Burst is used. SINGLE, INCR, INCR4 and INCR8 bursts are used. INCR is used for a burst of 2 and 3 beats.           |
| 3     | AHB_BLEN_INCR16 | AHB Access is started as soon as there is enough space in the FIFO to store a total amount of 16 data. An AHB INCR16 Burst is used. SINGLE, INCR, INCR4, INCR8 and INCR16 bursts are used. INCR is used for a burst of 2 and 3 beats. |

### Bit 0 – SIF Source Interface

| Value | Description   |
|-------|---|
| 0     | Base Layer data is retrieved through AHB interface 0. |
| 1     | Base Layer data is retrieved through AHB interface 1. |

**Bits 23:16 – RMASK[7:0]** Red Color Component Chroma Key Mask  
 Red Mask used when the compare function is used. If a bit is set then this bit is compared.

**Bits 15:8 – GMASK[7:0]** Green Color Component Chroma Key Mask  
 Green Mask used when the compare function is used. If a bit is set then this bit is compared.

**Bits 7:0 – BMASK[7:0]** Blue Color Component Chroma Key Mask  
 Blue Mask used when the compare function is used. If a bit is set then this bit is compared.

**Bits 23:16 – GA[7:0]** Blender Global Alpha  
 Global alpha blender for the current layer.

**Bit 10 – DSTKEY** Destination Chroma Keying

| Value | Description                        |
|-------|------------------------------------|
| 0     | Source Chroma keying is enabled.   |
| 1     | Destination Chroma keying is used. |

**Bit 9 – REP** Use Replication logic to expand RGB color to 24 bits

| Value | Description  |
|-------|--|
| 0     | When the selected pixel depth is less than 24 bpp the pixel is shifted and least significant bits are set to 0.          |
| 1     | When the selected pixel depth is less than 24 bpp the pixel is shifted and the least significant bit replicates the msb. |

**Bit 8 – DMA** Blender DMA Layer Enable

| Value | Description  |
|-------|--|
| 0     | The default color is used on the Overlay 1 Layer.            |
| 1     | The DMA channel retrieves the pixels stream from the memory. |

### Bit 7 – OVR Blender Overlay Layer Enable

| Value | Description  |
|-------|--|
| 0     | Overlay pixel color is set to the default overlay pixel color. |
| 1     | Overlay pixel color is set to the DMA channel pixel color.     |

### Bit 6 – LAEN Blender Local Alpha Enable

| Value | Description                                   |
|-------|---|
| 0     | Local alpha blending coefficient is disabled. |
| 1     | Local alpha blending coefficient is enabled.  |

### Bit 5 – GAEN Blender Global Alpha Enable

| Value | Description                                    |
|-------|--|
| 0     | Global alpha blending coefficient is disabled. |
| 1     | Global alpha blending coefficient is enabled.  |

### Bit 4 – REVALPHA Blender Reverse Alpha

| Value | Description                                  |
|-------|--|
| 0     | Pixel difference is multiplied by alpha.     |
| 1     | Pixel difference is multiplied by 1 - alpha. |

### Bit 3 – ITER Blender Use Iterated Color

| Value | Description  |
|-------|--|
| 0     | Pixel difference is set to 0.                        |
| 1     | Pixel difference is set to the iterated pixel value. |

### Bit 2 – ITER2BL Blender Iterated Color Enable

| Value | Description   |
|-------|---|
| 0     | Final adder stage operand is set to 0.                        |
| 1     | Final adder stage operand is set to the iterated pixel value. |

### Bit 1 – INV Blender Inverted Blender Output Enable

| Value | Description                           |
|-------|---------------------------------------|
| 0     | Iterated pixel is the blended pixel.  |
| 1     | Iterated pixel is the inverted pixel. |

### Bit 0 – CRKEY Blender Chroma Key Enable

| Value | Description                      |
|-------|----------------------------------|
| 0     | Chroma key matching is disabled. |
| 1     | Chroma key matching is enabled.  |

### 38.7.55 Overlay 2 Channel Enable Register

**Name:** LCDC\_OVR2CHER  
**Offset:** 0x00000240  
**Reset:** –  
**Property:** Write-only

#### Bit 2 – A2QEN Add To Queue Enable

| Value | Description   |
|-------|---|
| 0     | No effect   |
| 1     | Indicates that a valid descriptor has been written to memory, its memory location should be written to the DMA head pointer. The A2QSR status bit is set to one, and it is reset by hardware as soon as the descriptor pointed to by the DMA head pointer is added to the list. |

#### Bit 1 – UPDATEEN Update Overlay Attributes Enable

| Value | Description  |
|-------|--|
| 0     | No effect  |
| 1     | Updates windows attributes on the next start of frame. |

#### Bit 0 – CHEN Channel Enable

| Value | Description             |
|-------|-------------------------|
| 0     | No effect               |
| 1     | Enables the DMA channel |

### 38.7.56 Overlay 2 Channel Disable Register

**Name:** LCDC\_OVR2CHDR  
**Offset:** 0x00000244  
**Reset:** –  
**Property:** Write-only

#### Bit 8 – CHRST Channel Reset

| Value | Description   |
|-------|---|
| 0     | No effect   |
| 1     | Resets the layer immediately. The frame is aborted. |

#### Bit 0 – CHDIS Channel Disable

| Value | Description   |
|-------|---|
| 0     | No effect   |
| 1     | Disables the layer at the end of the current frame. The frame is completed. |

### 38.7.57 Overlay 2 Channel Status Register

**Name:** LCDC\_OVR2CHSR  
**Offset:** 0x00000248  
**Reset:** 0x00000000  
**Property:** Read-only

#### Bit 2 – A2QSR Add To Queue Status

| Value | Description              |
|-------|--------------------------|
| 0     | Add to queue not pending |
| 1     | Add to queue pending     |

#### Bit 1 – UPDATESR Update Overlay Attributes In Progress Status

| Value | Description  |
|-------|--|
| 0     | No update pending                                    |
| 1     | Overlay attributes will be updated on the next frame |

#### Bit 0 – CHSR Channel Status

| Value | Description    |
|-------|----------------|
| 0     | Layer disabled |
| 1     | Layer enabled  |

### 38.7.58 Overlay 2 Interrupt Enable Register

**Name:** LCDC\_OVR2IER  
**Offset:** 0x0000024C  
**Reset:** –  
**Property:** Write-only

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Enables the corresponding interrupt.

|        |    |    |    |    |    |    |    |    |
|--------|----|----|----|----|----|----|----|----|
| Bit    | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 |
|        |    |    |    |    |    |    |    |    |
| Access |    |    |    |    |    |    |    |    |
| Reset  |    |    |    |    |    |    |    |    |
|        |    |    |    |    |    |    |    |    |

**Bit 6 – OVR** Overflow Interrupt Enable

**Bit 5 – DONE** End of List Interrupt Enable

**Bit 4 – ADD** Head Descriptor Loaded Interrupt Enable

**Bit 3 – DSCR** Descriptor Loaded Interrupt Enable

**Bit 2 – DMA** End of DMA Transfer Interrupt Enable

**38.7.59 Overlay 2 Interrupt Disable Register**

**Name:** LCDC\_OVR2IDR  
**Offset:** 0x00000250  
**Reset:** –  
**Property:** Write-only

The following configuration values are valid for all listed bit names of this register:  
0: No effect.

1: Disables the corresponding interrupt.

| Reset  |    |  | 0  |  | 0  |  | 0  |  | 0  |  | 0  |  |    |  |    |

#### Bit 6 – OVR Overflow Detected

| Value | Description  |
|-------|--|
| 0     | No overflow occurred since last read of LCDC_OVR2ISR             |
| 1     | An overflow occurred. This flag is reset after a read operation. |

#### Bit 5 – DONE End of List Detected

| Value | Description  |
|-------|--|
| 0     | No End of List condition occurred since last read of LCDC_OVR2ISR              |
| 1     | End of List condition has occurred. This flag is reset after a read operation. |

#### Bit 4 – ADD Head Descriptor Loaded

| Value | Description  |
|-------|--|
| 0     | No descriptor has been loaded since last read of LCDC_OVR2ISR  |
| 1     | The descriptor pointed to by the LCDC_OVR2HEAD register has been loaded successfully. This flag is reset after a read operation. |

#### Bit 3 – DSCR DMA Descriptor Loaded

| Value | Description   |
|-------|---|
| 0     | No descriptor has been loaded since last read of LCDC_OVR2ISR |

# SAMA5D2 Series

## LCD Controller (LCDC)

---

---

| Value | Description   |
|-------|---|
| 1     | A descriptor has been loaded successfully. This flag is reset after a read operation. |

### Bit 2 – DMA End of DMA Transfer

| Value | Description   |
|-------|---|
| 0     | No End of Transfer has been detected since last read of LCDC_OVR2ISR          |
| 1     | End of Transfer has been detected. This flag is reset after a read operation. |

**38.7.62 Overlay 2 Head Register**

**Name:** LCDC\_OVR2HEAD  
**Offset:** 0x0000025C  
**Reset:** 0x00000000  
**Property:** Read/Write

|        |             |     |     |     |     |     |     |     |  |

#### Bit 13 – LOCKDIS Hardware Rotation Lock Disable

| Value | Description   |
|-------|---|
| 0     | AHB lock signal is asserted when a rotation is performed. |
| 1     | AHB lock signal is cleared when a rotation is performed.  |

#### Bit 12 – ROTDIS Hardware Rotation Optimization Disable

| Value | Description                        |
|-------|------------------------------------|
| 0     | Rotation optimization is enabled.  |
| 1     | Rotation optimization is disabled. |

#### Bit 8 – DLBO Defined Length Burst Only For Channel Bus Transaction

| Value | Description  |
|-------|--|
| 0     | Undefined length INCR burst is used for 2 and 3 beats burst.         |
| 1     | Only Defined Length burst is used (SINGLE, INCR4, INCR8 and INCR16). |

#### Bits 5:4 – BLEN[1:0] AHB Burst Length

# SAMA5D2 Series

## LCD Controller (LCDC)

| Value | Name       | Description   |
|-------|------------|---|
| 0     | AHB_SINGLE | AHB Access is started as soon as there is enough space in the FIFO to store one data. SINGLE, INCR, INCR4, INCR8 and INCR16 bursts are used. INCR is used for a burst of 2 and 3 beats.   |
| 1     | AHB_INCR4  | AHB Access is started as soon as there is enough space in the FIFO to store a total amount of 4 data. An AHB INCR4 Burst is used. SINGLE, INCR and INCR4 bursts are used. INCR is used for a burst of 2 and 3 beats.                  |
| 2     | AHB_INCR8  | AHB Access is started as soon as there is enough space in the FIFO to store a total amount of 8 data. An AHB INCR8 Burst is used. SINGLE, INCR, INCR4 and INCR8 bursts are used. INCR is used for a burst of 2 and 3 beats.           |
| 3     | AHB_INCR16 | AHB Access is started as soon as there is enough space in the FIFO to store a total amount of 16 data. An AHB INCR16 Burst is used. SINGLE, INCR, INCR4, INCR8 and INCR16 bursts are used. INCR is used for a burst of 2 and 3 beats. |

**Bits 23:16 – RKEY[7:0]** Red Color Component Chroma Key  
 Reference Red chroma key used to match the Red color of the current overlay.

**Bits 15:8 – GKEY[7:0]** Green Color Component Chroma Key  
 Reference Green chroma key used to match the Green color of the current overlay.

**Bits 7:0 – BKEY[7:0]** Blue Color Component Chroma Key  
 Reference Blue chroma key used to match the Blue color of the current overlay.

| Reset  | 0          | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

**Bits 23:16 – RMASK[7:0]** Red Color Component Chroma Key Mask

Red Mask used when the compare function is used. If a bit is set then this bit is compared.

**Bits 15:8 – GMASK[7:0]** Green Color Component Chroma Key Mask

Green Mask used when the compare function is used. If a bit is set then this bit is compared.

**Bits 7:0 – BMASK[7:0]** Blue Color Component Chroma Key Mask

Blue Mask used when the compare function is used. If a bit is set then this bit is compared.

| Reset  | 0       | 0    | 0    | 0        | 0    | 0       | 0   | 0     |

**Bits 23:16 – GA[7:0]** Blender Global Alpha  
 Global alpha blender for the current layer.

**Bit 10 – DSTKEY** Destination Chroma Keying

| Value | Description                        |
|-------|------------------------------------|
| 0     | Source Chroma keying is enabled.   |
| 1     | Destination Chroma keying is used. |

**Bit 9 – REP** Use Replication logic to expand RGB color to 24 bits

| Value | Description  |
|-------|--|
| 0     | When the selected pixel depth is less than 24 bpp the pixel is shifted and least significant bits are set to 0.          |
| 1     | When the selected pixel depth is less than 24 bpp the pixel is shifted and the least significant bit replicates the msb. |

**Bit 8 – DMA** Blender DMA Layer Enable

| Value | Description  |
|-------|--|
| 0     | The default color is used on the Overlay 1 Layer.            |
| 1     | The DMA channel retrieves the pixels stream from the memory. |

### Bit 7 – OVR Blender Overlay Layer Enable

| Value | Description  |
|-------|--|
| 0     | Overlay pixel color is set to the default overlay pixel color. |
| 1     | Overlay pixel color is set to the DMA channel pixel color.     |

### Bit 6 – LAEN Blender Local Alpha Enable

| Value | Description                                   |
|-------|---|
| 0     | Local alpha blending coefficient is disabled. |
| 1     | Local alpha blending coefficient is enabled.  |

### Bit 5 – GAEN Blender Global Alpha Enable

| Value | Description                                    |
|-------|--|
| 0     | Global alpha blending coefficient is disabled. |
| 1     | Global alpha blending coefficient is enabled.  |

### Bit 4 – REVALPHA Blender Reverse Alpha

| Value | Description                                  |
|-------|--|
| 0     | Pixel difference is multiplied by alpha.     |
| 1     | Pixel difference is multiplied by 1 - alpha. |

### Bit 3 – ITER Blender Use Iterated Color

| Value | Description  |
|-------|--|
| 0     | Pixel difference is set to 0.                        |
| 1     | Pixel difference is set to the iterated pixel value. |

### Bit 2 – ITER2BL Blender Iterated Color Enable

| Value | Description   |
|-------|---|
| 0     | Final adder stage operand is set to 0.                        |
| 1     | Final adder stage operand is set to the iterated pixel value. |

### Bit 1 – INV Blender Inverted Blender Output Enable

| Value | Description                           |
|-------|---------------------------------------|
| 0     | Iterated pixel is the blended pixel.  |
| 1     | Iterated pixel is the inverted pixel. |

### Bit 0 – CRKEY Blender Chroma Key Enable

| Value | Description                      |
|-------|----------------------------------|
| 0     | Chroma key matching is disabled. |
| 1     | Chroma key matching is enabled.  |

### 38.7.76 High-End Overlay Channel Enable Register

**Name:** LCDC\_HEOCHER  
**Offset:** 0x00000340  
**Reset:** –  
**Property:** Write-only

#### Bit 2 – A2QEN Add To Queue Enable

| Value | Description   |
|-------|---|
| 0     | No effect   |
| 1     | Indicates that a valid descriptor has been written to memory, its memory location should be written to the DMA head pointer. The A2QSR status bit is set to one, and it is reset by hardware as soon as the descriptor pointed to by the DMA head pointer is added to the list. |

#### Bit 1 – UPDATEEN Update Overlay Attributes Enable

| Value | Description  |
|-------|--|
| 0     | No effect  |
| 1     | Updates windows attributes on the next start of frame. |

#### Bit 0 – CHEN Channel Enable

| Value | Description             |
|-------|-------------------------|
| 0     | No effect               |
| 1     | Enables the DMA channel |

**38.7.77 High-End Overlay Channel Disable Register**

**Name:** LCDC\_HEOCHDR  
**Offset:** 0x00000344  
**Reset:** –  
**Property:** Write-only

**Bit 8 – CHRST** Channel Reset

| Value | Description   |
|-------|---|
| 0     | No effect   |
| 1     | Resets the layer immediately. The frame is aborted. |

**Bit 0 – CHDIS** Channel Disable

| Value | Description   |
|-------|---|
| 0     | No effect   |
| 1     | Disables the layer at the end of the current frame. The frame is completed. |

### 38.7.78 High-End Overlay Channel Status Register

**Name:** LCDC\_HEOCHSR  
**Offset:** 0x00000348  
**Reset:** 0x00000000  
**Property:** Read-only

#### Bit 2 – A2QSR Add To Queue Status

| Value | Description              |
|-------|--------------------------|
| 0     | Add to queue not pending |
| 1     | Add to queue pending     |

#### Bit 1 – UPDATESR Update Overlay Attributes In Progress Status

| Value | Description  |
|-------|--|
| 0     | No update pending                                    |
| 1     | Overlay attributes will be updated on the next frame |

#### Bit 0 – CHSR Channel Status

| Value | Description    |
|-------|----------------|
| 0     | Layer disabled |
| 1     | Layer enabled  |

### 38.7.79 High-End Overlay Interrupt Enable Register

**Name:** LCDC\_HEOIER  
**Offset:** 0x0000034C  
**Reset:** –  
**Property:** Write-only

The following configuration values are valid for all listed bit names of this register:  
 0: No effect.

1: Enables the corresponding interrupt.

|        |    |      |       |      |       |      |    |    |
|--------|----|------|-------|------|-------|------|----|----|
| Bit    | 31 | 30   | 29    | 28   | 27    | 26   | 25 | 24 |
|        |    |      |       |      |       |      |    |    |
| Access |    |      |       |      |       |      |    |    |
| Reset  |    |      |       |      |       |      |    |    |
|        |    |      |       |      |       |      |    |    |
| Bit    | 23 | 22   | 21    | 20   | 19    | 18   | 17 | 16 |

### 38.7.80 High-End Overlay Interrupt Disable Register

**Name:** LCDC\_HEOISR  
**Offset:** 0x00000350  
**Reset:** –  
**Property:** Write-only

The following configuration values are valid for all listed bit names of this register:  
 0: No effect.

1: Disables the corresponding interrupt.

|        |    |      |       |      |       |      |    |    |

**Bit 22 – VOVR** Overflow Detected for V Component

| Value | Description  |
|-------|--|
| 0     | No overflow occurred since last read of LCDC_HEOISR              |
| 1     | An overflow occurred. This flag is reset after a read operation. |

**Bit 21 – VDONE** End of List Detected for V Component

| Value | Description  |
|-------|--|
| 0     | No End of List condition occurred since last read of LCDC_HEOISR               |
| 1     | End of List condition has occurred. This flag is reset after a read operation. |

**Bit 20 – VADD** Head Descriptor Loaded for V Component

| Value | Description  |
|-------|--|
| 0     | No descriptor has been loaded since last read of LCDC_HEOISR   |
| 1     | The descriptor pointed to by the LCDC_HEOVHEAD register has been loaded successfully. This flag is reset after a read operation. |

**Bit 19 – VDSCR** DMA Descriptor Loaded for V Component

| Value | Description  |
|-------|--|
| 0     | No descriptor has been loaded since last read of LCDC_HEOISR |

| Value | Description   |
|-------|---|
| 1     | A descriptor has been loaded successfully. This flag is reset after a read operation. |

**Bit 18 – VDMA** End of DMA Transfer for V Component

| Value | Description   |
|-------|---|
| 0     | No End of Transfer has been detected since last read of LCDC_HEOISR           |
| 1     | End of Transfer has been detected. This flag is reset after a read operation. |

**Bit 14 – UOVR** Overflow Detected for U Component

| Value | Description  |
|-------|--|
| 0     | No overflow occurred since last read of LCDC_HEOISR              |
| 1     | An overflow occurred. This flag is reset after a read operation. |

**Bit 13 – UDONE** End of List Detected for U Component

| Value | Description  |
|-------|--|
| 0     | No End of List condition occurred since last read of LCDC_HEOISR               |
| 1     | End of List condition has occurred. This flag is reset after a read operation. |

**Bit 12 – UADD** Head Descriptor Loaded for U Component

| Value | Description  |
|-------|--|
| 0     | No descriptor has been loaded since last read of LCDC_HEOISR   |
| 1     | The descriptor pointed to by the LCDC_HEOUHEAD register has been loaded successfully. This flag is reset after a read operation. |

**Bit 11 – UDSCR** DMA Descriptor Loaded for U Component

| Value | Description   |
|-------|---|
| 0     | No descriptor has been loaded since last read of LCDC_HEOISR                          |
| 1     | A descriptor has been loaded successfully. This flag is reset after a read operation. |

**Bit 10 – UDMA** End of DMA Transfer for U Component

| Value | Description   |
|-------|---|
| 0     | No End of Transfer has been detected since last read of LCDC_HEOISR           |
| 1     | End of Transfer has been detected. This flag is reset after a read operation. |

**Bit 6 – OVR** Overflow Detected

| Value | Description  |
|-------|--|
| 0     | No overflow occurred since last read of LCDC_HEOISR              |
| 1     | An overflow occurred. This flag is reset after a read operation. |

**Bit 5 – DONE** End of List Detected

| Value | Description  |
|-------|--|
| 0     | No End of List condition occurred since last read of LCDC_HEOISR               |
| 1     | End of List condition has occurred. This flag is reset after a read operation. |

**Bit 4 – ADD** Head Descriptor Loaded

---

---

| Value | Description   |
|-------|---|
| 0     | No descriptor has been loaded since last read of LCDC_HEOISR  |
| 1     | The descriptor pointed to by the LCDC_HEOHEAD register has been loaded successfully. This flag is reset after a read operation. |

**Bit 3 – DSCR** DMA Descriptor Loaded

| Value | Description   |
|-------|---|
| 0     | No descriptor has been loaded since last read of LCDC_HEOISR                          |
| 1     | A descriptor has been loaded successfully. This flag is reset after a read operation. |

**Bit 2 – DMA** End of DMA Transfer

| Value | Description   |
|-------|---|
| 0     | No end of transfer has been detected since last read of LCDC_HEOISR           |
| 1     | End of Transfer has been detected. This flag is reset after a read operation. |

#### Bit 5 – DONEIEN End of List Interrupt Enable

| Value | Description                        |
|-------|------------------------------------|
| 0     | End of list interrupt is disabled. |
| 1     | End of list interrupt is enabled.  |

#### Bit 4 – ADDIEN Add Head Descriptor to Queue Interrupt Enable

| Value | Description   |
|-------|---|
| 0     | Transfer descriptor added to queue interrupt is enabled.  |
| 1     | Transfer descriptor added to queue interrupt is disabled. |

#### Bit 3 – DSCRIEN Descriptor Loaded Interrupt Enable

| Value | Description                                       |
|-------|---|
| 0     | Transfer descriptor loaded interrupt is enabled.  |
| 1     | Transfer descriptor loaded interrupt is disabled. |

#### Bit 2 – DMAIEN End of DMA Transfer Interrupt Enable

| Value | Description                                   |
|-------|---|
| 0     | DMA transfer completed interrupt is enabled.  |
| 1     | DMA transfer completed interrupt is disabled. |

**Bit 1 – LFETCH** Lookup Table Fetch Enable

| Value | Description                         |
|-------|-------------------------------------|
| 0     | Lookup Table DMA fetch is disabled. |
| 1     | Lookup Table DMA fetch is enabled.  |

**Bit 0 – DFETCH** Transfer Descriptor Fetch Enable

| Value | Description                            |
|-------|--|
| 0     | Transfer Descriptor fetch is disabled. |
| 1     | Transfer Descriptor fetch is enabled.  |

#### Bit 5 – VDONEIEN End of List Interrupt Enable

| Value | Description                        |
|-------|------------------------------------|
| 0     | End of list interrupt is disabled. |
| 1     | End of list interrupt is enabled.  |

#### Bit 4 – VADDIEN Add Head Descriptor to Queue Interrupt Enable

| Value | Description   |
|-------|---|
| 0     | Transfer descriptor added to queue interrupt is enabled.  |
| 1     | Transfer descriptor added to queue interrupt is disabled. |

#### Bit 3 – VDSCRIEN Descriptor Loaded Interrupt Enable

| Value | Description                                       |
|-------|---|
| 0     | Transfer descriptor loaded interrupt is enabled.  |
| 1     | Transfer descriptor loaded interrupt is disabled. |

#### Bit 2 – VDMAIEN End of DMA Transfer Interrupt Enable

| Value | Description                                   |
|-------|---|
| 0     | DMA transfer completed interrupt is enabled.  |
| 1     | DMA transfer completed interrupt is disabled. |

**Bit 0 – VDFETCH** Transfer Descriptor Fetch Enable

| Value | Description                            |
|-------|--|
| 0     | Transfer Descriptor fetch is disabled. |
| 1     | Transfer Descriptor fetch is enabled.  |

### 38.7.94 High-End Overlay V DMA Next Register

**Name:** LCDC\_HEOVNEXT

**Bit 13 – LOCKDIS** Hardware Rotation Lock Disable

| Value | Description   |
|-------|---|
| 0     | AHB lock signal is asserted when a rotation is performed. |
| 1     | AHB lock signal is cleared when a rotation is performed.  |

**Bit 12 – ROTDIS** Hardware Rotation Optimization Disable

| Value | Description                        |
|-------|------------------------------------|
| 0     | Rotation optimization is enabled.  |
| 1     | Rotation optimization is disabled. |

**Bit 8 – DLBO** Defined Length Burst Only For Channel Bus Transaction

| Value | Description  |
|-------|--|
| 0     | Undefined length INCR burst is used for a burst of 2 and 3 beats.    |
| 1     | Only Defined Length burst is used (SINGLE, INCR4, INCR8 and INCR16). |

**Bits 7:6 – BLENUV[1:0]** AHB Burst Length for U-V Channel

| Value | Name       | Description   |
|-------|------------|---|
| 0     | AHB_SINGLE | AHB Access is started as soon as there is enough space in the FIFO to store one data. SINGLE, INCR, INCR4, INCR8 and INCR16 bursts are used. INCR is used for a burst of 2 and 3 beats.   |
| 1     | AHB_INCR4  | AHB Access is started as soon as there is enough space in the FIFO to store a total amount of 4 data. An AHB INCR4 Burst is used. SINGLE, INCR and INCR4 bursts are used. INCR is used for a burst of 2 and 3 beats.                  |
| 2     | AHB_INCR8  | AHB Access is started as soon as there is enough space in the FIFO to store a total amount of 8 data. An AHB INCR8 Burst is used. SINGLE, INCR, INCR4 and INCR8 bursts are used. INCR is used for a burst of 2 and 3 beats.           |
| 3     | AHB_INCR16 | AHB Access is started as soon as there is enough space in the FIFO to store a total amount of 16 data. An AHB INCR16 Burst is used. SINGLE, INCR, INCR4, INCR8 and INCR16 bursts are used. INCR is used for a burst of 2 and 3 beats. |

### Bits 5:4 – BLEN[1:0] AHB Burst Length

| Value | Name            | Description   |
|-------|-----------------|---|
| 0     | AHB_BLEN_SINGLE | AHB Access is started as soon as there is enough space in the FIFO to store one data. SINGLE, INCR, INCR4, INCR8 and INCR16 bursts are used. INCR is used for a burst of 2 and 3 beats.   |
| 1     | AHB_BLEN_INCR4  | AHB Access is started as soon as there is enough space in the FIFO to store a total amount of 4 data. An AHB INCR4 Burst is used. SINGLE, INCR and INCR4 bursts are used. INCR is used for a burst of 2 and 3 beats.                  |
| 2     | AHB_BLEN_INCR8  | AHB Access is started as soon as there is enough space in the FIFO to store a total amount of 8 data. An AHB INCR8 Burst is used. SINGLE, INCR, INCR4 and INCR8 bursts are used. INCR is used for a burst of 2 and 3 beats.           |
| 3     | AHB_BLEN_INCR16 | AHB Access is started as soon as there is enough space in the FIFO to store a total amount of 16 data. An AHB INCR16 Burst is used. SINGLE, INCR, INCR4, INCR8 and INCR16 bursts are used. INCR is used for a burst of 2 and 3 beats. |

### Bit 0 – SIF Source Interface

| Value | Description   |
|-------|---|
| 0     | Base Layer data is retrieved through AHB interface 0. |
| 1     | Base Layer data is retrieved through AHB interface 1. |

| Reset  | 0   | 0   | 0   | 0         |    |    | 0         | 0         |

#### Bit 20 – DSCALEOPT Down Scaling Bandwidth Optimization

| Value | Description   |
|-------|---|
| 0     | Scaler Optimization is disabled.  |
| 1     | Scaler Optimization is enabled; only relevant pixels are retrieved from memory to fill the scaler filter. |

#### Bit 17 – YUV422SWP YUV 4:2:2 Swap

| Value | Description  |
|-------|--|
| 0     | The two Y components of the YUV 4:2:2 packed data stream are not swapped |
| 1     | The two Y components of the YUV 4:2:2 packed data stream are swapped     |

#### Bit 16 – YUV422ROT YUV 4:2:2 Rotation

This bit is relevant only when a rotation angle of 90 degrees or 270 degrees is used.

| Value | Description   |
|-------|---|
| 0     | Chroma Upsampling kernel is configured to use 0 and 180 degrees algorithm   |
| 1     | Chroma Upsampling kernel is configured to use the 4:2:2 Rotation Algorithm. |

#### Bits 15:12 – YUVMODE[3:0] YUV Mode Input Selection

# SAMA5D2 Series

## LCD Controller (LCDC)

| Value | Name                   | Description                     |
|-------|------------------------|---------------------------------|
| 0     | 32BPP_AYCBCR           | 32 bpp AYCbCr 444               |
| 1     | 16BPP_YCBCR_MODE0      | 16 bpp Cr(n)Y(n+1)Cb(n)Y(n) 422 |
| 2     | 16BPP_YCBCR_MODE1      | 16 bpp Y(n+1)Cr(n)Y(n)Cb(n) 422 |
| 3     | 16BPP_YCBCR_MODE2      | 16 bpp Cb(n)Y(+1)Cr(n)Y(n) 422  |
| 4     | 16BPP_YCBCR_MODE3      | 16 bpp Y(n+1)Cb(n)Y(n)Cr(n) 422 |
| 5     | 16BPP_YCBCR_SEMIPLANAR | 16 bpp Semiplanar 422 YCbCr     |
| 6     | 16BPP_YCBCR_PLANAR     | 16 bpp Planar 422 YCbCr         |
| 7     | 12BPP_YCBCR_SEMIPLANAR | 12 bpp Semiplanar 420 YCbCr     |
| 8     | 12BPP_YCBCR_PLANAR     | 12 bpp Planar 420 YCbCr         |

### Bits 9:8 – CLUTMODE[1:0] Color Lookup Table Mode Input Selection

| Value | Name      | Description                                     |
|-------|-----------|---|
| 0     | CLUT_1BPP | Color Lookup Table mode set to 1 bit per pixel  |
| 1     | CLUT_2BPP | Color Lookup Table mode set to 2 bits per pixel |
| 2     | CLUT_4BPP | Color Lookup Table mode set to 4 bits per pixel |
| 3     | CLUT_8BPP | Color Lookup Table mode set to 8 bits per pixel |

### Bits 7:4 – RGBMODE[3:0] RGB Mode Input Selection

| Value | Name                 | Description             |
|-------|----------------------|-------------------------|
| 0     | 12BPP_RGB_444        | 12 bpp RGB 444          |
| 1     | 16BPP_ARGB_4444      | 16 bpp ARGB 4444        |
| 2     | 16BPP_RGBA_4444      | 16 bpp RGBA 4444        |
| 3     | 16BPP_RGB_565        | 16 bpp RGB 565          |
| 4     | 16BPP_TRGB_1555      | 16 bpp TRGB 1555        |
| 5     | 18BPP_RGB_666        | 18 bpp RGB 666          |
| 6     | 18BPP_RGB_666PACKED  | 18 bpp RGB 666 PACKED   |
| 7     | 19BPP_TRGB_1666      | 19 bpp TRGB 1666        |
| 8     | 19BPP_TRGB_PACKED    | 19 bpp TRGB 1666 PACKED |
| 9     | 24BPP_RGB_888        | 24 bpp RGB 888          |
| 10    | 24BPP_RGB_888_PACKED | 24 bpp RGB 888 PACKED   |
| 11    | 25BPP_TRGB_1888      | 25 bpp TRGB 1888        |
| 12    | 32BPP_ARGB_8888      | 32 bpp ARGB 8888        |
| 13    | 32BPP_RGBA_8888      | 32 bpp RGBA 8888        |

### Bit 1 – YUVEN YUV Color Space Enable

Color Space is YUV

| Value | Description        |
|-------|--------------------|
| 0     | Color space is RGB |
| 1     | Color space is YUV |

### Bit 0 – CLUTEN Color Lookup Table Mode Enable

| Value | Description                          |
|-------|--------------------------------------|
| 0     | RGB mode is selected.                |
| 1     | Color Lookup Table mode is selected. |

| Reset  | 0       | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

**Bits 23:16 – GA[7:0]** Blender Global Alpha  
 Global alpha blender for the current layer.

**Bit 12 – VIDPRI** Video Priority

| Value | Description                    |
|-------|--------------------------------|
| 0     | OVR1 layer is above HEO layer. |
| 1     | OVR1 layer is below HEO layer. |

**Bit 10 – DSTKEY** Destination Chroma Keying

| Value | Description                        |
|-------|------------------------------------|
| 0     | Source Chroma keying is enabled.   |
| 1     | Destination Chroma keying is used. |

**Bit 9 – REP** Use Replication logic to expand RGB color to 24 bits

| Value | Description  |
|-------|--|
| 0     | When the selected pixel depth is less than 24 bpp the pixel is shifted and least significant bits are set to 0.          |
| 1     | When the selected pixel depth is less than 24 bpp the pixel is shifted and the least significant bit replicates the msb. |

**Bit 8 – DMA** Blender DMA Layer Enable

| Value | Description  |
|-------|--|
| 0     | The default color is used on the Overlay 1 Layer.            |
| 1     | The DMA channel retrieves the pixels stream from the memory. |

**Bit 7 – OVR** Blender Overlay Layer Enable

| Value | Description  |
|-------|--|
| 0     | Overlay pixel color is set to the default overlay pixel color. |
| 1     | Overlay pixel color is set to the DMA channel pixel color.     |

**Bit 6 – LAEN** Blender Local Alpha Enable

| Value | Description                                   |
|-------|---|
| 0     | Local alpha blending coefficient is disabled. |
| 1     | Local alpha blending coefficient is enabled.  |

**Bit 5 – GAEN** Blender Global Alpha Enable

| Value | Description                                    |
|-------|--|
| 0     | Global alpha blending coefficient is disabled. |
| 1     | Global alpha blending coefficient is enabled.  |

**Bit 4 – REVALPHA** Blender Reverse Alpha

| Value | Description                                  |
|-------|--|
| 0     | Pixel difference is multiplied by alpha.     |
| 1     | Pixel difference is multiplied by 1 - alpha. |

**Bit 3 – ITER** Blender Use Iterated Color

| Value | Description  |
|-------|--|
| 0     | Pixel difference is set to 0.                        |
| 1     | Pixel difference is set to the iterated pixel value. |

**Bit 2 – ITER2BL** Blender Iterated Color Enable

| Value | Description   |
|-------|---|
| 0     | Final adder stage operand is set to 0.                        |
| 1     | Final adder stage operand is set to the iterated pixel value. |

**Bit 1 – INV** Blender Inverted Blender Output Enable

| Value | Description                           |
|-------|---------------------------------------|
| 0     | Iterated pixel is the blended pixel.  |
| 1     | Iterated pixel is the inverted pixel. |

**Bit 0 – CRKEY** Blender Chroma Key Enable

| Value | Description                      |
|-------|----------------------------------|
| 0     | Chroma key matching is disabled. |
| 1     | Chroma key matching is enabled.  |

Coefficient format is 1 sign bit and 7 fractional bits.

**38.7.136 High-End Overlay Configuration Register 41**

**Name:** LCDC\_HEOCFG41  
**Offset:** 0x00000430  
**Reset:** 0x00000000  
**Property:** Read/Write

**Bits 18:16 – YPHIDEF[2:0]** Vertical Filter Phase Offset

YPHIDEF defines the index of the first coefficient set used when the vertical resampling operation is started.

**Bits 2:0 – XPHIDEF[2:0]** Horizontal Filter Phase Offset

XPHIDEF defines the index of the first coefficient set used when the horizontal resampling operation is started.

### 38.7.137 Post Processing Channel Enable Register

**Name:** LCDC\_PPCHER  
**Offset:** 0x00000540  
**Reset:** –  
**Property:** Write-only

#### Bit 2 – A2QEN Add To Queue Enable

| Value | Description   |
|-------|---|
| 0     | No effect   |
| 1     | Indicates that a valid descriptor has been written to memory, its memory location should be written to the DMA head pointer. The A2QSR status bit is set to one, and it is reset by hardware as soon as the descriptor pointed to by the DMA head pointer is added to the list. |

#### Bit 1 – UPDATEEN Update Overlay Attributes Enable

| Value | Description  |
|-------|--|
| 0     | No effect  |
| 1     | Updates windows attributes on the next start of frame. |

#### Bit 0 – CHEN Channel Enable

| Value | Description             |
|-------|-------------------------|
| 0     | No effect               |
| 1     | Enables the DMA channel |

### 38.7.138 Post Processing Channel Disable Register

**Name:** LCDC\_PPCHDR  
**Offset:** 0x00000544  
**Reset:** –  
**Property:** Write-only

#### Bit 8 – CHRST Channel Reset

| Value | Description   |
|-------|---|
| 0     | No effect   |
| 1     | Resets the layer immediately. The frame is aborted. |

#### Bit 0 – CHDIS Channel Disable

| Value | Description   |
|-------|---|
| 0     | No effect   |
| 1     | Disables the layer at the end of the current frame. The frame is completed. |

### 38.7.139 Post Processing Channel Status Register

**Name:** LCDC\_PPCHSR  
**Offset:** 0x00000548  
**Reset:** 0x00000000  
**Property:** Read-only

|        |    |    |    |    |    |       |          |      |  |
|--------|----|----|----|----|----|-------|----------|------|--|
| Bit    | 31 | 30 | 29 | 28 | 27 | 26    | 25       | 24   |  |
|        |    |    |    |    |    |       |          |      |  |
| Access |    |    |    |    |    |       |          |      |  |
| Reset  |    |    |    |    |    |       |          |      |  |
|        |    |    |    |    |    |       |          |      |  |

|        |    |    |    |    |    | A2QSR | UPDATESR | CHSR |  |
| Access |    |    |    |    |    | R     | R        | R    |  |
| Reset  |    |    |    |    |    | 0     | 0        | 0    |  |

#### Bit 2 – A2QSR Add To Queue Status

| Value | Description              |
|-------|--------------------------|
| 0     | Add to queue not pending |
| 1     | Add to queue pending     |

#### Bit 1 – UPDATESR Update Overlay Attributes In Progress Status

| Value | Description  |
|-------|--|
| 0     | No update pending                                    |
| 1     | Overlay attributes will be updated on the next frame |

#### Bit 0 – CHSR Channel Status

| Value | Description    |
|-------|----------------|
| 0     | Layer disabled |
| 1     | Layer enabled  |

**38.7.140 Post Processing Interrupt Enable Register**

**Name:** LCDC\_PPIER  
**Offset:** 0x0000054C  
**Reset:** –  
**Property:** Write-only

The following configuration values are valid for all listed bit names of this register:  
0: No effect.

1: Enables the corresponding interrupt.

**Bit 5 – DONE** End of List Interrupt Enable

**Bit 4 – ADD** Head Descriptor Loaded Interrupt Enable

**Bit 3 – DSCR** Descriptor Loaded Interrupt Enable

**Bit 2 – DMA** End of DMA Transfer Interrupt Enable

### 38.7.141 Post Processing Interrupt Disable Register

**Name:** LCDC\_PPIDR  
**Offset:** 0x00000550  
**Reset:** –  
**Property:** Write-only

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Disables the corresponding interrupt.

|        |    |    |      |     |      |     |    |    |

| Reset  |    |    | –    | –   | –    | –   |    |    |

**Bit 5 – DONE** End of List Interrupt Disable

**Bit 4 – ADD** Head Descriptor Loaded Interrupt Disable

**Bit 3 – DSCR** Descriptor Loaded Interrupt Disable

**Bit 2 – DMA** End of DMA Transfer Interrupt Disable

### 38.7.142 Post Processing Interrupt Mask Register

**Name:** LCDC\_PPIMR  
**Offset:** 0x00000554  
**Reset:** 0x00000000  
**Property:** Read-only

The following configuration values are valid for all listed bit names of this register:

0: The corresponding interrupt is disabled.

1: The corresponding interrupt is enabled.

**Bit 5 – DONE** End of List Interrupt Mask

**Bit 4 – ADD** Head Descriptor Loaded Interrupt Mask

**Bit 3 – DSCR** Descriptor Loaded Interrupt Mask

**Bit 2 – DMA** End of DMA Transfer Interrupt Mask

### 38.7.143 Post Processing Interrupt Status Register

**Name:** LCDC\_PPISR  
**Offset:** 0x00000558  
**Reset:** 0x00000000  
**Property:** Read-only

**Bit 5 – DONE** End of List Detected

| Value | Description  |
|-------|--|
| 0     | No End of List condition has occurred since last read of LCDC_PPISR            |
| 1     | End of List condition has occurred. This flag is reset after a read operation. |

**Bit 4 – ADD** Head Descriptor Loaded

| Value | Description  |
|-------|--|
| 0     | No descriptor has been loaded since last read of LCDC_PPISR  |
| 1     | The descriptor pointed to by the LCDC_PPHEAD register has been loaded successfully. This flag is reset after a read operation. |

**Bit 3 – DSCR** DMA Descriptor Loaded

| Value | Description   |
|-------|---|
| 0     | No descriptor has been loaded since last read of LCDC_PPISR                           |
| 1     | A descriptor has been loaded successfully. This flag is reset after a read operation. |

**Bit 2 – DMA** End of DMA Transfer

| Value | Description  |
|-------|--|
| 0     | No End of Transfer has been detected since last read of LCDC_PPISR |

# SAMA5D2 Series

## LCD Controller (LCDC)

---

---

| Value | Description   |
|-------|---|
| 1     | End of Transfer has been detected. This flag is reset after a read operation. |

**38.7.144 Post Processing Head Register**

**Name:** LCDC\_PPHEAD  
**Offset:** 0x0000055C  
**Reset:** 0x00000000  
**Property:** Read/Write

**Bit 8 – DLBO** Defined Length Burst Only For Channel Bus Transaction

| Value | Description  |
|-------|--|
| 0     | Undefined length INCR burst is used for 2 and 3 beats burst.         |
| 1     | Only Defined Length burst is used (SINGLE, INCR4, INCR8 and INCR16). |

**Bits 5:4 – BLEN[1:0]** AHB Burst Length

| Value | Name            | Description   |
|-------|-----------------|---|
| 0     | AHB_BLEN_SINGLE | AHB Access is started as soon as there is enough space in the FIFO to store one data. SINGLE, INCR, INCR4, INCR8 and INCR16 bursts are used. INCR is used for a burst of 2 and 3 beats.                                     |
| 1     | AHB_BLEN_INCR4  | AHB Access is started as soon as there is enough space in the FIFO to store a total amount of 4 data. An AHB INCR4 Burst is used. SINGLE, INCR and INCR4 bursts are used. INCR is used for a burst of 2 and 3 beats.        |
| 2     | AHB_BLEN_INCR8  | AHB Access is started as soon as there is enough space in the FIFO to store a total amount of 8 data. An AHB INCR8 Burst is used. SINGLE, INCR, INCR4 and INCR8 bursts are used. INCR is used for a burst of 2 and 3 beats. |

# SAMA5D2 Series

## LCD Controller (LCDC)

| Value | Name            | Description   |
|-------|-----------------|---|
| 3     | AHB_BLEN_INCR16 | AHB Access is started as soon as there is enough space in the FIFO to store a total amount of 16 data. An AHB INCR16 Burst is used. SINGLE, INCR, INCR4, INCR8 and INCR16 bursts are used. INCR is used for a burst of 2 and 3 beats. |

### Bit 0 – SIF Source Interface

| Value | Description   |
|-------|---|
| 0     | Base Layer data is retrieved through AHB interface 0. |
| 1     | Base Layer data is retrieved through AHB interface 1. |

### 38.7.149 Post Processing Configuration Register 1

**Name:** LCDC\_PPCFG1  
**Offset:** 0x00000570  
**Reset:** 0x00000000  
**Property:** Read/Write

#### Bit 4 – ITUBT601 Color Space Conversion Luminance

| Value | Description   |
|-------|---|
| 0     | Luminance and chrominance range is [0;255]  |
| 1     | Luminance values are clamped to [16;235] range. Chrominance values are clamped to [16;240] range. |

#### Bits 2:0 – PPMODE[2:0] Post Processing Output Format Selection

| Value | Name                      | Description               |
|-------|---------------------------|---------------------------|
| 0     | PPMODE_RGB_16BPP          | RGB 16 bpp                |
| 1     | PPMODE_RGB_24BPP_PACKED   | RGB 24 bpp PACKED         |
| 2     | PPMODE_RGB_24BPP_UNPACKED | RGB 24 bpp UNPACKED       |
| 3     | PPMODE_YCBCR_422_MODE0    | YCbCr 422 16 bpp (Mode 0) |
| 4     | PPMODE_YCBCR_422_MODE1    | YCbCr 422 16 bpp (Mode 1) |
| 5     | PPMODE_YCBCR_422_MODE2    | YCbCr 422 16 bpp (Mode 2) |
| 6     | PPMODE_YCBCR_422_MODE3    | YCbCr 422 16 bpp (Mode 3) |

## **39. Ethernet MAC (GMAC)**

### **39.1 Description**

The Ethernet MAC (GEMAC) module implements a 10/100 Mbps Ethernet MAC compatible with the IEEE 802.3 standard. The GEMAC can operate in either half or full duplex mode at all supported speeds. The [GMAC Network Configuration Register](#) is used to select the speed, duplex mode and interface type (MII, RMII).

### **39.2 Embedded Characteristics**

- Compatible with IEEE Standard 802.3
- 10, 100 Mbps Operation
- Full and Half Duplex Operation at all Supported Speeds of Operation
- Statistics Counter Registers for RMON/MIB
- MII/RMII Interface to the Physical Layer
- Integrated Physical Coding
- Direct Memory Access (DMA) Interface to External Memory
- Support for 3 Priority Queues
- 8 Kbytes Transmit RAM and 4 Kbytes Receive RAM (refer to [Table 39-4](#) for queue-specific sizes)
- Programmable Burst Length and Endianism for DMA
- Interrupt Generation to Signal Receive and Transmit Completion, Errors or Other Events
- Automatic Pad and Cyclic Redundancy Check (CRC) Generation on Transmitted Frames
- Automatic Discard of Frames Received with Errors
- Receive and Transmit IP, TCP and UDP Checksum Offload. Both IPv4 and IPv6 Packet Types Supported
- Address Checking Logic for Four Specific 48-bit Addresses, Four Type IDs, Promiscuous Mode, Hash Matching of Unicast and Multicast Destination Addresses and Wake-on-LAN
- Management Data Input/Output (MDIO) Interface for Physical Layer Management
- Support for Jumbo Frames up to 10240 Bytes
- Full Duplex Flow Control with Recognition of Incoming Pause Frames and Hardware Generation of Transmitted Pause Frames
- Half Duplex Flow Control by Forcing Collisions on Incoming Frames
- Support for 802.1Q VLAN Tagging with Recognition of Incoming VLAN and Priority Tagged Frames
- Support for 802.1Qbb Priority-based Flow Control
- Programmable Inter Packet Gap (IPG) Stretch
- Recognition of IEEE 1588 PTP Frames
- IEEE 1588 Timestamp Unit (TSU)
- Support for 802.1AS Timing and Synchronization
- Supports 802.1Qav Traffic Shaping on Two Highest Priority Queues

### 39.3 Block Diagram

Figure 39-1. Block Diagram

### 39.4 Signal Interfaces

The GEMAC includes the following signal interfaces:

- MII, RMII to an external PHY
- MDIO interface for external PHY management
- Slave APB interface for accessing GEMAC registers
- Master AHB interface for memory access
- GTSUCOMP signal for TSU timer count value comparison

Table 39-1. GEMAC Connections in Different Modes

| Signal Name          | Function                          | MII      | RMII     |
|----------------------|-----------------------------------|----------|----------|
| GTXCK <sup>(1)</sup> | Transmit Clock or Reference Clock | TXCK     | REFCK    |
| GTXEN                | Transmit Enable                   | TXEN     | TXEN     |
| GTX[3..0]            | Transmit Data                     | TXD[3:0] | TXD[1:0] |
| GTXER                | Transmit Coding Error             | TXER     | Not Used |
| GRXCK                | Receive Clock                     | RXCK     | Not Used |
| GRXDV                | Receive Data Valid                | RXDV     | CRSDV    |
| GRX[3..0]            | Receive Data                      | RXD[3:0] | RXD[1:0] |

| .....continued |                              |      |          |
|----------------|------------------------------|------|----------|
| Signal Name    | Function                     | MII  | RMII     |
| GRXER          | Receive Error                | RXER | RXER     |
| GCRS           | Carrier Sense and Data Valid | CRS  | Not Used |
| GCOL           | Collision Detect             | COL  | Not Used |
| GMDC           | Management Data Clock        | MDC  | MDC      |
| GMDIO          | Management Data Input/Output | MDIO | MDIO     |

**Note:**

1. Input only. GTXCK must be provided with a 25 MHz / 50 MHz external crystal oscillator for MII / RMII interfaces, respectively.

## 39.5 Product Dependencies

### 39.5.1 I/O Lines

The pins used for interfacing the GEMAC may be multiplexed with PIO lines. The programmer must first program the PIO Controller to assign the pins to their peripheral function. If I/O lines of the GEMAC are not used by the application, they can be used for other purposes by the PIO Controller.

### 39.5.2 Power Management

The GEMAC is not continuously clocked. The user must first enable the GEMAC clock in the Power Management Controller before using it.

### 39.5.3 Interrupt Sources

The GEMAC interrupt line is connected to one of the internal sources of the interrupt controller. Using the GEMAC interrupt requires prior programming of the interrupt controller.

The GEMAC features 3 interrupt sources. Refer to the table “Peripheral Identifiers” in the section “Peripherals” for the interrupt numbers for GEMAC priority queues.

## 39.6 Functional Description

### 39.6.1 Media Access Controller

The Media Access Controller (MAC) transmit block takes data from FIFO, adds preamble and, if necessary, pad and frame check sequence (FCS). Both half duplex and full duplex Ethernet modes of operation are supported. When operating in half duplex mode, the MAC transmit block generates data according to the carrier sense multiple access with collision detect (CSMA/CD) protocol. The start of transmission is deferred if carrier sense (CRS) is active. If collision (COL) becomes active during transmission, a jam sequence is asserted and the transmission is retried after a random backoff. The CRS and COL signals have no effect in full duplex mode.

The MAC receive block checks for valid preamble, FCS, alignment and length, and presents received frames to the MAC address checking block and FIFO. Software can configure the GMAC to receive jumbo frames up to 10240 bytes. It can optionally strip CRC from the received frame prior to transfer to FIFO.

The address checker recognizes four specific 48-bit addresses, can recognize four different type ID values, and contains a 64-bit Hash register for matching multicast and unicast addresses as required. It can recognize the broadcast address of all ones and copy all frames. The MAC can also reject all frames that are not VLAN tagged and recognize Wake on LAN events.

The MAC receive block supports offloading of IP, TCP and UDP checksum calculations (both IPv4 and IPv6 packet types supported), and can automatically discard bad checksum frames.

### 39.6.2 1588 Timestamp Unit

The 1588 timestamp unit (TSU) is implemented as a 94-bit timer.

The 48 upper bits [93:46] of the timer count seconds and are accessible in the [GMAC 1588 Timer Seconds High Register](#) (GMAC\_TSH) and [GMAC 1588 Timer Seconds Low Register](#) (GMAC\_TSL). The 30 lower bits [45:16] of the timer count nanoseconds and are accessible in the [GMAC 1588 Timer Nanoseconds Register](#) (GMAC\_TN). The lowest 16 bits [15:0] of the timer count sub-nanoseconds.

The 46 lower bits roll over when they have counted to one second. The timer increments by a programmable period (to approximately 15.2 femtoseconds resolution) with each MCK period and can also be adjusted in 1ns resolution (incremented or decremented) through APB register accesses.

### 39.6.3 AHB Direct Memory Access Interface

The GEMAC DMA controller is connected to the MAC FIFO interface and provides a scatter-gather type capability for packet data storage.

The DMA implements packet buffering where dual-port memories are used to buffer multiple frames.

#### 39.6.3.1 Packet Buffer DMA

- Easier to guarantee maximum line rate due to the ability to store multiple frames in the packet buffer, where the number of frames is limited by the amount of packet buffer memory and Ethernet frame size
- Full store and forward, or partial store and forward programmable options (partial store will cater for shorter latency requirements)
- Support for Transmit TCP/IP checksum offload
- Support for priority queueing
- When a collision on the line occurs during transmission, the packet will be automatically replayed directly from the packet buffer memory rather than having to re-fetch through the AHB (full store and forward ONLY)
- Received error packets are automatically dropped before any of the packet is presented to the AHB (full store and forward ONLY), thus reducing AHB activity
- Supports manual RX packet flush capabilities
- Optional RX packet flush when there is lack of AHB resource

#### 39.6.3.2 Partial Store and Forward Using Packet Buffer DMA

The DMA uses SRAM-based packet buffers, and can be programmed into a low latency mode, known as Partial Store and Forward. This allows for a reduced latency as the full packet is not buffered before forwarding. Note that this option is only available when the device is configured for full duplex operation.

This feature is enabled via the programmable TX and RX Partial Store and Forward registers. When the transmit Partial Store and Forward mode is activated, the transmitter will only begin to forward the packet to the MAC when there is enough packet data stored in the packet buffer. Likewise, when the receive Partial Store and Forward mode is activated, the receiver will only begin to forward the packet to the AHB when enough packet data is stored in the packet buffer. The amount of packet data required to activate

the forwarding process is programmable via watermark registers which are located at the same address as the partial store and forward enable bits.

Note that the minimum operational value for the TX partial store and forward watermark is 20. There is no operational limit for the RX partial store and forward watermark. Enabling partial store and forward is a useful means to reduce latency, but there are performance implications.

The GEMAC DMA uses separate transmit and receive lists of buffer descriptors, with each descriptor describing a buffer area in memory. This allows Ethernet packets to be broken up and scattered around the AHB memory space.

### 39.6.3.3 Receive AHB Buffers

Received frames, optionally including FCS, are written to receive AHB buffers stored in memory. The receive buffer depth is programmable in the range of 64 bytes to 16 Kbytes through the DMA Configuration register, with the default being 128 bytes.

The start location for each receive AHB buffer is stored in memory in a list of receive buffer descriptors at an address location pointed to by the receive buffer queue pointer. The base address for the receive buffer queue pointer is configured in software using the Receive Buffer Queue Base Address register.

Each list entry consists of two words. The first is the address of the receive AHB buffer and the second the receive status. If the length of a receive frame exceeds the AHB buffer length, the status word for the used buffer is written with zeroes except for the “start of frame” bit, which is always set for the first buffer in a frame. Bit zero of the address field is written to 1 to show the buffer has been used. The receive buffer manager then reads the location of the next receive AHB buffer and fills that with the next part of the received frame data. AHB buffers are filled until the frame is complete and the final buffer descriptor status word contains the complete frame status. Refer to the table below for details of the receive buffer descriptor list.

Each receive AHB buffer start location is a word address. The start of the first AHB buffer in a frame can be offset by up to three bytes, depending on the value written to bits 14 and 15 of the Network Configuration register. If the start location of the AHB buffer is offset, the available length of the first AHB buffer is reduced by the corresponding number of bytes.

**Table 39-2. Receive Buffer Descriptor Entry**

| Bit    | Function   |
|--------|--|
| Word 0 |  |
| 31:2   | Address of beginning of buffer   |
| 1      | Wrap—marks last descriptor in receive buffer descriptor list.  |
| 0      | Ownership—needs to be zero for the GEMAC to write data to the receive buffer. The GEMAC sets this to one once it has successfully written a frame to memory. Software has to clear this bit before the buffer can be used again. |
| Word 1 |  |
| 31     | Global all ones broadcast address detected   |
| 30     | Multicast hash match   |
| 29     | Unicast hash match   |
| 28     | —  |

| .....continued |  |
|----------------|--|
| Bit            | Function   |
| 27             | Specific Address Register match found, bit 25 and bit 26 indicate which Specific Address Register causes the match.  |
| 26:25          | Specific Address Register match. Encoded as follows:<br>00: Specific Address Register 1 match<br>01: Specific Address Register 2 match<br>10: Specific Address Register 3 match<br>11: Specific Address Register 4 match<br>If more than one specific address is matched only one is indicated with priority 4 down to 1.  |
| 24             | This bit has a different meaning depending on whether RX checksum offloading is enabled.<br><b>With RX checksum offloading disabled:</b> (bit 24 clear in Network Configuration Register)<br>Type ID register match found, bit 22 and bit 23 indicate which type ID register causes the match.<br><b>With RX checksum offloading enabled:</b> (bit 24 set in Network Configuration Register)<br>0: The frame was not SNAP encoded and/or had a VLAN tag with the Canonical Format Indicator (CFI) bit set.<br>1: The frame was SNAP encoded and had either no VLAN tag or a VLAN tag with the CFI bit not set.   |
| 23:22          | This bit has a different meaning depending on whether RX checksum offloading is enabled.<br><b>With RX checksum offloading disabled:</b> (bit 24 clear in Network Configuration)<br>Type ID register match. Encoded as follows:<br>00: Type ID register 1 match<br>01: Type ID register 2 match<br>10: Type ID register 3 match<br>11: Type ID register 4 match<br>If more than one Type ID is matched only one is indicated with priority 4 down to 1.<br><b>With RX checksum offloading enabled:</b> (bit 24 set in Network Configuration Register)<br>00: Neither the IP header checksum nor the TCP/UDP checksum was checked.<br>01: The IP header checksum was checked and was correct. Neither the TCP nor UDP checksum was checked.<br>10: Both the IP header and TCP checksum were checked and were correct.<br>11: Both the IP header and UDP checksum were checked and were correct. |
| 21             | VLAN tag detected—type ID of 0x8100. For packets incorporating the stacked VLAN processing feature, this bit will be set if the second VLAN tag has a type ID of 0x8100  |

| .....continued |  |
|----------------|--|
| Bit            | Function   |
| 20             | Priority tag detected—type ID of 0x8100 and null VLAN identifier. For packets incorporating the stacked VLAN processing feature, this bit will be set if the second VLAN tag has a type ID of 0x8100 and a null VLAN identifier.   |
| 19:17          | VLAN priority—only valid if bit 21 is set.   |
| 16             | Canonical format indicator (CFI) bit (only valid if bit 21 is set).  |
| 15             | End of frame—when set the buffer contains the end of a frame. If end of frame is not set, then the only valid status bit is start of frame (bit 14).   |
| 14             | Start of frame—when set the buffer contains the start of a frame. If both bits 15 and 14 are set, the buffer contains a whole frame.   |
| 13             | <p>This bit has a different meaning depending on whether jumbo frames and ignore FCS modes are enabled. If neither mode is enabled this bit will be zero.</p> <p><b>With jumbo frame mode enabled:</b> (bit 3 set in Network Configuration Register) Additional bit for length of frame (bit[13]), that is concatenated with bits[12:0]</p> <p><b>With ignore FCS mode enabled and jumbo frames disabled:</b> (bit 26 set in Network Configuration Register and bit 3 clear in Network Configuration Register) This indicates per frame FCS status as follows:</p> <p>0: Frame had good FCS</p> <p>1: Frame had bad FCS, but was copied to memory as ignore FCS enabled.</p>           |
| 12:0           | <p>These bits represent the length of the received frame which may or may not include FCS depending on whether FCS discard mode is enabled.</p> <p><b>With FCS discard mode disabled:</b> (bit 17 clear in Network Configuration Register)</p> <p>Least significant 12 bits for length of frame including FCS. If jumbo frames are enabled, these 12 bits are concatenated with bit[13] of the descriptor above.</p> <p><b>With FCS discard mode enabled:</b> (bit 17 set in Network Configuration Register)</p> <p>Least significant 12 bits for length of frame excluding FCS. If jumbo frames are enabled, these 12 bits are concatenated with bit[13] of the descriptor above.</p> |

To receive frames, the AHB buffer descriptors must be initialized by writing an appropriate address to bits 31:2 in the first word of each list entry. Bit 0 must be written with zero. Bit 1 is the wrap bit and indicates the last entry in the buffer descriptor list.

The start location of the receive buffer descriptor list must be written with the receive buffer queue base address before reception is enabled (receive enable in the Network Control register). Once reception is enabled, any writes to the Receive Buffer Queue Base Address register are ignored. When read, it will return the current pointer position in the descriptor list, though this is only valid and stable when receive is disabled.

If the filter block indicates that a frame should be copied to memory, the receive data DMA operation starts writing data into the receive buffer. If an error occurs, the buffer is recovered.

An internal counter within the GEMAC represents the receive buffer queue pointer and it is not visible through the CPU interface. The receive buffer queue pointer increments by two words after each buffer

has been used. It re-initializes to the receive buffer queue base address if any descriptor has its wrap bit set.

As receive AHB buffers are used, the receive AHB buffer manager sets bit zero of the first word of the descriptor to logic one indicating the AHB buffer has been used.

Software should search through the “used” bits in the AHB buffer descriptors to find out how many frames have been received, checking the start of frame and end of frame bits.

When the DMA is configured in the packet buffer Partial Store And Forward mode, received frames are written out to the AHB buffers as soon as enough frame data exists in the packet buffer. For both cases, this may mean several full AHB buffers are used before some error conditions can be detected. If a receive error is detected the receive buffer currently being written will be recovered. Previous buffers will not be recovered. As an example, when receiving frames with cyclic redundancy check (CRC) errors or excessive length, it is possible that a frame fragment might be stored in a sequence of AHB receive buffers. Software can detect this by looking for start of frame bit set in a buffer following a buffer with no end of frame bit set.

To function properly, a 10/100/1000 Ethernet system should have no excessive length frames or frames greater than 128 bytes with CRC errors. Collision fragments will be less than 128 bytes long, therefore it will be a rare occurrence to find a frame fragment in a receive AHB buffer, when using the default value of 128 bytes for the receive buffers size.

When in packet buffer full store and forward mode, only good received frames are written out of the DMA, so no fragments will exist in the AHB buffers due to MAC receiver errors. There is still the possibility of fragments due to DMA errors, for example used bit read on the second buffer of a multi-buffer frame.

If bit zero of the receive buffer descriptor is already set when the receive buffer manager reads the location of the receive AHB buffer, then the buffer has been already used and cannot be used again until software has processed the frame and cleared bit zero. In this case, the “buffer not available” bit in the Receive Status register is set and an interrupt triggered. The Receive Resource Error statistics register is also incremented.

When the DMA is configured in the packet buffer full store and forward mode, the user can optionally select whether received frames should be automatically discarded when no AHB buffer resource is available. This feature is selected via bit 24 of the DMA Configuration register (by default, the received frames are not automatically discarded). If this feature is off, then received packets will remain to be stored in the SRAM-based packet buffer until AHB buffer resource next becomes available. This may lead to an eventual packet buffer overflow if packets continue to be received when bit zero (used bit) of the receive buffer descriptor remains set. Note that after a used bit has been read, the receive buffer manager will re-read the location of the receive buffer descriptor every time a new packet is received. When the DMA is not configured in the packet buffer full store and forward mode and a used bit is read, the frame currently being received will be automatically discarded.

When the DMA is configured in the packet buffer full store and forward mode, a receive overrun condition occurs when the receive SRAM-based packet buffer is full, or because HRESP was not OK. In all other modes, a receive overrun condition occurs when either the AHB bus was not granted quickly enough, or because HRESP was not OK, or because a new frame has been detected by the receive block, but the status update or write back for the previous frame has not yet finished. For a receive overrun condition, the receive overrun interrupt is asserted and the buffer currently being written is recovered. The next frame that is received whose address is recognized reuses the buffer.

In any packet buffer mode, a write to bit 18 of GMAC\_NCR will force a packet from the external SRAM-based receive packet buffer to be flushed. This feature is only acted upon when the RX DMA is not

currently writing packet data out to AHB, i.e., it is in an IDLE state. If the RX DMA is active, a write to this bit is ignored.

### 39.6.3.4 Transmit AHB Buffers

Frames to transmit are stored in one or more transmit AHB buffers. Transmit frames can be between 1 and 16384 bytes long, so it is possible to transmit frames longer than the maximum length specified in the IEEE 802.3 standard. It should be noted that zero length AHB buffers are allowed and that the maximum number of buffers permitted for each transmit frame is 128.

The start location for each transmit AHB buffer is stored in memory in a list of transmit buffer descriptors at a location pointed to by the transmit buffer queue pointer. The base address for this queue pointer is set in software using the Transmit Buffer Queue Base Address register. Each list entry consists of two words. The first is the byte address of the transmit buffer and the second containing the transmit control and status. For the packet buffer DMA, the start location for each AHB buffer is a byte address, the bottom bits of the address being used to offset the start of the data from the data-word boundary (i.e., bits 2,1 and 0 are used to offset the address for 64-bit datapaths).

Frames can be transmitted with or without automatic CRC generation. If CRC is automatically generated, pad will also be automatically generated to take frames to a minimum length of 64 bytes. When CRC is not automatically generated (as defined in word 1 of the transmit buffer descriptor), the frame is assumed to be at least 64 bytes long and pad is not generated.

An entry in the transmit buffer descriptor list is described in the table below.

To transmit frames, the buffer descriptors must be initialized by writing an appropriate byte address to bits [31:0] in the first word of each descriptor list entry.

The second word of the transmit buffer descriptor is initialized with control information that indicates the length of the frame, whether or not the MAC is to append CRC and whether the buffer is the last buffer in the frame.

After transmission the status bits are written back to the second word of the first buffer along with the used bit. Bit 31 is the used bit which must be zero when the control word is read if transmission is to take place. It is written to one once the frame has been transmitted. Bits[29:20] indicate various transmit error conditions. Bit 30 is the wrap bit which can be set for any buffer within a frame. If no wrap bit is encountered the queue pointer continues to increment.

The Transmit Buffer Queue Base Address register can only be updated while transmission is disabled or halted; otherwise any attempted write will be ignored. When transmission is halted the transmit buffer queue pointer will maintain its value. Therefore when transmission is restarted the next descriptor read from the queue will be from immediately after the last successfully transmitted frame. While transmit is disabled (bit 3 of the Network Control register set low), the transmit buffer queue pointer resets to point to the address indicated by the Transmit Buffer Queue Base Address register. Note that disabling receive does not have the same effect on the receive buffer queue pointer.

Once the transmit queue is initialized, transmit is activated by writing to the transmit start bit (bit 9) of the Network Control register. Transmit is halted when a buffer descriptor with its used bit set is read, a transmit error occurs, or by writing to the transmit halt bit of the Network Control register. Transmission is suspended if a pause frame is received while the pause enable bit is set in the Network Configuration register. Rewriting the start bit while transmission is active is allowed. This is implemented with TXGO variable which is readable in the Transmit Status register at bit location 3. The TXGO variable is reset when:

- Transmit is disabled.
- A buffer descriptor with its ownership bit set is read.

- Bit 10, THALT, of the Network Control register is written.
- There is a transmit error such as too many retries or a transmit underrun.

To set TXGO, write TSTART to the bit 9 of the Network Control register. Transmit halt does not take effect until any ongoing transmit finishes.

If the DMA is configured for packet buffer Partial Store and Forward mode and a collision occurs during transmission of a multi-buffer frame, transmission will automatically restart from the first buffer of the frame. For packet buffer mode, the entire contents of the frame are read into the transmit packet buffer memory, so the retry attempt will be replayed directly from the packet buffer memory rather than having to re-fetch through the AHB.

If a used bit is read midway through transmission of a multi-buffer frame, this is treated as a transmit error. Transmission stops, GTXER is asserted and the FCS will be bad.

If transmission stops due to a transmit error or a used bit being read, transmission restarts from the first buffer descriptor of the frame being transmitted when the transmit start bit is rewritten.

**Table 39-3. Transmit Buffer Descriptor Entry**

| Bit    | Function  |
|--------|---|
| Word 0 |   |
| 31:0   | Byte address of buffer  |
| Word 1 |   |
| 31     | Used—must be zero for the GEMAC to read data to the transmit buffer. The GEMAC sets this to one for the first buffer of a frame once it has been successfully transmitted. Software must clear this bit before the buffer can be used again.  |
| 30     | Wrap—marks last descriptor in transmit buffer descriptor list. This can be set for any buffer within the frame.   |
| 29     | Retry limit exceeded, transmit error detected   |
| 28     | Reserved.   |
| 27     | Transmit frame corruption due to AHB error—set if an error occurs while midway through reading transmit frame from the AHB, including HRESP errors and buffers exhausted mid frame (if the buffers run out during transmission of a frame then transmission stops, FCS shall be bad and GTXER asserted).<br>Also set if single frame is too large for configured packet buffer memory size. |
| 26     | Late collision, transmit error detected.  |
| 25:23  | Reserved  |

| .....continued |   |
|----------------|---|
| Bit            | Function  |
| 22:20          | Transmit IP/TCP/UDP checksum generation offload errors:<br>000: No Error.<br><br>001: The Packet was identified as a VLAN type, but the header was not fully complete, or had an error in it.<br><br>010: The Packet was identified as a SNAP type, but the header was not fully complete, or had an error in it.<br><br>011: The Packet was not of an IP type, or the IP packet was invalidly short, or the IP was not of type IPv4/IPv6.<br><br>100: The Packet was not identified as VLAN, SNAP or IP.<br><br>101: Non supported packet fragmentation occurred. For IPv4 packets, the IP checksum was generated and inserted.<br><br>110: Packet type detected was not TCP or UDP. TCP/UDP checksum was therefore not generated. For IPv4 packets, the IP checksum was generated and inserted.<br><br>111: A premature end of packet was detected and the TCP/UDP checksum could not be generated. |
| 19:17          | Reserved  |
| 16             | No CRC to be appended by MAC. When set, this implies that the data in the buffers already contains a valid CRC, hence no CRC or padding is to be appended to the current frame by the MAC.<br><br>This control bit must be set for the first buffer in a frame and will be ignored for the subsequent buffers of a frame.<br><br>Note that this bit must be clear when using the transmit IP/TCP/UDP checksum generation offload, otherwise checksum generation and substitution will not occur.  |
| 15             | Last buffer, when set this bit will indicate the last buffer in the current frame has been reached.   |
| 14             | Reserved  |
| 13:0           | Length of buffer  |

### 39.6.3.5 DMA Bursting on the AHB

The DMA will always use SINGLE, or INCR type AHB accesses for buffer management operations. When performing data transfers, the AHB burst length used can be programmed using bits 4:0 of the DMA Configuration register so that either SINGLE, INCR or fixed length incrementing bursts (INCR4, INCR8 or INCR16) are used where possible.

When there is enough space and enough data to be transferred, the programmed fixed length bursts will be used. If there is not enough data or space available, for example when at the beginning or the end of a buffer, SINGLE type accesses are used. Also SINGLE type accesses are used at 1024 byte boundaries, so that the 1 Kbyte boundaries are not burst over as per AHB requirements.

The DMA will not terminate a fixed length burst early, unless an error condition occurs on the AHB or if receive or transmit are disabled in the Network Control register.

### 39.6.3.6 DMA Packet Buffer

The DMA uses packet buffers for both transmit and receive paths. This mode allows multiple packets to be buffered in both transmit and receive directions. This allows the DMA to withstand far greater access latencies on the AHB and make more efficient use of the AHB bandwidth. There are two modes of operation—Full Store and Forward and Partial Store and Forward.

As described in section [Partial Store and Forward Using Packet Buffer DMA](#), the DMA can be programmed into a low latency mode, known as Partial Store and Forward.

When the DMA is in full store and forward mode, full packets are buffered which provides the possibility to:

- Discard packets with error on the receive path before they are partially written out of the DMA, thus saving AHB bus bandwidth and driver processing overhead,
- Retry collided transmit frames from the buffer, thus saving AHB bus bandwidth,
- Implement transmit IP/TCP/UDP checksum generation offload.

With the packet buffers included, the structure of the GEMAC data paths is shown in the figure below.

**Figure 39-2. Data Paths with Packet Buffers Included**

### 39.6.3.7 Transmit Packet Buffer

The transmitter packet buffer will continue attempting to fetch frame data from the AHB system memory until the packet buffer itself is full, at which point it will attempt to maintain its full level.

To accommodate the status and statistics associated with each frame, three words per packet are reserved at the end of the packet data. If the packet is bad and requires to be dropped, the status and statistics are the only information held on that packet. Storing the status in the DPRAM is required in order to decouple the DMA interface of the buffer from the MAC interface, to update the MAC status/statistics and to generate interrupts in the order in which the packets that they represent were fetched from the AHB memory.

If any errors occur on the AHB while reading the transmit frame, the fetching of packet data from AHB memory is halted. The MAC transmitter will continue to fetch packet data, thereby emptying the packet buffer and allowing any good non-errored frames to be transmitted successfully. Once these have been fully transmitted, the status/statistics for the errored frame will be updated and software will be informed via an interrupt that an AHB error occurred. This way, the error is reported in the correct packet order.

The transmit packet buffer will only attempt to read more frame data from the AHB when space is available in the packet buffer memory. If space is not available it must wait until the a packet fetched by the MAC completes transmission and is subsequently removed from the packet buffer memory. Note that if full store and forward mode is active and if a single frame is fetched that is too large for the packet buffer memory, the frame is flushed and the DMA halted with an error status. This is because a complete frame must be written into the packet buffer before transmission can begin, and therefore the minimum packet buffer memory size should be chosen to satisfy the maximum frame to be transmitted in the application.

In full store and forward mode, once the complete transmit frame is written into the packet buffer memory, a trigger is sent across to the MAC transmitter, which will then begin reading the frame from the packet buffer memory. Since the whole frame is present and stable in the packet buffer memory an underflow of the transmitter is not possible. The frame is kept in the packet buffer until notification is received from the MAC that the frame data has either been successfully transmitted or can no longer be retransmitted (too many retries in half duplex mode). When this notification is received the frame is flushed from memory to make room for a new frame to be fetched from AHB system memory.

In Partial Store and Forward mode, a trigger is sent across to the MAC transmitter as soon as sufficient packet data is available, which will then begin fetching the frame from the packet buffer memory. If, after this point, the MAC transmitter is able to fetch data from the packet buffer faster than the AHB DMA can fill it, an underflow of the transmitter is possible. In this case, the transmission is terminated early, and the packet buffer is completely flushed. Transmission can only be restarted by writing to the transmit START bit.

In half duplex mode, the frame is kept in the packet buffer until notification is received from the MAC that the frame data has either been successfully transmitted or can no longer be retransmitted (too many retries in half duplex mode). When this notification is received the frame is flushed from memory to make room for a new frame to be fetched from AHB system memory.

In full duplex mode, the frame is removed from the packet buffer on the fly.

Other than underflow, the only MAC related errors that can occur are due to collisions during half duplex transmissions. When a collision occurs the frame still exists in the packet buffer memory so can be retried directly from there. Only once the MAC transmitter has failed to transmit after sixteen attempts is the frame finally flushed from the packet buffer.

### 39.6.3.8 Receive Packet Buffer

The receive packet buffer stores frames from the MAC receiver along with their status and statistics. Frames with errors are flushed from the packet buffer memory, while good frames are pushed onto the DMA AHB interface.

The receiver packet buffer monitors the FIFO write interface from the MAC receiver and translates the FIFO pushes into packet buffer writes. At the end of the received frame the status and statistics are buffered so that the information can be used when the frame is read out. When programmed in full store and forward mode, if the frame has an error the frame data is immediately flushed from the packet buffer memory allowing subsequent frames to utilise the freed up space. The status and statistics for bad frames are still used to update the GEMAC registers.

To accommodate the status and statistics associated with each frame, three words per packet (or two if configured in 64-bit datapath mode) are reserved at the end of the packet data. If the packet is bad and requires to be dropped, the status and statistics are the only information held on that packet.

The receiver packet buffer will also detect a full condition so that an overflow condition can be detected. If this occurs, subsequent packets are dropped and an RX overflow interrupt is raised.

For full store and forward, the DMA only begins packet fetches once the status and statistics for a frame are available. If the frame has a bad status due to a frame error, the status and statistics are passed on to the GEMAC registers. If the frame has a good status, the information is used to read the frame from the packet buffer memory and burst onto the AHB using the DMA buffer management protocol. Once the last frame data has been transferred to the packet buffer, the status and statistics are updated to the GEMAC registers.

If Partial Store and Forward mode is active, the DMA will begin fetching the packet data before the status is available. As soon as the status becomes available, the DMA will fetch this information as soon as possible before continuing to fetch the remainder of the frame. Once the last frame data has been transferred to the packet buffer, the status and statistics are updated to the GEMAC registers.

### 39.6.3.9 Priority Queueing in the DMA

The DMA by default uses a single transmit and receive queue. This means the list of transmit/receive buffer descriptors point to data buffers associated with a single transmit/receive data stream. The GEMAC can select up to 3 priority queues. Each queue has an independent list of buffer descriptors pointing to separate data streams.

The table below gives the DPRAM size associated with each queue:

**Table 39-4. Queue Size**

| Queue Number        | Queue Size |
|---------------------|------------|
| 2                   | 4 KB       |
| 1                   | 2 KB       |
| 0 (lowest priority) | 2 KB       |

In the transmit direction, higher priority queues are always serviced before lower priority queues, with Q0 as lowest priority and Q2 as highest priority. This strict priority scheme requires the user to ensure that high priority traffic is constrained so that lower priority traffic will have required bandwidth. The GEMAC DMA will determine the next queue to service by initiating a sequence of buffer descriptor reads interrogating the ownership bits of each. The buffer descriptor corresponding to the highest priority queue is read first. As an example, if the ownership bit of this descriptor is set, then the DMA will progress to

reading the 2nd highest priority queue's descriptor. If that ownership bit read of this lower priority queue is set, then the DMA will read the 3rd highest priority queue's descriptor. If all the descriptors return an ownership bit set, then a resource error has occurred, an interrupt is generated and transmission is automatically halted. Transmission can only be restarted by setting the START bit in the Network Control register. The GEMAC DMA will need to identify the highest available queue to transmit from when the START bit in the Network Control register is written to and the TX is in a halted state, or when the last word of any packet has been fetched from external AHB memory.

The GEMAC transmit DMA maximizes the effectiveness of priority queuing by ensuring that high priority traffic be transmitted as early as possible after being fetched from AHB. High priority traffic fetched from AHB will be pushed to the MAC layer, depending on traffic shaping being enabled and the associated credit value for that queue, before any lower priority traffic that may pre-exist in the transmit SRAM-based packet buffer. This is achieved by separating the transmit SRAM-based packet buffer into regions, one region per queue. The size of each region determines the amount of SRAM space allocated per queue.

For each queue, there is an associated Transmit Buffer Queue Base Address register. For the lowest priority queue (or the only queue when only one queue is selected), the Transmit Buffer Queue Base Address is located at address 0x1C. For all other queues, the Transmit Buffer Queue Base Address registers are located at sequential addresses starting at address 0x440.

In the receive direction each packet is written to AHB data buffers in the order that it is received. For each queue, there is an independent set of receive AHB buffers for each queue. There is therefore a separate Receive Buffer Queue Base Address register for each queue. For the lowest priority queue (or the only queue when only one queue is selected), the Receive Buffer Queue Base Address is located at address 0x18. For all other queues, the Receive Buffer Queue Base Address registers are located at sequential addresses starting at address 0x480. Every received packet will pass through a programmable screening algorithm which will allocate a particular queue to that frame. The user interface to the screeners is through two types of programmable registers:

- Screening Type 1 registers—The module features 4 Screening Type 1 registers. Screening Type 1 registers hold values to match against specific IP and UDP fields of the received frames. The fields matched against are DS (Differentiated Services field of IPv4 frames), TC (Traffic class field of IPv6 frames) and/or the UDP destination port.
- Screening Type 2 registers—The module features 8 Screening Type 2 registers GMAC\_ST2RPQ. Screening Type 2 registers operate independently of Screening Type 1 registers and offer additional match capabilities. Screening Type 2 allows a screen to be configured that is the combination of all or any of the following comparisons:
  1. An enable bit VLAN priority, VLANE. A VLAN priority match will be performed if the VLAN priority enable is set. The extracted priority field in the VLAN header is compared against VLANP in the GMAC\_ST2RPQ register itself.
  2. An enable bit EtherType, ETHE. The EtherType field I2ETH inside GMAC\_ST2RPQ maps to one of 4 EtherType match registers, GMAC\_ST2ER. The extracted EtherType is compared against GMAC\_ST2ER designated by this EtherType field.
  3. An enable bit Compare A, COMPAE. This bit is associated with a Screening Type 2 Compare Word 0/1 register x, GMAC\_ST2CW0/1.
  4. An enable bit Compare B, COMPBE. This bit is associated with a Screening Type 2 Compare Word 0/1 register x, GMAC\_ST2CW0/1.
  5. An enable bit Compare C, COMPCE. This bit is associated with a Screening Type 2 Compare Word 0/1 register x, GMAC\_ST2CW0/1.

Each screener type has an enable bit, a match pattern and a queue number. If a received frame matches on an enabled Screening register, then the frame will be tagged with the queue value in the associated Screening register, and forwarded onto the DMA and subsequently into the external memory associated with that queue. If two screeners are matched, then the one which resides at the lowest register address will take priority so care must be taken on the selection of the screener location.

When the priority queuing feature is enabled, the number of interrupt outputs from the GEMAC core is increased to match the number of supported queues. The number of Interrupt Status registers is increased by the same number. Only DMA related events are reported using the individual interrupt outputs, as the GEMAC can relate these events to specific queues. All other events generated within the GEMAC are reported in the interrupt associated with the lowest priority queue. For the lowest priority queue (or the only queue when only 1 queue is selected), the Interrupt Status register is located at address 0x24. For all other queues, the Interrupt Status register is located at sequential addresses starting at address 0x400.

**Note:** The address matching is the first level of filtering. If there is a match, the screeners are the next level of filtering for routing the data to the appropriate queue. See [MAC Filtering Block](#) for more details.

The additional screening done by the functions Compare A, B, and C each have an enable bit and compare register field. COMPA, COMPB and COMPC in GMAC\_ST2RPQ are pointers to a configured offset (OFFSVL), value (COMPVAL), and mask (MASKVAL). If enabled, the compare is true if the data at the offset into the frame, ANDed with MASKVAL, is equal to the value of COMPVAL ANDed with MASKVAL. A 16-bit word comparison is done. The byte at the offset number of bytes from the index start is compared to bits 7:0 of the configured COMPVAL and MASKVAL. The byte at the offset number of bytes + 1 from the index start is compared to bits 15:8 of the configured COMPVAL and MASKVAL.

The offset value in bytes, OFFSVL, ranges from 0 to 127 bytes from either the start of the frame, the byte after the EtherType field, the byte after the IP header (IPv4 or IPv6) or the byte after the TCP/UDP header. Note the logic to decode the IP header or the TCP/UDP header is reused from the TCP/UDP/IP checksum offload logic and therefore has the same restrictions on use (the main limitation is that IP fragmentation is not supported). Refer to the Checksum Offload for IP, TCP and UDP section of this documentation for further details.

Compare A, B, and C use a common set of 24 GMAC\_ST2CW0/1 registers, thus all COMPA, COMPB and COMPC fields in the registers GMAC\_ST2RPQ point to a single pool of 24 GMAC\_ST2CW0/1 registers.

Note that Compare A, B and C together allow matching against an arbitrary 48 bits of data and so can be used to match against a MAC address.

All enabled comparisons are ANDed together to form the overall type 2 screening match.

### 39.6.4 MAC Transmit Block

The MAC transmitter can operate in either half duplex or full duplex mode and transmits frames in accordance with the Ethernet IEEE 802.3 standard. In half duplex mode, the CSMA/CD protocol of the IEEE 802.3 specification is followed.

A small input buffer receives data through the FIFO interface which will extract data in 32-bit form. All subsequent processing prior to the final output is performed in bytes.

Transmit data can be output using the MII interface.

Frame assembly starts by adding preamble and the start frame delimiter. Data is taken from the transmit FIFO interface a word at a time.

If necessary, padding is added to take the frame length to 60 bytes. CRC is calculated using an order 32-bit polynomial. This is inverted and appended to the end of the frame taking the frame length to a minimum of 64 bytes. If the no CRC bit is set in the second word of the last buffer descriptor of a transmit frame, neither pad nor CRC are appended. The no CRC bit can also be set through the FIFO interface.

In full duplex mode (at all data rates), frames are transmitted immediately. Back to back frames are transmitted at least 96 bit times apart to guarantee the interframe gap.

In half duplex mode, the transmitter checks carrier sense. If asserted, the transmitter waits for the signal to become inactive, and then starts transmission after the interframe gap of 96 bit times. If the collision signal is asserted during transmission, the transmitter will transmit a jam sequence of 32 bits taken from the data register and then retry transmission after the backoff time has elapsed. If the collision occurs during either the preamble or Start Frame Delimiter (SFD), then these fields will be completed prior to generation of the jam sequence.

The backoff time is based on an XOR of the 10 least significant bits of the data coming from the transmit FIFO interface and a 10-bit pseudo random number generator. The number of bits used depends on the number of collisions seen. After the first collision 1 bit is used, then the second 2 bits and so on up to the maximum of 10 bits. All 10 bits are used above ten collisions. An error will be indicated and no further attempts will be made if 16 consecutive attempts cause collision. This operation is compliant with the description in Clause 4.2.3.2.5 of the IEEE 802.3 standard which refers to the truncated binary exponential backoff algorithm.

In 10/100 mode, both collisions and late collisions are treated identically, and backoff and retry will be performed up to 16 times. This condition is reported in the transmit buffer descriptor word 1 (late collision, bit 26) and also in the Transmit Status register (late collision, bit 7). An interrupt can also be generated (if enabled) when this exception occurs, and bit 5 in the Interrupt Status register will be set.

In all modes of operation, if the transmit DMA underruns, a bad CRC is automatically appended using the same mechanism as jam insertion and the GTXER signal is asserted. For a properly configured system this should never happen and also it is impossible if configured to use the DMA with packet buffers, as the complete frame is buffered in local packet buffer memory.

By setting when bit 28 is set in the Network Configuration register, the Inter Packet Gap (IPG) may be stretched beyond 96 bits depending on the length of the previously transmitted frame and the value written to the IPG Stretch register (GMAC\_IPGS). The least significant 8 bits of the IPG Stretch register multiply the previous frame length (including preamble). The next significant 8 bits (+1 so as not to get a divide by zero) divide the frame length to generate the IPG. IPG stretch only works in full duplex mode and when bit 28 is set in the Network Configuration register. The IPG Stretch register cannot be used to shrink the IPG below 96 bits.

### 39.6.5 MAC Receive Block

All processing within the MAC receive block is implemented using a 16-bit data path. The MAC receive block checks for valid preamble, FCS, alignment and length, presents received frames to the FIFO interface and stores the frame destination address for use by the address checking block.

If, during the frame reception, the frame is found to be too long, a bad frame indication is sent to the FIFO interface. The receiver logic ceases to send data to memory as soon as this condition occurs.

At end of frame reception the receive block indicates to the DMA block whether the frame is good or bad. The DMA block will recover the current receive buffer if the frame was bad.

Ethernet frames are normally stored in DMA memory complete with the FCS. Setting the FCS remove bit in the network configuration (bit 17) causes frames to be stored without their corresponding FCS. The reported frame length field is reduced by four bytes to reflect this operation.

The receive block signals to the register block to increment the alignment, CRC (FCS), short frame, long frame, jabber or receive symbol errors when any of these exception conditions occur.

If bit 26 is set in the network configuration, CRC errors will be ignored and CRC errored frames will not be discarded, though the Frame Check Sequence Errors statistic register will still be incremented. Additionally, if not enabled for jumbo frames mode, then bit[13] of the receiver descriptor word 1 will be updated to indicate the FCS validity for the particular frame. This is useful for applications such as EtherCAT whereby individual frames with FCS errors must be identified.

Received frames can be checked for length field error by setting the length field error frame discard bit of the Network Configuration register (bit-16). When this bit is set, the receiver compares a frame's measured length with the length field (bytes 13 and 14) extracted from the frame. The frame is discarded if the measured length is shorter. This checking procedure is for received frames between 64 bytes and 1518 bytes in length.

Each discarded frame is counted in the 10-bit Length Field Frame Error statistics register. Frames where the length field is greater than or equal to 0x0600 hex will not be checked.

### 39.6.6 Checksum Offload for IP, TCP and UDP

The GEMAC can be programmed to perform IP, TCP and UDP checksum offloading in both receive and transmit directions, which is enabled by setting bit 24 in the Network Configuration register for receive and bit 11 in the DMA Configuration register for transmit.

IPv4 packets contain a 16-bit checksum field, which is the 16-bit 1's complement of the 1's complement sum of all 16-bit words in the header. TCP and UDP packets contain a 16-bit checksum field, which is the 16-bit 1's complement of the 1's complement sum of all 16-bit words in the header, the data and a conceptual IP pseudo header.

To calculate these checksums in software requires each byte of the packet to be processed. For TCP and UDP this can use a large amount of processing power. Offloading the checksum calculation to hardware can result in significant performance improvements.

For IP, TCP or UDP checksum offload to be useful, the operating system containing the protocol stack must be aware that this offload is available so that it can make use of the fact that the hardware can either generate or verify the checksum.

#### 39.6.6.1 Receiver Checksum Offload

When receive checksum offloading is enabled in the GEMAC, the IPv4 header checksum is checked as per RFC 791, where the packet meets the following criteria:

- If present, the VLAN header must be four octets long and the CFI bit must not be set.
- Encapsulation must be RFC 894 Ethernet Type Encoding or RFC 1042 SNAP Encoding.
- IPv4 packet
- IP header is of a valid length

The GEMAC also checks the TCP checksum as per RFC 793, or the UDP checksum as per RFC 768, if the following criteria are met:

- IPv4 or IPv6 packet
- Good IP header checksum (if IPv4)

- No IP fragmentation
- TCP or UDP packet

When an IP, TCP or UDP frame is received, the receive buffer descriptor gives an indication if the GEMAC was able to verify the checksums. There is also an indication if the frame had SNAP encapsulation. These indication bits will replace the type ID match indication bits when the receive checksum offload is enabled. For details of these indication bits, refer to [Receive Buffer Descriptor Entry](#).

If any of the checksums are verified as incorrect by the GEMAC, the packet is discarded and the appropriate statistics counter incremented.

### 39.6.6.2 Transmitter Checksum Offload

The transmitter checksum offload is only available if the full store and forward mode is enabled. This is because the complete frame to be transmitted must be read into the packet buffer memory before the checksum can be calculated and written back into the headers at the beginning of the frame.

Transmitter checksum offload is enabled by setting bit [11] in the DMA Configuration register. When enabled, it will monitor the frame as it is written into the transmitter packet buffer memory to automatically detect the protocol of the frame. Protocol support is identical to the receiver checksum offload.

For transmit checksum generation and substitution to occur, the protocol of the frame must be recognized and the frame must be provided without the FCS field, by making sure that bit [16] of the transmit descriptor word 1 is clear. If the frame data already had the FCS field, this would be corrupted by the substitution of the new checksum fields.

If these conditions are met, the transmit checksum offload engine will calculate the IP, TCP and UDP checksums as appropriate. Once the full packet is completely written into packet buffer memory, the checksums will be valid and the relevant DPRAM locations will be updated for the new checksum fields as per standard IP/TCP and UDP packet structures.

If the transmitter checksum engine is prevented from generating the relevant checksums, bits [22:20] of the transmitter DMA writeback status will be updated to identify the reason for the error. Note that the frame will still be transmitted but without the checksum substitution, as typically the reason that the substitution did not occur was that the protocol was not recognized.

### 39.6.7 MAC Filtering Block

The filter block determines which frames should be written to the FIFO interface and on to the DMA.

Whether a frame is passed depends on what is enabled in the Network Configuration register, the state of the external matching pins, the contents of the specific address, type and Hash registers and the frame's destination address and type field.

If bit 25 of the Network Configuration register is not set, a frame will not be copied to memory if the GEMAC is transmitting in half duplex mode at the time a destination address is received.

Ethernet frames are transmitted a byte at a time, least significant bit first. The first six bytes (48 bits) of an Ethernet frame make up the destination address. The first bit of the destination address, which is the LSB of the first byte of the frame, is the group or individual bit. This is one for multicast addresses and zero for unicast. The all ones address is the broadcast address and a special case of multicast.

The GEMAC supports recognition of four specific addresses. Each specific address requires two registers, Specific Address Bottom register and Specific Address Top register. Specific Address Bottom register stores the first four bytes of the destination address and Specific Address Top register contains the last two bytes. The addresses stored can be specific, group, local or universal.

# SAMA5D2 Series

## Ethernet MAC (GMAC)

The destination address of received frames is compared against the data stored in the Specific Address registers once they have been activated. The addresses are deactivated at reset or when their corresponding Specific Address Bottom register is written. They are activated when Specific Address Top register is written. If a receive frame address matches an active address, the frame is written to the FIFO interface and on to DMA memory.

Frames may be filtered using the type ID field for matching. Four type ID registers exist in the register address space and each can be enabled for matching by writing a one to the MSB (bit 31) of the respective register. When a frame is received, the matching is implemented as an OR function of the various types of match.

The contents of each type ID register (when enabled) are compared against the length/type ID of the frame being received (e.g., bytes 13 and 14 in non-VLAN and non-SNAP encapsulated frames) and copied to memory if a match is found. The encoded type ID match bits (Word 0, Bit 22 and Bit 23) in the receive buffer descriptor status are set indicating which type ID register generated the match, if the receive checksum offload is disabled.

The reset state of the type ID registers is zero, hence each is initially disabled.

The following example illustrates the use of the address and type ID match registers for a MAC address of 21:43:65:87:A9:CB:

|                    |                   |
|--------------------|-------------------|
| Preamble           | 55                |
| SFD                | D5                |
| DA (Octet 0 - LSB) | 21                |
| DA (Octet 1)       | 43                |
| DA (Octet 2)       | 65                |
| DA (Octet 3)       | 87                |
| DA (Octet 4)       | A9                |
| DA (Octet 5 - MSB) | CB                |
| SA (LSB)           | 00 <sup>(1)</sup> |
| SA                 | 00 <sup>(1)</sup> |
| SA                 | 00 <sup>(1)</sup> |
| SA                 | 00 <sup>(1)</sup> |
| SA                 | 00 <sup>(1)</sup> |
| SA (MSB)           | 00 <sup>(1)</sup> |
| Type ID (MSB)      | 43                |
| Type ID (LSB)      | 21                |

**Note:**

1. Contains the address of the transmitting device.

The sequence above shows the beginning of an Ethernet frame. Byte order of transmission is from top to bottom as shown. For a successful match to specific address 1, the following address matching registers must be set up:

- Specific Address 1 Bottom register (GMAC\_SAB1) (Address 0x088) 0x87654321
- Specific Address 1 Top register (GMAC\_SAT1) (Address 0x08C) 0x0000CBA9

For a successful match to the type ID, the following Type ID Match 1 register must be set up:

- Type ID Match 1 register (GMAC\_TIDM1) (Address 0x0A8) 0x80004321

### 39.6.8 Broadcast Address

Frames with the broadcast address of 0xFFFFFFFF are stored to memory only if the 'no broadcast' bit in the Network Configuration register is set to zero.

### 39.6.9 Hash Addressing

The hash address register is 64 bits long and takes up two locations in the memory map. The least significant bits are stored in Hash Register Bottom and the most significant bits in Hash Register Top.

The unicast hash enable and the multicast hash enable bits in the Network Configuration register enable the reception of hash matched frames. The destination address is reduced to a 6-bit index into the 64-bit Hash register using the following hash function: The hash function is an XOR of every sixth bit of the destination address.

```

hash_index[05] = da[05] ^ da[11] ^ da[17] ^ da[23] ^ da[29] ^ da[35] ^ da[41] ^ da[47]
hash_index[04] = da[04] ^ da[10] ^ da[16] ^ da[22] ^ da[28] ^ da[34] ^ da[40] ^ da[46]
hash_index[03] = da[03] ^ da[09] ^ da[15] ^ da[21] ^ da[27] ^ da[33] ^ da[39] ^ da[45]
hash_index[02] = da[02] ^ da[08] ^ da[14] ^ da[20] ^ da[26] ^ da[32] ^ da[38] ^ da[44]
hash_index[01] = da[01] ^ da[07] ^ da[13] ^ da[19] ^ da[25] ^ da[31] ^ da[37] ^ da[43]
hash_index[00] = da[00] ^ da[06] ^ da[12] ^ da[18] ^ da[24] ^ da[30] ^ da[36] ^ da[42]
da[0]

```

represents the least significant bit of the first byte received, that is, the multicast/unicast indicator, and da[47] represents the most significant bit of the last byte received.

If the hash index points to a bit that is set in the Hash register then the frame will be matched according to whether the frame is multicast or unicast.

A multicast match will be signalled if the multicast hash enable bit is set, da[0] is logic 1 and the hash index points to a bit set in the Hash register.

A unicast match will be signalled if the unicast hash enable bit is set, da[0] is logic 0 and the hash index points to a bit set in the Hash register.

To receive all multicast frames, the Hash register should be set with all ones and the multicast hash enable bit should be set in the Network Configuration register.

### 39.6.10 Copy all Frames (Promiscuous Mode)

If the Copy All Frames bit is set in the Network Configuration register then all frames except those that are too long, too short, have FCS errors or have GRXER asserted during reception will be copied to memory. Frames with FCS errors will be copied if bit 26 is set in the Network Configuration register.

### 39.6.11 Disable Copy of Pause Frames

Pause frames can be prevented from being written to memory by setting the disable copying of pause frames control bit 23 in the Network Configuration register. When set, pause frames are not copied to memory regardless of the Copy All Frames bit, whether a hash match is found, a type ID match is identified or if a destination address match is found.

### 39.6.12 VLAN Support

The following table describes an Ethernet encoded 802.1Q VLAN tag.

**Table 39-5. 802.1Q VLAN Tag**

|  |   |
|--|---|
| TPID (Tag Protocol Identifier) 16 bits | TCI (Tag Control Information) 16 bits                 |
| 0x8100                                 | First 3 bits priority, then CFI bit, last 12 bits VID |

The VLAN tag is inserted at the 13th byte of the frame adding an extra four bytes to the frame. To support these extra four bytes, the GEMAC can accept frame lengths up to 1536 bytes by setting bit 8 in the Network Configuration register.

If the VID (VLAN identifier) is null (0x000) this indicates a priority-tagged frame.

The following bits in the receive buffer descriptor status word give information about VLAN tagged frames:-

- Bit 21 set if receive frame is VLAN tagged (i.e., type ID of 0x8100).
- Bit 20 set if receive frame is priority tagged (i.e., type ID of 0x8100 and null VID). (If bit 20 is set, bit 21 will be set also.)
- Bit 19, 18 and 17 set to priority if bit 21 is set.
- Bit 16 set to CFI if bit 21 is set.

The GEMAC can be configured to reject all frames except VLAN tagged frames by setting the discard non-VLAN frames bit in the Network Configuration register.

### 39.6.13 Wake on LAN Support

The receive block supports Wake on LAN by detecting the following events on incoming receive frames:

- Magic packet
- Address Resolution Protocol (ARP) request to the device IP address
- Specific address 1 filter match
- Multicast hash filter match

These events can be individually enabled through bits [19:16] of the Wake on LAN register. Also, for Wake on LAN detection to occur, receive enable must be set in the Network Control register, however a receive buffer does not have to be available.

In case of an ARP request, specific address 1 or multicast filter events will occur even if the frame is errored. For magic packet events, the frame must be correctly formed and error free.

A magic packet event is detected if all of the following are true:

- Magic packet events are enabled through bit 16 of the Wake on LAN register
- The frame's destination address matches specific address 1
- The frame is correctly formed with no errors
- The frame contains at least 6 bytes of 0xFF for synchronization
- There are 16 repetitions of the contents of Specific Address 1 register immediately following the synchronization

An ARP request event is detected if all of the following are true:

- ARP request events are enabled through bit 17 of the Wake on LAN register
- Broadcasts are allowed by bit 5 in the Network Configuration register
- The frame has a broadcast destination address (bytes 1 to 6)
- The frame has a type ID field of 0x0806 (bytes 13 and 14)

- The frame has an ARP operation field of 0x0001 (bytes 21 and 22)
- The least significant 16 bits of the frame's ARP target protocol address (bytes 41 and 42) match the value programmed in bits[15:0] of the Wake on LAN register

The decoding of the ARP fields adjusts automatically if a VLAN tag is detected within the frame. The reserved value of 0x0000 for the Wake on LAN target address value will not cause an ARP request event, even if matched by the frame.

A specific address 1 filter match event will occur if all of the following are true:

- Specific address 1 events are enabled through bit 18 of the Wake on LAN register
- The frame's destination address matches the value programmed in the Specific Address 1 registers

A multicast filter match event will occur if all of the following are true:

- Multicast hash events are enabled through bit 19 of the Wake on LAN register
- Multicast hash filtering is enabled through bit 6 of the Network Configuration register
- The frame destination address matches against the multicast hash filter
- The frame destination address is not a broadcast

### 39.6.14 IEEE 1588 Support

IEEE 1588 is a standard for precision time synchronization in local area networks. It works with the exchange of special Precision Time Protocol (PTP) frames. The PTP messages can be transported over IEEE 802.3/Ethernet, over Internet Protocol Version 4 or over Internet Protocol Version 6 as described in the annex of IEEE P1588.D2.1.

The GEMAC indicates the message timestamp point (asserted on the start packet delimiter and de-asserted at end of frame) for all frames and the passage of PTP event frames (asserted when a PTP event frame is detected and de-asserted at end of frame).

IEEE 802.1AS is a subset of IEEE 1588. One difference is that IEEE 802.1AS uses the Ethernet multicast address 0180C200000E for sync frame recognition whereas IEEE 1588 does not. GEMAC is designed to recognize sync frames with both IEEE 802.1AS and IEEE 1588 addresses and so can support both 1588 and 802.1AS frame recognition simultaneously.

Synchronization between master and slave clocks is a two stage process.

First, the offset between the master and slave clocks is corrected by the master sending a sync frame to the slave with a follow up frame containing the exact time the sync frame was sent. Hardware assist modules at the master and slave side detect exactly when the sync frame was sent by the master and received by the slave. The slave then corrects its clock to match the master clock.

Second, the transmission delay between the master and slave is corrected. The slave sends a delay request frame to the master which sends a delay response frame in reply. Hardware assist modules at the master and slave side detect exactly when the delay request frame was sent by the slave and received by the master. The slave will now have enough information to adjust its clock to account for delay. For example, if the slave was assuming zero delay, the actual delay will be half the difference between the transmit and receive time of the delay request frame (assuming equal transmit and receive times) because the slave clock will be lagging the master clock by the delay time already.

The timestamp is taken when the message timestamp point passes the clock timestamp point. This can generate an interrupt if enabled (GMAC\_IER). However, MAC Filtering configuration is needed to actually 'copy' the message to memory. For Ethernet, the message timestamp point is the SFD and the clock timestamp point is the MII interface. (The IEEE 1588 specification refers to sync and delay\_req messages as event messages as these require timestamping. These events are captured in the registers

GMAC\_EFTx and GMAC\_EFRx, respectively. Follow up, delay response and management messages do not require timestamping and are referred to as general messages.)

1588 version 2 defines two additional PTP event messages. These are the peer delay request (Pdelay\_Req) and peer delay response (Pdelay\_Resp) messages. These events are captured in the registers GMAC\_PEFTx and GMAC\_PEFRx, respectively. These messages are used to calculate the delay on a link. Nodes at both ends of a link send both types of frames (regardless of whether they contain a master or slave clock). The Pdelay\_Resp message contains the time at which a Pdelay\_Req was received and is itself an event message. The time at which a Pdelay\_Resp message is received is returned in a Pdelay\_Resp\_Follow\_Up message.

1588 version 2 introduces transparent clocks of which there are two kinds, peer-to-peer (P2P) and end-to-end (E2E). Transparent clocks measure the transit time of event messages through a bridge and amend a correction field within the message to allow for the transit time. P2P transparent clocks additionally correct for the delay in the receive path of the link using the information gathered from the peer delay frames. With P2P transparent clocks delay\_req messages are not used to measure link delay. This simplifies the protocol and makes larger systems more stable.

The GEMAC recognizes four different encapsulations for PTP event messages:

1. 1588 version 1 (UDP/IPv4 multicast)
2. 1588 version 2 (UDP/IPv4 multicast)
3. 1588 version 2 (UDP/IPv6 multicast)
4. 1588 version 2 (Ethernet multicast)

**Table 39-6. Example of Sync Frame in 1588 Version 1 Format**

| Frame Segment                 | Value                |
|-------------------------------|----------------------|
| Preamble/SFD                  | 55555555555555D5     |
| DA (Octets 0–5)               | –                    |
| SA (Octets 6–11)              | –                    |
| Type (Octets 12–13)           | 0800                 |
| IP stuff (Octets 14–22)       | –                    |
| UDP (Octet 23)                | 11                   |
| IP stuff (Octets 24–29)       | –                    |
| IP DA (Octets 30–32)          | E00001               |
| IP DA (Octet 33)              | 81 or 82 or 83 or 84 |
| Source IP port (Octets 34–35) | –                    |
| Dest IP port (Octets 36–37)   | 013F                 |
| Other stuff (Octets 38–42)    | –                    |
| Version PTP (Octet 43)        | 01                   |
| Other stuff (Octets 44–73)    | –                    |
| Control (Octet 74)            | 00                   |
| Other stuff (Octets 75–168)   | –                    |

**Table 39-7. Example of Delay Request Frame in 1588 Version 1 Format**

| Frame Segment                 | Value                |
|-------------------------------|----------------------|
| Preamble/SFD                  | 55555555555555D5     |
| DA (Octets 0–5)               | –                    |
| SA (Octets 6–11)              | –                    |
| Type (Octets 12–13)           | 0800                 |
| IP stuff (Octets 14–22)       | –                    |
| UDP (Octet 23)                | 11                   |
| IP stuff (Octets 24–29)       | –                    |
| IP DA (Octets 30–32)          | E00001               |
| IP DA (Octet 33)              | 81 or 82 or 83 or 84 |
| Source IP port (Octets 34–35) | –                    |
| Dest IP port (Octets 36–37)   | 013F                 |
| Other stuff (Octets 38–42)    | –                    |
| Version PTP (Octet 43)        | 01                   |
| Other stuff (Octets 44–73)    | –                    |
| Control (Octet 74)            | 01                   |
| Other stuff (Octets 75–168)   | –                    |

For 1588 version 1 messages, sync and delay request frames are indicated by the GEMAC if the frame type field indicates TCP/IP, UDP protocol is indicated, the destination IP address is 224.0.1.129/130/131 or 132, the destination UDP port is 319 and the control field is correct.

The control field is 0x00 for sync frames and 0x01 for delay request frames.

For 1588 version 2 messages, the type of frame is determined by looking at the message type field in the first byte of the PTP frame. Whether a frame is version 1 or version 2 can be determined by looking at the version PTP field in the second byte of both version 1 and version 2 PTP frames.

In version 2 messages sync frames have a message type value of 0x0, delay\_req have 0x1, Pdelay\_Req have 0x2 and Pdelay\_Resp have 0x3.

**Table 39-8. Example of Sync Frame in 1588 Version 2 (UDP/IPv4) Format**

| Frame Segment           | Value            |

| UDP (Octet 20)                | 11               |
| IP stuff (Octets 21–37)       | –                |
| IP DA (Octets 38–53)          | FF0200000000006B |
| Source IP port (Octets 54–55) | –                |
| Dest IP port (Octets 56–57)   | 013F             |
| Other stuff (Octets 58–61)    | –                |
| Message type (Octet 62)       | 03               |
| Other stuff (Octets 63–93)    | –                |
| Version PTP (Octet 94)        | 02               |

For the multicast address 011B19000000 sync and delay request frames are recognized depending on the message type field, 00 for sync and 01 for delay request.

**Table 39-12. Example of Sync Frame in 1588 Version 2 (Ethernet Multicast) Format**

| Frame Segment   | Value            |
|-----------------|------------------|
| Preamble/SFD    | 55555555555555D5 |
| DA (Octets 0–5) | 011B19000000     |

| .....continued          |       |
|-------------------------|-------|
| Frame Segment           | Value |
| SA (Octets 6–11)        | –     |
| Type (Octets 12–13)     | 88F7  |
| Message type (Octet 14) | 00    |
| Version PTP (Octet 15)  | 02    |

Pdelay request frames need a special multicast address so they can pass through ports blocked by the spanning tree protocol. For the multicast address 0180C200000E sync, Pdelay\_Req and Pdelay\_Resp frames are recognized depending on the message type field, 00 for sync, 02 for pdelay request and 03 for pdelay response.

**Table 39-13. Example of Pdelay\_Req Frame in 1588 Version 2 (Ethernet Multicast) Format**

| Frame Segment           | Value            |
|-------------------------|------------------|
| Preamble/SFD            | 55555555555555D5 |
| DA (Octets 0–5)         | 0180C200000E     |
| SA (Octets 6–11)        | –                |
| Type (Octets 12–13)     | 88F7             |
| Message type (Octet 14) | 00               |
| Version PTP (Octet 15)  | 02               |

### 39.6.15 Timestamp Unit

The TSU consists of a timer and registers to capture the time at which PTP event frames cross the message timestamp point. An interrupt is issued when a capture register is updated.

The timer is implemented as a 94-bit register with the upper 48 bits counting seconds, the next 30 bits counting nanoseconds and the lowest 16 bits counting sub-nanoseconds. The lower 46 bits rolls over when they have counted to one second. An interrupt is generated when the seconds increment. The timer value can be read, written and adjusted through the APB interface. The timer is clocked by MCK.

The amount by which the timer increments each clock cycle is controlled by the timer increment registers (GMAC\_TI). Bits 7:0 are the default increment value in nanoseconds and an additional 16 bits of sub-nanosecond resolution are available using the Timer Increment Sub-nanoseconds register (GMAC\_TISUBN). If the rest of the register is written with zero, the timer increments by the value in [7:0], plus the value of GMAC\_TISUBN, each clock cycle.

The GMAC\_TISUBN register allows a resolution of approximately 15 femtoseconds.

Bits 15:8 of the increment register are the alternative increment value in nanoseconds and bits 23:16 are the number of increments after which the alternative increment value is used. If 23:16 are zero then the alternative increment value will never be used.

Taking the example of 10.2 MHz, there are 102 cycles every ten microseconds or 51 every five microseconds. So a timer with a 10.2 MHz clock source is constructed by incrementing by 98 ns for fifty cycles and then incrementing by 100 ns ( $98 \times 50 + 100 = 5000$ ). This is programmed by setting the 1588 Timer Increment register to 0x00326462.

For a 49.8 MHz clock source it would be 20 ns for 248 cycles followed by an increment of 40 ns ( $20 \times 248 + 40 = 5000$ ) programmed as 0x00F82814.

Having eight bits for the “number of increments” field allows frequencies up to 50 MHz to be supported with 200 kHz resolution.

Without the alternative increment field the period of the clock would be limited to an integer number of nanoseconds, resulting in supported clock frequencies of 8, 10, 20, 25, 40, 50, 100, 125, 200 and 250 MHz.

There are eight additional 80-bit registers that capture the time at which PTP event frames are transmitted and received. An interrupt is issued when these registers are updated. The TSU timer count value can be compared to a programmable comparison value. For the comparison, the 48 bits of the seconds value and the upper 22 bits of the nanoseconds value are used. A signal (GTSUCOMP) is provided to indicate when the TSU timer count value is equal to the comparison value stored in the TSU timer comparison value registers (0x0DC, 0x0E0, and 0x0E4). The GTSUCOMP signal can be routed to the Timer peripheral to automatically toggle pin TOIA11/PD21. This can be used as the reference clock for an external PLL to regenerate the audio clock in Ethernet AVB. An interrupt can also be generated (if enabled) when the TSU timer count value and comparison value are equal, mapped to bit 29 of the Interrupt Status register.

### 39.6.16 MAC 802.3 Pause Frame Support

**Note:** See Clause 31, and Annex 31A and 31B of the IEEE standard 802.3 for a full description of MAC 802.3 pause operation.

The following table shows the start of a MAC 802.3 pause frame.

**Table 39-14. Start of an 802.3 Pause Frame**

| Address        |         | Type<br>(MAC Control Frame) | Pause  |         |
|----------------|---------|-----------------------------|--------|---------|
| Destination    | Source  |                             | Opcode | Time    |
| 0x0180C2000001 | 6 bytes | 0x8808                      | 0x0001 | 2 bytes |

The GEMAC supports both hardware controlled pause of the transmitter, upon reception of a pause frame, and hardware generated pause frame transmission.

#### 39.6.16.1 802.3 Pause Frame Reception

Bit 13 of the Network Configuration register is the pause enable control for reception. If this bit is set, transmission pauses if a non zero pause quantum frame is received.

If a valid pause frame is received, then the Pause Time register is updated with the new frame's pause time, regardless of whether a previous pause frame is active or not. An interrupt (either bit 12 or bit 13 of the Interrupt Status register) is triggered when a pause frame is received, but only if the interrupt has been enabled (bit 12 and bit 13 of the Interrupt Mask register). Pause frames received with non zero quantum are indicated through the interrupt bit 12 of the Interrupt Status register. Pause frames received with zero quantum are indicated on bit 13 of the Interrupt Status register.

Once the Pause Time register is loaded and the frame currently being transmitted has been sent, no new frames are transmitted until the pause time reaches zero. The loading of a new pause time, and hence the pausing of transmission, only occurs when the GEMAC is configured for full duplex operation. If the GEMAC is configured for half duplex there will be no transmission pause, but the pause frame received interrupt will still be triggered. A valid pause frame is defined as having a destination address that matches either the address stored in Specific Address 1 register or if it matches the reserved address of

0x0180C2000001. It must also have the MAC control frame type ID of 0x8808 and have the pause opcode of 0x0001.

Pause frames that have frame check sequence (FCS) or other errors will be treated as invalid and will be discarded. 802.3 Pause frames that are received after Priority-based Flow Control (PFC) has been negotiated will also be discarded. Valid pause frames received will increment the Pause Frames Received statistic register.

The Pause Time register decrements every 512 bit times once transmission has stopped. For test purposes, the retry test bit can be set (bit 12 in the Network Configuration register) which causes the Pause Time register to decrement every GTXCK cycle once transmission has stopped.

The interrupt (bit 13 in the Interrupt Status register) is asserted whenever the Pause Time register decrements to zero (assuming it has been enabled by bit 13 in the Interrupt Mask register). This interrupt is also set when a zero quantum pause frame is received.

### 39.6.16.2 802.3 Pause Frame Transmission

Automatic transmission of pause frames is supported through the transmit pause frame bits of the Network Control register. If either bit 11 or bit 12 of the Network Control register is written with logic 1, an 802.3 pause frame will be transmitted, providing full duplex is selected in the Network Configuration register and the transmit block is enabled in the Network Control register.

Pause frame transmission will happen immediately if transmit is inactive or if transmit is active between the current frame and the next frame due to be transmitted.

Transmitted pause frames comprise the following:

- A destination address of 01-80-C2-00-00-01
- A source address taken from Specific Address 1 register
- A type ID of 88-08 (MAC control frame)
- A pause opcode of 00-01
- A Pause Quantum register
- Fill of 00 to take the frame to minimum frame length
- Valid FCS

The pause quantum used in the generated frame will depend on the trigger source for the frame as follows:

- If bit 11 is written with a one, the pause quantum will be taken from the Transmit Pause Quantum register. The Transmit Pause Quantum register resets to a value of 0xFFFF giving maximum pause quantum as default.
- If bit 12 is written with a one, the pause quantum will be zero.

After transmission, a pause frame transmitted interrupt will be generated (bit 14 of the Interrupt Status register) and the only the statistics register Pause Frames Transmitted is incremented.

Pause frames can also be transmitted by the MAC using normal frame transmission methods.

### 39.6.17 MAC PFC Priority-based Pause Frame Support

**Note:** Refer to the 802.1Qbb standard for a full description of priority-based pause operation.

The following table shows the start of a Priority-based Flow Control (PFC) pause frame.

**Table 39-15. Start of a PFC Pause Frame**

| Address        |         | Type<br>(Mac Control Frame) | Pause Opcode | Priority Enable<br>Vector | Pause Time  |
|----------------|---------|-----------------------------|--------------|---------------------------|-------------|
| Destination    | Source  |                             |              |                           |             |
| 0x0180C2000001 | 6 bytes | 0x8808                      | 0x1001       | 2 bytes                   | 8 × 2 bytes |

The GEMAC supports PFC priority-based pause transmission and reception. Before PFC pause frames can be received, bit 16 of the Network Control register must be set.

### 39.6.17.1 PFC Pause Frame Reception

The ability to receive and decode priority-based pause frames is enabled by setting bit 16 of the Network Control register. When this bit is set, the GEMAC will match either classic 802.3 pause frames or PFC priority-based pause frames. Once a priority-based pause frame has been received and matched, then from that moment on the GEMAC will only match on priority-based pause frames (this is an 802.1Qbb requirement, known as PFC negotiation). Once priority-based pause has been negotiated, any received 802.3x format pause frames will not be acted upon.

If a valid priority-based pause frame is received then the GEMAC will decode the frame and determine which, if any, of the eight priorities require to be paused. Up to eight Pause Time registers are then updated with the eight pause times extracted from the frame regardless of whether a previous pause operation is active or not. An interrupt (either bit 12 or bit 13 of the Interrupt Status register) is triggered when a pause frame is received, but only if the interrupt has been enabled (bit 12 and bit 13 of the Interrupt Mask register). Pause frames received with non zero quantum are indicated through the interrupt bit 12 of the Interrupt Status register. Pause frames received with zero quantum are indicated on bit 13 of the Interrupt Status register. The loading of a new pause time only occurs when the GEMAC is configured for full duplex operation. If the GEMAC is configured for half duplex, the pause time counters will not be loaded, but the pause frame received interrupt will still be triggered. A valid pause frame is defined as having a destination address that matches either the address stored in Specific Address 1 register or if it matches the reserved address of 0x0180C2000001. It must also have the MAC control frame type ID of 0x8808 and have the pause opcode of 0x0101.

Pause frames that have frame check sequence (FCS) or other errors will be treated as invalid and will be discarded. Valid pause frames received will increment the Pause Frames Received Statistic register.

The Pause Time registers decrement every 512 bit times immediately following the PFC frame reception. For test purposes, the retry test bit can be set (bit 12 in the Network Configuration register) which causes the Pause Time register to decrement every GRXCK cycle once transmission has stopped.

The interrupt (bit 13 in the Interrupt Status register) is asserted whenever the Pause Time register decrements to zero (assuming it has been enabled by bit 13 in the Interrupt Mask register). This interrupt is also set when a zero quantum pause frame is received.

### 39.6.17.2 PFC Pause Frame Transmission

Automatic transmission of pause frames is supported through the transmit priority-based pause frame bit of the Network Control register. If bit 17 of the Network Control register is written with logic 1, a PFC pause frame will be transmitted providing full duplex is selected in the Network Configuration register and the transmit block is enabled in the Network Control register. When bit 17 of the Network Control register is set, the fields of the priority-based pause frame will be built using the values stored in the Transmit PFC Pause register.

Pause frame transmission will happen immediately if transmit is inactive or if transmit is active between the current frame and the next frame due to be transmitted.

Transmitted pause frames comprise the following:

- A destination address of 01-80-C2-00-00-01
- A source address taken from Specific Address 1 register
- A type ID of 88-08 (MAC control frame)
- A pause opcode of 01-01
- A priority enable vector taken from Transmit PFC Pause register
- 8 Pause Quantum registers
- Fill of 00 to take the frame to minimum frame length
- Valid FCS

The Pause Quantum registers used in the generated frame will depend on the trigger source for the frame as follows:

- If bit 17 of the Network Control register is written with a one, then the priority enable vector of the priority-based pause frame will be set equal to the value stored in the Transmit PFC Pause register [7:0]. For each entry equal to zero in the Transmit PFC Pause register [15:8], the pause quantum field of the pause frame associated with that entry will be taken from the Transmit Pause Quantum register. For each entry equal to one in the Transmit PFC Pause register [15:8], the pause quantum associated with that entry will be zero.
- The Transmit Pause Quantum register resets to a value of 0xFFFF giving maximum pause quantum as default.

After transmission, a pause frame transmitted interrupt will be generated (bit 14 of the Interrupt Status register) and the only statistics register that will be incremented will be the Pause Frames Transmitted register.

PFC Pause frames can also be transmitted by the MAC using normal frame transmission methods.

### 39.6.18 Energy-efficient Ethernet Support

IEEE 802.3az adds support for energy efficiency to Ethernet. These are the key features of 802.3az:

- Allows a system's transmit path to enter a low power mode if there is nothing to transmit.
- Allows a PHY to detect whether its link partner's transmit path is in low power mode, therefore allowing the system's receive path to enter low power mode.
- Link remains up during lower power mode and no frames are dropped.
- Asymmetric, one direction can be in low power mode while the other is transmitting normally.
- LPI (Low Power Idle) signaling is used to control entry and exit to and from low power modes.
- LPI signaling can only take place if both sides have indicated support for it through auto-negotiation.

These are the key features of 802.3az operation:

- Low power control is done at the MII (reconciliation sublayer).
- As an architectural convenience in writing the 802.3az it is assumed that transmission is deferred by asserting carrier sense, in practice it will not be done this way. This system will know when it has nothing to transmit and only enter low power mode when it is not transmitting.
- LPI should not be requested unless the link has been up for at least one second.
- LPI is signaled on the transmit path by asserting 0x01 on txd with tx\_en low and tx\_er high.
- A PHY on seeing LPI requested on the MII will send the sleep signal before going quiet. After going quiet it will periodically transmit refresh signals.

- LPI mode ends by transmitting normal idle for the wake time. There is a default time for this but it can be adjusted in software using the Link Layer Discovery Protocol (LLDP) described in Clause 79 of 802.3az.
- LPI is indicated at the receive side when sleep and refresh signaling has been detected.

### 39.6.19 802.1Qav Support - Credit-based Shaping

A credit-based shaping algorithm is available on the two highest priority queues and is defined in the standard 802.1Qav: Forwarding and Queuing Enhancements for Time-Sensitive Streams. This allows traffic on these queues to be limited and to allow other queues to transmit.

Traffic shaping is enabled via the CBS (Credit Based Shaping) Control register. This enables a counter which stores the amount of transmit 'credit', measured in bytes that a particular queue has. A queue may only transmit if it has non-negative credit. If a queue has data to send, but is held off from doing as another queue is transmitting, then credit will accumulate in the credit counter at the rate defined in the IdleSlope register (GMAC\_CBSISQx) for that queue.

**portTransmitRate** is the transmission rate, in bits per second, that the underlying MAC service that supports transmission through the Port provides. The value of this parameter is determined by the operation of the MAC.

**IdleSlope** is the rate of change of increasing credit when waiting to transmit and must be less than the value of the portTransmitRate.

The max value of IdleSlope (or sendSlope) is  $(\text{portTransmitRate} / \text{bits\_per\_MII\_Clock})$ .

In case of 100Mbps, maximum IdleSlope =  $(100\text{Mbps} / 4) = 0x17D7840$ .

When this queue is transmitting, the credit counter is decremented at the rate of sendSlope, which is defined as  $(\text{portTransmitRate} - \text{IdleSlope})$ . A queue can accumulate negative credit when transmitting which will hold off any other transfers from that queue until credit returns to a non-negative value. No transfers are halted when a queue's credit becomes negative; it will accumulate negative credit until the transfer completes.

The highest priority queue always has priority regardless of which queue has the most credit.

### 39.6.20 LPI Operation in the GEMAC

It is best to use firmware to control LPI. LPI operation happens at the system level. Firmware gives maximum control and flexibility of operation. LPI operation is straightforward and firmware should be capable of responding within the required timeframes.

Autonegotiation:

1. Indicate EEE capability using next page autonegotiation.

For the transmit path:

1. If the link has been up for 1 second and there is nothing being transmitted, write to the TXLPIEN bit in the Network Control register.
2. Wake up by clearing the TXLPIEN bit in the Network Control register.

For the receive path:

1. Enable RXLPISBC bit in GMAC\_IER. The bit RXLPIS is set in Network Status Register triggering an interrupt.
2. Wait for an interrupt to indicate that LPI has been received.
3. Disable relevant parts of the receive path if desired.

4. The RXLPIS bit in Network Status Register gets cleared to indicate that regular idle has been received. This triggers an interrupt.
5. Re-enable the receive path.

### 39.6.21 PHY Interface

Different PHY interfaces are supported by the Ethernet MAC:

- MII
- RMII

The MII interface is provided for 10/100 operation and uses txd[3:0] and rxd[3:0]. The RMII interface is provided for 10/100 operation and uses txd[1:0] and rxd[1:0].

### 39.6.22 10/100 Operation

The 10/100Mbps speed bit in the Network Configuration register is used to select between 10Mbps and 100Mbps.

### 39.6.23 Jumbo Frames

The jumbo frames enable bit in the Network Configuration register allows the GEMAC, in its default configuration, to receive jumbo frames up to 10240 bytes in size. This operation does not form part of the IEEE 802.3 specification and is normally disabled. When jumbo frames are enabled, frames received with a frame size greater than 10240 bytes are discarded.

## 39.7 Programming Interface

### 39.7.1 Initialization

#### 39.7.1.1 Configuration

Initialization of the GEMAC configuration (e.g., loop back mode, frequency ratios) must be done while the transmit and receive circuits are disabled. See the description of the Network Control register and Network Configuration register earlier in this document.

To change loop back mode, the following sequence of operations must be followed:

1. Write to Network Control register to disable transmit and receive circuits.
2. Write to Network Control register to change loop back mode.
3. Write to Network Control register to re-enable transmit or receive circuits.

**Note:** These writes to the Network Control register cannot be combined in any way.

#### 39.7.1.2 Receive Buffer List

Receive data is written to areas of data (i.e., buffers) in system memory. These buffers are listed in another data structure that also resides in main memory. This data structure (receive buffer queue) is a sequence of descriptor entries as defined in [Receive Buffer Descriptor Entry](#).

The Receive Buffer Queue Pointer register points to this data structure.

**Figure 39-3. Receive Buffer List**

To create the list of buffers:

1. Allocate a number (N) of buffers of X bytes in system memory, where X is the DMA buffer length programmed in the DMA Configuration register.
2. Allocate an area 8N bytes for the receive buffer descriptor list in system memory and create N entries in this list. Mark all entries in this list as owned by GEMAC, i.e., bit 0 of word 0 set to 0.
3. Mark the last descriptor in the queue with the wrap bit (bit 1 in word 0 set to 1).
4. Write address of receive buffer descriptor list and control information to GEMAC register receive buffer queue pointer
5. The receive circuits can then be enabled by writing to the address recognition registers and the Network Control register.  
**Note:** The queue pointers must be initialized and point to USED descriptors for all queues including those not intended for use.

### 39.7.1.3 Transmit Buffer List

Transmit data is read from areas of data (the buffers) in system memory. These buffers are listed in another data structure that also resides in main memory. This data structure (Transmit Buffer Queue) is a sequence of descriptor entries as defined in [Transmit Buffer Descriptor Entry](#).

The Transmit Buffer Queue Pointer register points to this data structure.

To create this list of buffers:

1. Allocate a number (N) of buffers of between 1 and 2047 bytes of data to be transmitted in system memory. Up to 128 buffers per frame are allowed.
2. Allocate an area 8N bytes for the transmit buffer descriptor list in system memory and create N entries in this list. Mark all entries in this list as owned by GEMAC, i.e., bit 31 of word 1 set to 0.
3. Mark the last descriptor in the queue with the wrap bit (bit 30 in word 1 set to 1).
4. Write address of transmit buffer descriptor list and control information to GEMAC register transmit buffer queue pointer.
5. The transmit circuits can then be enabled by writing to the Network Control register.  
**Note:** The queue pointers must be initialized and point to USED descriptors for all queues including those not intended for use.

### 39.7.1.4 Address Matching

The GEMAC Hash register pair and the four Specific Address register pairs must be written with the required values. Each register pair comprises of a bottom register and top register, with the bottom register being written first. The address matching is disabled for a particular register pair after the bottom register has been written and re-enabled when the top register is written. Each register pair may be written at any time, regardless of whether the receive circuits are enabled or disabled.

As an example, to set Specific Address 1 register to recognize destination address 21:43:65:87:A9:CB, the following values are written to Specific Address 1 Bottom register and Specific Address 1 Top register:

- Specific Address 1 Bottom register bits 31:0 (0x98): 0x8765\_4321.
- Specific Address 1 Top register bits 31:0 (0x9C): 0x0000\_CBA9.

**Note:** The address matching is the first level of filtering. If there is a match, the screeners are the next level of filtering for routing the data to the appropriate queue. See [Priority Queueing in the DMA](#) for more details.

### 39.7.1.5 PHY Maintenance

The PHY Maintenance register is implemented as a shift register. Writing to the register starts a shift operation which is signalled as complete when bit two is set in the Network Status register (about 2000 MCK cycles later when bits 18:16 are set to 010 in the Network Configuration register). An interrupt is generated as this bit is set.

During this time, the MSB of the register is output on the MDIO pin and the LSB updated from the MDIO pin with each Management Data Clock (MDC) cycle. This causes the transmission of a PHY management frame on MDIO. See section 22.2.4.5 of the IEEE 802.3 standard.

Reading during the shift operation will return the current contents of the shift register. At the end of the management operation the bits will have shifted back to their original locations. For a read operation the data bits are updated with data read from the PHY. It is important to write the correct values to the register to ensure a valid PHY management frame is produced.

The Management Data Clock (MDC) should not toggle faster than 2.5 MHz (minimum period of 400 ns), as defined by the IEEE 802.3 standard. MDC is generated by dividing down MCK. Three bits in the Network Configuration register determine by how much MCK should be divided to produce MDC.

### 39.7.1.6 Interrupts

There are 18 interrupt conditions that are detected within the GEMAC. The conditions are ORed to make multiple interrupts. Depending on the overall system design this may be passed through a further level of interrupt collection (interrupt controller). On receipt of the interrupt signal, the CPU enters the interrupt handler. Refer to the device interrupt controller documentation to identify that it is the GEMAC that is generating the interrupt. To ascertain which interrupt, read the Interrupt Status register. Note that in the default configuration this register will clear itself after being read, though this may be configured to be write-one-to-clear if desired.

At reset all interrupts are disabled. To enable an interrupt, write to Interrupt Enable register with the pertinent interrupt bit set to 1. To disable an interrupt, write to Interrupt Disable register with the pertinent interrupt bit set to 1. To check whether an interrupt is enabled or disabled, read Interrupt Mask register. If the bit is set to 1, the interrupt is disabled.

### 39.7.1.7 Transmitting Frames

The procedure to set up a frame for transmission is the following:

1. Enable transmit in the Network Control register.

2. Allocate an area of system memory for transmit data. This does not have to be contiguous, varying byte lengths can be used if they conclude on byte borders.
3. Set-up the transmit buffer list by writing buffer addresses to word zero of the transmit buffer descriptor entries and control and length to word one.
4. Write data for transmission into the buffers pointed to by the descriptors.
5. Write the address of the first buffer descriptor to transmit buffer descriptor queue pointer.
6. Enable appropriate interrupts.
7. Write to the transmit start bit (TSTART) in the Network Control register.

### 39.7.1.8 Receiving Frames

When a frame is received and the receive circuits are enabled, the GEMAC checks the address and, in the following cases, the frame is written to system memory:

- If it matches one of the four Specific Address registers.
- If it matches one of the four Type ID registers.
- If it matches the hash address function.
- If it is a broadcast address (0xFFFFFFFF) and broadcasts are allowed.
- If the GEMAC is configured to “copy all frames”.

The register receive buffer queue pointer points to the next entry in the receive buffer descriptor list and the GEMAC uses this as the address in system memory to write the frame to.

Once the frame has been completely and successfully received and written to system memory, the GEMAC then updates the receive buffer descriptor entry (see [Receive Buffer Descriptor Entry](#)) with the reason for the address match and marks the area as being owned by software. Once this is complete, a receive complete interrupt is set. Software is then responsible for copying the data to the application area and releasing the buffer (by writing the ownership bit back to 0).

If the GEMAC is unable to write the data at a rate to match the incoming frame, then a receive overrun interrupt is set. If there is no receive buffer available, i.e., the next buffer is still owned by software, a receive buffer not available interrupt is set. If the frame is not successfully received, a statistics register is incremented and the frame is discarded without informing software.

### 39.7.2 Statistics Registers

Statistics registers are described in the User Interface beginning with [GMAC Octets Transmitted Low Register](#) and ending with [GMAC UDP Checksum Errors Register](#).

The statistics register block begins at 0x100 and runs to 0x1B0, and comprises the registers listed below.

|  |   |
|--|---|
| Octets Transmitted Low Register            | Broadcast Frames Received Register        |
| Octets Transmitted High Register           | Multicast Frames Received Register        |
| Frames Transmitted Register                | Pause Frames Received Register            |
| Broadcast Frames Transmitted Register      | 64 Byte Frames Received Register          |
| Multicast Frames Transmitted Register      | 65 to 127 Byte Frames Received Register   |
| Pause Frames Transmitted Register          | 128 to 255 Byte Frames Received Register  |
| 64 Byte Frames Transmitted Register        | 256 to 511 Byte Frames Received Register  |
| 65 to 127 Byte Frames Transmitted Register | 512 to 1023 Byte Frames Received Register |

## SAMA5D2 Series Ethernet MAC (GMAC)

|  |   |
|--|---|
| 128 to 255 Byte Frames Transmitted Register        | 1024 to 1518 Byte Frames Received Register    |
| 256 to 511 Byte Frames Transmitted Register        | 1519 to Maximum Byte Frames Received Register |
| 512 to 1023 Byte Frames Transmitted Register       | Undersize Frames Received Register            |
| 1024 to 1518 Byte Frames Transmitted Register      | Oversize Frames Received Register             |
| Greater Than 1518 Byte Frames Transmitted Register | Jabbers Received Register                     |
| Transmit Underruns Register                        | Frame Check Sequence Errors Register          |
| Single Collision Frames Register                   | Length Field Frame Errors Register            |
| Multiple Collision Frames Register                 | Receive Symbol Errors Register                |
| Excessive Collisions Register                      | Alignment Errors Register                     |
| Late Collisions Register                           | Receive Resource Errors Register              |
| Deferred Transmission Frames Register              | Receive Overrun Register                      |
| Carrier Sense Errors Register                      | IP Header Checksum Errors Register            |
| Octets Received Low Register                       | TCP Checksum Errors Register                  |
| Octets Received High Register                      | UDP Checksum Errors Register                  |
| Frames Received Register                           |   |

These registers reset to zero on a read and stick at all ones when they count to their maximum value. They should be read frequently enough to prevent loss of data.

The receive statistics registers are only incremented when the receive enable bit (RXEN) is set in the Network Control register.

Once a statistics register has been read, it is automatically cleared. When reading the Octets Transmitted and Octets Received registers, bits 31:0 should be read prior to bits 47:32 to ensure reliable operation.

### 39.8 Register Summary

| Offset | Name       | Bit Pos. |             |          |                |            |          |            |        |        |  |
|--------|------------|----------|-------------|----------|----------------|------------|----------|------------|--------|--------|--|
| 0x00   | GMAC_NCR   | 7:0      | WESTAT      | INCSTAT  | CLRSTAT        | MPE        | TXEN     | RXEN       | LBL    |        |  |
|        |            | 15:8     | SRTSM       |          |                | TXZQPF     | TXPF     | THALT      | TSTART | BP     |  |
|        |            | 23:16    |             |          |                |            | TXLPIEN  | FNP        | TXPBPF | ENPBPR |  |
|        |            | 31:24    |             |          |                |            |          |            |        |        |  |

### 39.8.1 GMAC Network Control Register

**Name:** GMAC\_NCR  
**Offset:** 0x000  
**Reset:** 0x00000000  
**Property:** Read/Write

|        |        |         |         |        |         |       |        |        |
|--------|--------|---------|---------|--------|---------|-------|--------|--------|
| Bit    | 31     | 30      | 29      | 28     | 27      | 26    | 25     | 24     |
|        |        |         |         |        |         |       |        |        |
| Access |        |         |         |        |         |       |        |        |
| Reset  |        |         |         |        |         |       |        |        |
| Bit    | 23     | 22      | 21      | 20     | 19      | 18    | 17     | 16     |
|        |        |         |         |        | TXLPIEN | FNP   | TXPBPF | ENPBPR |
| Access |        |         |         |        | R/W     | R/W   | R/W    | R/W    |
| Reset  |        |         |         |        | 0       | 0     | 0      | 0      |
| Bit    | 15     | 14      | 13      | 12     | 11      | 10    | 9      | 8      |
|        | SRTSM  |         |         | TXZQPF | TXPF    | THALT | TSTART | BP     |
| Access | R/W    |         |         | R/W    | R/W     | R/W   | R/W    | R/W    |
| Reset  | 0      |         |         | 0      | 0       | 0     | 0      | 0      |
| Bit    | 7      | 6       | 5       | 4      | 3       | 2     | 1      | 0      |
|        | WESTAT | INCSTAT | CLRSTAT | MPE    | TXEN    | RXEN  | LBL    |        |
| Access | R/W    | R/W     | R/W     | R/W    | R/W     | R/W   | R/W    |        |
| Reset  | 0      | 0       | 0       | 0      | 0       | 0     | 0      |        |

**Bit 19 – TXLPIEN** Enable LPI Transmission  
 When set, LPI (low power idle) is immediately transmitted.

**Bit 18 – FNP** Flush Next Packet  
 Flush the next packet from the external RX DPRAM. Writing one to this bit will only have an effect if the DMA is not currently writing a packet already stored in the DPRAM to memory.

**Bit 17 – TXPBPF** Transmit PFC Priority-based Pause Frame  
 Takes the values stored in the Transmit PFC Pause Register.

**Bit 16 – ENPBPR** Enable PFC Priority-based Pause Reception  
 Enables PFC Priority Based Pause Reception capabilities. Setting this bit enables PFC negotiation and recognition of priority-based pause frames.

**Bit 15 – SRTSM** Store Receive Timestamp to Memory

| Value | Description   |
|-------|---|
| 0     | Normal operation.   |
| 1     | Causes the CRC of every received frame to be replaced with the value of the nanoseconds field of the 1588 timer that was captured as the receive frame passed the message timestamp point. Note that bit RFCS in register GMAC_NCFGR may not be set to 1 when the timer should be captured. |

**Bit 12 – TXZQPF** Transmit Zero Quantum Pause Frame

Writing one to this bit causes a pause frame with zero quantum to be transmitted.

**Bit 11 – TXPF** Transmit Pause Frame

Writing one to this bit causes a pause frame to be transmitted.

**Bit 10 – THALT** Transmit Halt

Writing one to this bit halts transmission as soon as any ongoing frame transmission ends.

**Bit 9 – TSTART** Start Transmission

Writing one to this bit starts transmission.

**Bit 8 – BP** Back pressure

If set in 10M or 100M half duplex mode, forces collisions on all received frames.

**Bit 7 – WESTAT** Write Enable for Statistics Registers

Setting this bit to one makes the statistics registers writable for functional test purposes.

**Bit 6 – INCSTAT** Increment Statistics Registers

This bit is write-only. Writing a one increments all the statistics registers by one for test purposes.

**Bit 5 – CLRSTAT** Clear Statistics Registers

This bit is write-only. Writing a one clears the statistics registers.

**Bit 4 – MPE** Management Port Enable

Set to one to enable the management port. When zero, forces MDIO to high impedance state and MDC low.

**Bit 3 – TXEN** Transmit Enable

When set, TXEN enables the GMAC transmitter to send data. When reset transmission will stop immediately, the transmit pipeline and control registers will be cleared and the Transmit Queue Pointer Register will reset to point to the start of the transmit descriptor list.

**Bit 2 – RXEN** Receive Enable

When set, RXEN enables the GMAC to receive data. When reset frame reception stops immediately and the receive pipeline will be cleared. The Receive Queue Pointer Register is unaffected.

**Bit 1 – LBL** Loop Back Local

Connects GTX to GRX, GTXEN to GRXDV and forces full duplex mode. GRXCK and GTXCK may malfunction as the GMAC is switched into and out of internal loop back. It is important that receive and transmit circuits have already been disabled when making the switch into and out of internal loop back.

### 39.8.2 GMAC Network Configuration Register

**Name:** GMAC\_NCFGR  
**Offset:** 0x004  
**Reset:** 0x00080000  
**Property:** Read/Write

| Access | R/W         | R/W      | R/W  | R/W      | R/W    | R/W    | R/W   | R/W    |
| Reset  | 0           | 0        | 0    | 0        | 0      | 0      | 0     | 0      |

**Bit 30 – IRXER** Ignore IPG GRXER

When set, GRXER has no effect on the GMAC's operation when GRXDV is low.

**Bit 29 – RXBP** Receive Bad Preamble

When set, frames with non-standard preamble are not rejected.

**Bit 28 – IPGSEN** IP Stretch Enable

When set, the transmit IPG can be increased above 96 bit times depending on the previous frame length using the IPG Stretch Register.

**Bit 26 – IRXFCS** Ignore RX FCS

When set, frames with FCS/CRC errors will not be rejected. FCS error statistics will still be collected for frames with bad FCS and FCS status will be recorded in frame's DMA descriptor. For normal operation this bit must be set to zero.

**Bit 25 – EFRHD** Enable Frames Received in Half Duplex

Enable frames to be received in half-duplex mode while transmitting.

**Bit 24 – RXCOEN** Receive Checksum Offload Enable

When set, the receive checksum engine is enabled. Frames with bad IP, TCP or UDP checksums are discarded.

**Bit 23 – DCPF** Disable Copy of Pause Frames

Set to one to prevent valid pause frames being copied to memory. When set, pause frames are not copied to memory regardless of the state of the Copy All Frames bit, whether a hash match is found or whether a type ID match is identified. If a destination address match is found, the pause frame will be copied to memory. Note that valid pause frames received will still increment pause statistics and pause the transmission of frames as required.

**Bits 22:21 – DBW[1:0]** Data Bus Width

Should always be written to '0'.

**Bits 20:18 – CLK[2:0]** MDC CLock Division

Set according to MCK speed. These three bits determine the number MCK will be divided by to generate Management Data Clock (MDC). For conformance with the 802.3 specification, MDC must not exceed 2.5 MHz (MDC is only active during MDIO read and write operations).

| Value | Name   | Description                           |
|-------|--------|---------------------------------------|
| 0     | MCK_8  | MCK divided by 8 (MCK up to 20 MHz)   |
| 1     | MCK_16 | MCK divided by 16 (MCK up to 40 MHz)  |
| 2     | MCK_32 | MCK divided by 32 (MCK up to 80 MHz)  |
| 3     | MCK_48 | MCK divided by 48 (MCK up to 120 MHz) |
| 4     | MCK_64 | MCK divided by 64 (MCK up to 160 MHz) |
| 5     | MCK_96 | MCK divided by 96 (MCK up to 240 MHz) |

**Bit 17 – RFCS** Remove FCS

Setting this bit will cause received frames to be written to memory without their frame check sequence (last 4 bytes). The frame length indicated will be reduced by four bytes in this mode.

**Bit 16 – LFERD** Length Field Error Frame Discard

Setting this bit causes frames with a measured length shorter than the extracted length field (as indicated by bytes 13 and 14 in a non-VLAN tagged frame) to be discarded. This only applies to frames with a length field less than 0x0600.

**Bits 15:14 – RXBUFO[1:0]** Receive Buffer Offset

Indicates the number of bytes by which the received data is offset from the start of the receive buffer

**Bit 13 – PEN** Pause Enable

When set, transmission will pause if a non-zero 802.3 classic pause frame is received and PFC has not been negotiated.

**Bit 12 – RTY** Retry Test

Must be set to zero for normal operation. If set to one the backoff between collisions will always be one slot time. Setting this bit to one helps test the too many retries condition. Also used in the pause frame tests to reduce the pause counter's decrement time from 512 bit times, to every GRXCK cycle.

**Bit 8 – MAXFS** 1536 Maximum Frame Size

Setting this bit means the GMAC will accept frames up to 1536 bytes in length. Normally the GMAC would reject any frame above 1518 bytes.

**Bit 7 – UNIHEN** Unicast Hash Enable

When set, unicast frames will be accepted when the 6-bit hash function of the destination address points to a bit that is set in the Hash Register.

**Bit 6 – MTIHEN** Multicast Hash Enable

When set, multicast frames will be accepted when the 6-bit hash function of the destination address points to a bit that is set in the Hash Register.

**Bit 5 – NBC** No Broadcast

When set to logic one, frames addressed to the broadcast address of all ones will not be accepted.

**Bit 4 – CAF** Copy All Frames

When set to logic one, all valid frames will be accepted.

**Bit 3 – JFRAME** Jumbo Frame Size

Set to one to enable jumbo frames up to 10240 bytes to be accepted. The default length is 10240 bytes.

**Bit 2 – DNVLAN** Discard Non-VLAN FRAMES

When set only VLAN tagged frames will be passed to the address matching logic.

**Bit 1 – FD** Full Duplex

If set to logic one, the transmit block ignores the state of collision and carrier sense and allows receive while transmitting.

**Bit 0 – SPD** Speed

Set to logic one to indicate 100 Mbps operation, logic zero for 10 Mbps.

**39.8.3 GMAC Network Status Register**

**Name:** GMAC\_NSR  
**Offset:** 0x008  
**Reset:** 0x000001x0  
**Property:** Read-only

**Bit 7 – RXLPIS** LPI Indication

Low power idle has been detected on receive. This bit is set when LPI is detected and reset when normal idle is detected. An interrupt is generated when the state of this bit changes.

**Bit 2 – IDLE** PHY Management Logic Idle

The PHY management logic is idle (i.e., has completed).

**Bit 1 – MDIO** MDIO Input Status

Returns status of the MDIO pin.

### 39.8.4 GMAC User Register

**Name:** GMAC\_UR  
**Offset:** 0x00C  
**Reset:** 0x00000000  
**Property:** Read/Write

#### Bit 0 – RMII Reduced MII Mode

| Value | Description                     |
|-------|---------------------------------|
| 0     | MII mode is selected (default). |
| 1     | RMII mode is selected.          |

**39.8.5 GMAC DMA Configuration Register**

**Name:** GMAC\_DCFGR  
**Offset:** 0x010  
**Reset:** 0x00000000  
**Property:** Read/Write

|        |           |      |     |            |        |        |            |      |
|--------|-----------|------|-----|------------|--------|--------|------------|------|
| Bit    | 31        | 30   | 29  | 28         | 27     | 26     | 25         | 24   |
|        |           |      |     |            |        |        |            | DDRP |

| Reset  | 0         | 0    |     | 0          | 0      | 0      | 0          | 0    |

**Bit 24 – DDRP** DMA Discard Receive Packets

When set, the GMAC DMA will automatically discard receive packets from the receiver packet buffer memory when no AHB resource is available.

When low, the received packets will remain to be stored in the SRAM based packet buffer until AHB buffer resource next becomes available.

A write to this bit is ignored if the DMA is not configured in the packet buffer full store and forward mode.

**Bits 23:16 – DRBS[7:0]** DMA Receive Buffer Size

DMA receive buffer size in AHB system memory. The value defined by these bits determines the size of buffer to use in main AHB system memory when writing received data.

The value is defined in multiples of 64 bytes, thus a value of 0x01 corresponds to buffers of 64 bytes, 0x02 corresponds to 128 bytes etc.

For example:

- 0x02: 128 bytes
- 0x18: 1536 bytes (1 × max length frame/buffer)
- 0xA0: 10240 bytes (1 × 10K jumbo frame/buffer)

Note that this value should never be written as zero.

### Bit 11 – TXCOEN Transmitter Checksum Generation Offload Enable

Transmitter IP, TCP and UDP checksum generation offload enable. When set, the transmitter checksum generation engine is enabled to calculate and substitute checksums for transmit frames. When clear, frame data is unaffected.

### Bit 10 – TXPBMS Transmitter Packet Buffer Memory Size Select

Having this bit at zero halves the amount of memory used for the transmit packet buffer. This reduces the amount of memory used by the GMAC. It is important to set this bit to one if the full configured physical memory is available. The value in brackets below represents the size that would result for the default maximum configured memory size of 4 Kbytes.

| Value | Description                                       |
|-------|---|
| 0     | Do not use top address bit (2 Kbytes).            |
| 1     | Use full configured addressable space (4 Kbytes). |

### Bits 9:8 – RXBMS[1:0] Receiver Packet Buffer Memory Size Select

The default receive packet buffer size is 4 Kbytes. The table below shows how to configure this memory to FULL, HALF, QUARTER or EIGHTH of the default size.

| Value | Name    | Description            |
|-------|---------|------------------------|
| 0     | EIGHTH  | 4/8 Kbyte Memory Size  |
| 1     | QUARTER | 4/4 Kbytes Memory Size |
| 2     | HALF    | 4/2 Kbytes Memory Size |
| 3     | FULL    | 4 Kbytes Memory Size   |

### Bit 7 – ESPA Endian Swap Mode Enable for Packet Data Accesses

When set, selects swapped endianness for AHB transfers. When clear, selects little endian mode.

### Bit 6 – ESMA Endian Swap Mode Enable for Management Descriptor Accesses

When set, selects swapped endianness for AHB transfers. When clear, selects little endian mode.

### Bits 4:0 – FBDLO[4:0] Fixed Burst Length for DMA Data Operations

Selects the burst length to attempt to use on the AHB when transferring frame data. Not used for DMA management operations and only used where space and data size allow. Otherwise SINGLE type AHB transfers are used.

One-hot priority encoding enforced automatically on register writes as follows, where 'x' represents don't care:

| Value | Name   | Description                                      |
|-------|--------|--|
| 0     | –      | Reserved   |
| 1     | SINGLE | 00001: Always use SINGLE AHB bursts              |
| 2     | –      | Reserved   |
| 4     | INCR4  | 001xx: Attempt to use INCR4 AHB bursts (Default) |
| 8     | INCR8  | 01xxx: Attempt to use INCR8 AHB bursts           |
| 16    | INCR16 | 1xxxx: Attempt to use INCR16 AHB bursts          |

### 39.8.6 GMAC Transmit Status Register

**Name:** GMAC\_TSR  
**Offset:** 0x014  
**Reset:** 0x00000000  
**Property:** Read/Write

|        |    |    |        |     |      |     |     |       |
|--------|----|----|--------|-----|------|-----|-----|-------|
| Bit    | 31 | 30 | 29     | 28  | 27   | 26  | 25  | 24    |
|        |    |    |        |     |      |     |     |       |
| Access |    |    |        |     |      |     |     |       |
| Reset  |    |    |        |     |      |     |     |       |
|        |    |    |        |     |      |     |     |       |
| Bit    | 23 | 22 | 21     | 20  | 19   | 18  | 17  | 16    |
|        |    |    |        |     |      |     |     |       |
| Access |    |    |        |     |      |     |     |       |
| Reset  |    |    |        |     |      |     |     |       |
|        |    |    |        |     |      |     |     |       |
| Bit    | 15 | 14 | 13     | 12  | 11   | 10  | 9   | 8     |
|        |    |    |        |     |      |     |     | HRESP |
| Access |    |    |        |     |      |     |     | R/W   |
| Reset  |    |    |        |     |      |     |     | 0     |
|        |    |    |        |     |      |     |     |       |
| Bit    | 7  | 6  | 5      | 4   | 3    | 2   | 1   | 0     |
|        |    |    | TXCOMP | TFC | TXGO | RLE | COL | UBR   |
| Access |    |    | R/W    | R/W | R/W  | R/W | R/W | R/W   |
| Reset  |    |    | 0      | 0   | 0    | 0   | 0   | 0     |

**Bit 8 – HRESP** HRESP Not OK  
 Set when the DMA block sees HRESP not OK. Writing a one clears this bit.

**Bit 5 – TXCOMP** Transmit Complete  
 Set when a frame has been transmitted. Writing a one clears this bit.

**Bit 4 – TFC** Transmit Frame Corruption Due to AHB Error  
 Transmit frame corruption due to AHB error. Set if an error occurs while midway through reading transmit frame from the AHB, including HRESP errors and buffers exhausted mid frame (if the buffers run out during transmission of a frame then transmission stops, FCS shall be bad and GTXER asserted).  
 Also set in DMA packet buffer mode if single frame is too large for configured packet buffer memory size.  
 Writing a one clears this bit.

**Bit 3 – TXGO** Transmit Go  
 Transmit go, if high transmit is active. When using the DMA interface, this bit represents the TXGO variable as specified in the transmit buffer description.

**Bit 2 – RLE** Retry Limit Exceeded  
 Writing a one clears this bit.

**Bit 1 – COL** Collision Occurred

Set by the assertion of collision. Writing a one clears this bit. When operating in 10/100 mode, this status indicates either a collision or a late collision.

**Bit 0 – UBR** Used Bit Read

Set when a transmit buffer descriptor is read with its used bit set. Writing a one clears this bit.

**39.8.7 GMAC Receive Buffer Queue Base Address Register**

**Name:** GMAC\_RBQB  
**Offset:** 0x018  
**Reset:** 0x00000000  
**Property:** Read/Write

This register holds the start address of the receive buffer queue (receive buffers descriptor list). The receive buffer queue base address must be initialized before receive is enabled through bit 2 of the Network Control Register. Once reception is enabled, any write to the Receive Buffer Queue Base Address Register is ignored. Reading this register returns the location of the descriptor currently being accessed. This value increments as buffers are used. Software should not use this register for determining where to remove received frames from the queue as it constantly changes as new frames are received. Software should instead work its way through the buffer descriptor queue checking the “used” bits.

In terms of AMBA AHB operation, the descriptors are read from memory using a single 32-bit AHB access. The descriptors should be aligned at 32-bit boundaries and the descriptors are written to using two individual non sequential accesses.

|        |             |     |     |     |     |     |     |     |  |

**Bits 31:2 – ADDR[29:0]** Receive Buffer Queue Base Address  
 Written with the address of the start of the receive queue.

### 39.8.8 GMAC Transmit Buffer Queue Base Address Register

**Name:** GMAC\_TBQB  
**Offset:** 0x01C  
**Reset:** 0x00000000  
**Property:** Read/Write

This register holds the start address of the transmit buffer queue (transmit buffers descriptor list). The Transmit Buffer Queue Base Address Register must be initialized before transmit is started through bit 9 of the Network Control Register. Once transmission has started, any write to the Transmit Buffer Queue Base Address Register is illegal and therefore ignored.

Note that due to clock boundary synchronization, it takes a maximum of four MCK cycles from the writing of the transmit start bit before the transmitter is active. Writing to the Transmit Buffer Queue Base Address Register during this time may produce unpredictable results.

Reading this register returns the location of the descriptor currently being accessed. Since the DMA handles two frames at once, this may not necessarily be pointing to the current frame being transmitted.

In terms of AMBA AHB operation, the descriptors are written to memory using a single 32-bit AHB access. The descriptors should be aligned at 32-bit boundaries and the descriptors are read from memory using two individual non sequential accesses.

|        |     |             |     |     |     |     |     |     |     |  |

**Bits 31:2 – ADDR[29:0]** Transmit Buffer Queue Base Address  
 Written with the address of the start of the transmit queue.

**39.8.9 GMAC Receive Status Register**

**Name:** GMAC\_RSR  
**Offset:** 0x020  
**Reset:** 0x00000000  
**Property:** Read/Write

This register, when read, provides receive status details. Once read, individual bits may be cleared by writing a one to them. It is not possible to set a bit to 1 by writing to the register.

**Bit 3 – HNO** HRESP Not OK

Set when the DMA block sees HRESP not OK. Writing a one clears this bit.

**Bit 2 – RXOVR** Receive Overrun

This bit is set if the receive status was not taken at the end of the frame. This bit is also set if the packet buffer overflows. The buffer will be recovered if an overrun occurs. Writing a one clears this bit.

**Bit 1 – REC** Frame Received

One or more frames have been received and placed in memory. Writing a one clears this bit.

**Bit 0 – BNA** Buffer Not Available

An attempt was made to get a new buffer and the pointer indicated that it was owned by the processor. The DMA will re-read the pointer each time an end of frame is received until a valid pointer is found. This bit is set following each descriptor read attempt that fails, even if consecutive pointers are unsuccessful and software has in the mean time cleared the status flag. Writing a one clears this bit.

**39.8.10 GMAC Interrupt Status Register**

**Name:** GMAC\_ISR  
**Offset:** 0x024  
**Reset:** 0x00000000  
**Property:** Read-only

This register indicates the source of the interrupt. In order that the bits of this register read 1, the corresponding interrupt source must be enabled in the mask register. If any bit is set in this register, the GMAC interrupt signal will be asserted in the system.

| Bit    | 31     | 30     | 29         | 28    | 27       | 26    | 25     | 24     |

| Access | R      | R      | R          | R     | R        | R     | R      | R      |
| Reset  | 0      | 0      | 0          | 0     | 0        | 0     | 0      | 0      |

**Bit 29 – TSUTIMCOMP** TSU Timer Comparison

Indicates when TSU timer count value is equal to programmed value. Cleared on read.

**Bit 28 – WOL** Wake On LAN

WOL interrupt. Indicates a WOL event has been received.

**Bit 27 – RXLPISBC** Receive LPI indication Status Bit Change

Receive LPI indication status bit change. Cleared on read.

**Bit 26 – SRI** TSU Seconds Register Increment

Indicates the register has incremented. Cleared on read.

**Bit 25 – PDRSFT** PDelay Response Frame Transmitted

Indicates a PTP pdelay\_resp frame has been transmitted. Cleared on read.

**Bit 24 – PDRQFT** PDelay Request Frame Transmitted

Indicates a PTP pdelay\_req frame has been transmitted. Cleared on read.

**Bit 23 – PDRSFR** PDelay Response Frame Received

Indicates a PTP pdelay\_resp frame has been received. Cleared on read.

**Bit 22 – PDRQFR** PDelay Request Frame Received

Indicates a PTP pdelay\_req frame has been received. Cleared on read.

**Bit 21 – SFT** PTP Sync Frame Transmitted

Indicates a PTP sync frame has been transmitted. Cleared on read.

**Bit 20 – DRQFT** PTP Delay Request Frame Transmitted

Indicates a PTP delay\_req frame has been transmitted. Cleared on read.

**Bit 19 – SFR** PTP Sync Frame Received

Indicates a PTP sync frame has been received. Cleared on read.

**Bit 18 – DRQFR** PTP Delay Request Frame Received

Indicates a PTP delay\_req frame has been received. Cleared on read.

**Bit 14 – PFTR** Pause Frame Transmitted

Indicates a pause frame has been successfully transmitted after being initiated from the Network Control register. Cleared on read.

**Bit 13 – PTZ** Pause Time Zero

Set when either the Pause Time register at address 0x38 decrements to zero, or when a valid pause frame is received with a zero pause quantum field. Cleared on read.

**Bit 12 – PFNZ** Pause Frame with Non-zero Pause Quantum Received

Indicates a valid pause has been received that has a non-zero pause quantum field. Cleared on read.

**Bit 11 – HRESP** HRESP Not OK

Set when the DMA block sees HRESP not OK. Cleared on read.

**Bit 10 – ROVR** Receive Overrun

Set when the receive overrun status bit is set. Cleared on read.

**Bit 7 – TCOMP** Transmit Complete

Set when a frame has been transmitted. Cleared on read.

**Bit 6 – TFC** Transmit Frame Corruption Due to AHB Error

Transmit frame corruption due to AHB error. Set if an error occurs while midway through reading transmit frame from the AHB, including HRESP errors and buffers exhausted mid frame.

**Bit 5 – RLEX** Retry Limit Exceeded

Transmit error. Cleared on read.

**Bit 4 – TUR** Transmit Underrun

This interrupt is set if the transmitter was forced to terminate a frame that it has already began transmitting due to further data being unavailable.

This interrupt is set if a transmitter status write back has not completed when another status write back is attempted.

This interrupt is also set when the transmit DMA has written the SOP data into the FIFO and either the AHB bus was not granted in time for further data, or because an AHB not OK response was returned, or because the used bit was read.

**Bit 3 – TXUBR** TX Used Bit Read

Set when a transmit buffer descriptor is read with its used bit set. Cleared on read.

**Bit 2 – RXUBR** RX Used Bit Read

Set when a receive buffer descriptor is read with its used bit set. Cleared on read.

**Bit 1 – RCOMP** Receive Complete

A frame has been stored in memory. Cleared on read.

**Bit 0 – MFS** Management Frame Sent

The PHY Maintenance Register has completed its operation. Cleared on read.

**39.8.11 GMAC Interrupt Enable Register**

**Name:** GMAC\_IER  
**Offset:** 0x028  
**Reset:** –  
**Property:** Write-only

This register is write-only and when read will return zero.

The following values are valid for all listed bit names of this register:

0: No effect.

1: Enables the corresponding interrupt.

|        |        |        |            |       |          |       |        |        |

### 39.8.12 GMAC Interrupt Disable Register

**Name:** GMAC\_IDR  
**Offset:** 0x02C  
**Reset:** –  
**Property:** Write-only

This register is write-only and when read will return zero.

The following values are valid for all listed bit names of this register:

0: No effect.

1: Disables the corresponding interrupt.

|        |     |        |        |            |       |          |       |        |        |
|--------|-----|--------|--------|------------|-------|----------|-------|--------|--------|
|        | Bit | 31     | 30     | 29         | 28    | 27       | 26    | 25     | 24     |
|        |     |        |        | TSUTIMCOMP | WOL   | RXLPISBC | SRI   | PDRSFT | PDRQFT |
| Access |     |        |        | W          | W     | W        | W     | W      | W      |
| Reset  |     |        |        | –          | –     | –        | –     | –      | –      |

### 39.8.13 GMAC Interrupt Mask Register

**Name:** GMAC\_IMR  
**Offset:** 0x030  
**Reset:** 0x07FFFFFFF  
**Property:** Read/Write

The Interrupt Mask Register is a read-only register indicating which interrupts are masked. All bits are set at reset and can be reset individually by writing to the Interrupt Enable Register or set individually by writing to the Interrupt Disable Register. Having separate address locations for enable and disable saves the need for performing a read modify write when updating the Interrupt Mask Register.

For test purposes there is a write-only function to this register that allows the bits in the Interrupt Status Register to be set or cleared, regardless of the state of the mask register. A write to this register directly affects the state of the corresponding bit in the Interrupt Status Register, causing an interrupt to be generated if a 1 is written.

The following values are valid for all listed bit names of this register when read:

0: The corresponding interrupt is enabled.

1: The corresponding interrupt is not enabled.

|        |        |        |            |       |          |       |        |        |
|--------|--------|--------|------------|-------|----------|-------|--------|--------|
| Bit    | 31     | 30     | 29         | 28    | 27       | 26    | 25     | 24     |
|        |        |        | TSUTIMCOMP | WOL   | RXLPISBC | SRI   | PDRSFT | PDRQFT |
| Access |        |        | R/W        | R/W   | R/W      | R/W   | R/W    | R/W    |
| Reset  |        |        | 0          | 0     | 0        | 1     | 1      | 1      |
|        |        |        |            |       |          |       |        |        |

**39.8.14 GMAC PHY Maintenance Register**

**Name:** GMAC\_MAN  
**Offset:** 0x034  
**Reset:** 0x00000000  
**Property:** Read/Write

The PHY Maintenance Register is implemented as a shift register. Writing to the register starts a shift operation which is signalled as complete when bit 2 is set in the Network Status Register. It takes about 2000 MCK cycles to complete, when MDC is set for MCK divide by 32 in the Network Configuration Register. An interrupt is generated upon completion.

During this time, the MSB of the register is output on the MDIO pin and the LSB updated from the MDIO pin with each MDC cycle. This causes transmission of a PHY management frame on MDIO. See Section 22.2.4.5 of the IEEE 802.3 standard.

Reading during the shift operation returns the current contents of the shift register. At the end of management operation, the bits will have shifted back to their original locations. For a read operation, the data bits are updated with data read from the PHY. It is important to write the correct values to the register to ensure a valid PHY management frame is produced.

The MDIO interface can read IEEE 802.3 clause 45 PHYs as well as clause 22 PHYs. To read clause 45 PHYs, bit 30 should be written with a 0 rather than a 1. To write clause 45 PHYs, bits 31:28 should be written as 0x0001. See the table below.

**Table 39-16. Clause 22/Clause 45 PHYs Read/Write Access Configuration (GMAC\_MAN Bits 31:28)**

| PHY       | Access         | Bit Value |       |       |       |
|-----------|----------------|-----------|-------|-------|-------|
|           |                | WZO       | CLTTO | OP[1] | OP[0] |
| Clause 22 | Read           | 0         | 1     | 1     | 0     |
|           | Write          | 0         | 1     | 0     | 1     |
| Clause 45 | Read           | 0         | 0     | 1     | 1     |
|           | Write          | 0         | 0     | 0     | 1     |
|           | Read + Address | 0         | 0     | 1     | 0     |

For a description of MDC generation, see [GMAC Network Configuration Register](#).

### Bit 31 – WZO Write ZERO

Must be written with 0.

### Bit 30 – CLTTO Clause 22 Operation

| Value | Description         |
|-------|---------------------|
| 0     | Clause 45 operation |
| 1     | Clause 22 operation |

### Bits 29:28 – OP[1:0] Operation

| Value | Description |
|-------|-------------|
| 01    | Write       |
| 10    | Read        |

### Bits 27:23 – PHYA[4:0] PHY Address

### Bits 22:18 – REGA[4:0] Register Address

Specifies the register in the PHY to access.

### Bits 17:16 – WTN[1:0] Write Ten

Must be written to 10.

### Bits 15:0 – DATA[15:0] PHY Data

For a write operation this field is written with the data to be written to the PHY. After a read operation this field contains the data read from the PHY.

### 39.8.15 GMAC Receive Pause Quantum Register

**Name:** GMAC\_RPQ  
**Offset:** 0x038  
**Reset:** 0x00000000  
**Property:** Read-only

**Bits 13:0 – FML[13:0]** Frame Max Length  
 Rx jumbo frame maximum length.

### 39.8.20 GMAC Hash Register Bottom

**Name:** GMAC\_HRB  
**Offset:** 0x080  
**Reset:** 0x00000000  
**Property:** Read/Write

The unicast hash enable (UNIHEN) and the multicast hash enable (MITIHEN) bits in the Network Configuration Register ([GMAC Network Configuration Register](#)) enable the reception of hash matched frames. See [Hash Addressing](#).

**Bits 31:0 – ADDR[31:0] Specific Address 1**

Least significant 32 bits of the destination address, that is, bits 31:0. Bit zero indicates whether the address is multicast or unicast and corresponds to the least significant bit of the first byte received.

### 39.8.23 GMAC Specific Address 1 Top Register

**Name:** GMAC\_SAT1  
**Offset:** 0x08C  
**Reset:** 0x00000000  
**Property:** Read/Write

The addresses stored in the Specific Address Registers are deactivated at reset or when their corresponding Specific Address Register Bottom is written. They are activated when Specific Address Register Top is written.

**Bits 15:0 – ADDR[15:0] Specific Address 1**

The most significant bits of the destination address, that is, bits 47:32.

### 39.8.24 GMAC Specific Address 2 Bottom Register

**Name:** GMAC\_SAB2  
**Offset:** 0x090  
**Reset:** 0x00000000  
**Property:** Read/Write

The addresses stored in the Specific Address Registers are deactivated at reset or when their corresponding Specific Address Register Bottom is written. They are activated when Specific Address Register Top is written.

#### Bits 31:0 – ADDR[31:0] Specific Address 2

Least significant 32 bits of the destination address, that is, bits 31:0. Bit zero indicates whether the address is multicast or unicast and corresponds to the least significant bit of the first byte received.

**39.8.25 GMAC Specific Address 2 Top Register**

**Name:** GMAC\_SAT2  
**Offset:** 0x094  
**Reset:** 0x00000000  
**Property:** Read/Write

The addresses stored in the Specific Address Registers are deactivated at reset or when their corresponding Specific Address Register Bottom is written. They are activated when Specific Address Register Top is written.

**Bits 15:0 – ADDR[15:0] Specific Address 2**

The most significant bits of the destination address, that is, bits 47:32.

### 39.8.26 GMAC Specific Address 3 Bottom Register

**Name:** GMAC\_SAB3  
**Offset:** 0x098  
**Reset:** 0x00000000  
**Property:** Read/Write

The addresses stored in the Specific Address Registers are deactivated at reset or when their corresponding Specific Address Register Bottom is written. They are activated when Specific Address Register Top is written.

| Reset  |     | 0           | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

#### Bits 31:0 – ADDR[31:0] Specific Address 3

Least significant 32 bits of the destination address, that is, bits 31:0. Bit zero indicates whether the address is multicast or unicast and corresponds to the least significant bit of the first byte received.

**39.8.27 GMAC Specific Address 3 Top Register**

**Name:** GMAC\_SAT3  
**Offset:** 0x09C  
**Reset:** 0x00000000  
**Property:** Read/Write

The addresses stored in the Specific Address Registers are deactivated at reset or when their corresponding Specific Address Register Bottom is written. They are activated when Specific Address Register Top is written.

**Bits 15:0 – ADDR[15:0] Specific Address 3**

The most significant bits of the destination address, that is, bits 47:32.

### 39.8.28 GMAC Specific Address 4 Bottom Register

**Name:** GMAC\_SAB4  
**Offset:** 0x0A0  
**Reset:** 0x00000000  
**Property:** Read/Write

The addresses stored in the Specific Address Registers are deactivated at reset or when their corresponding Specific Address Register Bottom is written. They are activated when Specific Address Register Top is written.

#### Bits 31:0 – ADDR[31:0] Specific Address 4

Least significant 32 bits of the destination address, that is, bits 31:0. Bit zero indicates whether the address is multicast or unicast and corresponds to the least significant bit of the first byte received.

### 39.8.29 GMAC Specific Address 4 Top Register

**Name:** GMAC\_SAT4  
**Offset:** 0x0A4  
**Reset:** 0x00000000  
**Property:** Read/Write

The addresses stored in the Specific Address Registers are deactivated at reset or when their corresponding Specific Address Register Bottom is written. They are activated when Specific Address Register Top is written.

**Bits 15:0 – ADDR[15:0] Specific Address 4**

The most significant bits of the destination address, that is, bits 47:32.

**39.8.30 GMAC Type ID Match 1 Register**

**Name:** GMAC\_TIDM1  
**Offset:** 0x0A8  
**Reset:** 0x00000000  
**Property:** Read/Write

| Access | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

**Bit 19 – MTI** Multicast Hash Event Enable  
 Wake on LAN multicast hash event enable.

**Bit 18 – SA1** Specific Address Register 1 Event Enable  
 Wake on LAN Specific Address Register 1 event enable.

**Bit 17 – ARP** ARP Request Event Enable  
 Wake on LAN ARP request event enable.

**Bit 16 – MAG** Magic Packet Event Enable  
 Wake on LAN magic packet event enable.

**Bits 15:0 – IP[15:0]** ARP Request IP Address  
 Wake on LAN ARP request IP address. Written to define the least significant 16 bits of the target IP address that is matched to generate a Wake on LAN event. A value of zero will not generate an event, even if this is matched by the received frame.

**39.8.35 GMAC IPG Stretch Register**

**Name:** GMAC\_IPGS  
**Offset:** 0x0BC  
**Reset:** 0x00000000  
**Property:** Read/Write

**Bits 15:0 – FL[15:0] Frame Length**

Bits 7:0 are multiplied with the previously transmitted frame length (including preamble). Bits 15:8 +1 divide the frame length. If the resulting number is greater than 96 and bit 28 is set in the Network Configuration Register then the resulting number is used for the transmit inter-packet-gap. 1 is added to bits 15:8 to prevent a divide by zero. See [MAC Transmit Block](#).

### 39.8.36 GMAC Stacked VLAN Register

**Name:** GMAC\_SVLAN  
**Offset:** 0x0C0  
**Reset:** 0x00000000  
**Property:** Read/Write

#### Bit 31 – ESVLAN Enable Stacked VLAN Processing Mode

| Value | Description                              |
|-------|--|
| 0     | Disable the stacked VLAN processing mode |
| 1     | Enable the stacked VLAN processing mode  |

#### Bits 15:0 – VLAN\_TYPE[15:0] User Defined VLAN\_TYPE Field

User defined VLAN\_TYPE field. When Stacked VLAN is enabled, the first VLAN tag in a received frame will only be accepted if the VLAN type field is equal to this user defined VLAN\_TYPE, OR equal to the standard VLAN type (0x8100). Note that the second VLAN tag of a Stacked VLAN packet will only be matched correctly if its VLAN\_TYPE field equals 0x8100.

**39.8.37 GMAC Transmit PFC Pause Register**

**Name:** GMAC\_TPFCP  
**Offset:** 0x0C4  
**Reset:** 0x00000000  
**Property:** Read/Write

**Bits 15:8 – PQ[7:0] Pause Quantum**

If bit 17 of the Network Control Register is written with a one then for each entry equal to zero in the Transmit PFC Pause Register[15:8], the PFC pause frame's pause quantum field associated with that entry will be taken from the Transmit Pause Quantum Register. For each entry equal to one in the Transmit PFC Pause Register [15:8], the pause quantum associated with that entry will be zero.

**Bits 7:0 – PEV[7:0] Priority Enable Vector**

If bit 17 of the Network Control Register is written with a one then the priority enable vector of the PFC priority based pause frame will be set equal to the value stored in this register [7:0].

**Bits 15:0 – RUD[15:0] Register Update**

The register is updated with the value that the 1588 timer seconds register held when the SFD of a PTP transmit peer event crosses the MII interface. An interrupt is issued when the register is updated.

### 39.8.46 GMAC PTP Peer Event Frame Received Seconds High Register

**Name:** GMAC\_PEFRSH  
**Offset:** 0x0F4  
**Reset:** 0x00000000  
**Property:** Read-only

**Bits 31:0 – TXO[31:0] Transmitted Octets**

Transmitted octets in frame without errors [31:0]. The number of octets transmitted in valid frames of any type. This counter is 48-bits, and is read through two registers. This count does not include octets from automatically generated pause frames.

**39.8.48 GMAC Octets Transmitted High Register**

**Name:** GMAC\_OTHI  
**Offset:** 0x104  
**Reset:** 0x00000000  
**Property:** Read-only

When reading the Octets Transmitted and Octets Received Registers, bits 31:0 should be read prior to bits 47:32 to ensure reliable operation.

**Bits 15:0 – TXO[15:0] Transmitted Octets**

Transmitted octets in frame without errors [47:32]. The number of octets transmitted in valid frames of any type. This counter is 48-bits, and is read through two registers. This count does not include octets from automatically generated pause frames.

**Bits 17:0 – MCOL[17:0] Multiple Collision**

This register counts the number of frames experiencing between two and fifteen collisions prior to being successfully transmitted, i.e., no underrun and not too many retries.

**39.8.63 GMAC Excessive Collisions Register**

**Name:** GMAC\_EC  
**Offset:** 0x140

**Bits 9:0 – LCOL[9:0] Late Collisions**

This register counts the number of late collisions occurring after the slot time (512 bits) has expired. In 10/100 mode, late collisions are counted twice i.e., both as a collision and a late collision.

### 39.8.65 GMAC Deferred Transmission Frames Register

**Bits 17:0 – DEFT[17:0] Deferred Transmission**

This register counts the number of frames experiencing deferral due to carrier sense being active on their first attempt at transmission. Frames involved in any collision are not counted nor are frames that experienced a transmit underrun.

**39.8.66 GMAC Carrier Sense Errors Register**

**Name:** GMAC\_CSE  
**Offset:** 0x14C  
**Reset:** 0x00000000  
**Property:** Read-only

**Bits 9:0 – CSR[9:0] Carrier Sense Error**

This register counts the number of frames transmitted where carrier sense was not seen during transmission or where carrier sense was deasserted after being asserted in a transmit frame without collision (no underrun). Only incremented in half duplex mode. The only effect of a carrier sense error is to increment this register. The behavior of the other statistics registers is unaffected by the detection of a carrier sense error.

**39.8.67 GMAC Octets Received Low Register**

**Name:** GMAC\_ORLO  
**Offset:** 0x150  
**Reset:** 0x00000000  
**Property:** Read-only

When reading the Octets Transmitted and Octets Received Registers, bits [31:0] should be read prior to bits [47:32] to ensure reliable operation.

**Bits 31:0 – RXO[31:0] Received Octets**

Received octets in frame without errors [31:0]. The number of octets received in valid frames of any type. This counter is 48-bits and is read through two registers. This count does not include octets from pause frames, and is only incremented if the frame is successfully filtered and copied to memory.

**39.8.68 GMAC Octets Received High Register**

**Name:** GMAC\_ORHI  
**Offset:** 0x154  
**Reset:** 0x00000000  
**Property:** Read-only

When reading the Octets Transmitted and Octets Received Registers, bits 31:0 should be read prior to bits 47:32 to ensure reliable operation.

**Bits 15:0 – RXO[15:0] Received Octets**

Received octets in frame without errors [47:32]. The number of octets received in valid frames of any type. This counter is 48-bits and is read through two registers. This count does not include octets from pause frames, and is only incremented if the frame is successfully filtered and copied to memory.

**39.8.69 GMAC Frames Received Register**

**Bits 31:0 – NFRX[31:0] 1024 to 1518 Byte Frames Received without Error**

This register counts the number of 1024 to 1518 byte frames successfully received without error, i.e., no underrun and not too many retries.

### 39.8.79 GMAC 1519 to Maximum Byte Frames Received Register

**Bits 31:0 – NFRX[31:0]** 1519 to Maximum Byte Frames Received without Error

This register counts the number of 1519 byte or above frames successfully received without error. Maximum frame size is determined by the Network Configuration Register bit 8 (1536 maximum frame size) or bit 3 (jumbo frame size). Excludes pause frames, and is only incremented if the frame is successfully filtered and copied to memory. See [GMAC Network Configuration Register](#).

**39.8.80 GMAC Undersized Frames Received Register**

#### Bits 9:0 – FCKR[9:0] Frame Check Sequence Errors

The register counts frames that are an integral number of bytes, have bad CRC and are between 64 and 1518 bytes in length (1536 if bit 8 is set in Network Configuration Register). This register is also incremented if a symbol error is detected and the frame is of valid length and has an integral number of bytes.

This register is incremented for a frame with bad FCS, regardless of whether it is copied to memory due to ignore FCS mode being enabled in bit 26 of the Network Configuration Register. See [GMAC Network Configuration Register](#).

**39.8.84 GMAC Length Field Frame Errors Register**

**Name:** GMAC\_LFFE  
**Offset:** 0x194  
**Reset:** 0x00000000  
**Property:** Read-only

**Bits 9:0 – LFER[9:0] Length Field Frame Errors**

This register counts the number of frames received that have a measured length shorter than that extracted from the length field (bytes 13 and 14). This condition is only counted if the value of the length field is less than 0x0600, the frame is not of excessive length and checking is enabled through bit 16 of the Network Configuration Register. See [GMAC Network Configuration Register](#).

**39.8.85 GMAC Receive Symbol Errors Register**

**Name:** GMAC\_RSE  
**Offset:** 0x198  
**Reset:** 0x00000000  
**Property:** Read-only

**Bits 9:0 – RXSE[9:0] Receive Symbol Errors**

This register counts the number of frames that had GRXER asserted during reception. For 10/100 mode symbol errors are counted regardless of frame length checks. Receive symbol errors will also be counted as an FCS or alignment error if the frame is between 64 and 1518 bytes (1536 bytes if bit 8 is set in the Network Configuration Register). If the frame is larger it will be recorded as a jabber error. See [GMAC Network Configuration Register](#).

**39.8.86 GMAC Alignment Errors Register**

**Name:** GMAC\_AE  
**Offset:** 0x19C  
**Reset:** 0x0000'0000  
**Property:** Read-only

**Bits 9:0 – AER[9:0] Alignment Errors**

This register counts the frames that are not an integral number of bytes long and have bad CRC when their length is truncated to an integral number of bytes and are between 64 and 1518 bytes in length (1536 if bit 8 is set in Network Configuration Register). This register is also incremented if a symbol error is detected and the frame is of valid length and does not have an integral number of bytes. See [GMAC Network Configuration Register](#).

**39.8.87 GMAC Receive Resource Errors Register**

**Name:** GMAC\_RRE  
**Offset:** 0x1A0  
**Reset:** 0x00000000  
**Property:** Read-only

**Bits 9:0 – RXOVR[9:0] Receive Overruns**

This register counts the number of frames that are address recognized but were not copied to memory due to a receive overrun.

**39.8.89 GMAC IP Header Checksum Errors Register**

**Name:** GMAC\_IHCE  
**Offset:** 0x1A8  
**Reset:** 0x00000000  
**Property:** Read-only

**Bits 7:0 – HCKER[7:0] IP Header Checksum Errors**

This register counts the number of frames discarded due to an incorrect IP header checksum, but are between 64 and 1518 bytes (1536 bytes if bit 8 is set in the Network Configuration Register) and do not have a CRC error, an alignment error, nor a symbol error.

**39.8.90 GMAC TCP Checksum Errors Register**

**Name:** GMAC\_TCE  
**Offset:** 0x1AC  
**Reset:** 0x00000000  
**Property:** Read-only

**Bits 7:0 – TCKER[7:0] TCP Checksum Errors**

This register counts the number of frames discarded due to an incorrect TCP checksum, but are between 64 and 1518 bytes (1536 bytes if bit 8 is set in the Network Configuration Register) and do not have a CRC error, an alignment error, nor a symbol error.

**39.8.91 GMAC UDP Checksum Errors Register**

**Name:** GMAC\_UCE  
**Offset:** 0x1B0  
**Reset:** 0x00000000  
**Property:** Read-only

**Bits 7:0 – UCKER[7:0] UDP Checksum Errors**

This register counts the number of frames discarded due to an incorrect UDP checksum, but are between 64 and 1518 bytes (1536 bytes if bit 8 is set in the Network Configuration Register) and do not have a CRC error, an alignment error, nor a symbol error.

**39.8.92 GMAC 1588 Timer Increment Sub-nanoseconds Register**

**Name:** GMAC\_TISUBN  
**Offset:** 0x1BC  
**Reset:** 0x00000000  
**Property:** Read/Write

|        |                   |     |     |     |     |     |     |     |

**Bits 15:0 – LSBTIR[15:0] Lower Significant Bits of Timer Increment Register**

Lower significant bits of Timer Increment Register[15:0] giving a 24-bit timer\_increment counter. These bits are the sub-ns value which the 1588 timer will be incremented each clock cycle. Bit n =  $2^{(n-16)}$  nsec giving a resolution of approximately  $15.2E^{-15}$  sec.

### 39.8.93 GMAC 1588 Timer Seconds High Register

**Name:** GMAC\_TSH  
**Offset:** 0x1C0  
**Reset:** 0x00000000  
**Property:** Read/Write

**Bit 31 – ADJ** Adjust 1588 Timer

Write as one to subtract from the 1588 timer. Write as zero to add to it.

**Bits 29:0 – ITDT[29:0]** Increment/Decrement

The number of nanoseconds to increment or decrement the 1588 Timer Nanoseconds Register. If necessary, the 1588 Seconds Register will be incremented or decremented.

**39.8.97 GMAC 1588 Timer Increment Register**

**Bits 31:0 – RUD[31:0] Register Update**

The register is updated with the value that the 1588 Timer Seconds Register holds when the SFD of a PTP receive primary event crosses the MII interface. An interrupt is issued when the register is updated.

**Bits 23:0 – LPITIME[23:0]** Time in LPI (cleared on read)

This field increments once every 16 MCK cycles when the bit Enable LPI Transmission (bit 19) is set in the Network Control register.

**39.8.110 GMAC Interrupt Status Register Priority Queue x**

**Name:** GMAC\_ISR PQx  
**Offset:** 0x03FC + x\*0x04 [x=0..1]  
**Reset:** 0x00000000  
**Property:** Read/Write

**Bit 11 – HRESP** HRESP Not OK

**Bit 10 – ROVR** Receive Overrun

**Bit 7 – TCOMP** Transmit Complete

**Bit 6 – TFC** Transmit Frame Corruption Due to AHB Error  
 Transmit frame corruption due to AHB error—set if an error occurs whilst midway through reading transmit frame from the AHB, including HRESP errors and buffers exhausted mid frame.

**Bit 5 – RLEX** Retry Limit Exceeded or Late Collision

**Bit 2 – RXUBR** RX Used Bit Read

**Bit 1 – RCOMP** Receive Complete

### 39.8.111 GMAC Transmit Buffer Queue Base Address Register Priority Queue x

**Name:** GMAC\_TBQBAPQx  
**Offset:** 0x043C + x\*0x04 [x=0..1]  
**Reset:** 0x00000000  
**Property:** Read/Write

These registers hold the start address of the transmit buffer queues (transmit buffers descriptor lists) for the additional queues and must be initialized to the address of valid descriptors, even if the priority queues are not used.

**Bits 31:2 – TXBQBA[29:0]** Transmit Buffer Queue Base Address  
 Written with the address of the start of the transmit queue.

### 39.8.112 GMAC Receive Buffer Queue Base Address Register Priority Queue x

**Name:** GMAC\_RBQBAPQx  
**Offset:** 0x047C + x\*0x04 [x=0..1]  
**Reset:** 0x00000000  
**Property:** Read/Write

These registers hold the start address of the receive buffer queues (receive buffers descriptor lists) for the additional queues and must be initialized to the address of valid descriptors, even if the priority queues are not used.

**Reset:** 0x00000002  
**Property:** Read/Write

**Bits 15:0 – RBS[15:0] Receive Buffer Size**

DMA receive buffer size in AHB system memory. The value defined by these bits determines the size of buffer to use in main AHB system memory when writing received data.

The value is defined in multiples of 64 bytes such that a value of 0x01 corresponds to buffers of 64 bytes, 0x02 corresponds to 128 bytes etc.

For example:

0x02: 128bytes

0x18: 1536bytes (1 × max length frame/buffer)

0xA0: 10240bytes (1 × 10K jumbo frame/buffer)

Note that this value should never be written as zero.

**39.8.114 GMAC Credit-Based Shaping Control Register**

**Name:** GMAC\_CBSCR  
**Offset:** 0x4BC  
**Reset:** 0x00000000  
**Property:** Read/Write

**Bits 31:0 – IS[31:0] IdleSlope**  
IdleSlope value for queue A in bytes/second.

The IdleSlope value is defined as the rate of change of credit when a packet is waiting to be sent. This must not exceed the port transmit rate which is dependent on the speed of operation, e.g., 100 Mb/second = 32'h017D7840

If 50% of bandwidth was to be allocated to a particular queue in 100 Mb/second mode, then the IdleSlope value for that queue would be calculated as 32'h017D7840 / 2.

**39.8.116 GMAC Credit-Based Shaping IdleSlope Register for Queue B**

**Name:** GMAC\_CBSISQB  
**Offset:** 0x4C4  
**Reset:** 0x00000000  
**Property:** Read/Write

Credit-based shaping must be disabled in GMAC\_CBSCR before updating this register.

**Bit 29 – UDPE** UDP Port Match Enable

When UDP port match enable is set (bit 29), the UDP Destination Port of the received UDP frame is matched against bits 27:12.

**Bit 28 – DSTCE** Differentiated Services or Traffic Class Match Enable

When DS/TC match enable is set (bit 28), the DS (differentiated services) field of the received IPv4 header or TC field (traffic class) of IPv6 headers are matched against bits 11:4.

**Bits 27:12 – UDPM[15:0]** UDP Port Match

When UDP port match enable is set (bit 29), the UDP Destination Port of the received UDP frame is matched against bits 27:12.

**Bits 11:4 – DSTCM[7:0]** Differentiated Services or Traffic Class Match

When DS/TC match enable is set (bit 28), the DS (differentiated services) field of the received IPv4 header or TC field (traffic class) of IPv6 headers are matched against bits 11:4.

**Bits 2:0 – QNB[2:0]** Queue Number (0–2)

If a match is successful, then the queue value programmed in bits 2:0 is allocated to the frame.

### 39.8.118 GMAC Screening Type 2 Register x Priority Queue

**Name:** GMAC\_ST2RPQx  
**Offset:** 0x0540 + x\*0x04 [x=0..7]  
**Reset:** 0x00000000  
**Property:** Read/Write

Screening type 2 registers are used to allocate up to 3 priority queues to received frames based on the VLAN priority field of received ethernet frames.

| 1     | Comparison via the register designated by index COMPC is enabled.  |

**Bits 29:25 – COMPC[4:0]** Index of Screening Type 2 Compare Word 0/Word 1 register x  
 COMPC is a pointer to the compare registers GMAC\_ST2CW0x and GMAC\_ST2CW1x. When COMPCE is set, the compare is true if the data at the frame offset ANDed with the value MASKVAL is equal to the value of COMPVAL ANDed with the value of MASKVAL.

#### Bit 24 – COMPBE Compare B Enable

| Value | Description  |
|-------|--|
| 0     | Comparison via the register designated by index COMPB is disabled. |
| 1     | Comparison via the register designated by index COMPB is enabled.  |

**Bits 23:19 – COMPB[4:0]** Index of Screening Type 2 Compare Word 0/Word 1 register x  
 COMPB is a pointer to the compare registers GMAC\_ST2CW0x and GMAC\_ST2CW1x. When COMPBE is set, the compare is true if the data at the frame offset ANDed with the value MASKVAL is equal to the value of COMPVAL ANDed with the value of MASKVAL.

**Bit 18 – COMPAE** Compare A Enable

| Value | Description  |
|-------|--|
| 0     | Comparison via the register designated by index COMPA is disabled. |
| 1     | Comparison via the register designated by index COMPA is enabled.  |

**Bits 17:13 – COMPA[4:0]** Index of Screening Type 2 Compare Word 0/Word 1 register x  
 COMPA is a pointer to the compare registers GMAC\_ST2CW0x and GMAC\_ST2CW1x. When COMPAE is set, the compare is true if the data at the frame offset ANDed with the value MASKVAL is equal to the value of COMPVAL ANDed with the value of MASKVAL.

**Bit 12 – ETHE** EtherType Enable

| Value | Description  |
|-------|--|
| 0     | EtherType match with bits 15:0 in the register designated by the value of I2ETH is disabled. |
| 1     | EtherType match with bits 15:0 in the register designated by the value of I2ETH is enabled.  |

**Bits 11:9 – I2ETH[2:0]** Index of Screening Type 2 EtherType register x  
 When ETHE is set (bit 12), the field EtherType (last EtherType in the header if the frame is VLAN tagged) is compared with bits 15:0 in the register designated by the value of I2ETH.

**Bit 8 – VLANE** VLAN Enable

| Value | Description             |
|-------|-------------------------|
| 0     | VLAN match is disabled. |
| 1     | VLAN match is enabled.  |

**Bits 6:4 – VLANP[2:0]** VLAN Priority  
 When VLAN match enable is set (bit 8), the VLAN priority field of the received frame is matched against bits 7:4 of this register.

**Bits 2:0 – QNB[2:0]** Queue Number (0–2)  
 If a match is successful, then the queue value programmed in QNB is allocated to the frame.

### 39.8.119 GMAC Interrupt Enable Register Priority Queue x

**Name:** GMAC\_IERPQx  
**Offset:** 0x05FC + x\*0x04 [x=0..1]  
**Reset:** –  
**Property:** Write-only

The following values are valid for all listed bit names of this register:

0: No effect.

1: Enables the corresponding interrupt.

### 39.8.121 GMAC Interrupt Mask Register Priority Queue x

**Name:** GMAC\_IMRPQx  
**Offset:** 0x063C + x\*0x04 [x=0..1]  
**Reset:** 0x00000000  
**Property:** Read/Write

A read of this register returns the value of the receive complete interrupt mask.

A write to this register directly affects the state of the corresponding bit in the Interrupt Status Register, causing an interrupt to be generated if a 1 is written.

The following values are valid for all listed bit names of this register:

0: Corresponding interrupt is enabled.

1: Corresponding interrupt is disabled.

|        |  |      |     |       |       |       |     |    |       |     |      |  |       |       |       |  |  |

**Bits 31:16 – COMPVAL[15:0]** Compare Value

The byte stored in bits [23:16] is compared against the first byte of the 2 bytes extracted from the frame.

The byte stored in bits [31:24] is compared against the second byte of the 2 bytes extracted from the frame.

**Bits 15:0 – MASKVAL[15:0]** Mask Value

The value of MASKVAL ANDed with the 2 bytes extracted from the frame is compared to the value of MASKVAL ANDed with the value of COMPVAL.

### 39.8.124 GMAC Screening Type 2 Compare Word 1 Register x

**Name:** GMAC\_ST2CW1x  
**Offset:** 0x0704 + x\*0x08 [x=0..23]  
**Reset:** 0x00000000  
**Property:** Read/Write

#### Bits 8:7 – OFFSSTRT[1:0] Ethernet Frame Offset Start

| Value | Name       | Description   |
|-------|------------|---|
| 0     | FRAMESTART | Offset from the start of the frame                  |
| 1     | ETHERTYPE  | Offset from the byte after the EtherType field      |
| 2     | IP         | Offset from the byte after the IP header field      |
| 3     | TCP_UDP    | Offset from the byte after the TCP/UDP header field |

#### Bits 6:0 – OFFSVAL[6:0] Offset Value in Bytes

The value of OFFSVAL ranges from 0 to 127 bytes, and is counted from either the start of the frame, the byte after the EtherType field (last EtherType in the header if the frame is VLAN tagged), the byte after the IP header (IPv4 or IPv6) or the byte after the TCP/UDP header.

## **40. USB High Speed Device Port (UDPHS)**

### **40.1 Description**

The USB High Speed Device Port (UDPHS) is compliant with the Universal Serial Bus (USB), rev 2.0 High Speed device specification.

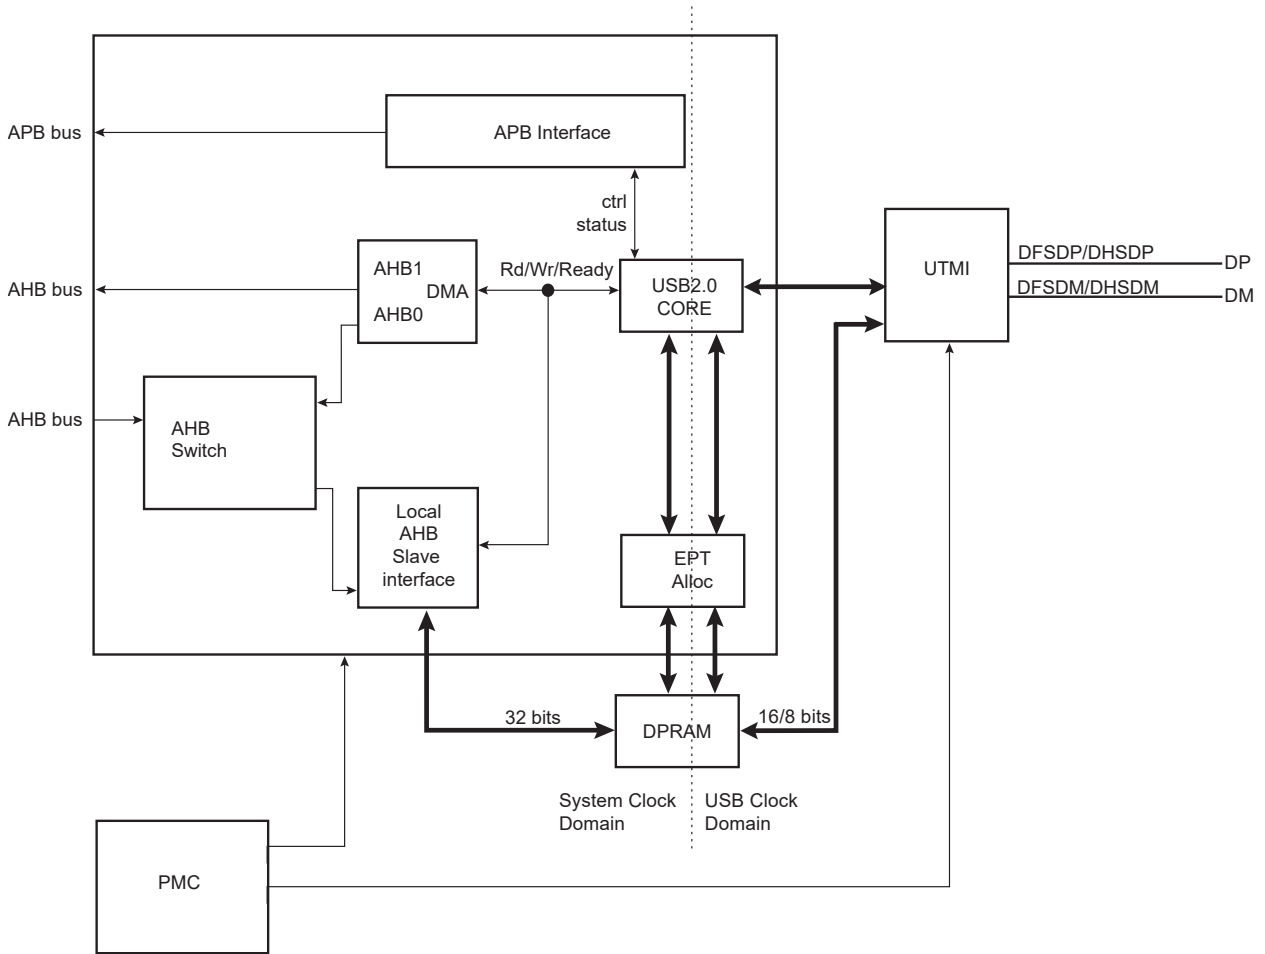

Each endpoint can be configured in one of several USB transfer types. It can be associated with one, two or three banks of a Dual-port RAM used to store the current data payload. If two or three banks are used, one DPR bank is read or written by the processor, while the other is read or written by the USB device peripheral. This feature is mandatory for isochronous endpoints.

### **40.2 Embedded Characteristics**

- 1 High-speed Device
- 1 UTMI transceiver shared between Host and Device
- USB v2.0 High Speed (480 Mbits/s) Compliant
- 16 Endpoints up to 1024 bytes
- Embedded Dual-port RAM for Endpoints
- Suspend/Resume Logic (Command of UTMI)
- Up to Three Memory Banks for Endpoints (Not for Control Endpoint)
- 8 Kbytes of DPRAM

**40.3 Block Diagram**

**Figure 40-1. Block Diagram**

## 40.4 Typical Connection

Figure 40-2. Board Schematic

**Note:**

1. The values shown on the 22 kΩ and 15 kΩ resistors are only valid with 3V3-supplied PIOs.
2. CRPB: Upstream Facing Port Bypass Capacitance of 1 μF to 10 μF (refer to “DC Electrical Characteristics” in Universal Serial Bus Specification Rev. 2)
3. 10 pF capacitor on VBG is a provision and may not be populated.

## 40.5 Product Dependencies

### 40.5.1 Power Management

The UDPHS is not continuously clocked.

To use the UDPHS, the programmer must first enable the UDPHS Clock in the Power Management Controller Peripheral Clock Enable Register (PMC\_PCER), then enable the PLL in the PMC UTMI Clock Configuration Register (CKGR\_UCKR). Finally, the programmer must enable BIAS in CKGR\_UCKR.

However, if the application does not require UDPHS operations, the UDPHS clock can be stopped when not needed and restarted later.

### 40.5.2 Interrupt Sources

The UDPHS interrupt line is connected on one of the internal sources of the interrupt controller. Using the UDPHS interrupt requires the interrupt controller to be programmed first.

## 40.6 Functional Description

### 40.6.1 UTMI Transceivers Sharing

The High Speed USB Host Port A is shared with the High Speed USB Device port and connected to the second UTMI transceiver. The selection between Host Port A and USB Device is controlled by the UDPHS enable bit (EN\_UDPHS) located in the UDPHS\_CTRL register.

**Figure 40-3. USB Selection**

### 40.6.2 USB V2.0 High Speed Device Port Introduction

The USB V2.0 High Speed Device Port provides communication services between host and attached USB devices. Each device is offered with a collection of communication flows (pipes) associated with each endpoint. Software on the host communicates with a USB Device through a set of communication flows.

### 40.6.3 USB V2.0 High Speed Transfer Types

A communication flow is carried over one of four transfer types defined by the USB device.

A device provides several logical communication pipes with the host. To each logical pipe is associated an endpoint. Transfer through a pipe belongs to one of the four transfer types:

- **Control Transfers:** Used to configure a device at attach time and can be used for other device-specific purposes, including control of other pipes on the device.
- **Bulk Data Transfers:** Generated or consumed in relatively large burst quantities and have wide dynamic latitude in transmission constraints.
- **Interrupt Data Transfers:** Used for timely but reliable delivery of data, for example, characters or coordinates with human-perceptible echo or feedback response characteristics.
- **Isochronous Data Transfers:** Occupy a prenegotiated amount of USB bandwidth with a prenegotiated delivery latency. (Also called streaming real time transfers.)

As indicated below, transfers are sequential events carried out on the USB bus.

Endpoints must be configured according to the transfer type they handle.

**Table 40-1. USB Communication Flow**

| Transfer    | Direction      | Bandwidth      | Endpoint Size | Error Detection | Retrying  |
|-------------|----------------|----------------|---------------|-----------------|-----------|
| Control     | Bidirectional  | Not guaranteed | 8, 16, 32, 64 | Yes             | Automatic |
| Isochronous | Unidirectional | Guaranteed     | 8–1024        | Yes             | No        |
| Interrupt   | Unidirectional | Not guaranteed | 8–1024        | Yes             | Yes       |
| Bulk        | Unidirectional | Not guaranteed | 8–512         | Yes             | Yes       |

### 40.6.4 USB Transfer Event Definitions

A transfer is composed of one or several transactions as shown in the table below.

**Table 40-2. USB Transfer Events**

| Transfer                 |   | Transaction   |
|--------------------------|---|---|
| Direction                | Type                                    |   |
| CONTROL (bidirectional)  | Control Transfer <sup>(1)</sup>         | <ul style="list-style-type: none"> <li>• Setup transaction → Data IN transactions → Status OUT transaction</li> <li>• Setup transaction → Data OUT transactions → Status IN transaction</li> <li>• Setup transaction → Status IN transaction</li> </ul> |
| IN (device toward host)  | Bulk IN Transfer                        | • Data IN transaction → Data IN transaction   |
|                          | Interrupt IN Transfer                   | • Data IN transaction → Data IN transaction   |
|                          | Isochronous IN Transfer <sup>(2)</sup>  | • Data IN transaction → Data IN transaction   |
| OUT (host toward device) | Bulk OUT Transfer                       | • Data OUT transaction → Data OUT transaction   |
|                          | Interrupt OUT Transfer                  | • Data OUT transaction → Data OUT transaction   |
|                          | Isochronous OUT Transfer <sup>(2)</sup> | • Data OUT transaction → Data OUT transaction   |

**Note:**

1. Control transfer must use endpoints with one bank and can be aborted using a stall handshake.
2. Isochronous transfers must use endpoints configured with two or three banks.

An endpoint handles all transactions related to the type of transfer for which it has been configured.

**Table 40-3. UDPHS Endpoint Description**

| Endpoint # | Mnemonic | Nb Bank | DMA | High Band Width | Max. Endpoint Size | Endpoint Type                           |
|------------|----------|---------|-----|-----------------|--------------------|---|
| 0          | EPT_0    | 1       | N   | N               | 64                 | Control                                 |
| 1          | EPT_1    | 3       | Y   | Y               | 1024               | Ctrl/Bulk/Iso <sup>(1)</sup> /Interrupt |
| 2          | EPT_2    | 3       | Y   | Y               | 1024               | Ctrl/Bulk/Iso <sup>(1)</sup> /Interrupt |
| 3          | EPT_3    | 2       | Y   | N               | 1024               | Ctrl/Bulk/Iso <sup>(1)</sup> /Interrupt |
| 4          | EPT_4    | 2       | Y   | N               | 1024               | Ctrl/Bulk/Iso <sup>(1)</sup> /Interrupt |
| 5          | EPT_5    | 2       | Y   | N               | 1024               | Ctrl/Bulk/Iso <sup>(1)</sup> /Interrupt |
| 6          | EPT_6    | 2       | Y   | N               | 1024               | Ctrl/Bulk/Iso <sup>(1)</sup> /Interrupt |
| 7          | EPT_7    | 2       | Y   | N               | 1024               | Ctrl/Bulk/Iso <sup>(1)</sup> /Interrupt |
| 8          | EPT_8    | 2       | N   | N               | 1024               | Ctrl/Bulk/Iso <sup>(1)</sup> /Interrupt |
| 9          | EPT_9    | 2       | N   | N               | 1024               | Ctrl/Bulk/Iso <sup>(1)</sup> /Interrupt |
| 10         | EPT_10   | 2       | N   | N               | 1024               | Ctrl/Bulk/Iso <sup>(1)</sup> /Interrupt |
| 11         | EPT_11   | 2       | N   | N               | 1024               | Ctrl/Bulk/Iso <sup>(1)</sup> /Interrupt |

.....continued

| Endpoint # | Mnemonic | Nb Bank | DMA | High Band Width | Max. Endpoint Size | Endpoint Type                           |
|------------|----------|---------|-----|-----------------|--------------------|---|
| 12         | EPT_12   | 2       | N   | N               | 1024               | Ctrl/Bulk/Iso <sup>(1)</sup> /Interrupt |
| 13         | EPT_13   | 2       | N   | N               | 1024               | Ctrl/Bulk/Iso <sup>(1)</sup> /Interrupt |
| 14         | EPT_14   | 2       | N   | N               | 1024               | Ctrl/Bulk/Iso <sup>(1)</sup> /Interrupt |
| 15         | EPT_15   | 2       | N   | N               | 1024               | Ctrl/Bulk/Iso <sup>(1)</sup> /Interrupt |

**Note:**

1. In Isochronous (Iso) mode, it is preferable that High Band Width capability is available.

The size of the internal DPRAM is 8 Kbytes.

Suspend and resume are automatically detected by the UDPHS device, which notifies the processor by raising an interrupt.

### 40.6.5 USB V2.0 High Speed BUS Transactions

Each transfer results in one or more transactions over the USB bus.

There are five kinds of transactions flowing across the bus in packets:

1. Setup Transaction
2. Data IN Transaction
3. Data OUT Transaction
4. Status IN Transaction
5. Status OUT Transaction

A status IN or OUT transaction is identical to a data IN or OUT transaction.

**Figure 40-4. Control Read and Write Sequences**

### 40.6.6 Endpoint Configuration

The endpoint 0 is always a control endpoint, it must be programmed and active in order to be enabled when the End Of Reset interrupt occurs.

To configure the endpoints:

- Fill the configuration register (UDPHS\_EPTCFG) with the endpoint size, direction (IN or OUT), type (CTRL, Bulk, IT, ISO) and the number of banks.
- Fill the number of transactions (NB\_TRANS) for isochronous endpoints.

Note: For control endpoints the direction has no effect.

- Verify that the EPT\_MAPD flag is set. This flag is set if the endpoint size and the number of banks are correct for this endpoint and compared to the FIFO maximum capacity and the maximum number of allowed banks.
- Configure control flags of the endpoint and enable it in UDPHS\_EPTCTLENBx according to the section [UDPHS Endpoint Control Disable Register \(Isochronous Endpoint\)](#).

Control endpoints can generate interrupts and use only 1 bank.

All endpoints (except endpoint 0) can be configured either as Bulk, Interrupt or Isochronous. Refer to the table [UDPHS Endpoint Description](#).

The maximum packet size they can accept corresponds to the maximum endpoint size.

**Note:** The endpoint size of 1024 is reserved for isochronous endpoints.

The size of the DPRAM is 8 Kbytes. The DPR is shared by all active endpoints. The memory size required by the active endpoints must not exceed the size of the DPRAM.

SIZE\_DPRAM = SIZE\_EPT0

+ NB\_BANK\_EPT1 x SIZE\_EPT1

+ NB\_BANK\_EPT2 x SIZE\_EPT2

+ NB\_BANK\_EPT3 x SIZE\_EPT3

+ NB\_BANK\_EPT4 x SIZE\_EPT4

+ NB\_BANK\_EPT5 x SIZE\_EPT5

+ NB\_BANK\_EPT6 x SIZE\_EPT6

+... (refer to [UDPHS Endpoint Configuration Register](#))

If a user tries to configure endpoints with a size the sum of which is greater than the DPRAM, then the EPT\_MAPD is not set.

The application has access to the physical block of DPR reserved for the endpoint through a 64-Kbyte logical address space.

The physical block of DPR reserved for the endpoint is remapped all along the 64-Kbyte logical address space. The application can write a 64-Kbyte buffer linearly.

**Figure 40-5. Logical Address Space for DPR Access**

Configuration examples of `UDPHS_EPTCTLx` ([UDPHS Endpoint Control Disable Register \(Isochronous Endpoint\)](#)) for Bulk IN endpoint type follow below.

- With DMA
  - `AUTO_VALID`: Automatically validate the packet and switch to the next bank.
  - `EPT_ENABL`: Enable endpoint.
- Without DMA:
  - `TXRDY`: An interrupt is generated after each transmission.
  - `EPT_ENABL`: Enable endpoint.

Configuration examples of Bulk OUT endpoint type follow below.

- With DMA
  - `AUTO_VALID`: Automatically validate the packet and switch to the next bank.
  - `EPT_ENABL`: Enable endpoint.
- Without DMA
  - `RXRDY_TXKL`: An interrupt is sent after a new packet has been stored in the endpoint FIFO.
  - `EPT_ENABL`: Enable endpoint.

#### 40.6.7 DPRAM Management

Endpoints can only be allocated in ascending order, from the endpoint 0 to the last endpoint to be allocated. The user shall therefore configure them in the same order.

The allocation of an endpoint  $x$  starts when the Number of Banks field in the `UDPHS` Endpoint Configuration Register (`UDPHS_EPTCFGx.BK_NUMBER`) is different from zero. Then, the hardware allocates a memory area in the DPRAM and inserts it between the  $x - 1$  and  $x + 1$  endpoints. The  $x + 1$  endpoint memory window slides up and its data is lost. Note that the following endpoint memory windows (from  $x + 2$ ) do not slide.

Disabling an endpoint, by writing a one to the Endpoint Disable bit in the `UDPHS` Endpoint Control Disable Register (`UDPHS_EPTCTLDISx.EPT_DISABL`), does not reset its configuration:

- Endpoint Banks (UDPHS\_EPTCFGx.BK\_NUMBER)
- Endpoint Size (UDPHS\_EPTCFGx.EPT\_SIZE)
- Endpoint Direction (UDPHS\_EPTCFGx.EPT\_DIR)
- Endpoint Type (UDPHS\_EPTCFGx.EPT\_TYPE)

To free its memory, the user shall write a zero to the UDPHS\_EPTCFGx.BK\_NUMBER field. The x+ 1 endpoint memory window then slides down and its data is lost. Note that the following endpoint memory windows (from x+ 2) do not slide.

The following figure illustrates the allocation and reorganization of the DPRAM in a typical example.

**Figure 40-6. Example of DPRAM Allocation and Reorganization**

DPRAM allocation sequence:

1. The endpoints 0 to 5 are enabled, configured and allocated in ascending order. Each endpoint then owns a memory area in the DPRAM.
2. The endpoint 3 is disabled, but its memory is kept allocated by the controller.
3. In order to free its memory, its UDPHS\_EPTCFGx.BK\_NUMBER field is written to zero. The endpoint 4 memory window slides down, but the endpoint 5 does not move.
4. If the user chooses to reconfigure the endpoint 3 with a larger size, the controller allocates a memory area after the endpoint 2 memory area and automatically slides up the endpoint 4 memory window. The endpoint 5 does not move and a memory conflict appears as the memory windows of the endpoints 4 and 5 overlap. The data of these endpoints is potentially lost.

**Note:**

1. There is no way the data of the endpoint 0 can be lost (except if it is de-allocated) as the memory allocation and de-allocation may affect only higher endpoints.
2. Deactivating then reactivating the same endpoint with the same configuration only modifies temporarily the controller DPRAM pointer and size for this endpoint. Nothing changes in the DPRAM, higher endpoints seem not to have been moved and their data is preserved as far as nothing has been written or received into them while changing the allocation state of the first endpoint.
3. When the user writes a value different from zero to the UDPHS\_EPTCFGx.BK\_NUMBER field, the Endpoint Mapped bit (UDPHS\_EPTCFGx.EPT\_MAPD) is set only if the configured size and

number of banks are correct as compared to the endpoint maximal allowed values and to the maximal FIFO size (i.e., the DPRAM size). The UDPHS\_EPTCFGx.EPT\_MAPD value does not consider memory allocation conflicts.

### 40.6.8 Transfer With DMA

USB packets of any length may be transferred when required by the UDPHS device. These transfers always feature sequential addressing.

Packet data AHB bursts may be locked on a DMA buffer basis for drastic overall AHB bus bandwidth performance boost with paged memories. These clock-cycle consuming memory row (or bank) changes will then likely not occur, or occur only once instead of several times, during a single big USB packet DMA transfer in case another AHB master addresses the memory. The locked bursts result in up to 128-word single-cycle unbroken AHB bursts for bulk endpoints and 256-word single-cycle unbroken bursts for isochronous endpoints.

This maximum burst length is then controlled by the lowest programmed USB endpoint size (EPT\_SIZE field in the UDPHS\_EPTCFGx register) and DMA Size (BUFF\_LENGTH field in the UDPHS\_DMACONTROLx register).

The USB 2.0 device average throughput may be up to nearly 60 Mbyte/s. Its internal slave average access latency decreases as burst length increases due to the 0 wait-state side effect of unchanged endpoints. If at least 0 wait-state word burst capability is also provided by the external DMA AHB bus slaves, each of both DMA AHB busses need less than 50% bandwidth allocation for full USB 2.0 bandwidth usage at 30 MHz, and less than 25% at 60 MHz.

The UDPHS DMA Channel Transfer Descriptor is described in the section [UDPHS DMA Channel Transfer Descriptor](#).

**Note:** In case of debug, be careful to address the DMA to an SRAM address even if a remap is done.

**Figure 40-7. Example of DMA Chained List**

### 40.6.9 Transfer Without DMA

**Important:** If the DMA is not to be used, it is necessary to disable it, otherwise it can be enabled by previous versions of software without warning. If this should occur, the DMA can process data before an interrupt without knowledge of the user.

The recommended means to disable DMA are as follows:

```
// Reset IP UDPHS
AT91C_BASE_UDPHS->UDPHS_CTRL &= ~AT91C_UDPHS_EN_UDPHS;
AT91C_BASE_UDPHS->UDPHS_CTRL |= AT91C_UDPHS_EN_UDPHS;//
With OR without DMA !!!
for( i=1; i<=((AT91C_BASE_UDPHS->UDPHS_IPFEATURES &
AT91C_UDPHS_DMA_CHANNEL_NBR)>>4); i++ ) {
// RESET endpoint canal DMA:
// DMA stop channel command
AT91C_BASE_UDPHS->UDPHS_DMA[i].UDPHS_DMACONTROL = 0; // STOP
command
// Disable endpoint
AT91C_BASE_UDPHS->UDPHS_EPT[i].UDPHS_EPTCTLDIS |= 0xFFFFFFFF;
// Reset endpoint config
AT91C_BASE_UDPHS->UDPHS_EPT[i].UDPHS_EPTCLCFG = 0;
// Reset DMA channel (Buff count and Control field)
AT91C_BASE_UDPHS->UDPHS_DMA[i].UDPHS_DMACONTROL = 0x02; // NON
STOP command
// Reset DMA channel 0 (STOP)
AT91C_BASE_UDPHS->UDPHS_DMA[i].UDPHS_DMACONTROL = 0; // STOP
command
// Clear DMA channel status (read the register for clear it)
AT91C_BASE_UDPHS->UDPHS_DMA[i].UDPHS_DMASTATUS =
AT91C_BASE_UDPHS->UDPHS_DMA[i].UDPHS_DMASTATUS;
}
```

### 40.6.10 Handling Transactions with USB V2.0 Device Peripheral

#### 40.6.10.1 Setup Transaction

The setup packet is valid in the DPR while RX\_SETUP is set. Once RX\_SETUP is cleared by the application, the UDPHS accepts the next packets sent over the device endpoint.

When a valid setup packet is accepted by the UDPHS:

- The UDPHS device automatically acknowledges the setup packet (sends an ACK response)
- Payload data is written in the endpoint
- Sets the RX\_SETUP interrupt
- The BYTE\_COUNT field in the UDPHS\_EPTSTAx register is updated

An endpoint interrupt is generated while RX\_SETUP in the UDPHS\_EPTSTAx register is not cleared. This interrupt is carried out to the microcontroller if interrupts are enabled for this endpoint.

Thus, firmware must detect RX\_SETUP polling UDPHS\_EPTSTAx or catching an interrupt, read the setup packet in the FIFO, then clear the RX\_SETUP bit in the UDPHS\_EPTCLRSTA register to acknowledge the setup stage.

If STALL\_SNT was set to 1, then this bit is automatically reset when a setup token is detected by the device. Then, the device still accepts the setup stage. (See the section [STALL](#)).

#### 40.6.10.2 NYET

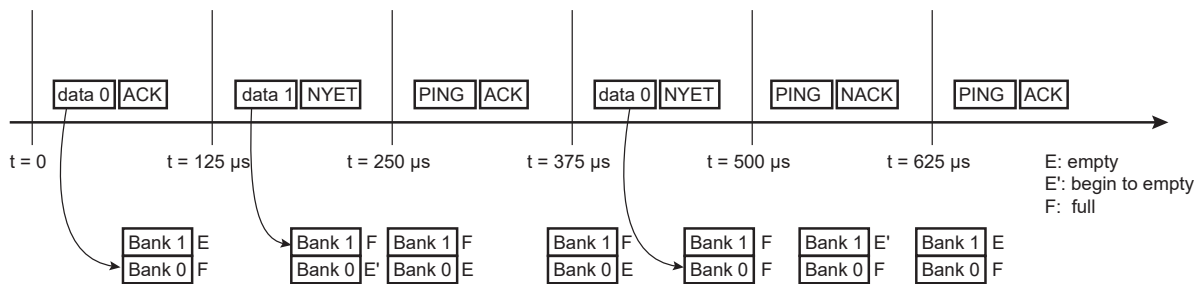

NYET is a High Speed only handshake. It is returned by a High Speed endpoint as part of the PING protocol.

High Speed devices must support an improved NAK mechanism for Bulk OUT and control endpoints (except setup stage). This mechanism allows the device to tell the host whether it has sufficient endpoint space for the next OUT transfer (refer to USB 2.0 spec 8.5.1 NAK Limiting via Ping Flow Control).

The NYET/ACK response to a High Speed Bulk OUT transfer and the PING response are automatically handled by hardware in the UDPHS\_EPTCTLx register (except when the user wants to force a NAK response by using the NYET\_DIS bit).

If the endpoint responds instead to the OUT/DATA transaction with an NYET handshake, this means that the endpoint accepted the data but does not have room for another data payload. The host controller must return to using a PING token until the endpoint indicates it has space available.

**Figure 40-8. NYET Example with Two Endpoint Banks**

### 40.6.10.3 Data IN

- Bulk IN or Interrupt IN

Data IN packets are sent by the device during the data or the status stage of a control transfer or during an (interrupt/bulk/isochronous) IN transfer. Data buffers are sent packet by packet under the control of the application or under the control of the DMA channel.

There are three ways for an application to transfer a buffer in several packets over the USB:

- packet by packet (see [Bulk IN or Interrupt IN: Sending a Packet Under Application Control \(Device to Host\)](#) below)
- 64 Kbytes (see [Bulk IN or Interrupt IN: Sending a Packet Under Application Control \(Device to Host\)](#) below)
- DMA (see [Bulk IN or Interrupt IN: Sending a Buffer Using DMA \(Device to Host\)](#) below)
  - Bulk IN or Interrupt IN: Sending a Packet Under Application Control (Device to Host)
- Bulk IN or Interrupt IN: Sending a Packet Under Application Control (Device to Host)

The application can write one or several banks.

A simple algorithm can be used by the application to send packets regardless of the number of banks associated to the endpoint.

#### Algorithm Description for Each Packet

- The application waits for the TXRDY flag to be cleared in the UDPHS\_EPTSTAx register before it can perform a write access to the DPR.
- The application writes one USB packet of data in the DPR through the 64 Kbytes endpoint logical memory window.
- The application sets TXRDY flag in the UDPHS\_EPTSETSTAx register.

The application is notified that it is possible to write a new packet to the DPR by the TXRDY interrupt. This interrupt can be enabled or masked by setting the TXRDY bit in the UDPHS\_EPTCTLENB/UDPHS\_EPTCTLDIS register.

### Algorithm Description to Fill Several Packets

Using the previous algorithm, the application is interrupted for each packet. It is possible to reduce the application overhead by writing linearly several banks at the same time. The AUTO\_VALID bit in the UDPHS\_EPTCTLx must be set by writing the AUTO\_VALID bit in the UDPHS\_EPTCTLENBx register.

The auto-valid-bank mechanism allows the transfer of data (IN and OUT) without the intervention of the CPU. This means that bank validation (set TXRDY or clear the RXRDY\_TXKL bit) is done by hardware.

- The application checks the BUSY\_BANK\_STA field in the UDPHS\_EPTSTAx register. The application must wait that at least one bank is free.
- The application writes a number of bytes inferior to the number of free DPR banks for the endpoint. Each time the application writes the last byte of a bank, the TXRDY signal is automatically set by the UDPHS.
- If the last packet is incomplete (i.e., the last byte of the bank has not been written) the application must set the TXRDY bit in the UDPHS\_EPTSETSTAx register.

The application is notified that all banks are free, so that it is possible to write another burst of packets by the BUSY\_BANK interrupt. This interrupt can be enabled or masked by setting the BUSY\_BANK flag in the UDPHS\_EPTCTLENB and UDPHS\_EPTCTLDIS registers.

This algorithm must not be used for isochronous transfer. In this case, the ping-pong mechanism does not operate.

A Zero Length Packet can be sent by setting just the TXRDY flag in the UDPHS\_EPTSETSTAx register.

- Bulk IN or Interrupt IN: Sending a Buffer Using DMA (Device to Host)

The UDPHS integrates a DMA host controller. This DMA controller can be used to transfer a buffer from the memory to the DPR or from the DPR to the processor memory under the UDPHS control. The DMA can be used for all transfer types except control transfer.

Example DMA configuration:

1. Program UDPHS\_DMAADDRESS x with the address of the buffer that should be transferred.
2. Enable the interrupt of the DMA in UDPHS\_IEN
3. Program UDPHS\_DMACONTROLx:
  - Size of buffer to send: size of the buffer to be sent to the host.
  - END\_B\_EN: The endpoint can validate the packet (according to the values programmed in the AUTO\_VALID and SHRT\_PCKT fields of UDPHS\_EPTCTLx.) (see section [UDPHS Endpoint Control Disable Register \(Isochronous Endpoint\)](#) and [Figure 40-13](#))
  - END\_BUFFERIT: generate an interrupt when the BUFF\_COUNT in UDPHS\_DMASTATUSx reaches 0.
  - CHANN\_ENB: Run and stop at end of buffer

The auto-valid-bank mechanism allows the transfer of data (IN & OUT) without the intervention of the CPU. This means that bank validation (set TXRDY or clear the RXRDY\_TXKL bit) is done by hardware.

A transfer descriptor can be used. Instead of programming the register directly, a descriptor should be programmed and the address of this descriptor is then given to UDPHS\_DMANXTDSC to be processed after setting the LDNXT\_DSC field (Load Next Descriptor Now) in UDPHS\_DMACONTROLx register.

The structure that defines this transfer descriptor must be aligned.

Each buffer to be transferred must be described by a DMA Transfer descriptor (see section [UDPHS DMA Channel Transfer Descriptor](#)). Transfer descriptors are chained. Before executing transfer of the buffer, the UDPHS may fetch a new transfer descriptor from the memory address pointed by the `UDPHS_DMANTDSCx` register. Once the transfer is complete, the transfer status is updated in the `UDPHS_DMASTATUSx` register.

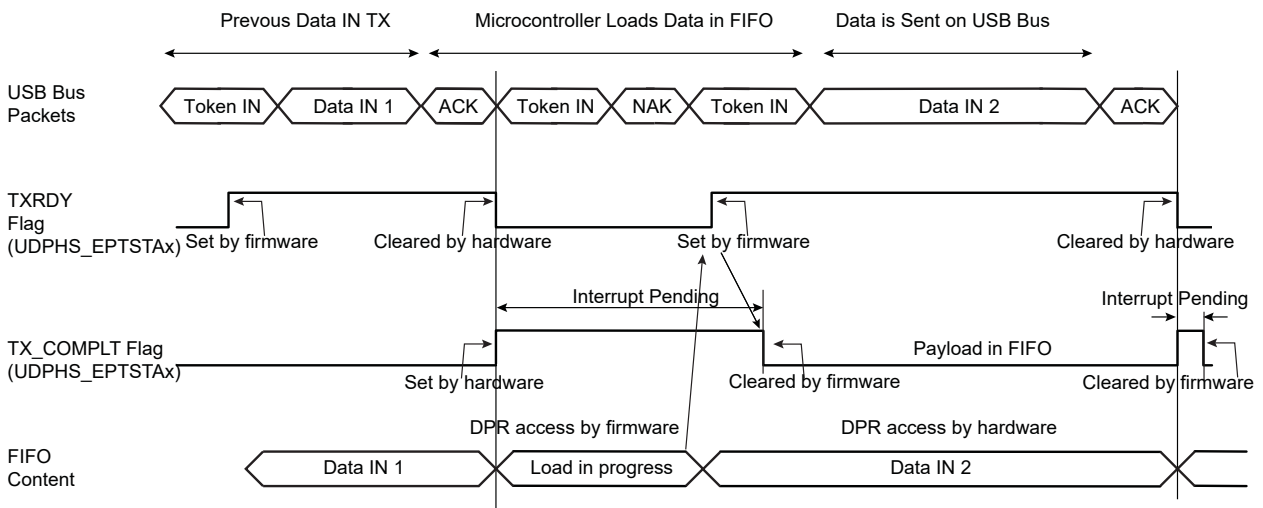

To chain a new transfer descriptor with the current DMA transfer, the DMA channel must be stopped. To do so, `INTDIS_DMA` and `TXRDY` may be set in the `UDPHS_EPTCTLENBx` register. It is also possible for the application to wait for the completion of all transfers. In this case the `LDNXT_DSC` bit in the last transfer descriptor `UDPHS_DMACONTROLx` register must be set to 0 and the `CHANN_ENB` bit set to 1.

Then the application can chain a new transfer descriptor.

The `INTDIS_DMA` can be used to stop the current DMA transfer if an enabled interrupt is triggered. This can be used to stop DMA transfers in case of errors.

The application can be notified at the end of any buffer transfer (`ENB_BUFFIT` bit in the `UDPHS_DMACONTROLx` register).

**Figure 40-9. Data IN Transfer for Endpoint with One Bank**

**Figure 40-10. Data IN Transfer for Endpoint with Two Banks**

**Figure 40-11. Data IN Followed By Status OUT Transfer at the End of a Control Transfer**

**Note:** A NAK handshake is always generated at the first status stage token.

**Figure 40-12. Data OUT Followed by Status IN Transfer**

**Note:** Before proceeding to the status stage, the software should determine that there is no risk of extra data from the host (data stage). If not certain (non-predictable data stage length), then the software should wait for a NAK-IN interrupt before proceeding to the status stage. This precaution should be taken to avoid collision in the FIFO.

**Figure 40-13. Autovalid with DMA**

**Note:** In the illustration above Autovalid validates a bank as full, although this might not be the case, in order to continue processing data and to send to DMA.

- Isochronous IN

Isochronous-IN is used to transmit a stream of data whose timing is implied by the delivery rate. Isochronous transfer provides periodic, continuous communication between host and device.

It guarantees bandwidth and low latencies appropriate for telephony, audio, video, etc.

If the endpoint is not available (TXRDY\_TRER = 0), then the device does not answer to the host. An ERR\_FL\_ISO interrupt is generated in the UDPHS\_EPTSTAx register and once enabled, then sent to the CPU.

The STALL\_SNT command bit is not used for an ISO-IN endpoint.

- High Bandwidth Isochronous Endpoint Handling: IN Example

For high bandwidth isochronous endpoints, the DMA can be programmed with the number of transactions (BUFF\_LENGTH field in UDPHS\_DMACONTROLx) and the system should provide the required number of packets per microframe, otherwise, the host will notice a sequencing problem.

A response should be made to the first token IN recognized inside a microframe under the following conditions:

- If at least one bank has been validated, the correct DATAx corresponding to the programmed Number Of Transactions per Microframe (NB\_TRANS) should be answered. In case of a subsequent missed or corrupted token IN inside the microframe, the USB 2.0 Core available data bank(s) that should normally have been transmitted during that microframe shall be flushed at its end. If this flush occurs, an error condition is flagged (ERR\_FLUSH is set in UDPHS\_EPTSTAx).
- If no bank is validated yet, the default DATA0 ZLP is answered and underflow is flagged (ERR\_FL\_ISO is set in UDPHS\_EPTSTAx). Then, no data bank is flushed at microframe end.
- If no data bank has been validated at the time when a response should be made for the second transaction of NB\_TRANS = 3 transactions microframe, a DATA1 ZLP is answered and underflow is flagged (ERR\_FL\_ISO is set in UDPHS\_EPTSTAx). If and only if remaining untransmitted banks for that microframe are available at its end, they are flushed and an error condition is flagged (ERR\_FLUSH is set in UDPHS\_EPTSTAx).
- If no data bank has been validated at the time when a response should be made for the last programmed transaction of a microframe, a DATA0 ZLP is answered and underflow is flagged (ERR\_FL\_ISO is set in UDPHS\_EPTSTAx). If and only if the remaining untransmitted data bank for that microframe is available at its end, it is flushed and an error condition is flagged (ERR\_FLUSH is set in UDPHS\_EPTSTAx).
- If at the end of a microframe no valid token IN has been recognized, no data bank is flushed and no error condition is reported.

At the end of a microframe in which at least one data bank has been transmitted, if less than NB\_TRANS banks have been validated for that microframe, an error condition is flagged (ERR\_TRANS is set in UDPHS\_EPTSTAx).

#### Cases of Error (in UDPHS\_EPTSTAx)

- ERR\_FL\_ISO: There was no data to transmit inside a microframe, so a ZLP is answered by default.
- ERR\_FLUSH: At least one packet has been sent inside the microframe, but the number of token INs received is less than the number of transactions actually validated (TXRDY\_TRER) and likewise with the NB\_TRANS programmed.

- **ERR\_TRANS:** At least one packet has been sent inside the microframe, but the number of token INs received is less than the number of programmed NB\_TRANS transactions and the packets not requested were not validated.
- **ERR\_FL\_ISO + ERR\_FLUSH:** At least one packet has been sent inside the microframe, but the data has not been validated in time to answer one of the following token INs.
- **ERR\_FL\_ISO + ERR\_TRANS:** At least one packet has been sent inside the microframe, but the data has not been validated in time to answer one of the following token INs and the data can be discarded at the microframe end.
- **ERR\_FLUSH + ERR\_TRANS:** The first token IN has been answered and it was the only one received, a second bank has been validated but not the third, whereas NB\_TRANS was waiting for three transactions.
- **ERR\_FL\_ISO + ERR\_FLUSH + ERR\_TRANS:** The first token IN has been treated, the data for the second Token IN was not available in time, but the second bank has been validated before the end of the microframe. The third bank has not been validated, but three transactions have been set in NB\_TRANS.

#### 40.6.10.4 Data OUT

- Bulk OUT or Interrupt OUT

Like data IN, data OUT packets are sent by the host during the data or the status stage of control transfer or during an interrupt/bulk/isochronous OUT transfer. Data buffers are sent packet by packet under the control of the application or under the control of the DMA channel.

- Bulk OUT or Interrupt OUT: Receiving a Packet Under Application Control (Host to Device)

#### Algorithm Description for Each Packet:

- The application enables an interrupt on RXRDY\_TXKL.
- When an interrupt on RXRDY\_TXKL is received, the application knows that UDPHS\_EPTSTAx register BYTE\_COUNT bytes have been received.
- The application reads the BYTE\_COUNT bytes from the endpoint.
- The application clears RXRDY\_TXKL.

**Note:** If the application does not know the size of the transfer, it may not be a good option to use AUTO\_VALID. Because if a zero-length-packet is received, the RXRDY\_TXKL is automatically cleared by the AUTO\_VALID hardware and if the endpoint interrupt is triggered, the software will not find its originating flag when reading the UDPHS\_EPTSTAx register.

#### Algorithm to Fill Several Packets

- The application enables the interrupts of BUSY\_BANK and AUTO\_VALID.
- When a BUSY\_BANK interrupt is received, the application knows that all banks available for the endpoint have been filled. Thus, the application can read all banks available.

If the application does not know the size of the receive buffer, instead of using the BUSY\_BANK interrupt, the application must use RXRDY\_TXKL.

- Bulk OUT or Interrupt OUT: Sending a Buffer Using DMA (Host To Device)

To use the DMA setting, the AUTO\_VALID field is mandatory.

See [Bulk IN or Interrupt IN: Sending a Buffer Using DMA \(Device to Host\)](#) for more information.

DMA Configuration Example:

1. First program UDPHS\_DMAADDRESSx with the address of the buffer that should be transferred.

2. Enable the interrupt of the DMA in UDPHS\_IEN
3. Program the DMA Channelx Control Register:
  - Size of buffer to be sent.
  - END\_B\_EN: Can be used for OUT packet truncation (discarding of unbuffered packet data) at the end of DMA buffer.
  - END\_BUFFERIT: Generate an interrupt when BUFF\_COUNT in the UDPHS\_DMASTATUSx register reaches 0.
  - END\_TR\_EN: End of transfer enable, the UDPHS device can put an end to the current DMA transfer, in case of a short packet.
  - END\_TR\_IT: End of transfer interrupt enable, an interrupt is sent after the last USB packet has been transferred by the DMA, if the USB transfer ended with a short packet. (Beneficial when the receive size is unknown.)
  - CHANN\_ENB: Run and stop at end of buffer.

For OUT transfer, the bank will be automatically cleared by hardware when the application has read all the bytes in the bank (the bank is empty).

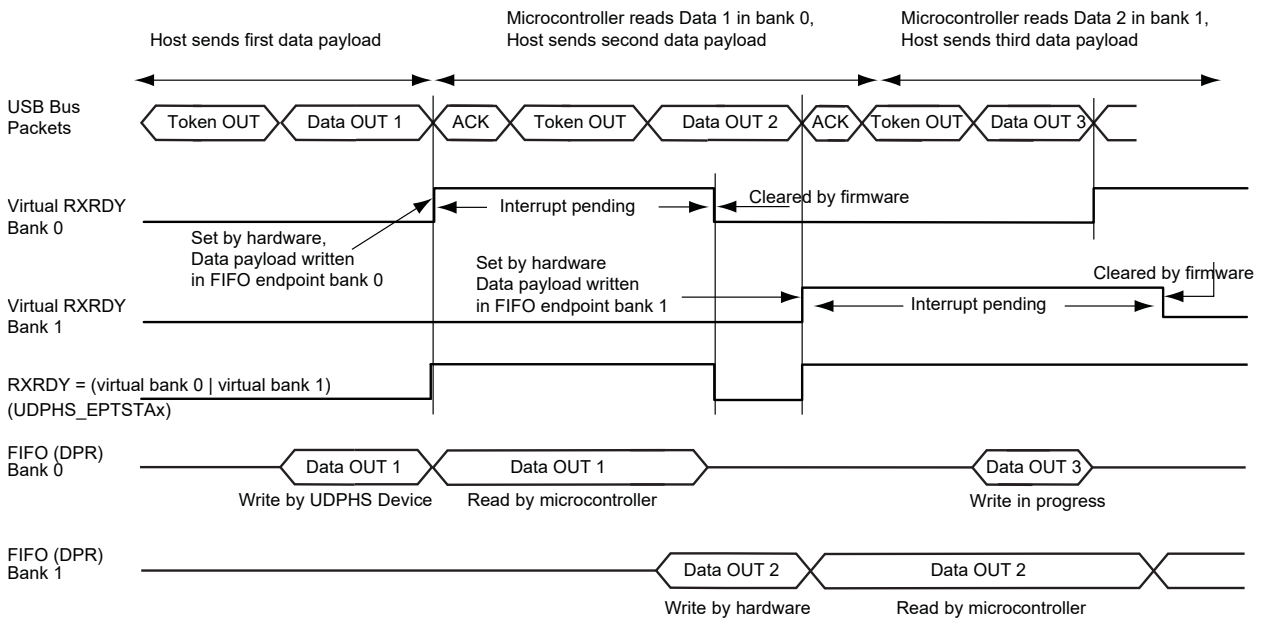

**Note:**

1. When a zero-length-packet is received, RXRDY\_TXKL bit in UDPHS\_EPTSTAx is cleared automatically by AUTO\_VALID, and the application knows of the end of buffer by the presence of the END\_TR\_IT.
2. If the host sends a zero-length packet, and the endpoint is free, then the device sends an ACK. No data is written in the endpoint, the RXRDY\_TXKL interrupt is generated, and the BYTE\_COUNT field in UDPHS\_EPTSTAx is null.

**Figure 40-14. Data OUT Transfer for Endpoint with One Bank**

**Figure 40-15. Data OUT Transfer for an Endpoint with Two Banks**

- High Bandwidth Isochronous Endpoint OUT

USB 2.0 supports individual High Speed isochronous endpoints that require data rates up to 192 Mb/s (24 MB/s): 3x1024 data bytes per microframe.

To support such a rate, two or three banks may be used to buffer the three consecutive data packets. The microcontroller (or the DMA) should be able to empty the banks very rapidly (at least 24 MB/s on average).

NB\_TRANS field in UDPHS\_EPTCFGx register = Number Of Transactions per Microframe.

If NB\_TRANS > 1 then it is High Bandwidth.

Example:

- If NB\_TRANS = 3, the sequence should be either
  - MData0
  - MData0/Data1
  - MData0/Data1/Data2
- If NB\_TRANS = 2, the sequence should be either
  - MData0
  - MData0/Data1
- If NB\_TRANS = 1, the sequence should be
  - Data0

**Figure 40-16. Bank Management, Example of Three Transactions per Microframe**

• **Isochronous Endpoint Handling: OUT Example**

The user can ascertain the bank status (free or busy), and the toggle sequencing of the data packet for each bank with the UDPHS\_EPTSTAx register in the three fields as follows:

- TOGGLESQ\_STA: PID of the data stored in the current bank
- CURBK: Number of the bank currently being accessed by the microcontroller.
- BUSY\_BANK\_STA: Number of busy bank

This is particularly useful in case of a missing data packet.

If the inter-packet delay between the OUT token and the Data is greater than the USB standard, then the ISO-OUT transaction is ignored. (Payload data is not written, no interrupt is generated to the CPU.)

If there is a data CRC (Cyclic Redundancy Check) error, the payload is, none the less, written in the endpoint. The ERR\_CRC\_NTR flag is set in UDPHS\_EPTSTAx register.

If the endpoint is already full, the packet is not written in the DPRAM. The ERR\_FL\_ISO flag is set in UDPHS\_EPTSTAx.

If the payload data is greater than the maximum size of the endpoint, then the ERR\_OVFLW flag is set. It is the task of the CPU to manage this error. The data packet is written in the endpoint (except the extra data).

If the host sends a Zero Length Packet, and the endpoint is free, no data is written in the endpoint, the RXRDY\_TXKL flag is set, and the BYTE\_COUNT field in UDPHS\_EPTSTAx register is null.

The FRCESTALL command bit is unused for an isochronous endpoint.

Otherwise, payload data is written in the endpoint, the RXRDY\_TXKL interrupt is generated and the BYTE\_COUNT in UDPHS\_EPTSTAx register is updated.

**40.6.10.5 STALL**

STALL is returned by a function in response to an IN token or after the data phase of an OUT or in response to a PING transaction. STALL indicates that a function is unable to transmit or receive data, or that a control pipe request is not supported.

- OUT

To stall an endpoint, set the FRCESTALL bit in UDPHS\_EPTSETSTAx register and after the STALL\_SNT flag has been set, set the TOGGLE\_SEG bit in the UDPHS\_EPTCLRSTAx register.

- IN

Set the FRCESTALL bit in UDPHS\_EPTSETSTAx register.

**Figure 40-17. Stall Handshake Data OUT Transfer**

**Figure 40-18. Stall Handshake Data IN Transfer**

### 40.6.11 Speed Identification

The high speed reset is managed by hardware.

At the connection, the host makes a reset which could be a classic reset (full speed) or a high speed reset.

At the end of the reset process (full or high), the ENDRESET interrupt is generated.

Then the CPU should read the SPEED bit in UDPHS\_INTSTAx to ascertain the speed mode of the device.

### 40.6.12 USB V2.0 High Speed Global Interrupt

Interrupts are defined in [UDPHS Interrupt Enable Register \(UDPHS\\_IEN\)](#) and in [UDPHS Interrupt Status Register \(UDPHS\\_INTSTA\)](#).

### 40.6.13 Endpoint Interrupts

Interrupts are enabled in UDPHS\_IEN (see [UDPHS Interrupt Enable Register](#)) and individually masked in UDPHS\_EPTCTLENBx (see [UDPHS Endpoint Control Enable Register \(Control, Bulk, Interrupt Endpoints\)](#)).

**Table 40-4. Endpoint Interrupt Source Masks**

|                  |                             |
|------------------|-----------------------------|
| SHRT_PCKT        | Short Packet Interrupt      |
| BUSY_BANK        | Busy Bank Interrupt         |
| NAK_OUT          | NAKOUT Interrupt            |
| NAK_IN/ERR_FLUSH | NAKIN/Error Flush Interrupt |

# SAMA5D2 Series

## USB High Speed Device Port (UDPHS)

|                       |  |
|-----------------------|--|
| STALL_SNT/ERR_CRC_NTR | Stall Sent/CRC error/Number of Transaction Error Interrupt |
| RX_SETUP/ERR_FL_ISO   | Received SETUP/Error Flow Interrupt                        |
| TXRDY_TRER            | TX Packet Read/Transaction Error Interrupt                 |
| TX_COMPLT             | Transmitted IN Data Complete Interrupt                     |
| RXRDY_TXKL            | Received OUT Data Interrupt                                |
| ERR_OVFLW             | Overflow Error Interrupt                                   |
| MDATA_RX              | MDATA Interrupt  |
| DATAx_RX              | DATAx Interrupt  |

**Figure 40-19. UDPHS Interrupt Control Interface**

### 40.6.14 Power Modes

#### 40.6.14.1 Controlling Device States

A USB device has several possible states. Refer to Chapter 9 (USB Device Framework) of the Universal Serial Bus Specification, Rev 2.0.

**Figure 40-20. UDPHS Device State Diagram**

Movement from one state to another depends on the USB bus state or on standard requests sent through control transactions via the default endpoint (endpoint 0).

After a period of bus inactivity, the USB device enters Suspend mode. Accepting Suspend/Resume requests from the USB host is mandatory. Constraints in Suspend mode are very strict for bus-powered applications; devices may not consume more than 500  $\mu$ A on the USB bus.

While in Suspend mode, the host may wake up a device by sending a resume signal (bus activity) or a USB device may send a wakeup request to the host, e.g., waking up a PC by moving a USB mouse.

The wakeup feature is not mandatory for all devices and must be negotiated with the host.

#### 40.6.14.2 Not Powered State

Self powered devices can detect 5V VBUS using a PIO. When the device is not connected to a host, device power consumption can be reduced by the DETACH bit in UDPHS\_CTRL. Disabling the transceiver is automatically done. HSDM, HSDP, FSDP and FSDP lines are tied to GND pulldowns integrated in the hub downstream ports.

#### 40.6.14.3 Entering Attached State

When no device is connected, the USB FSDP and FSDM signals are tied to GND by 15 K $\Omega$  pulldowns integrated in the hub downstream ports. When a device is attached to an hub downstream port, the device connects a 1.5 K $\Omega$  pullup on FSDP. The USB bus line goes into IDLE state, FSDP is pulled up by the device 1.5 K $\Omega$  resistor to 3.3V and FSDM is pulled down by the 15 K $\Omega$  resistor to GND of the host.

After pullup connection, the device enters the powered state. The transceiver remains disabled until bus activity is detected.

In case of low power consumption need, the device can be stopped. When the device detects the VBUS, the software must enable the USB transceiver by enabling the EN\_UDPHS bit in UDPHS\_CTRL register.

The software can detach the pullup by setting DETACH bit in UDPHS\_CTRL register.

#### 40.6.14.4 From Powered State to Default State (Reset)

After its connection to a USB host, the USB device waits for an end-of-bus reset. The unmasked flag ENDRESET is set in the UDPHS\_IEN register and an interrupt is triggered.

Once the ENDRESET interrupt has been triggered, the device enters Default State. In this state, the UDPHS software must:

- Enable the default endpoint, setting the EPT\_ENABL flag in the UDPHS\_EPTCTLENB[0] register and, optionally, enabling the interrupt for endpoint 0 by writing 1 in EPT\_0 of the UDPHS\_IEN register. The enumeration then begins by a control transfer.
- Configure the Interrupt Mask Register which has been reset by the USB reset detection
- Enable the transceiver.

In this state, the EN\_UDPHS bit in UDPHS\_CTRL register must be enabled.

#### 40.6.14.5 From Default State to Address State (Address Assigned)

After a Set Address standard device request, the USB host peripheral enters the address state.

Before the device enters address state, it must achieve the Status IN transaction of the control transfer, i.e., the UDPHS device sets its new address once the TX\_COMPLT flag in the UDPHS\_EPTCTL[0] register has been received and cleared.

To move to address state, the driver software sets the DEV\_ADDR field and the FADDR\_EN flag in the UDPHS\_CTRL register.

#### 40.6.14.6 From Address State to Configured State (Device Configured)

Once a valid Set Configuration standard request has been received and acknowledged, the device enables endpoints corresponding to the current configuration. This is done by setting the BK\_NUMBER, EPT\_TYPE, EPT\_DIR and EPT\_SIZE fields in the UDPHS\_EPTCFGx registers and enabling them by setting the EPT\_ENABL flag in the UDPHS\_EPTCTLENBx registers, and, optionally, enabling corresponding interrupts in the UDPHS\_IEN register.

#### 40.6.14.7 Entering Suspend State (Bus Activity)

When a Suspend (no bus activity on the USB bus) is detected, the DET\_SUSPD signal in the UDPHS\_STA register is set. This triggers an interrupt if the corresponding bit is set in the UDPHS\_IEN register. This flag is cleared by writing to the UDPHS\_CLRINT register. Then the device enters Suspend mode.

In this state bus powered devices must drain less than 500  $\mu$ A from the 5V VBUS. As an example, the microcontroller switches to slow clock, disables the PLL and main oscillator, and goes into Idle mode. It may also switch off other devices on the board.

The UDPHS device peripheral clocks can be switched off. Resume event is asynchronously detected.

#### 40.6.14.8 Receiving a Host Resume

In Suspend mode, a resume event on the USB bus line is detected asynchronously, transceiver and clocks disabled (however, the pullup should not be removed).

Once the resume is detected on the bus, the signal WAKE\_UP in the UDPHS\_INTSTA is set. It may generate an interrupt if the corresponding bit in the UDPHS\_IEN register is set. This interrupt may be used to wake up the core, enable PLL and main oscillators and configure clocks.

### 40.6.14.9 Sending an External Resume

In Suspend State it is possible to wake up the host by sending an external resume.

The device waits at least 5 ms after being entered in Suspend State before sending an external resume.

The device must force a K state from 1 to 15 ms to resume the host.

### 40.6.15 Test Mode

A device must support the TEST\_MODE feature when in the Default, Address or Configured High Speed device states.

TEST\_MODE can be:

- Test\_J
- Test\_K
- Test\_Packet
- Test\_SEO\_NAK

(See [UDPHS Test Register](#) for definitions of each test mode.)

```
const char test_packet_buffer[] = {
0x00,0x00,0x00,0x00,0x00,0x00,0x00,0x00,0x00,0x00, // JKJKJKJK * 9
0xAA,0xAA,0xAA,0xAA,0xAA,0xAA,0xAA,0xAA, // JKKKJJKK * 8
0xEE,0xEE,0xEE,0xEE,0xEE,0xEE,0xEE,0xEE, // JKKKJJKK * 8
0xFE,0xFF,0xFF,0xFF,0xFF,0xFF,0xFF,0xFF,0xFF,0xFF,0xFF,0xFF, // JJJJJJJJKKKKKK * 8
0x7F,0xBF,0xDF,0xEF,0xF7,0xFB,0xFD, // JJJJJJKK * 8
0xFC,0x7E,0xBF,0xDF,0xEF,0xF7,0xFB,0xFD,0x7E // {JJKKKKKK * 10}, JK
};
```

### 40.7 Register Summary

**Note:**

The registers below have two modes: Control, Bulk, Interrupt Endpoints mode and Isochronous Endpoints mode.

In this register summary, both modes are displayed at the same offset.

- UDPHS\_EPTCTLENB
- UDPHS\_EPTCTLDIS
- UDPHS\_EPTCTL
- UDPHS\_EPTSETSTA
- UDPHS\_EPTCLRSTA
- UDPHS\_EPTSTA

| Offset              | Name         | Bit Pos. |                   |               |                    |          |                      |           |           |          |  |  |
|---------------------|--------------|----------|-------------------|---------------|--------------------|----------|----------------------|-----------|-----------|----------|--|--|
| 0x00                | UDPHS_CTRL   | 7:0      | FADDR_EN          | DEV_ADDR[6:0] |                    |          |                      |           |           |          |  |  |
|                     |              | 15:8     |                   |               |                    |          | PULLD_DIS            | REWAKEUP  | DETACH    | EN_UDPHS |  |  |
|                     |              | 23:16    |                   |               |                    |          |                      |           |           |          |  |  |
|                     |              | 31:24    |                   |               |                    |          |                      |           |           |          |  |  |
| 0x04                | UDPHS_FNUM   | 7:0      | FRAME_NUMBER[4:0] |               |                    |          | MICRO_FRAME_NUM[2:0] |           |           |          |  |  |
|                     |              | 15:8     |                   |               | FRAME_NUMBER[10:5] |          |                      |           |           |          |  |  |
|                     |              | 23:16    |                   |               |                    |          |                      |           |           |          |  |  |
|                     |              | 31:24    | FNUM_ERR          |               |                    |          |                      |           |           |          |  |  |
| 0x08<br>...<br>0x0F | Reserved     |          |                   |               |                    |          |                      |           |           |          |  |  |

**Bit 11 – PULLD\_DIS** Pulldown Disable (cleared upon USB reset)  
 When set, there is no pulldown on DP & DM. (DM Pulldown = DP Pulldown = 0).

**Note:** If the DETACH bit is also set, device DP & DM are left in high impedance state.  
 (See description of bit “DETACH”).

| DETACH | PULLD_DIS | DP                   | DM                   | Condition                          |
|--------|-----------|----------------------|----------------------|------------------------------------|
| 0      | 0         | Pullup               | Pulldown             | Not recommended                    |
| 0      | 1         | Pullup               | High impedance state | VBUS present                       |
| 1      | 0         | Pulldown             | Pulldown             | No VBUS                            |
| 1      | 1         | High impedance state | High impedance state | VBUS present & software disconnect |

**Bit 10 – REWAKEUP** Send Remote Wakeup (cleared upon USB reset)  
 An Upstream Resume is sent only after the UDPHS bus has been in SUSPEND state for at least 5 ms.  
 This bit is automatically cleared by hardware at the end of the Upstream Resume.

| Value | Description  |
|-------|--|
| 0     | Remote Wakeup is disabled (read), or this bit has no effect (write). |

# SAMA5D2 Series

## USB High Speed Device Port (UDPHS)

| Value | Description   |
|-------|---|
| 1     | Remote Wakeup is enabled (read), or this bit forces an external interrupt on the UDPHS controller for Remote Wakeup purposes. |

**Bit 9 – DETACH** Detach Command  
See description of bit “PULL\_DIS”.

| Value | Description   |
|-------|---|
| 0     | UDPHS is attached (read), or this bit pulls up the DP line (attach command) (write).  |
| 1     | UDPHS is detached, UTMI transceiver is suspended (read), or this bit simulates a detach on the UDPHS line and forces the UTMI transceiver into suspend state (Suspend M = 0) (write). |

**Bit 8 – EN\_UDPHS** UDPHS Enable

| Value | Description  |
|-------|--|
| 0     | UDPHS is disabled (read), or this bit disables and resets the UDPHS controller (write). Switch the host to UTMI. |
| 1     | UDPHS is enabled (read), or this bit enables the UDPHS controller (write). Switch the host to UTMI.              |

**Bit 7 – FADDR\_EN** Function Address Enable (cleared upon USB reset)

| Value | Description  |
|-------|--|
| 0     | Device is not in address state (read), or only the default function address is used (write).   |
| 1     | Device is in address state (read), or this bit is set by the device firmware after a successful status phase of a SET_ADDRESS transaction (write). When set, the only address accepted by the UDPHS controller is the one stored in the UDPHS Address field. It will not be cleared afterwards by the device firmware. It is cleared by hardware on hardware reset, or when UDPHS bus reset is received. |

**Bits 6:0 – DEV\_ADDR[6:0]** UDPHS Address (cleared upon USB reset)

This field contains the default address (0) after power-up or UDPHS bus reset (read), or it is written with the value set by a SET\_ADDRESS request received by the device firmware (write).

### 40.7.2 UDPHS Frame Number Register

**Name:**       UDPHS\_FNUM  
**Offset:**     0x04  
**Reset:**      0x00000000  
**Property:**   Read-only

|        |                   |    |                    |    |                      |    |    |    |  |
|--------|-------------------|----|--------------------|----|----------------------|----|----|----|--|
| Bit    | 31                | 30 | 29                 | 28 | 27                   | 26 | 25 | 24 |  |
|        | FNUM_ERR          |    |                    |    |                      |    |    |    |  |
| Access | R                 |    |                    |    |                      |    |    |    |  |
| Reset  | 0                 |    |                    |    |                      |    |    |    |  |
|        |                   |    |                    |    |                      |    |    |    |  |
| Bit    | 23                | 22 | 21                 | 20 | 19                   | 18 | 17 | 16 |  |
|        |                   |    |                    |    |                      |    |    |    |  |
| Access |                   |    |                    |    |                      |    |    |    |  |
| Reset  |                   |    |                    |    |                      |    |    |    |  |
|        |                   |    |                    |    |                      |    |    |    |  |
| Bit    | 15                | 14 | 13                 | 12 | 11                   | 10 | 9  | 8  |  |
|        |                   |    | FRAME_NUMBER[10:5] |    |                      |    |    |    |  |
| Access |                   |    | R                  | R  | R                    | R  | R  | R  |  |
| Reset  |                   |    | 0                  | 0  | 0                    | 0  | 0  | 0  |  |
|        |                   |    |                    |    |                      |    |    |    |  |
| Bit    | 7                 | 6  | 5                  | 4  | 3                    | 2  | 1  | 0  |  |
|        | FRAME_NUMBER[4:0] |    |                    |    | MICRO_FRAME_NUM[2:0] |    |    |    |  |
| Access | R                 | R  | R                  | R  | R                    | R  | R  | R  |  |
| Reset  | 0                 | 0  | 0                  | 0  | 0                    | 0  | 0  | 0  |  |

**Bit 31 – FNUM\_ERR** Frame Number CRC Error (cleared upon USB reset)  
 This bit is set by hardware when a corrupted Frame Number in Start of Frame packet (or Micro SOF) is received.

This bit and the INT\_SOF (or MICRO\_SOF) interrupt are updated at the same time.

**Bits 13:3 – FRAME\_NUMBER[10:0]** Frame Number as defined in the Packet Field Formats (cleared upon USB reset)

This field is provided in the last received SOF packet (see INT\_SOF in the UDPHS Interrupt Status Register).

**Bits 2:0 – MICRO\_FRAME\_NUM[2:0]** Microframe Number (cleared upon USB reset)

Number of the received microframe (0 to 7) in one frame. This field is reset at the beginning of each new frame (1 ms).

One microframe is received each 125 microseconds (1 ms/8).

### 40.7.3 UDPHS Interrupt Enable Register

**Name:** UDPHS\_IEN  
**Offset:** 0x10  
**Reset:** 0x00000010  
**Property:** Read/Write

|        |           |          |         |          |         |           |           |       |
|--------|-----------|----------|---------|----------|---------|-----------|-----------|-------|
| Bit    | 31        | 30       | 29      | 28       | 27      | 26        | 25        | 24    |

| Bit    | 7         | 6        | 5       | 4        | 3       | 2         | 1         | 0     |
|        | UPSTR_RES | ENDOFRSM | WAKE_UP | ENDRESET | INT_SOF | MICRO_SOF | DET_SUSPD |       |
| Access | R/W       | R/W      | R/W     | R/W      | R/W     | R/W       | R/W       |       |
| Reset  | 0         | 0        | 0       | 1        | 0       | 0         | 0         |       |

**Bits 25, 26, 27, 28, 29, 30, 31 – DMA\_x** DMA Channel x Interrupt Enable (cleared upon USB reset)

| Value | Description                              |
|-------|--|
| 0     | Disable the interrupts for this channel. |
| 1     | Enable the interrupts for this channel.  |

**Bits 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23 – EPT\_x** Endpoint x Interrupt Enable (cleared upon USB reset)

| Value | Description                               |
|-------|---|
| 0     | Disable the interrupts for this endpoint. |
| 1     | Enable the interrupts for this endpoint.  |

**Bit 7 – UPSTR\_RES** Upstream Resume Interrupt Enable (cleared upon USB reset)

| Value | Description                        |
|-------|------------------------------------|
| 0     | Disable Upstream Resume Interrupt. |
| 1     | Enable Upstream Resume Interrupt.  |

**Bit 6 – ENDOFRSM** End Of Resume Interrupt Enable (cleared upon USB reset)

| Value | Description               |
|-------|---------------------------|
| 0     | Disable Resume Interrupt. |

# SAMA5D2 Series

## USB High Speed Device Port (UDPHS)

| Value | Description              |
|-------|--------------------------|
| 1     | Enable Resume Interrupt. |

**Bit 5 – WAKE\_UP** Wake Up CPU Interrupt Enable (cleared upon USB reset)

| Value | Description                    |
|-------|--------------------------------|
| 0     | Disable Wake-up CPU Interrupt. |
| 1     | Enable Wake-up CPU Interrupt.  |

**Bit 4 – ENDRESET** End Of Reset Interrupt Enable (cleared upon USB reset)

| Value | Description   |
|-------|---|
| 0     | Disable End Of Reset Interrupt.                                       |
| 1     | Enable End Of Reset Interrupt. Automatically enabled after USB reset. |

**Bit 3 – INT\_SOF** SOF Interrupt Enable (cleared upon USB reset)

| Value | Description            |
|-------|------------------------|
| 0     | Disable SOF Interrupt. |
| 1     | Enable SOF Interrupt.  |

**Bit 2 – MICRO\_SOF** Micro-SOF Interrupt Enable (cleared upon USB reset)

| Value | Description                  |
|-------|------------------------------|
| 0     | Disable Micro-SOF Interrupt. |
| 1     | Enable Micro-SOF Interrupt.  |

**Bit 1 – DET\_SUSPD** Suspend Interrupt Enable (cleared upon USB reset)

| Value | Description                |
|-------|----------------------------|
| 0     | Disable Suspend Interrupt. |
| 1     | Enable Suspend Interrupt.  |

### 40.7.4 UDPHS Interrupt Status Register

**Name:** UDPHS\_INTSTA  
**Offset:** 0x14  
**Reset:** 0x00000000  
**Property:** Read-only

|        |           |          |         |          |         |           |           |       |
|--------|-----------|----------|---------|----------|---------|-----------|-----------|-------|
| Bit    | 31        | 30       | 29      | 28       | 27      | 26        | 25        | 24    |
|        | DMA_7     | DMA_6    | DMA_5   | DMA_4    | DMA_3   | DMA_2     | DMA_1     |       |
| Access | R         | R        | R       | R        | R       | R         | R         |       |
| Reset  | 0         | 0        | 0       | 0        | 0       | 0         | 0         |       |
|        |           |          |         |          |         |           |           |       |
| Bit    | 23        | 22       | 21      | 20       | 19      | 18        | 17        | 16    |
|        | EPT_15    | EPT_14   | EPT_13  | EPT_12   | EPT_11  | EPT_10    | EPT_9     | EPT_8 |
| Access | R         | R        | R       | R        | R       | R         | R         | R     |
| Reset  | 0         | 0        | 0       | 0        | 0       | 0         | 0         | 0     |
|        |           |          |         |          |         |           |           |       |
| Bit    | 15        | 14       | 13      | 12       | 11      | 10        | 9         | 8     |
|        | EPT_7     | EPT_6    | EPT_5   | EPT_4    | EPT_3   | EPT_2     | EPT_1     | EPT_0 |
| Access | R         | R        | R       | R        | R       | R         | R         | R     |
| Reset  | 0         | 0        | 0       | 0        | 0       | 0         | 0         | 0     |
|        |           |          |         |          |         |           |           |       |
| Bit    | 7         | 6        | 5       | 4        | 3       | 2         | 1         | 0     |
|        | UPSTR_RES | ENDOFRSM | WAKE_UP | ENDRESET | INT_SOF | MICRO_SOF | DET_SUSPD | SPEED |
| Access | R         | R        | R       | R        | R       | R         | R         | R     |
| Reset  | 0         | 0        | 0       | 0        | 0       | 0         | 0         | 0     |

**Bits 25, 26, 27, 28, 29, 30, 31 – DMA\_x** DMA Channel x Interrupt

| Value | Description  |
|-------|--|
| 0     | Reset when the UDPHS_DMASTATUSx interrupt source is cleared.   |
| 1     | Set by hardware when an interrupt is triggered by the DMA Channelx and this endpoint interrupt is enabled by the DMA_x bit in UDPHS_IEN. |

**Bits 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23 – EPT\_x** Endpoint x Interrupt (cleared upon USB reset)

| Value | Description  |
|-------|--|
| 0     | Reset when the UDPHS_EPTSTAx interrupt source is cleared.  |
| 1     | Set by hardware when an interrupt is triggered by the UDPHS_EPTSTAx register and this endpoint interrupt is enabled by the EPT_x bit in UDPHS_IEN. |

**Bit 7 – UPSTR\_RES** Upstream Resume Interrupt

| Value | Description  |
|-------|--|
| 0     | Cleared by setting the UPSTR_RES bit in UDPHS_CLRINT.  |
| 1     | Set by hardware when the UDPHS controller is sending a resume signal called “upstream resume”. This triggers a UDPHS interrupt when the UPSTR_RES bit is set in UDPHS_IEN. |

### Bit 6 – ENDOFRSM End Of Resume Interrupt

| Value | Description   |
|-------|---|
| 0     | Cleared by setting the ENDOFRSM bit in UDPHS_CLRINT.  |
| 1     | Set by hardware when the UDPHS controller detects a good end of resume signal initiated by the host. This triggers a UDPHS interrupt when the ENDOFRSM bit is set in UDPHS_IEN. |

### Bit 5 – WAKE\_UP Wake Up CPU Interrupt

| Value | Description  |
|-------|--|
| 0     | Cleared by setting the WAKE_UP bit in UDPHS_CLRINT.  |
| 1     | Set by hardware when the UDPHS controller is in SUSPEND state and is re-activated by a filtered non-idle signal from the UDPHS line (not by an upstream resume). This triggers a UDPHS interrupt when the WAKE_UP bit is set in UDPHS_IEN register. When receiving this interrupt, the user has to enable the device controller clock prior to operation.<br><br><b>Note:</b> this interrupt is generated even if the device controller clock is disabled. |

### Bit 4 – ENDRESET End Of Reset Interrupt

| Value | Description  |
|-------|--|
| 0     | Cleared by setting the ENDRESET bit in UDPHS_CLRINT.   |
| 1     | Set by hardware when an End Of Reset has been detected by the UDPHS controller. This triggers a UDPHS interrupt when the ENDRESET bit is set in UDPHS_IEN. |

### Bit 3 – INT\_SOF Start Of Frame Interrupt

**Note:** The Micro Start Of Frame Interrupt (MICRO\_SOF), and the Start Of Frame Interrupt (INT\_SOF) are not generated at the same time.

| Value | Description  |
|-------|--|
| 0     | Cleared by setting the INT_SOF bit in UDPHS_CLRINT.  |
| 1     | Set by hardware when an UDPHS Start Of Frame PID (SOF) has been detected (every 1 ms) or synthesized by the macro. This triggers a UDPHS interrupt when the INT_SOF bit is set in UDPHS_IEN register. In case of detected SOF, in High Speed mode, the MICRO_FRAME_NUMBER field is cleared in UDPHS_FNUM register and the FRAME_NUMBER field is updated. |

### Bit 2 – MICRO\_SOF Micro Start Of Frame Interrupt

**Note:** The Micro Start Of Frame Interrupt (MICRO\_SOF), and the Start Of Frame Interrupt (INT\_SOF) are not generated at the same time.

| Value | Description   |
|-------|---|
| 0     | Cleared by setting the MICRO_SOF bit in UDPHS_CLRINT register.  |
| 1     | Set by hardware when an UDPHS micro start of frame PID (SOF) has been detected (every 125 us) or synthesized by the macro. This triggers a UDPHS interrupt when the MICRO_SOF bit is set in UDPHS_IEN. In case of detected SOF, the MICRO_FRAME_NUM field in UDPHS_FNUM register is incremented and the FRAME_NUMBER field does not change. |

### Bit 1 – DET\_SUSPD Suspend Interrupt

# SAMA5D2 Series

## USB High Speed Device Port (UDPHS)

| Value | Description   |
|-------|---|
| 0     | Cleared by setting the DET_SUSPD bit in UDPHS_CLRINT register.  |
| 1     | Set by hardware when a UDPHS Suspend (Idle bus for three frame periods, a J state for 3 ms) is detected. This triggers a UDPHS interrupt when the DET_SUSPD bit is set in UDPHS_IEN register. |

### Bit 0 – SPEED Speed Status

| Value | Description  |
|-------|--|
| 0     | Reset by hardware when the hardware is in Full Speed mode. |
| 1     | Set by hardware when the hardware is in High Speed mode.   |

### 40.7.5 UDPHS Clear Interrupt Register

**Name:** UDPHS\_CLRINT  
**Offset:** 0x18  
**Reset:** –  
**Property:** Write-only

|        |           |          |         |          |         |           |           |    |
|--------|-----------|----------|---------|----------|---------|-----------|-----------|----|

|        | UPSTR_RES | ENDOFRSM | WAKE_UP | ENDRESET | INT_SOF | MICRO_SOF | DET_SUSPD |    |
| Access | W         | W        | W       | W        | W       | W         | W         |    |
| Reset  | –         | –        | –       | –        | –       | –         | –         |    |

**Bit 7 – UPSTR\_RES** Upstream Resume Interrupt Clear

| Value | Description                              |
|-------|--|
| 0     | No effect.                               |
| 1     | Clear the UPSTR_RES bit in UDPHS_INTSTA. |

**Bit 6 – ENDOFRSM** End Of Resume Interrupt Clear

| Value | Description                             |
|-------|---|
| 0     | No effect.                              |
| 1     | Clear the ENDOFRSM bit in UDPHS_INTSTA. |

**Bit 5 – WAKE\_UP** Wake Up CPU Interrupt Clear

| Value | Description                            |
|-------|--|
| 0     | No effect.                             |
| 1     | Clear the WAKE_UP bit in UDPHS_INTSTA. |

**Bit 4 – ENDRESET** End Of Reset Interrupt Clear

| Value | Description                             |
|-------|---|
| 0     | No effect.                              |
| 1     | Clear the ENDRESET bit in UDPHS_INTSTA. |

**Bit 3 – INT\_SOF** Start Of Frame Interrupt Clear

| Value | Description                            |
|-------|--|
| 0     | No effect.                             |
| 1     | Clear the INT_SOF bit in UDPHS_INTSTA. |

**Bit 2 – MICRO\_SOF** Micro Start Of Frame Interrupt Clear

| Value | Description                              |
|-------|--|
| 0     | No effect.                               |
| 1     | Clear the MICRO_SOF bit in UDPHS_INTSTA. |

**Bit 1 – DET\_SUSPD** Suspend Interrupt Clear

| Value | Description                              |
|-------|--|
| 0     | No effect.                               |
| 1     | Clear the DET_SUSPD bit in UDPHS_INTSTA. |

### 40.7.6 UDPHS Endpoints Reset Register

**Name:** UDPHS\_EPTRST  
**Offset:** 0x1C  
**Reset:** –  
**Property:** Write-only

|        |                                  |        |        |        |        |        |       |       |
|--------|----------------------------------|--------|--------|--------|--------|--------|-------|-------|
| Bit    | 31                               | 30     | 29     | 28     | 27     | 26     | 25    | 24    |
|        | [Greyed out register bits 31-24] |        |        |        |        |        |       |       |
| Access |                                  |        |        |        |        |        |       |       |
| Reset  |                                  |        |        |        |        |        |       |       |

| Reset  | –                                | –      | –      | –      | –      | –      | –     | –     |
| Bit    | 7                                | 6      | 5      | 4      | 3      | 2      | 1     | 0     |
|        | EPT_7                            | EPT_6  | EPT_5  | EPT_4  | EPT_3  | EPT_2  | EPT_1 | EPT_0 |
| Access | W                                | W      | W      | W      | W      | W      | W     | W     |
| Reset  | –                                | –      | –      | –      | –      | –      | –     | –     |

**Bits 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15 – EPT\_x** Endpoint x Reset  
 Setting this bit clears all bits in the Endpoint status UDPHS\_EPTSTAx register except the TOGGLESQ\_STA field.

| Value | Description                |
|-------|----------------------------|
| 0     | No effect.                 |
| 1     | Reset the Endpointx state. |

### 40.7.7 UDPHS Test Register

**Name:** UDPHS\_TST  
**Offset:** 0xE0  
**Reset:** 0x00000000  
**Property:** Read/Write

#### Bit 5 – OPMODE2 OpMode2

**Note:** For the Test mode, Test\_SE0\_NAK (refer to Universal Serial Bus Specification, Revision 2.0: 7.1.20, Test Mode Support). Force the device in High Speed mode, and configure a bulk-type endpoint. Do not fill this endpoint for sending NAK to the host.

Upon command, a port's transceiver must enter the High Speed Receive mode and remain in that mode until the exit action is taken. This enables the testing of output impedance, low level output voltage and loading characteristics. In addition, while in this mode, upstream facing ports (and only upstream facing ports) must respond to any IN token packet with a NAK handshake (only if the packet CRC is determined to be correct) within the normal allowed device response time. This enables testing of the device squelch level circuitry and, additionally, provides a general purpose stimulus/response test for basic functional testing.

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | Set to force the OpMode signal (UTMI interface) to "10", to disable the bit-stuffing and the NRZI encoding. |

#### Bit 4 – TST\_PKT Test Packet Mode

| Value | Description |
|-------|-------------|
| 0     | No effect.  |

# SAMA5D2 Series

## USB High Speed Device Port (UDPHS)

| Value | Description   |
|-------|---|
| 1     | Set to repetitively transmit the packet stored in the current bank. This enables the testing of rise and fall times, eye patterns, jitter, and any other dynamic waveform specifications. |

### Bit 3 – TST\_K Test K Mode

| Value | Description  |
|-------|--|
| 0     | No effect.   |
| 1     | Set to send the K state on the UDPHS line. This enables the testing of the high output drive level on the D- line. |

### Bit 2 – TST\_J Test J Mode

| Value | Description  |
|-------|--|
| 0     | No effect.   |
| 1     | Set to send the J state on the UDPHS line. This enables the testing of the high output drive level on the D+ line. |

### Bits 1:0 – SPEED\_CFG[1:0] Speed Configuration

| Value | Name       | Description  |
|-------|------------|--|
| 0     | NORMAL     | Normal mode: The macro is in Full Speed mode, ready to make a High Speed identification, if the host supports it and then to automatically switch to High Speed mode.      |
| 1     | –          | Reserved   |
| 2     | HIGH_SPEED | Force High Speed: Set this value to force the hardware to work in High Speed mode. Only for debug or test purpose.   |
| 3     | FULL_SPEED | Force Full Speed: Set this value to force the hardware to work only in Full Speed mode. In this configuration, the macro will not respond to a High Speed reset handshake. |

### 40.7.8 UDPHS Endpoint Configuration Register

**Name:** UDPHS\_EPTCFGx  
**Offset:** 0x0100 + x\*0x20 [x=0..15]  
**Reset:** 0x00000000  
**Property:** Read/Write

|        |                |     |               |     |         |               |               |     |
|--------|----------------|-----|---------------|-----|---------|---------------|---------------|-----|
| Bit    | 31             | 30  | 29            | 28  | 27      | 26            | 25            | 24  |
|        | EPT_MAPD       |     |               |     |         |               |               |     |
| Access | R/W            |     |               |     |         |               |               |     |
| Reset  | 0              |     |               |     |         |               |               |     |
|        |                |     |               |     |         |               |               |     |
| Bit    | 23             | 22  | 21            | 20  | 19      | 18            | 17            | 16  |

| Access |                |     |               |     |         |               |               |     |
| Reset  |                |     |               |     |         |               |               |     |
|        |                |     |               |     |         |               |               |     |
| Bit    | 15             | 14  | 13            | 12  | 11      | 10            | 9             | 8   |
|        |                |     |               |     |         |               | NB_TRANS[1:0] |     |
| Access |                |     |               |     |         |               | R/W           | R/W |
| Reset  |                |     |               |     |         |               | 0             | 0   |
|        |                |     |               |     |         |               |               |     |
| Bit    | 7              | 6   | 5             | 4   | 3       | 2             | 1             | 0   |
|        | BK_NUMBER[1:0] |     | EPT_TYPE[1:0] |     | EPT_DIR | EPT_SIZE[2:0] |               |     |
| Access | R/W            | R/W | R/W           | R/W | R/W     | R/W           | R/W           | R/W |
| Reset  | 0              | 0   | 0             | 0   | 0       | 0             | 0             | 0   |

**Bit 31 – EPT\_MAPD** Endpoint Mapped (cleared upon USB reset)

| Value | Description  |
|-------|--|
| 0     | The user should reprogram the register with correct values.  |
| 1     | Set by hardware when the endpoint size (EPT_SIZE) and the number of banks (BK_NUMBER) are correct regarding: <ul style="list-style-type: none"> <li>– The max endpoint size for this endpoint</li> <li>– The number of allowed banks for this endpoint</li> <li>– The number of endpoints/banks already allocated</li> <li>– The FIFO max capacity (FIFO_MAX_SIZE in UDPHS_IPFEATURES register)</li> </ul> |

**Bits 9:8 – NB\_TRANS[1:0]** Number Of Transactions per Microframe (cleared upon USB reset)  
 The number of transactions per microframe is set by software.

**Note:** Meaningful for high bandwidth isochronous endpoint only.

**Bits 7:6 – BK\_NUMBER[1:0]** Number of Banks (cleared upon USB reset)  
 Set this field according to the endpoint's number of banks (see section [Endpoint Configuration](#)).

| Value | Name | Description                                     |
|-------|------|---|
| 0     | 0    | Zero bank, the endpoint is not mapped in memory |

# SAMA5D2 Series

## USB High Speed Device Port (UDPHS)

| Value | Name | Description                          |
|-------|------|--------------------------------------|
| 1     | 1    | One bank (bank 0)                    |
| 2     | 2    | Double bank (Ping-Pong: bank0/bank1) |
| 3     | 3    | Triple bank (bank0/bank1/bank2)      |

**Bits 5:4 – EPT\_TYPE[1:0]** Endpoint Type (cleared upon USB reset)

Set this field according to the endpoint type (see section [Endpoint Configuration](#)).

(Endpoint 0 should always be configured as control).

| Value | Name  | Description          |
|-------|-------|----------------------|
| 0     | CTRL8 | Control endpoint     |
| 1     | ISO   | Isochronous endpoint |
| 2     | BULK  | Bulk endpoint        |
| 3     | INT   | Interrupt endpoint   |

**Bit 3 – EPT\_DIR** Endpoint Direction (cleared upon USB reset)

For Control endpoints this bit has no effect and should be left at zero.

| Value | Description  |
|-------|--|
| 0     | Clear this bit to configure OUT direction for Bulk, Interrupt and Isochronous endpoints. |
| 1     | Set this bit to configure IN direction for Bulk, Interrupt and Isochronous endpoints.    |

**Bits 2:0 – EPT\_SIZE[2:0]** Endpoint Size (cleared upon USB reset)

Set this field according to the endpoint size in bytes (see the section [Endpoint Configuration](#)). Note that 1024 bytes is only for isochronous endpoints.

| Value | Name | Description |
|-------|------|-------------|
| 0     | 8    | 8 bytes     |
| 1     | 16   | 16 bytes    |
| 2     | 32   | 32 bytes    |
| 3     | 64   | 64 bytes    |
| 4     | 128  | 128 bytes   |
| 5     | 256  | 256 bytes   |
| 6     | 512  | 512 bytes   |
| 7     | 1024 | 1024 bytes  |

### 40.7.9 UDPHS Endpoint Control Enable Register (Control, Bulk, Interrupt Endpoints)

**Name:** UDPHS\_EPTCTLENBx  
**Offset:** 0x0104 + x\*0x20 [x=0..15]  
**Reset:** –  
**Property:** Write-only

This register view is relevant only if EPT\_TYPE = 0x0, 0x2 or 0x3 in UDPHS Endpoint Configuration Register.

For additional information, see UDPHS Endpoint Control Register (Control, Bulk, Interrupt Endpoints).

|        |           |        |           |          |            |           |            |           |   |

**Bit 31 – SHRT\_PCKT** Short Packet Send/Short Packet Interrupt Enable

For IN endpoints: Guarantees short packet at end of DMA Transfer if the UDPHS\_DMACONTROLx register END\_B\_EN and UDPHS\_EPTCTLx register AUTOVALID bits are also set.

For OUT endpoints:

| Value | Description                    |
|-------|--------------------------------|
| 0     | No effect.                     |
| 1     | Enable Short Packet Interrupt. |

**Bit 18 – BUSY\_BANK** Busy Bank Interrupt Enable

| Value | Description                 |
|-------|-----------------------------|
| 0     | No effect.                  |
| 1     | Enable Busy Bank Interrupt. |

**Bit 15 – NAK\_OUT** NAKOUT Interrupt Enable

| Value | Description              |
|-------|--------------------------|
| 0     | No effect.               |
| 1     | Enable NAKOUT Interrupt. |

**Bit 14 – NAK\_IN** NAKIN Interrupt Enable

| Value | Description             |
|-------|-------------------------|
| 0     | No effect.              |
| 1     | Enable NAKIN Interrupt. |

**Bit 13 – STALL\_SNT** Stall Sent Interrupt Enable

| Value | Description                  |
|-------|------------------------------|
| 0     | No effect.                   |
| 1     | Enable Stall Sent Interrupt. |

**Bit 12 – RX\_SETUP** Received SETUP

| Value | Description                |
|-------|----------------------------|
| 0     | No effect.                 |
| 1     | Enable RX_SETUP Interrupt. |

**Bit 11 – TXRDY** TX Packet Ready Interrupt Enable

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | Enable TX Packet Ready/Transaction Error Interrupt. |

**Bit 10 – TX\_COMPLT** Transmitted IN Data Complete Interrupt Enable

| Value | Description                                    |
|-------|--|
| 0     | No effect.                                     |
| 1     | Enable Transmitted IN Data Complete Interrupt. |

**Bit 9 – RXRDY\_TXKL** Received OUT Data Interrupt Enable

| Value | Description                         |
|-------|-------------------------------------|
| 0     | No effect.                          |
| 1     | Enable Received OUT Data Interrupt. |

**Bit 8 – ERR\_OVFLW** Overflow Error Interrupt Enable

| Value | Description                      |
|-------|----------------------------------|
| 0     | No effect.                       |
| 1     | Enable Overflow Error Interrupt. |

**Bit 4 – NYET\_DIS** NYET Disable (Only for High Speed Bulk OUT endpoints)

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | Forces an ACK response to the next High Speed Bulk OUT transfer instead of a NYET response. |

# SAMA5D2 Series

## USB High Speed Device Port (UDPHS)

---

---

### Bit 3 – INTDIS\_DMA Interrupts Disable DMA

| Value | Description  |
|-------|--|
| 0     | No effect.   |
| 1     | If set, when an enabled endpoint-originated interrupt is triggered, the DMA request is disabled. |

### Bit 1 – AUTO\_VALID Packet Auto-Valid Enable

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | Enable this bit to automatically validate the current packet and switch to the next bank for both IN and OUT transfers. |

### Bit 0 – EPT\_ENABL Endpoint Enable

| Value | Description  |
|-------|--|
| 0     | No effect.   |
| 1     | Enable endpoint according to the device configuration. |

### 40.7.10 UDPHS Endpoint Control Enable Register (Isochronous Endpoints)

**Name:**        UDPHS\_EPTCTLENBx  
**Offset:**     0x0104 + x\*0x20 [x=0..15]  
**Reset:**       –  
**Property:**   Write-only

This register view is relevant only if EPT\_TYPE = 0x1 in UDPHS Endpoint Configuration Register.  
 For additional information, see UDPHS Endpoint Control Register (Isochronous Endpoint).

|        |           |           |            |            |            |           |            |           |  |

| Access | W         | W         |            |            | W          |           | W          | W         |  |
| Reset  | –         | –         |            |            | –          |           | –          | –         |  |

**Bit 31 – SHRT\_PCKT** Short Packet Send/Short Packet Interrupt Enable  
 For IN endpoints: Guarantees short packet at end of DMA Transfer if the UDPHS\_DMACONTROLx register END\_B\_EN and UDPHS\_EPTCTLx register AUTOVALID bits are also set.

For OUT endpoints:

| Value | Description                    |
|-------|--------------------------------|
| 0     | No effect.                     |
| 1     | Enable Short Packet Interrupt. |

**Bit 18 – BUSY\_BANK** Busy Bank Interrupt Enable

| Value | Description                 |
|-------|-----------------------------|
| 0     | No effect.                  |
| 1     | Enable Busy Bank Interrupt. |

**Bit 14 – ERR\_FLUSH** Bank Flush Error Interrupt Enable

| Value | Description                        |
|-------|------------------------------------|
| 0     | No effect.                         |
| 1     | Enable Bank Flush Error Interrupt. |

**Bit 13 – ERR\_CRC\_NTR** ISO CRC Error/Number of Transaction Error Interrupt Enable

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | Enable Error CRC ISO/Error Number of Transaction Interrupt. |

**Bit 12 – ERR\_FL\_ISO** Error Flow Interrupt Enable

| Value | Description                      |
|-------|----------------------------------|
| 0     | No effect.                       |
| 1     | Enable Error Flow ISO Interrupt. |

**Bit 11 – TXRDY\_TRER** TX Packet Ready/Transaction Error Interrupt Enable

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | Enable TX Packet Ready/Transaction Error Interrupt. |

**Bit 10 – TX\_COMPLT** Transmitted IN Data Complete Interrupt Enable

| Value | Description                                    |
|-------|--|
| 0     | No effect.                                     |
| 1     | Enable Transmitted IN Data Complete Interrupt. |

**Bit 9 – RXRDY\_TXKL** Received OUT Data Interrupt Enable

| Value | Description                         |
|-------|-------------------------------------|
| 0     | No effect.                          |
| 1     | Enable Received OUT Data Interrupt. |

**Bit 8 – ERR\_OVFLW** Overflow Error Interrupt Enable

| Value | Description                      |
|-------|----------------------------------|
| 0     | No effect.                       |
| 1     | Enable Overflow Error Interrupt. |

**Bit 7 – MDATA\_RX** MDATA Interrupt Enable (Only for high bandwidth Isochronous OUT endpoints)

| Value | Description             |
|-------|-------------------------|
| 0     | No effect.              |
| 1     | Enable MDATA Interrupt. |

**Bit 6 – DATAx\_RX** DATAx Interrupt Enable (Only for high bandwidth Isochronous OUT endpoints)

| Value | Description             |
|-------|-------------------------|
| 0     | No effect.              |
| 1     | Enable DATAx Interrupt. |

# SAMA5D2 Series

## USB High Speed Device Port (UDPHS)

---

---

### Bit 3 – INTDIS\_DMA Interrupts Disable DMA

| Value | Description  |
|-------|--|
| 0     | No effect.   |
| 1     | If set, when an enabled endpoint-originated interrupt is triggered, the DMA request is disabled. |

### Bit 1 – AUTO\_VALID Packet Auto-Valid Enable

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | Enable this bit to automatically validate the current packet and switch to the next bank for both IN and OUT transfers. |

### Bit 0 – EPT\_ENABL Endpoint Enable

| Value | Description  |
|-------|--|
| 0     | No effect.   |
| 1     | Enable endpoint according to the device configuration. |

### 40.7.11 UDPHS Endpoint Control Disable Register (Control, Bulk, Interrupt Endpoints)

**Name:**        UDPHS\_EPTCTLDISx  
**Offset:**     0x0108 + x\*0x20 [x=0..15]  
**Reset:**       –  
**Property:**   Write-only

This register view is relevant only if EPT\_TYPE = 0x0, 0x2 or 0x3 in UDPHS Endpoint Configuration Register.

For additional information, see UDPHS Endpoint Control Register (Control, Bulk, Interrupt Endpoints).

|        |     |           |        |           |          |            |           |            |            |            |

**Bit 31 – SHRT\_PCKT** Short Packet Interrupt Disable

For IN endpoints: Never automatically add a zero length packet at end of DMA transfer.

For OUT endpoints:

| Value | Description                     |
|-------|---------------------------------|
| 0     | No effect.                      |
| 1     | Disable Short Packet Interrupt. |

**Bit 18 – BUSY\_BANK** Busy Bank Interrupt Disable

| Value | Description                  |
|-------|------------------------------|
| 0     | No effect.                   |
| 1     | Disable Busy Bank Interrupt. |

**Bit 15 – NAK\_OUT** NAKOUT Interrupt Disable

| Value | Description |
|-------|-------------|
| 0     | No effect.  |

# SAMA5D2 Series

## USB High Speed Device Port (UDPHS)

| Value | Description               |
|-------|---------------------------|
| 1     | Disable NAKOUT Interrupt. |

**Bit 14 – NAK\_IN** NAKIN Interrupt Disable

| Value | Description              |
|-------|--------------------------|
| 0     | No effect.               |
| 1     | Disable NAKIN Interrupt. |

**Bit 13 – STALL\_SNT** Stall Sent Interrupt Disable

| Value | Description                   |
|-------|-------------------------------|
| 0     | No effect.                    |
| 1     | Disable Stall Sent Interrupt. |

**Bit 12 – RX\_SETUP** Received SETUP Interrupt Disable

| Value | Description                 |
|-------|-----------------------------|
| 0     | No effect.                  |
| 1     | Disable RX_SETUP Interrupt. |

**Bit 11 – TXRDY** TX Packet Ready Interrupt Disable

| Value | Description  |
|-------|--|
| 0     | No effect.   |
| 1     | Disable TX Packet Ready/Transaction Error Interrupt. |

**Bit 10 – TX\_COMPLT** Transmitted IN Data Complete Interrupt Disable

| Value | Description                                     |
|-------|---|
| 0     | No effect.                                      |
| 1     | Disable Transmitted IN Data Complete Interrupt. |

**Bit 9 – RXRDY\_TXKL** Received OUT Data Interrupt Disable

| Value | Description                          |
|-------|--------------------------------------|
| 0     | No effect.                           |
| 1     | Disable Received OUT Data Interrupt. |

**Bit 8 – ERR\_OVFLW** Overflow Error Interrupt Disable

| Value | Description                       |
|-------|-----------------------------------|
| 0     | No effect.                        |
| 1     | Disable Overflow Error Interrupt. |

**Bit 4 – NYET\_DIS** NYET Enable (Only for High Speed Bulk OUT endpoints)

| Value | Description  |
|-------|--|
| 0     | No effect.   |
| 1     | Let the hardware handle the handshake response for the High Speed Bulk OUT transfer. |

**Bit 3 – INTDIS\_DMA** Interrupts Disable DMA

# SAMA5D2 Series

## USB High Speed Device Port (UDPHS)

---

---

| Value | Description                           |
|-------|---------------------------------------|
| 0     | No effect.                            |
| 1     | Disable the "Interrupts Disable DMA". |

**Bit 1 – AUTO\_VALID** Packet Auto-Valid Disable

| Value | Description  |
|-------|--|
| 0     | No effect.   |
| 1     | Disable this bit to not automatically validate the current packet. |

**Bit 0 – EPT\_DISABL** Endpoint Disable

| Value | Description       |
|-------|-------------------|
| 0     | No effect.        |
| 1     | Disable endpoint. |

### 40.7.12 UDPHS Endpoint Control Disable Register (Isochronous Endpoint)

**Name:** UDPHS\_EPTCTLDISx  
**Offset:** 0x0108 + x\*0x20 [x=0..15]  
**Reset:** –  
**Property:** Write-only

This register view is relevant only if EPT\_TYPE = 0x1 in UDPHS Endpoint Configuration Register.  
 For additional information, see “UDPHS Endpoint Control Register (Isochronous Endpoint)”.

**Bit 31 – SHRT\_PCKT** Short Packet Interrupt Disable  
 For IN endpoints: Never automatically add a zero length packet at end of DMA transfer.  
 For OUT endpoints:

| Value | Description                     |
|-------|---------------------------------|
| 0     | No effect.                      |
| 1     | Disable Short Packet Interrupt. |

**Bit 18 – BUSY\_BANK** Busy Bank Interrupt Disable

| Value | Description                  |
|-------|------------------------------|
| 0     | No effect.                   |
| 1     | Disable Busy Bank Interrupt. |

**Bit 14 – ERR\_FLUSH** bank flush error Interrupt Disable

| Value | Description |
|-------|-------------|
| 0     | No effect.  |

# SAMA5D2 Series

## USB High Speed Device Port (UDPHS)

| Value | Description                         |
|-------|-------------------------------------|
| 1     | Disable Bank Flush Error Interrupt. |

**Bit 13 – ERR\_CRC\_NTR** ISO CRC Error/Number of Transaction Error Interrupt Disable

| Value | Description  |
|-------|--|
| 0     | No effect.   |
| 1     | Disable Error CRC ISO/Error Number of Transaction Interrupt. |

**Bit 12 – ERR\_FL\_ISO** Error Flow Interrupt Disable

| Value | Description                       |
|-------|-----------------------------------|
| 0     | No effect.                        |
| 1     | Disable Error Flow ISO Interrupt. |

**Bit 11 – TXRDY\_TRER** TX Packet Ready/Transaction Error Interrupt Disable

| Value | Description  |
|-------|--|
| 0     | No effect.   |
| 1     | Disable TX Packet Ready/Transaction Error Interrupt. |

**Bit 10 – TX\_COMPLT** Transmitted IN Data Complete Interrupt Disable

| Value | Description                                     |
|-------|---|
| 0     | No effect.                                      |
| 1     | Disable Transmitted IN Data Complete Interrupt. |

**Bit 9 – RXRDY\_TXKL** Received OUT Data Interrupt Disable

| Value | Description                          |
|-------|--------------------------------------|
| 0     | No effect.                           |
| 1     | Disable Received OUT Data Interrupt. |

**Bit 8 – ERR\_OVFLW** Overflow Error Interrupt Disable

| Value | Description                       |
|-------|-----------------------------------|
| 0     | No effect.                        |
| 1     | Disable Overflow Error Interrupt. |

**Bit 7 – MDATA\_RX** MDATA Interrupt Disable (Only for High Bandwidth Isochronous OUT endpoints)

| Value | Description              |
|-------|--------------------------|
| 0     | No effect.               |
| 1     | Disable MDATA Interrupt. |

**Bit 6 – DATAx\_RX** DATAx Interrupt Disable (Only for High Bandwidth Isochronous OUT endpoints)

| Value | Description              |
|-------|--------------------------|
| 0     | No effect.               |
| 1     | Disable DATAx Interrupt. |

**Bit 3 – INTDIS\_DMA** Interrupts Disable DMA

# SAMA5D2 Series

## USB High Speed Device Port (UDPHS)

---

---

| Value | Description                           |
|-------|---------------------------------------|
| 0     | No effect.                            |
| 1     | Disable the "Interrupts Disable DMA". |

**Bit 1 – AUTO\_VALID** Packet Auto-Valid Disable

| Value | Description  |
|-------|--|
| 0     | No effect.   |
| 1     | Disable this bit to not automatically validate the current packet. |

**Bit 0 – EPT\_DISABL** Endpoint Disable

| Value | Description       |
|-------|-------------------|
| 0     | No effect.        |
| 1     | Disable endpoint. |

### 40.7.13 UDPHS Endpoint Control Register (Control, Bulk, Interrupt Endpoints)

**Name:** UDPHS\_EPTCTLx  
**Offset:** 0x010C + x\*0x20 [x=0..15]  
**Reset:** 0x00000000  
**Property:** Read-only

This register view is relevant only if EPT\_TYPE = 0x0, 0x2 or 0x3 in UDPHS Endpoint Configuration Register.

The reset value for UDPHS\_EPTCTL0 is 0x00000001.

|        |     |           |        |           |          |            |           |            |            |           |

|        |     |           |        |           |          |            |           |            |            |           |
|        | Bit | 7         | 6      | 5         | 4        | 3          | 2         | 1          | 0          |           |
|        |     |           |        |           | NYET_DIS | INTDIS_DMA |           |            | AUTO_VALID | EPT_ENABL |
| Access |     |           |        |           | R        | R          |           |            | R          | R         |
| Reset  |     |           |        |           | 0        | 0          |           |            | 0          | 0         |

**Bit 31 – SHRT\_PCKT** Short Packet Interrupt Enabled (cleared upon USB reset)

For OUT endpoints: sends an Interrupt when a Short Packet has been received.

For IN endpoints: a Short Packet transmission is guaranteed upon end of the DMA Transfer, thus signaling a BULK or INTERRUPT end of transfer, but only if the UDPHS\_DMACONTROLx register END\_B\_EN and UDPHS\_EPTCTLx register AUTO\_VALID bits are also set.

| Value | Description                        |
|-------|------------------------------------|
| 0     | Short Packet Interrupt is masked.  |
| 1     | Short Packet Interrupt is enabled. |

**Bit 18 – BUSY\_BANK** Busy Bank Interrupt Enabled (cleared upon USB reset)

For OUT endpoints: an interrupt is sent when all banks are busy.

For IN endpoints: an interrupt is sent when all banks are free.

| Value | Description                     |
|-------|---------------------------------|
| 0     | BUSY_BANK Interrupt is masked.  |
| 1     | BUSY_BANK Interrupt is enabled. |

**Bit 15 – NAK\_OUT** NAKOUT Interrupt Enabled (cleared upon USB reset)

| Value | Description                  |
|-------|------------------------------|
| 0     | NAKOUT Interrupt is masked.  |
| 1     | NAKOUT Interrupt is enabled. |

**Bit 14 – NAK\_IN** NAKIN Interrupt Enabled (cleared upon USB reset)

| Value | Description                 |
|-------|-----------------------------|
| 0     | NAKIN Interrupt is masked.  |
| 1     | NAKIN Interrupt is enabled. |

**Bit 13 – STALL\_SNT** Stall Sent Interrupt Enabled (cleared upon USB reset)

| Value | Description                      |
|-------|----------------------------------|
| 0     | Stall Sent Interrupt is masked.  |
| 1     | Stall Sent Interrupt is enabled. |

**Bit 12 – RX\_SETUP** Received SETUP Interrupt Enabled (cleared upon USB reset)

| Value | Description                |
|-------|----------------------------|
| 0     | Received SETUP is masked.  |
| 1     | Received SETUP is enabled. |

**Bit 11 – TXRDY** TX Packet Ready Interrupt Enabled (cleared upon USB reset)

Interrupt source is active as long as the corresponding UDPHS\_EPTSTAx register TXRDY flag remains low. If there are no more banks available for transmitting after the software has set UDPHS\_EPTSTAx/TXRDY for the last transmit packet, then the interrupt source remains inactive until the first bank becomes free again to transmit at UDPHS\_EPTSTAx/TXRDY hardware clear.

| Value | Description                           |
|-------|---------------------------------------|
| 0     | TX Packet Ready Interrupt is masked.  |
| 1     | TX Packet Ready Interrupt is enabled. |

**Bit 10 – TX\_COMPLT** Transmitted IN Data Complete Interrupt Enabled (cleared upon USB reset)

| Value | Description  |
|-------|--|
| 0     | Transmitted IN Data Complete Interrupt is masked.  |
| 1     | Transmitted IN Data Complete Interrupt is enabled. |

**Bit 9 – RXRDY\_TXKL** Received OUT Data Interrupt Enabled (cleared upon USB reset)

| Value | Description                             |
|-------|---|
| 0     | Received OUT Data Interrupt is masked.  |
| 1     | Received OUT Data Interrupt is enabled. |

**Bit 8 – ERR\_OVFLW** Overflow Error Interrupt Enabled (cleared upon USB reset)

# SAMA5D2 Series

## USB High Speed Device Port (UDPHS)

| Value | Description                          |
|-------|--------------------------------------|
| 0     | Overflow Error Interrupt is masked.  |
| 1     | Overflow Error Interrupt is enabled. |

**Bit 4 – NYET\_DIS** NYET Disable (Only for High Speed Bulk OUT Endpoints) (cleared upon USB reset)

**Note:** According to the Universal Serial Bus Specification, Rev 2.0 (8.5.1.1 NAK Responses to OUT/ DATA During PING Protocol), a NAK response to an HS Bulk OUT transfer is expected to be an unusual occurrence.

| Value | Description   |
|-------|---|
| 0     | Lets the hardware handle the handshake response for the High Speed Bulk OUT transfer.       |
| 1     | Forces an ACK response to the next High Speed Bulk OUT transfer instead of a NYET response. |

**Bit 3 – INTDIS\_DMA** Interrupt Disables DMA (cleared upon USB reset)

If set, when an enabled endpoint-originated interrupt is triggered, the DMA request is disabled regardless of the UDPHS\_IEN register EPT\_x bit for this endpoint. Then, the firmware will have to clear or disable the interrupt source or clear this bit if transfer completion is needed.

If the exception raised is associated with the new system bank packet, then the previous DMA packet transfer is normally completed, but the new DMA packet transfer is not started (not requested).

If the exception raised is not associated to a new system bank packet (NAK\_IN, NAK\_OUT, etc.), then the request cancellation may happen at any time and may immediately stop the current DMA transfer.

This may be used, for example, to identify or prevent an erroneous packet to be transferred into a buffer or to complete a DMA buffer by software after reception of a short packet.

**Bit 1 – AUTO\_VALID** Packet Auto-Valid Enabled (Not for CONTROL Endpoints) (cleared upon USB reset)

Set this bit to automatically validate the current packet and switch to the next bank for both IN and OUT endpoints.

#### For IN Transfer:

If this bit is set, the UDPHS\_EPTSTAx register TXRDY bit is set automatically when the current bank is full and at the end of DMA buffer if the UDPHS\_DMACONTROLx register END\_B\_EN bit is set.

The user may still set the UDPHS\_EPTSTAx register TXRDY bit if the current bank is not full, unless the user needs to send a Zero Length Packet by software.

#### For OUT Transfer:

If this bit is set, the UDPHS\_EPTSTAx register RXRDY\_TXKL bit is automatically reset for the current bank when the last packet byte has been read from the bank FIFO or at the end of DMA buffer if the UDPHS\_DMACONTROLx register END\_B\_EN bit is set. For example, to truncate a padded data packet when the actual data transfer size is reached.

The user may still clear the UDPHS\_EPTSTAx register RXRDY\_TXKL bit, for example, after completing a DMA buffer by software if UDPHS\_DMACONTROLx register END\_B\_EN bit was disabled or in order to cancel the read of the remaining data bank(s).

**Bit 0 – EPT\_ENABL** Endpoint Enable (cleared upon USB reset)

# SAMA5D2 Series

## USB High Speed Device Port (UDPHS)

| Value | Description  |
|-------|--|
| 0     | The endpoint is disabled according to the device configuration. Endpoint 0 should always be enabled after a hardware or UDPHS bus reset and participate in the device configuration. |
| 1     | The endpoint is enabled according to the device configuration.   |

### 40.7.14 UDPHS Endpoint Control Register (Isochronous Endpoint)

**Name:**        UDPHS\_EPTCTLx  
**Offset:**     0x010C + x\*0x20 [x=0..15]  
**Reset:**       0x00000000  
**Property:**   Read-only

This register view is relevant only if EPT\_TYPE = 0x1 in UDPHS Endpoint Configuration Register.  
 The reset value for UDPHS\_EPTCTL0 is 0x00000001.

|        |     |           |           |           |            |    |            |            |            |   |  |

| Access |     | R         |           | R         |            | R  |            | R          |            | R |  |
| Reset  |     | 0         |           | 0         |            | 0  |            | 0          |            | 0 |  |

**Bit 31 – SHRT\_PCKT** Short Packet Interrupt Enabled (cleared upon USB reset)

For OUT endpoints: Send an Interrupt when a Short Packet has been received.

For IN endpoints: A Short Packet transmission is guaranteed upon end of the DMA Transfer, thus signaling an end of isochronous (micro-)frame data, but only if the UDPHS\_DMACONTROLx register END\_B\_EN and UDPHS\_EPTCTLx register AUTO\_VALID bits are also set.

| Value | Description                        |
|-------|------------------------------------|
| 0     | Short Packet Interrupt is masked.  |
| 1     | Short Packet Interrupt is enabled. |

**Bit 18 – BUSY\_BANK** Busy Bank Interrupt Enabled (cleared upon USB reset)

For OUT endpoints: An interrupt is sent when all banks are busy.

For IN endpoints: An interrupt is sent when all banks are free.

| Value | Description                     |
|-------|---------------------------------|
| 0     | BUSY_BANK Interrupt is masked.  |
| 1     | BUSY_BANK Interrupt is enabled. |

**Bit 14 – ERR\_FLUSH** Bank Flush Error Interrupt Enabled (cleared upon USB reset)

| Value | Description                            |
|-------|--|
| 0     | Bank Flush Error Interrupt is masked.  |
| 1     | Bank Flush Error Interrupt is enabled. |

**Bit 13 – ERR\_CRC\_NTR** ISO CRC Error/Number of Transaction Error Interrupt Enabled (cleared upon USB reset)

| Value | Description   |
|-------|---|
| 0     | ISO CRC error/number of Transaction Error Interrupt is masked.  |
| 1     | ISO CRC error/number of Transaction Error Interrupt is enabled. |

**Bit 12 – ERR\_FL\_ISO** Error Flow Interrupt Enabled (cleared upon USB reset)

| Value | Description                      |
|-------|----------------------------------|
| 0     | Error Flow Interrupt is masked.  |
| 1     | Error Flow Interrupt is enabled. |

**Bit 11 – TXRDY\_TRER** TX Packet Ready/Transaction Error Interrupt Enabled (cleared upon USB reset)

**⚠ CAUTION** Interrupt source is active as long as the corresponding UDPHS\_EPTSTAx register TXRDY\_TRER flag remains low. If there are no more banks available for transmitting after the software has set UDPHS\_EPTSTAx/TXRDY\_TRER for the last transmit packet, then the interrupt source remains inactive until the first bank becomes free again to transmit at UDPHS\_EPTSTAx/TXRDY\_TRER hardware clear.

| Value | Description   |
|-------|---|
| 0     | TX Packet Ready/Transaction Error Interrupt is masked.  |
| 1     | TX Packet Ready/Transaction Error Interrupt is enabled. |

**Bit 10 – TX\_COMPLT** Transmitted IN Data Complete Interrupt Enabled (cleared upon USB reset)

| Value | Description  |
|-------|--|
| 0     | Transmitted IN Data Complete Interrupt is masked.  |
| 1     | Transmitted IN Data Complete Interrupt is enabled. |

**Bit 9 – RXRDY\_TXKL** Received OUT Data Interrupt Enabled (cleared upon USB reset)

| Value | Description                             |
|-------|---|
| 0     | Received OUT Data Interrupt is masked.  |
| 1     | Received OUT Data Interrupt is enabled. |

**Bit 8 – ERR\_OVFLW** Overflow Error Interrupt Enabled (cleared upon USB reset)

| Value | Description                          |
|-------|--------------------------------------|
| 0     | Overflow Error Interrupt is masked.  |
| 1     | Overflow Error Interrupt is enabled. |

**Bit 7 – MDATA\_RX** MDATA Interrupt Enabled (Only for High Bandwidth Isochronous OUT endpoints) (cleared upon USB reset)

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | Send an interrupt when an MDATA packet has been received and so at least one packet of the microframe data payload has been received. |

**Bit 6 – DATA\_RX** DATAx Interrupt Enabled (Only for High Bandwidth Isochronous OUT endpoints) (cleared upon USB reset)

| Value | Description  |
|-------|--|
| 0     | No effect.   |
| 1     | Send an interrupt when a DATA2, DATA1 or DATA0 packet has been received meaning the whole microframe data payload has been received. |

**Bit 3 – INTDIS\_DMA** Interrupt Disables DMA (cleared upon USB reset)

If set, when an enabled endpoint-originated interrupt is triggered, the DMA request is disabled regardless of the UDPHS\_IEN register EPT\_x bit for this endpoint. Then, the firmware will have to clear or disable the interrupt source or clear this bit if transfer completion is needed.

If the exception raised is associated with the new system bank packet, then the previous DMA packet transfer is normally completed, but the new DMA packet transfer is not started (not requested).

If the exception raised is not associated to a new system bank packet (ex: ERR\_FL\_ISO), then the request cancellation may happen at any time and may immediately stop the current DMA transfer.

This may be used, for example, to identify or prevent an erroneous packet to be transferred into a buffer or to complete a DMA buffer by software after reception of a short packet, or to perform buffer truncation on ERR\_FL\_ISO interrupt for adaptive rate.

**Bit 1 – AUTO\_VALID** Packet Auto-Valid Enabled (cleared upon USB reset)

Set this bit to automatically validate the current packet and switch to the next bank for both IN and OUT endpoints.

**For IN Transfer:**

If this bit is set, the UDPHS\_EPTSTAx register TXRDY\_TRER bit is set automatically when the current bank is full and at the end of DMA buffer if the UDPHS\_DMACONTROLx register END\_B\_EN bit is set.

The user may still set the UDPHS\_EPTSTAx register TXRDY\_TRER bit if the current bank is not full, unless the user needs to send a Zero Length Packet by software.

**For OUT Transfer:**

If this bit is set, the UDPHS\_EPTSTAx register RXRDY\_TXKL bit is automatically reset for the current bank when the last packet byte has been read from the bank FIFO or at the end of DMA buffer if the UDPHS\_DMACONTROLx register END\_B\_EN bit is set. For example, to truncate a padded data packet when the actual data transfer size is reached.

The user may still clear the UDPHS\_EPTSTAx register RXRDY\_TXKL bit, for example, after completing a DMA buffer by software if UDPHS\_DMACONTROLx register END\_B\_EN bit was disabled or in order to cancel the read of the remaining data bank(s).

**Bit 0 – EPT\_ENABL** Endpoint Enable (cleared upon USB reset)

# SAMA5D2 Series

## USB High Speed Device Port (UDPHS)

| Value | Description  |
|-------|--|
| 0     | The endpoint is disabled according to the device configuration. Endpoint 0 should always be enabled after a hardware or UDPHS bus reset and participate in the device configuration. |
| 1     | The endpoint is enabled according to the device configuration.   |

### 40.7.15 UDPHS Endpoint Set Status Register (Control, Bulk, Interrupt Endpoints)

**Name:** UDPHS\_EPTSETSTAx  
**Offset:** 0x0114 + x\*0x20 [x=0..15]  
**Reset:** –  
**Property:** Write-only

This register view is relevant only if EPT\_TYPE = 0x0, 0x2 or 0x3 in UDPHS Endpoint Configuration Register.

For additional information, see UDPHS Endpoint Status Register (Control, Bulk, Interrupt Endpoints).

#### Bit 11 – TXRDY TX Packet Ready Set

| Value | Description |
|-------|-------------|
| 0     | No effect.  |

# SAMA5D2 Series

## USB High Speed Device Port (UDPHS)

| Value | Description   |
|-------|---|
| 1     | <p>Set this bit after a packet has been written into the endpoint FIFO for IN data transfers</p> <ul style="list-style-type: none"> <li>– This flag is used to generate a Data IN transaction (device to host).</li> <li>– Device firmware checks that it can write a data payload in the FIFO, checking that TXRDY is cleared.</li> <li>– Transfer to the FIFO is done by writing in the “Buffer Address” register.</li> <li>– Once the data payload has been transferred to the FIFO, the firmware notifies the UDPHS device setting TXRDY to one.</li> <li>– UDPHS bus transactions can start.</li> <li>– TXCOMP is set once the data payload has been received by the host.</li> <li>– Data should be written into the endpoint FIFO only after this bit has been cleared.</li> <li>– Set this bit without writing data to the endpoint FIFO to send a Zero Length Packet.</li> </ul> |

**Bit 9 – RXRDY\_TXKL** KILL Bank Set (for IN Endpoint)

| Value | Description                 |
|-------|-----------------------------|
| 0     | No effect.                  |
| 1     | Kill the last written bank. |

**Bit 5 – FRCESTALL** Stall Handshake Request Set

Refer to chapters 8.4.5 (Handshake Packets) and 9.4.5 (Get Status) of the Universal Serial Bus Specification, Rev 2.0 for more information on the STALL handshake.

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | Set this bit to request a STALL answer to the host for the next handshake |

### 40.7.16 UDPHS Endpoint Set Status Register (Isochronous Endpoint)

**Name:** UDPHS\_EPTSETSTAx  
**Offset:** 0x0114 + x\*0x20 [x=0..15]  
**Reset:** –  
**Property:** Write-only

This register view is relevant only if EPT\_TYPE = 0x1 in UDPHS Endpoint Configuration Register.  
 For additional information, see UDPHS Endpoint Status Register (Isochronous Endpoint).

#### Bit 11 – TXRDY\_TRER TX Packet Ready Set

| Value | Description  |
|-------|--|
| 0     | No effect.   |
| 1     | Set this bit after a packet has been written into the endpoint FIFO for IN data transfers <ul style="list-style-type: none"> <li>– This flag is used to generate a Data IN transaction (device to host).</li> <li>– Device firmware checks that it can write a data payload in the FIFO, checking that TXRDY_TRER is cleared.</li> <li>– Transfer to the FIFO is done by writing in the “Buffer Address” register.</li> <li>– Once the data payload has been transferred to the FIFO, the firmware notifies the UDPHS device setting TXRDY_TRER to one.</li> <li>– UDPHS bus transactions can start.</li> <li>– TXCOMP is set once the data payload has been sent.</li> <li>– Data should be written into the endpoint FIFO only after this bit has been cleared.</li> <li>– Set this bit without writing data to the endpoint FIFO to send a Zero Length Packet.</li> </ul> |

# SAMA5D2 Series

**Bit 9 – RXRDY\_TXKL** KILL Bank Set (for IN Endpoint)

| Value | Description                 |
|-------|-----------------------------|
| 0     | No effect.                  |
| 1     | Kill the last written bank. |

### 40.7.17 UDPHS Endpoint Clear Status Register (Control, Bulk, Interrupt Endpoints)

**Name:**        UDPHS\_EPTCLRSTAx  
**Offset:**     0x0118 + x\*0x20 [x=0..15]  
**Reset:**       –  
**Property:**   Write-only

This register view is relevant only if EPT\_TYPE = 0x0, 0x2 or 0x3 in UDPHS Endpoint Configuration Register.

For additional information, see UDPHS Endpoint Status Register (Control, Bulk, Interrupt Endpoints).

|        |         |          |           |          |    |           |            |    |
|--------|---------|----------|-----------|----------|----|-----------|------------|----|

| Reset  |         | –        | –         |          |    |           |            |    |

#### Bit 15 – NAK\_OUT NAKOUT Clear

| Value | Description                              |
|-------|--|
| 0     | No effect.                               |
| 1     | Clear the NAK_OUT flag of UDPHS_EPTSTAx. |

#### Bit 14 – NAK\_IN NAKIN Clear

| Value | Description                              |
|-------|--|
| 0     | No effect.                               |
| 1     | Clear the NAK_IN flags of UDPHS_EPTSTAx. |

#### Bit 13 – STALL\_SNT Stall Sent Clear

| Value | Description                                 |
|-------|---|
| 0     | No effect.                                  |
| 1     | Clear the STALL_SNT flags of UDPHS_EPTSTAx. |

#### Bit 12 – RX\_SETUP Received SETUP Clear

# SAMA5D2 Series

## USB High Speed Device Port (UDPHS)

| Value | Description                                |
|-------|--|
| 0     | No effect.                                 |
| 1     | Clear the RX_SETUP flags of UDPHS_EPTSTAx. |

**Bit 10 – TX\_COMPLT** Transmitted IN Data Complete Clear

| Value | Description                                |
|-------|--|
| 0     | No effect.                                 |
| 1     | Clear the TX_COMPLT flag of UDPHS_EPTSTAx. |

**Bit 9 – RXRDY\_TXKL** Received OUT Data Clear

| Value | Description                                 |
|-------|---|
| 0     | No effect.                                  |
| 1     | Clear the RXRDY_TXKL flag of UDPHS_EPTSTAx. |

**Bit 6 – TOGGLESQ** Data Toggle Clear

For OUT endpoints, the next received packet should be a DATA0.

For IN endpoints, the next packet will be sent with a DATA0 PID.

| Value | Description                            |
|-------|--|
| 0     | No effect.                             |
| 1     | Clear the PID data of the current bank |

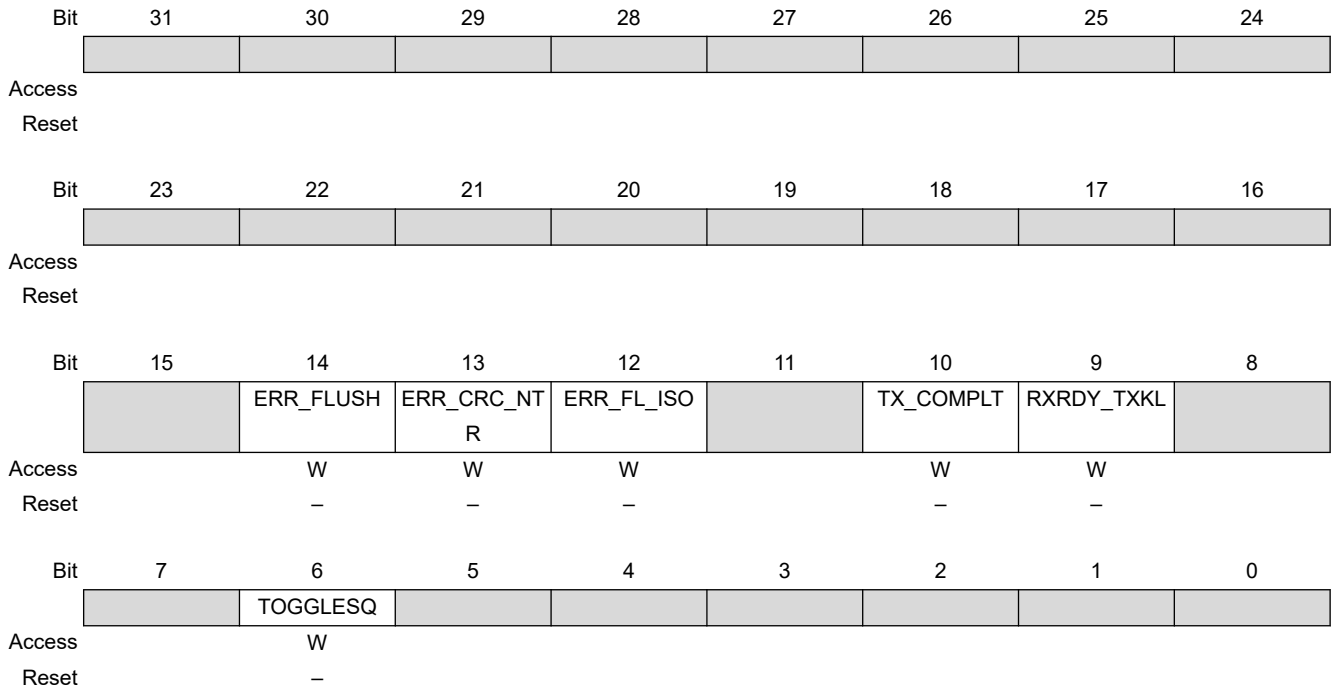

**Bit 5 – FRCESTALL** Stall Handshake Request Clear

| Value | Description  |
|-------|--|
| 0     | No effect.   |
| 1     | Clear the STALL request. The next packets from host will not be STALLED. |

### 40.7.18 UDPHS Endpoint Clear Status Register (Isochronous Endpoint)

**Name:** UDPHS\_EPTCLRSTAx  
**Offset:** 0x0118 + x\*0x20 [x=0..15]  
**Reset:** –  
**Property:** Write-only

This register view is relevant only if EPT\_TYPE = 0x1 in UDPHS Endpoint Configuration Register.  
 For additional information, see UDPHS Endpoint Status Register (Isochronous Endpoint).

#### Bit 14 – ERR\_FLUSH Bank Flush Error Clear

| Value | Description                                 |
|-------|---|
| 0     | No effect.                                  |
| 1     | Clear the ERR_FLUSH flags of UDPHS_EPTSTAx. |

#### Bit 13 – ERR\_CRC\_NTR Number of Transaction Error Clear

| Value | Description                                   |
|-------|---|
| 0     | No effect.                                    |
| 1     | Clear the ERR_CRC_NTR flags of UDPHS_EPTSTAx. |

#### Bit 12 – ERR\_FL\_ISO Error Flow Clear

| Value | Description                                  |
|-------|--|
| 0     | No effect.                                   |
| 1     | Clear the ERR_FL_ISO flags of UDPHS_EPTSTAx. |

#### Bit 10 – TX\_COMPLT Transmitted IN Data Complete Clear

# SAMA5D2 Series

## USB High Speed Device Port (UDPHS)

| Value | Description                                |
|-------|--|
| 0     | No effect.                                 |
| 1     | Clear the TX_COMPLT flag of UDPHS_EPTSTAx. |

**Bit 9 – RXRDY\_TXKL** Received OUT Data Clear

| Value | Description                                 |
|-------|---|
| 0     | No effect.                                  |
| 1     | Clear the RXRDY_TXKL flag of UDPHS_EPTSTAx. |

**Bit 6 – TOGGLESQ** Data Toggle Clear

For OUT endpoints, the next received packet should be a DATA0.

For IN endpoints, the next packet will be sent with a DATA0 PID.

| Value | Description                            |
|-------|--|
| 0     | No effect.                             |
| 1     | Clear the PID data of the current bank |

### 40.7.19 UDPHS Endpoint Status Register (Control, Bulk, Interrupt Endpoints)

**Name:** UDPHS\_EPTSTAx  
**Offset:** 0x011C + x\*0x20 [x=0..15]  
**Reset:** 0x00000040  
**Property:** Read-only

This register view is relevant only if EPT\_TYPE = 0x0, 0x2 or 0x3 in UDPHS Endpoint Configuration Register.

|        |                   |                  |           |                    |       |           |                   |           |

|        | NAK_OUT           | NAK_IN           | STALL_SNT | RX_SETUP           | TXRDY | TX_COMPLT | RXRDY_TXKL        | ERR_OVFLW |
| Access | R                 | R                | R         | R                  | R     | R         | R                 | R         |
| Reset  | 0                 | 0                | 0         | 0                  | 0     | 0         | 0                 | 0         |
| Bit    | 7                 | 6                | 5         | 4                  | 3     | 2         | 1                 | 0         |
|        | TOGGLESQ_STA[1:0] |                  | FRCESTALL |                    |       |           |                   |           |
| Access | R                 | R                | R         |                    |       |           |                   |           |
| Reset  | 0                 | 1                | 0         |                    |       |           |                   |           |

**Bit 31 – SHRT\_PCKT** Short Packet (cleared upon USB reset)

An OUT Short Packet is detected when the receive byte count is less than the configured UDPHS\_EPTCFGx register EPT\_Size.

This bit is updated at the same time as the BYTE\_COUNT field.

It is reset by UDPHS\_EPTRST register EPT\_x (reset endpoint) and by UDPHS\_EPTCTLDISx (disable endpoint).

**Bits 30:20 – BYTE\_COUNT[10:0]** UDPHS Byte Count (cleared upon USB reset)

Byte count of a received data packet.

This field is incremented after each write into the endpoint (to prepare an IN transfer). It is decremented after each reading into the endpoint (OUT transfer).

This field is also updated at RXRDY\_TXKL flag clear with the next bank, and at TXRDY flag set with the next bank.

This field is reset by UDPHS\_EPTRST.EPT\_x.

**Bits 19:18 – BUSY\_BANK\_STA[1:0]** Busy Bank Number (cleared upon USB reset)

These bits are set by hardware to indicate the number of busy banks.

# SAMA5D2 Series

## USB High Speed Device Port (UDPHS)

IN endpoint: Indicates the number of busy banks filled by the user, ready for IN transfer.

OUT endpoint: Indicates the number of busy banks filled by OUT transaction from the Host.

| Value | Name       | Description        |
|-------|------------|--------------------|
| 0     | 0BUSYBANK  | All banks are free |
| 1     | 1BUSYBANK  | 1 busy bank        |
| 2     | 2BUSYBANKS | 2 busy banks       |
| 3     | 3BUSYBANKS | 3 busy banks       |

**Bits 17:16 – CURBK\_CTLDIR[1:0]** Current Bank/Control Direction (cleared upon USB reset)

**Control Direction (for Control endpoint only):**

0: A Control Write is requested by the Host.

1: A Control Read is requested by the Host.

**Note:**

1. Corresponds to the the 7th bit of the bmRequestType (Byte 0 of the Setup Data).
2. Updated after receiving new setup data.

**Current Bank (not relevant for Control endpoint):**

- Set by hardware to indicate the number of the current bank.
- Reset by UDPHS\_EPTRST register EPT\_x (reset endpoint) and by UDPHS\_EPTCTLDISx (disable endpoint).
- The current bank is updated each time the user:
  - Sets the TX Packet Ready bit to prepare the next IN transfer and to switch to the next bank.
  - Clears the received OUT data bit to access the next bank.

| Value | Name  | Description             |
|-------|-------|-------------------------|
| 0     | BANK0 | Bank 0 (or single bank) |
| 1     | BANK1 | Bank 1                  |
| 2     | BANK2 | Bank 2                  |

**Bit 15 – NAK\_OUT** NAK OUT (cleared upon USB reset)

This bit is set by hardware when a NAK handshake has been sent in response to an OUT or PING request from the Host.

This bit is reset by UDPHS\_EPTRST register EPT\_x (reset endpoint) and by EPT\_CTL\_DISx (disable endpoint).

**Bit 14 – NAK\_IN** NAK IN (cleared upon USB reset)

This bit is set by hardware when a NAK handshake has been sent in response to an IN request from the Host.

This bit is cleared by software.

**Bit 13 – STALL\_SNT** Stall Sent (cleared upon USB reset)

For Control, Bulk and Interrupt endpoints.

This bit is set by hardware after a STALL handshake has been sent as requested by the UDPHS\_EPTSTAx register FRCESTALL bit.

This bit is reset by UDPHS\_EPTRST register EPT\_x (reset endpoint) and by UDPHS\_EPTCTLDISx (disable endpoint).

**Bit 12 – RX\_SETUP** Received SETUP (cleared upon USB reset)

For Control endpoint only.

This bit is set by hardware when a valid SETUP packet has been received from the host.

It is cleared by the device firmware after reading the SETUP data from the endpoint FIFO.

This bit is reset by UDPHS\_EPTRST register EPT\_x (reset endpoint), and by UDPHS\_EPTCTLDISx (disable endpoint).

**Bit 11 – TXRDY** TX Packet Ready (cleared upon USB reset)

This bit is cleared by hardware after the host has acknowledged the packet.

For Multi-bank endpoints, this bit may remain clear even after software is set if another bank is available to transmit.

Hardware clear of this bit may generate an interrupt if enabled by the UDPHS\_EPTCTLx register TXRDY bit.

This bit is reset by UDPHS\_EPTRST register EPT\_x (reset endpoint), and by UDPHS\_EPTCTLDISx (disable endpoint).

**Bit 10 – TX\_COMPLT** Transmitted IN Data Complete (cleared upon USB reset)

This bit is set by hardware after an IN packet has been accepted (ACK'ed) by the host.

This bit is reset by UDPHS\_EPTRST register EPT\_x (reset endpoint), and by UDPHS\_EPTCTLDISx (disable endpoint).

**Bit 9 – RXRDY\_TXKL** Received OUT Data/KILL Bank (cleared upon USB reset)

**Received OUT Data (for OUT endpoint or Control endpoint):**

- This bit is set by hardware after a new packet has been stored in the endpoint FIFO.
- This bit is cleared by the device firmware after reading the OUT data from the endpoint.
- For multi-bank endpoints, this bit may remain active even when cleared by the device firmware, this if an other packet has been received meanwhile.
- Hardware assertion of this bit may generate an interrupt if enabled by the UDPHS\_EPTCTLx register RXRDY\_TXKL bit.
- This bit is reset by UDPHS\_EPTRST register EPT\_x (reset endpoint) and by UDPHS\_EPTCTLDISx (disable endpoint).

**KILL Bank (for IN endpoint):**

- The bank is really cleared or the bank is sent, BUSY\_BANK\_STA is decremented.
- The bank is not cleared but sent on the IN transfer, TX\_COMPLT
- The bank is not cleared because it was empty. The user should wait that this bit is cleared before trying to clear another packet.

**Note:** “Kill a packet” may be refused if at the same time, an IN token is coming and the current packet is sent on the UDPHS line. In this case, the TX\_COMPLT bit is set. Take notice however, that if at least two banks are ready to be sent, there is no problem to kill a packet even if an IN token is coming. In fact, in that case, the current bank is sent (IN transfer) and the last bank is killed.

**Bit 8 – ERR\_OVFLW** Overflow Error (cleared upon USB reset)

This bit is set by hardware when a new too-long packet is received.

# SAMA5D2 Series

## USB High Speed Device Port (UDPHS)

Example: If the user programs an endpoint 64 bytes wide and the host sends 128 bytes in an OUT transfer, then the Overflow Error bit is set.

This bit is updated at the same time as the BYTE\_COUNT field.

This bit is reset by UDPHS\_EPTRST register EPT\_x (reset endpoint) and by UDPHS\_EPTCTLDISx (disable endpoint).

**Bits 7:6 – TOGGLESQ\_STA[1:0]** Toggle Sequencing (cleared upon USB reset)

In OUT transfer, the Toggle information is meaningful only when the current bank is busy (Received OUT Data = 1).

This field is updated for OUT transfer:

- A new data has been written into the current bank.
- The user has just cleared the Received OUT Data bit to switch to the next bank.

This field is reset to DATA1 by the UDPHS\_EPTCLRSTAx register TOGGLESQ bit, and by UDPHS\_EPTCTLDISx (disable endpoint).

Toggle Sequencing:

- IN endpoint: Indicates the PID Data Toggle that will be used for the next packet sent. This is not relative to the current bank.
- CONTROL and OUT endpoints: Set by hardware to indicate the PID data of the current bank.

| Value | Name  | Description                                      |
|-------|-------|--|
| 0     | DATA0 | DATA0  |
| 1     | DATA1 | DATA1  |
| 2     | DATA2 | Reserved for High Bandwidth Isochronous Endpoint |
| 3     | MDATA | Reserved for High Bandwidth Isochronous Endpoint |

**Bit 5 – FRCESTALL** Stall Handshake Request (cleared upon USB reset)

This bit is reset by hardware upon received SETUP.

| Value | Description  |
|-------|--|
| 0     | No effect.   |
| 1     | If set a STALL answer will be done to the host for the next handshake. |

### 40.7.20 UDPHS Endpoint Status Register (Isochronous Endpoint)

**Name:**        UDPHS\_EPTSTAx  
**Offset:**     0x011C + x\*0x20 [x=0..15]  
**Reset:**       0x00000040  
**Property:**   Read-only

This register view is relevant only if EPT\_TYPE = 0x1 in “UDPHS Endpoint Configuration Register”.

|        |     | TOGGLESQ_STA[1:0] |           |                  |                    |            |           |            |           |
| Access |     | R                 | R         |                  |                    |            |           |            |           |
| Reset  |     | 0                 | 1         |                  |                    |            |           |            |           |

**Bit 31 – SHRT\_PCKT** Short Packet (cleared upon USB reset)  
 An OUT Short Packet is detected when the receive byte count is less than the configured UDPHS\_EPTCFGx register EPT\_Size.

This bit is updated at the same time as the BYTE\_COUNT field.

This bit is reset by UDPHS\_EPTRST register EPT\_x (reset endpoint) and by UDPHS\_EPTCTLDISx (disable endpoint).

**Bits 30:20 – BYTE\_COUNT[10:0]** UDPHS Byte Count (cleared upon USB reset)  
 Byte count of a received data packet.

This field is incremented after each write into the endpoint (to prepare an IN transfer).

This field is decremented after each reading into the endpoint (OUT transfer).

This field is also updated at RXRDY\_TXKL flag clear with the next bank.

This field is also updated at TXRDY\_TRER flag set with the next bank.

This field is reset by EPT\_x of UDPHS\_EPTRST register.

# SAMA5D2 Series

## USB High Speed Device Port (UDPHS)

**Bits 19:18 – BUSY\_BANK\_STA[1:0]** Busy Bank Number (cleared upon USB reset)

These bits are set by hardware to indicate the number of busy banks.

IN endpoint: It indicates the number of busy banks filled by the user, ready for IN transfer.

OUT endpoint: It indicates the number of busy banks filled by OUT transaction from the Host.

| Value | Name       | Description        |
|-------|------------|--------------------|
| 0     | 0BUSYBANK  | All banks are free |
| 1     | 1BUSYBANK  | 1 busy bank        |
| 2     | 2BUSYBANKS | 2 busy banks       |
| 3     | 3BUSYBANKS | 3 busy banks       |

**Bits 17:16 – CURBK[1:0]** Current Bank (cleared upon USB reset)

These bits are set by hardware to indicate the number of the current bank.

The current bank is updated each time the user:

- Sets the TX Packet Ready bit to prepare the next IN transfer and to switch to the next bank.
- Clears the received OUT data bit to access the next bank.

This bit is reset by UDPHS\_EPTRST register EPT\_x (reset endpoint) and by UDPHS\_EPTCTLDISx (disable endpoint).

| Value | Name  | Description             |
|-------|-------|-------------------------|
| 0     | BANK0 | Bank 0 (or single bank) |
| 1     | BANK1 | Bank 1                  |
| 2     | BANK2 | Bank 2                  |

**Bit 14 – ERR\_FLUSH** Bank Flush Error (cleared upon USB reset)

For High Bandwidth Isochronous IN endpoints.

This bit is set when flushing unsent banks at the end of a microframe.

This bit is reset by UDPHS\_EPTRST register EPT\_x (reset endpoint) and by EPT\_CTL\_DISx (disable endpoint).

**Bit 13 – ERR\_CRC\_NTR** CRC ISO Error/Number of Transaction Error (cleared upon USB reset)

**CRC ISO Error (for Isochronous OUT endpoints) (Read-only):**

This bit is set by hardware if the last received data is corrupted (CRC error on data).

This bit is updated by hardware when new data is received (Received OUT Data bit).

**Number of Transaction Error (for High Bandwidth Isochronous IN endpoints):**

This bit is set at the end of a microframe in which at least one data bank has been transmitted, if less than the number of transactions per micro-frame banks (UDPHS\_EPTCFGx register NB\_TRANS) have been validated for transmission inside this microframe.

This bit is reset by UDPHS\_EPTRST register EPT\_x (reset endpoint) and by UDPHS\_EPTCTLDISx (disable endpoint).

**Bit 12 – ERR\_FL\_ISO** Error Flow (cleared upon USB reset)

This bit is set by hardware when a transaction error occurs.

- Isochronous IN transaction is missed, the micro has no time to fill the endpoint (underflow).
- Isochronous OUT data is dropped because the bank is busy (overflow).

This bit is reset by UDPHS\_EPTRST register EPT\_x (reset endpoint) and by UDPHS\_EPTCTLDISx (disable endpoint).

**Bit 11 – TXRDY\_TRER** TX Packet Ready/Transaction Error (cleared upon USB reset)

**TX Packet Ready**

This bit is cleared by hardware, as soon as the packet has been sent.

For Multi-bank endpoints, this bit may remain clear even after software is set if another bank is available to transmit.

Hardware clear of this bit may generate an interrupt if enabled by the UDPHS\_EPTCTLx register TXRDY\_TRER bit.

This bit is reset by UDPHS\_EPTRST register EPT\_x (reset endpoint), and by UDPHS\_EPTCTLDISx (disable endpoint).

**Transaction Error (for high bandwidth isochronous OUT endpoints) (Read-Only):**

This bit is set by hardware when a transaction error occurs inside one microframe.

If one toggle sequencing problem occurs among the n-transactions (n = 1, 2 or 3) inside a microframe, then this bit is still set as long as the current bank contains one “bad” n-transaction (see CURBK field description). As soon as the current bank is relative to a new “good” n-transactions, then this bit is reset.

**Note:**

1. A transaction error occurs when the toggle sequencing does not comply with the Universal Serial Bus Specification, Rev 2.0 (5.9.2 High Bandwidth Isochronous endpoints) (Bad PID, missing data, etc.)
2. When a transaction error occurs, the user may empty all the “bad” transactions by clearing the Received OUT Data flag (RXRDY\_TXKL).

If this bit is reset, then the user should consider that a new n-transaction is coming.

This bit is reset by UDPHS\_EPTRST register EPT\_x (reset endpoint), and by UDPHS\_EPTCTLDISx (disable endpoint).

**Bit 10 – TX\_COMPLT** Transmitted IN Data Complete (cleared upon USB reset)

This bit is set by hardware after an IN packet has been sent.

This bit is reset by UDPHS\_EPTRST register EPT\_x (reset endpoint), and by UDPHS\_EPTCTLDISx (disable endpoint).

**Bit 9 – RXRDY\_TXKL** Received OUT Data/KILL Bank (cleared upon USB reset)

**Received OUT Data (for OUT endpoint or Control endpoint):**

- This bit is set by hardware after a new packet has been stored in the endpoint FIFO.
- This bit is cleared by the device firmware after reading the OUT data from the endpoint.
- For multi-bank endpoints, this bit may remain active even when cleared by the device firmware, this if an other packet has been received meanwhile.
- Hardware assertion of this bit may generate an interrupt if enabled by the UDPHS\_EPTCTLx register RXRDY\_TXKL bit.
- This bit is reset by UDPHS\_EPTRST register EPT\_x (reset endpoint) and by UDPHS\_EPTCTLDISx (disable endpoint).

**KILL Bank (for IN endpoint):**

- The bank is really cleared or the bank is sent, BUSY\_BANK\_STA is decremented.

- The bank is not cleared but sent on the IN transfer, TX\_COMPLT
- The bank is not cleared because it was empty. The user should wait that this bit is cleared before trying to clear another packet.  
**Note:** “Kill a packet” may be refused if at the same time, an IN token is coming and the current packet is sent on the UDPHS line. In this case, the TX\_COMPLT bit is set. Take notice however, that if at least two banks are ready to be sent, there is no problem to kill a packet even if an IN token is coming. In fact, in that case, the current bank is sent (IN transfer) and the last bank is killed.

**Bit 8 – ERR\_OVFLW** Overflow Error (cleared upon USB reset)

This bit is set by hardware when a new too-long packet is received.

Example: If the user programs an endpoint 64 bytes wide and the host sends 128 bytes in an OUT transfer, then the Overflow Error bit is set.

This bit is updated at the same time as the BYTE\_COUNT field.

This bit is reset by UDPHS\_EPTRST register EPT\_x (reset endpoint) and by UDPHS\_EPTCTLDISx (disable endpoint).

**Bits 7:6 – TOGGLESQ\_STA[1:0]** Toggle Sequencing (cleared upon USB reset)

In OUT transfer, the Toggle information is meaningful only when the current bank is busy (Received OUT Data = 1).

This field is updated for OUT transfer:

- A new data has been written into the current bank.
- The user has just cleared the Received OUT Data bit to switch to the next bank.

For High Bandwidth Isochronous Out endpoint, it is recommended to check the UDPHS\_EPTSTAx/ TXRDY\_TRER bit to know if the toggle sequencing is correct or not.

This field is reset to DATA1 by the UDPHS\_EPTCLRSTAx register TOGGLESQ bit, and by UDPHS\_EPTCTLDISx (disable endpoint).

Toggle Sequencing:

- IN endpoint: Indicates the PID Data Toggle that will be used for the next packet sent. This is not relative to the current bank.
- OUT endpoint: Set by hardware to indicate the PID data of the current bank:

| Value | Name  | Description  |
|-------|-------|--|
| 0     | DATA0 | DATA0  |
| 1     | DATA1 | DATA1  |
| 2     | DATA2 | Data2 (only for High Bandwidth Isochronous Endpoint) |
| 3     | MDATA | MData (only for High Bandwidth Isochronous Endpoint) |

### 40.7.21 UDPHS DMA Channel Transfer Descriptor

The DMA channel transfer descriptor is loaded from the memory. Be careful with the alignment of this buffer. The structure of the DMA channel transfer descriptor is defined by three parameters as described below:

- Offset 0:
  - The address must be aligned: 0xXXXXX0
  - Next Descriptor Address Register: UDPHS\_DMANXTDSCx

- Offset 4:
  - The address must be aligned: 0xXXXX4
  - DMA Channelx Address Register: UDPHS\_DMAADDRESSx
- Offset 8:
  - The address must be aligned: 0xXXXX8
  - DMA Channelx Control Register: UDPHS\_DMACONTROLx

To use the DMA channel transfer descriptor, fill the structures with the correct value (as described in the following pages). Then write directly in UDPHS\_DMANTDSCx the address of the descriptor to be used first. Then write '1' in the LDNXT\_DSC bit of UDPHS\_DMACONTROLx (load next channel transfer descriptor). The descriptor is automatically loaded upon Endpointx request for packet transfer.

### 40.7.22 UDPHS DMA Next Descriptor Address Register

**Name:** UDPHS\_DMANXTDSCx  
**Offset:** 0x0300 + x\*0x10 [x=0..6]  
**Reset:** 0x00000000  
**Property:** Read/Write

Channel 0 is not used.

|        |     | BUFF_ADD[7:0]   |     |     |     |     |     |     |     |
| Access |     | R/W             | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  |     | 0               | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

#### Bits 31:0 – BUFF\_ADD[31:0] Buffer Address

This field determines the AHB bus starting address of a DMA channel transfer.

Channel start and end addresses may be aligned on any byte boundary.

The firmware may write this field only when the UDPHS\_DMASTATUS register CHANN\_ENB bit is clear.

This field is updated at the end of the address phase of the current access to the AHB bus. It is incrementing of the access byte width. The access width is 4 bytes (or less) at packet start or end, if the start or end address is not aligned on a word boundary.

The packet start address is either the channel start address or the next channel address to be accessed in the channel buffer.

The packet end address is either the channel end address or the latest channel address accessed in the channel buffer.

The channel start address is written by software or loaded from the descriptor, whereas the channel end address is either determined by the end of buffer or the UDPHS device, USB end of transfer if the UDPHS\_DMACONTROLx register END\_TR\_EN bit is set.

### 40.7.24 UDPHS DMA Channel Control Register

**Name:** UDPHS\_DMACONTROLx  
**Offset:** 0x0308 + x\*0x10 [x=0..6]  
**Reset:** 0x00000000  
**Property:** Read/Write

Channel 0 is not used.

Bits [31:2] are only writable when issuing a channel Control Command other than “Stop Now”.

For reliability it is highly recommended to wait for both UDPHS\_DMASTATUS.CHAN\_ACT and CHAN\_ENB flags at 0, thus ensuring the channel has been stopped before issuing a command other than “Stop Now”.

|        |     |                   |            |            |           |          |           |           |           |
|--------|-----|-------------------|------------|------------|-----------|----------|-----------|-----------|-----------|
|        | Bit | 31                | 30         | 29         | 28        | 27       | 26        | 25        | 24        |
|        |     | BUFF_LENGTH[15:8] |            |            |           |          |           |           |           |
| Access |     | R/W               | R/W        | R/W        | R/W       | R/W      | R/W       | R/W       | R/W       |
| Reset  |     | 0                 | 0          | 0          | 0         | 0        | 0         | 0         | 0         |
|        |     |                   |            |            |           |          |           |           |           |
|        | Bit | 23                | 22         | 21         | 20        | 19       | 18        | 17        | 16        |
|        |     | BUFF_LENGTH[7:0]  |            |            |           |          |           |           |           |
| Access |     | R/W               | R/W        | R/W        | R/W       | R/W      | R/W       | R/W       | R/W       |
| Reset  |     | 0                 | 0          | 0          | 0         | 0        | 0         | 0         | 0         |
|        |     |                   |            |            |           |          |           |           |           |
|        | Bit | 15                | 14         | 13         | 12        | 11       | 10        | 9         | 8         |

| Access |     |                   |            |            |           |          |           |           |           |
| Reset  |     |                   |            |            |           |          |           |           |           |
|        |     |                   |            |            |           |          |           |           |           |
|        | Bit | 7                 | 6          | 5          | 4         | 3        | 2         | 1         | 0         |
|        |     | BURST_LCK         | DESC_LD_IT | END_BUFFIT | END_TR_IT | END_B_EN | END_TR_EN | LDNXT_DSC | CHANN_ENB |
| Access |     | R/W               | R/W        | R/W        | R/W       | R/W      | R/W       | R/W       | R/W       |
| Reset  |     | 0                 | 0          | 0          | 0         | 0        | 0         | 0         | 0         |

**Bits 31:16 – BUFF\_LENGTH[15:0]** Buffer Byte Length (Write-only)

This field determines the number of bytes to be transferred until end of buffer. The maximum channel transfer size (64 KBytes) is reached when this field is 0 (default value). If the transfer size is unknown, this field should be set to 0, but the transfer end may occur earlier under UDPHS device control.

When this field is written, the UDPHS\_DMASTATUS.BUFF\_COUNT field is updated with the write value.

**Bit 7 – BURST\_LCK** Burst Lock Enable

| Value | Description   |
|-------|---|
| 0     | The DMA never locks bus access.   |
| 1     | USB packets AHB data bursts are locked for maximum optimization of the bus bandwidth usage and maximization of fly-by AHB burst duration. |

**Bit 6 – DESC\_LD\_IT** Descriptor Loaded Interrupt Enable

# SAMA5D2 Series

## USB High Speed Device Port (UDPHS)

| Value | Description   |
|-------|---|
| 0     | UDPHS_DMASTATUS.DESC_LDST rising will not trigger any interrupt.          |
| 1     | An interrupt is generated when a descriptor has been loaded from the bus. |

### Bit 5 – END\_BUFFIT End of Buffer Interrupt Enable

| Value | Description   |
|-------|---|
| 0     | UDPHS_DMASTATUS.END_BF_ST rising will not trigger any interrupt.            |
| 1     | An interrupt is generated when the UDPHS_DMASTATUS.BUFF_COUNT reaches zero. |

### Bit 4 – END\_TR\_IT End of Transfer Interrupt Enable

| Value | Description   |
|-------|---|
| 0     | UDPHS device initiated buffer transfer completion will not trigger any interrupt at UDPHS_STATUS.END_TR_ST rising.  |
| 1     | An interrupt is sent after the buffer transfer is complete, if the UDPHS device has ended the buffer transfer.<br><br>Use when the receive size is unknown. |

### Bit 3 – END\_B\_EN End of Buffer Enable (Control)

| Value | Description  |
|-------|--|
| 0     | DMA Buffer End has no impact on USB packet transfer.   |
| 1     | Endpoint can validate the packet (according to the values programmed in the UDPHS_EPTCTL.AUTO_VALID and SHRT_PCKT fields) at DMA Buffer End, i.e., when the UDPHS_DMASTATUS.BUFF_COUNT reaches 0.<br><br>This is mainly for short packet IN validation initiated by the DMA reaching end of buffer, but could be used for OUT packet truncation (discarding of unwanted packet data) at the end of DMA buffer. |

### Bit 2 – END\_TR\_EN End of Transfer Enable (Control)

Used for OUT transfers only.

| Value | Description  |
|-------|--|
| 0     | USB end of transfer is ignored.  |
| 1     | UDPHS device can put an end to the current buffer transfer.<br><br>When set, a BULK or INTERRUPT short packet or the last packet of an ISOCHRONOUS (micro) frame (DATAx) will close the current buffer and the UDPHS_DMASTATUS.END_TR_ST flag will be raised.<br><br>This is intended for UDPHS non-prenegotiated end of transfer (BULK or INTERRUPT) or ISOCHRONOUS microframe data buffer closure. |

### Bit 1 – LDNXT\_DSC Load Next Channel Transfer Descriptor Enable (Command)

0: No channel register is loaded after the end of the channel transfer.

1: The channel controller loads the next descriptor after the end of the current transfer, i.e., when the UDPHS\_DMASTATUS/CHANN\_ENB bit is reset.

If CHANN\_ENB is cleared, the next descriptor is immediately loaded upon transfer request.

DMA Channel Control Command Summary

# SAMA5D2 Series

## USB High Speed Device Port (UDPHS)

| LDNXT_DSC | CHANN_ENB | Description                   |
|-----------|-----------|-------------------------------|
| 0         | 0         | Stop now                      |
| 0         | 1         | Run and stop at end of buffer |
| 1         | 0         | Load next descriptor now      |
| 1         | 1         | Run and link at end of buffer |

### Bit 0 – CHANN\_ENB (Channel Enable Command)

| Value | Description   |
|-------|---|
| 0     | <p>DMA channel is disabled at and no transfer will occur upon request. This bit is also cleared by hardware when the channel source bus is disabled at end of buffer.</p> <p>If the UDPHS_DMACONTROL register LDNXT_DSC bit has been cleared by descriptor loading, the firmware will have to set the corresponding CHANN_ENB bit to start the described transfer, if needed.</p> <p>If the UDPHS_DMACONTROL register LDNXT_DSC bit is cleared, the channel is frozen and the channel registers may then be read and/or written reliably as soon as both UDPHS_DMASTATUS register CHANN_ENB and CHANN_ACT flags read as 0.</p> <p>If a channel request is currently serviced when this bit is cleared, the DMA FIFO buffer is drained until it is empty, then the UDPHS_DMASTATUS register CHANN_ENB bit is cleared.</p> <p>If the LDNXT_DSC bit is set at or after this bit clearing, then the currently loaded descriptor is skipped (no data transfer occurs) and the next descriptor is immediately loaded.</p> |
| 1     | <p>UDPHS_DMASTATUS register CHANN_ENB bit will be set, thus enabling DMA channel data transfer. Then any pending request will start the transfer. This may be used to start or resume any requested transfer.</p>   |

#### 40.7.25 UDPHS DMA Channel Status Register

**Name:**        UDPHS\_DMASTATUSx  
**Offset:**     0x030C + x\*0x10 [x=0..6]  
**Reset:**       0x00000000  
**Property:**   Read/Write

Channel 0 is not used.

|        |     |                  |    |           |           |    |    |           |           |
|--------|-----|------------------|----|-----------|-----------|----|----|-----------|-----------|

|        |     | BUFF_COUNT[15:8] |    |           |           |    |    |           |           |
| Access |     |                  |    |           |           |    |    |           |           |
| Reset  |     | 0                | 0  | 0         | 0         | 0  | 0  | 0         | 0         |
|        | Bit | 23               | 22 | 21        | 20        | 19 | 18 | 17        | 16        |
|        |     | BUFF_COUNT[7:0]  |    |           |           |    |    |           |           |
| Access |     |                  |    |           |           |    |    |           |           |
| Reset  |     | 0                | 0  | 0         | 0         | 0  | 0  | 0         | 0         |
|        | Bit | 15               | 14 | 13        | 12        | 11 | 10 | 9         | 8         |
|        |     |                  |    |           |           |    |    |           |           |
| Access |     |                  |    |           |           |    |    |           |           |
| Reset  |     |                  |    |           |           |    |    |           |           |
|        | Bit | 7                | 6  | 5         | 4         | 3  | 2  | 1         | 0         |
|        |     | DESC_LDST        |    | END_BF_ST | END_TR_ST |    |    | CHANN_ACT | CHANN_ENB |
| Access |     |                  |    |           |           |    |    |           |           |
| Reset  |     | 0                | 0  | 0         | 0         | 0  | 0  | 0         | 0         |

**Bits 31:16 – BUFF\_COUNT[15:0]** Buffer Byte Count

This field determines the current number of bytes still to be transferred for this buffer.

This field is decremented from the AHB source bus access byte width at the end of this bus address phase.

The access byte width is 4 by default, or less, at DMA start or end, if the start or end address is not aligned on a word boundary.

At the end of buffer, the DMA accesses the UDPHS device only for the number of bytes needed to complete it.

This field value is reliable (stable) only if the channel has been stopped or frozen (UDPHS\_EPTCTLx register NT\_DIS\_DMA bit is used to disable the channel request) and the channel is no longer active CHANN\_ACT flag is 0.

**Note:** For OUT endpoints, if the receive buffer byte length (BUFF\_LENGTH) has been defaulted to zero because the USB transfer length is unknown, the actual buffer byte length received is 0x10000-BUFF\_COUNT.

**Bit 6 – DESC\_LDST** Descriptor Loaded Status

Valid until the CHANN\_ENB flag is cleared at the end of the next buffer transfer.

# SAMA5D2 Series

## USB High Speed Device Port (UDPHS)

| Value | Description  |
|-------|--|
| 0     | Cleared automatically when read by software.                           |
| 1     | Set by hardware when a descriptor has been loaded from the system bus. |

### Bit 5 – END\_BF\_ST End of Channel Buffer Status

Valid until the CHANN\_ENB flag is cleared at the end of the next buffer transfer.

| Value | Description   |
|-------|---|
| 0     | Cleared automatically when read by software.                |
| 1     | Set by hardware when the BUFF_COUNT countdown reaches zero. |

### Bit 4 – END\_TR\_ST End of Channel Transfer Status

Valid until the CHANN\_ENB flag is cleared at the end of the next buffer transfer.

| Value | Description  |
|-------|--|
| 0     | Cleared automatically when read by software.   |
| 1     | Set by hardware when the last packet transfer is complete, if the UDPHS device has ended the transfer. |

### Bit 1 – CHANN\_ACT Channel Active Status

When a packet transfer is ended this bit is automatically reset.

When a packet transfer cannot be completed due to an END\_BF\_ST, this flag stays set during the next channel descriptor load (if any) and potentially until UDPHS packet transfer completion, if allowed by the new descriptor.

| Value | Description   |
|-------|---|
| 0     | The DMA channel is no longer trying to source the packet data.  |
| 1     | The DMA channel is currently trying to source packet data, i.e., selected as the highest-priority requesting channel. |

### Bit 0 – CHANN\_ENB Channel Enable Status

When any transfer is ended either due to an elapsed byte count or a UDPHS device initiated transfer end, this bit is automatically reset.

This bit is normally set or cleared by writing into the UDPHS\_DMACONTROLx register CHANN\_ENB bit either by software or descriptor loading.

If a channel request is currently serviced when the UDPHS\_DMACONTROLx register CHANN\_ENB bit is cleared, the DMA FIFO buffer is drained until it is empty, then this status bit is cleared.

| Value | Description  |
|-------|--|
| 0     | The DMA channel no longer transfers data, and may load the next descriptor if the UDPHS_DMACONTROLx register LDNXT_DSC bit is set. |
| 1     | The DMA channel is currently enabled and transfers data upon request.  |

## **41. USB Host High Speed Port (UHPHS)**

### **41.1 Description**

The USB Host High Speed Port (UHPHS) interfaces the USB with the host application. It handles Open HCI protocol (Open Host Controller Interface) as well as Enhanced HCI protocol (Enhanced Host Controller Interface).

### **41.2 Embedded Characteristics**

- Compliant with Enhanced HCI Rev 1.0 Specification
  - Compliant with USB V2.0 High-speed
  - Supports High-speed 480 Mbps
- Compliant with Open HCI Rev 1.0 Specification
  - Compliant with USB V2.0 Full-speed and Low-speed Specification
  - Supports both Low-speed 1.5 Mbps and Full-speed 12 Mbps USB devices
- Root Hub Integrated with 3 Downstream USB HS Ports
- Embedded USB Transceivers
- Supports Power Management
- 3 Hosts (A, B and C) High Speed (EHCI), Port A shared with UHPHS
  - 1 Host (C) High Speed Inter-Chip Only (HSIC)

### 41.3 Block Diagram

**Figure 41-1. Block Diagram**

Access to the USB host operational registers is achieved through the system bus slave interface. The Open HCI host controller and Enhanced HCI host controller initialize master DMA transfers through the system bus master interface as follows:

- Fetches endpoint descriptors and transfer descriptors
- Access to endpoint data from system memory
- Access to the HC communication area
- Write status and retire transfer descriptor

Memory access errors (abort, misalignment) lead to an “Unrecoverable Error” indicated by the corresponding flag in the host controller operational registers.

The USB root hub is integrated in the USB host. Several USB downstream ports are available. The number of downstream ports can be determined by the software driver reading the root hub’s operational registers. Device connection is automatically detected by the USB host port logic.

USB physical transceivers are integrated in the product and driven by the root hub’s ports.

## 41.4 Typical Connection

**Figure 41-2. Board Schematic to Interface UHP High-speed Host Controller**

## 41.5 Product Dependencies

### 41.5.1 I/O Lines

HFSDPs, HFSDMs, HHSDPs and HHSDMs are not controlled by any PIO controllers. The embedded USB High Speed physical transceivers are controlled by the USB host controller.

One transceiver is shared with the USB High Speed Device (port A). The selection between Host Port A and USB Device is controlled by the UPHS enable bit (EN\_UDPHS) located in the UPHS\_CTRL register.

In the case the port A is driven by the USB High Speed Device, the output signals are DFSDP, DFSDM, DHSDP and DHSDM. The transceiver is automatically selected for Device operation once the USB High Speed Device is enabled.

In the case the port A is driven by the USB High Speed Host, the output signals are HFSDPA, HFSDMA, HHSDPA and HHSDMA.

### 41.5.2 Power Management

The system embeds 3 transceivers.

The USB Host High Speed requires a 480 MHz clock for the embedded High-speed transceivers. This clock (UPLLCK) is provided by the UTMI PLL.

In case power consumption is saved by stopping the UTMI PLL, high-speed operations are not possible. Nevertheless, OHCI Full-speed operations remain possible by selecting PLLACK as the input clock of OHCI.

The High-speed transceiver returns a 30 MHz clock to the USB Host controller.

The USB Host controller requires 48 MHz and 12 MHz clocks for OHCI full-speed operations. These clocks must be generated by a PLL with a correct accuracy of +/-0.25% using the USBDIV field.

# SAMA5D2 Series

## USB Host High Speed Port (UHPHS)

Thus the USB Host peripheral receives three clocks from the Power Management Controller (PMC): the Peripheral Clock (MCK domain), the UHP48M and the UHP12M (built-in UHP48M divided by four) used by the OHCI to interface with the bus USB signals (recovered 12 MHz domain) in Full-speed operations.

For High-speed operations, the user has to perform the following:

- Enable UHP peripheral clock in PMC\_PCER.
- Write PLLCOUNT field in CKGR\_UCKR.
- Enable UPLL with UPLLEN bit in CKGR\_UCKR.
- Wait until UTMI\_PLL is locked (LOCKU bit in PMC\_SR).
- Select UPLLCK as Input clock of OHCI part (USBS bit in PMC\_USB register).
- Program OHCI clocks (UHP48M and UHP12M) with USBDIV field in PMC\_USB register. USBDIV must be 9 (division by 10) if UPLLCK is selected.
- Enable OHCI clocks with UHP bit in PMC\_SCER.

For OHCI Full-speed operations only, the user has to perform the following:

- Enable UHP peripheral clock in PMC\_PCER.
- Select PLLACK as Input clock of OHCI part (USBS bit in PMC\_USB register).
- Program OHCI clocks (UHP48M and UHP12M) with USBDIV field in PMC\_USB register. USBDIV value is to be calculated according to the PLLACK value and USB Full-speed accuracy.
- Enable the OHCI clocks with UHP bit in PMC\_SCER.

**Figure 41-3. UHP Clock Trees**

### 41.5.3 Interrupt Sources

The USB host interface has an interrupt line connected to the interrupt controller.

Handling USB host interrupts requires programming the interrupt controller before configuring the UHPHS.

## 41.6 Functional Description

### 41.6.1 UTMI Transceivers Sharing

The High Speed USB Host Port A is shared with the High Speed USB Device port and connected to the second UTMI transceiver. The selection between Host Port A and USB device is controlled by the UDPHS enable bit (EN\_UDPHS) located in the UDPHS\_CTRL register.

**Figure 41-4. USB Selection**

### 41.6.2 EHCI

The USB Host Port controller is fully compliant with the Enhanced HCI specification. The USB Host Port User Interface (registers description) can be found in the Enhanced HCI Rev 1.0 Specification available on [www.usb.org](http://www.usb.org)

### 41.6.3 OHCI

The USB Host Port integrates a root hub and transceivers on downstream ports. It provides several Full-speed half-duplex serial communication ports at a baud rate of 12 Mbps. Up to 127 USB devices (printer, camera, mouse, keyboard, disk, etc.) and the USB hub can be connected to the USB host in the USB “tiered star” topology.

The USB Host Port controller is fully compliant with the Open HCI specification. The USB Host Port User Interface (registers description) can be found in the Open HCI Rev 1.0 Specification available on [www.usb.org](http://www.usb.org).

All standard class devices are automatically detected and available to the user's application. As an example, integrating an HID (Human Interface Device) class driver provides a plug & play feature for all USB keyboards and mice.

### 41.6.4 HSIC

The High-Speed Inter-Chip (HSIC) is a standard for USB chip-to-chip interconnect with a 2-signal (strobe, data) source synchronous serial interface using 240 MHz DDR signaling to provide only high-speed 480 Mbps data rate.

External cables, connectors and hot plug & play are not supported.

# **SAMA5D2 Series**

## **USB Host High Speed Port (UHPHS)**

---

---

The HSIC interface operates at high speed, 480 Mbps, and is fully compatible with existing USB software stacks. It meets all data transfer needs through a single unified USB software stack.

### 41.7 Register Summary

The Enhanced USB Host Controller contains two sets of software-accessible hardware registers: memory-mapped Host Controller Registers and optional PCI configuration registers. Note that the PCI configuration registers are only needed for PCI devices that implement the Host Controller.

- Memory-mapped USB Host Controller Registers—This block of registers is memory-mapped into non-cacheable memory. This memory space must begin on a DWord (32-bit) boundary. This register space is divided into two sections: a set of read-only capability registers and a set of read/write operational registers. The table below describes each register space.  
**Note:** Host controllers are not required to support exclusive-access mechanisms (such as PCI LOCK) for accesses to the memory-mapped register space. Therefore, if software attempts exclusive-access mechanisms to the host controller memory-mapped register space, the results are undefined.
- PCI Configuration Registers (for PCI devices)—In addition to the normal PCI header, power management, and device-specific registers, two registers are needed in the PCI configuration space to support USB. The normal PCI header and device-specific registers are beyond the scope of this document (the UHPHS\_CLASSC register is shown in this document). Note that HCD does not interact with the PCI configuration space. This space is used only by the PCI enumerator to identify the USB Host Controller, and assign the appropriate system resources.  
 The table below summarizes the enhanced interface register sets.

| Offset     | Register Set          | Explanation   |
|------------|-----------------------|---|
| 0 to N-1   | Capability Registers  | The capability registers specify the limits, restrictions, and capabilities of a host controller implementation. These values are used as parameters to the host controller driver. |
| N to N+M-1 | Operational Registers | The operational registers are used by system software to control and monitor the operational state of the host controller.  |

**Note:** Software must not modify reserved bits in Read/Write registers.

| Offset              | Name            | Bit Pos. |                 |  |     |              |      |      |             |  |

|        | CAPLENGTH[7:0]   |    |    |    |    |    |    |    |
| Access | R                | R  | R  | R  | R  | R  | R  | R  |
| Reset  | 0                | 0  | 0  | 1  | 0  | 0  | 0  | 0  |

**Bits 31:16 – HCIVERSION[15:0]** Host Controller Interface Version Number

This is a two-byte field containing a BCD encoding of the EHCI revision number supported by this host controller. The most significant byte of this field represents the major revision and the least significant byte the minor revision.

**Bits 7:0 – CAPLENGTH[7:0]** Capability Registers Length

This field is used as an offset to add to the register base to find the beginning of the Operational Register Space.

### 41.7.2 UHPHS Host Controller Structural Parameters Register

**Name:** UHPHS\_HCSPARAMS  
**Offset:** 0x04  
**Reset:** 0x00001116  
**Property:** Read-only

These fields define structural parameters: number of downstream ports, etc.

|        |     |           |    |    |     |              |    |    |             |  |
|--------|-----|-----------|----|----|-----|--------------|----|----|-------------|--|
|        | Bit | 31        | 30 | 29 | 28  | 27           | 26 | 25 | 24          |  |
|        |     |           |    |    |     |              |    |    |             |  |
| Access |     |           |    |    |     |              |    |    |             |  |
| Reset  |     |           |    |    |     |              |    |    |             |  |
|        |     |           |    |    |     |              |    |    |             |  |
|        | Bit | 23        | 22 | 21 | 20  | 19           | 18 | 17 | 16          |  |
|        |     | N_DP[3:0] |    |    |     |              |    |    | P_INDICATOR |  |
| Access |     | R         | R  | R  | R   |              |    |    | R           |  |
| Reset  |     | 0         | 0  | 0  | 0   |              |    |    | 0           |  |
|        |     |           |    |    |     |              |    |    |             |  |
|        | Bit | 15        | 14 | 13 | 12  | 11           | 10 | 9  | 8           |  |
|        |     | N_CC[3:0] |    |    |     | N_PCC[3:0]   |    |    |             |  |
| Access |     | R         | R  | R  | R   | R            | R  | R  | R           |  |
| Reset  |     | 0         | 0  | 0  | 1   | 0            | 0  | 0  | 1           |  |
|        |     |           |    |    |     |              |    |    |             |  |
|        | Bit | 7         | 6  | 5  | 4   | 3            | 2  | 1  | 0           |  |
|        |     |           |    |    | PPC | N_PORTS[3:0] |    |    |             |  |
| Access |     |           |    |    | R   | R            | R  | R  | R           |  |
| Reset  |     |           |    |    | 1   | 0            | 1  | 1  | 0           |  |

**Bits 23:20 – N\_DP[3:0]** Debug Port Number

Optional. This register identifies which of the host controller ports is the debug port. The value is the port number (1-based) of the debug port. A non-zero value in this field indicates the presence of a debug port. The value in this register must not be greater than N\_PORTS (see above).

**Bit 16 – P\_INDICATOR** Port Indicators

This bit indicates whether the ports support port indicator control. When this bit is a 1, the port status and control registers include a read/writeable field for controlling the state of the port indicator. See [UHPHS Port Status and Control Register](#) for a definition of the port indicator control field.

**Bits 15:12 – N\_CC[3:0]** Number of Companion Controllers

This field indicates the number of companion controllers associated with this USB 2.0 host controller.

A zero in this field indicates there are no companion host controllers. Port-ownership hand-off is not supported. Only high-speed devices are supported on the host controller root ports.

A value larger than zero in this field indicates there are companion USB 1.1 host controller(s). Port-ownership hand-offs are supported. High, Full- and Low-speed devices are supported on the host controller root ports.

**Bits 11:8 – N\_PCC[3:0] Number of Ports per Companion Controller**

This field indicates the number of ports supported per companion host controller. It is used to indicate the port routing configuration to system software.

For example, if N\_PORTS has a value of 6 and N\_CC has a value of 2, then N\_PCC could have a value of 3. The convention is that the first N\_PCC ports are assumed to be routed to companion controller 1, the next N\_PCC ports to companion controller 2, etc. In the previous example, the N\_PCC could have been 4, where the first four are routed to companion controller 1 and the last two are routed to companion controller 2.

The number in this field must be consistent with N\_PORTS and N\_CC.

**Bit 4 – PPC Port Power Control**

This field indicates whether the host controller implementation includes port power control. A one in this bit indicates the ports have port power switches. A zero in this bit indicates the ports do not have port power switches. The value of this field affects the functionality of the Port Power field in each port status and control register (see [UHPHS Port Status and Control Register](#)).

**Bits 3:0 – N\_PORTS[3:0] Number of Ports**

This field specifies the number of physical downstream ports implemented on this host controller. The value of this field determines how many port registers are addressable in the Operational Register Space. Valid values are in the range of 1 to 15.

A zero in this field is undefined.

### 41.7.3 UHPHS Host Controller Capability Parameters Register

**Name:** UHPHS\_HCCPARAMS  
**Offset:** 0x08  
**Reset:** 0x0000A010  
**Property:** Read-only

These fields define capability parameters: Multiple Mode control (time-base bit functionality), addressing capability, etc.

|        |     |                         |    |    |    |                    |      |      |    |
|--------|-----|-------------------------|----|----|----|--------------------|------|------|----|

|        |     | EECP[7:0]               |    |    |    |                    |      |      |    |
| Access | R   | R                       | R  | R  | R  | R                  | R    | R    | R  |
| Reset  | 1   | 0                       | 1  | 0  | 0  | 0                  | 0    | 0    | 0  |
|        | Bit | 7                       | 6  | 5  | 4  | 3                  | 2    | 1    | 0  |
|        |     | IST[3:0]                |    |    |    | [Grayed out bit 3] | ASPC | PFLF | AC |
| Access | R   | R                       | R  | R  |    | R                  | R    | R    |    |
| Reset  | 0   | 0                       | 0  | 1  |    | 0                  | 0    | 0    |    |

**Bits 15:8 – EECP[7:0]** EHCI Extended Capabilities Pointer

Indicates the existence of a capabilities list. A value of 0 indicates no extended capabilities are implemented. A non-zero value in this register indicates the offset in the PCI configuration space of the first EHCI extended capability. The pointer value must be 64 or greater if implemented to maintain the consistency of the PCI header defined for this class of device.

**Bits 7:4 – IST[3:0]** Isochronous Scheduling Threshold

Indicates, relative to the current position of the executing host controller, where software can reliably update the isochronous schedule. When bit [7] is 0, the value of the least significant three bits indicates the number of microframes a host controller can hold a set of isochronous data structures (one or more) before flushing the state. When bit [7] is set to 1, the host software assumes the host controller may cache an isochronous data structure for an entire frame.

**Bit 2 – ASPC** Asynchronous Schedule Park Capability

The park capability can be disabled or enabled and set to a specific level by using the Asynchronous Schedule Park Mode Enable and Asynchronous Schedule Park Mode Count fields in the UHPHS\_USBCMD register.

| Value | Description  |
|-------|--|
| 0     | Host controller does not supports the park feature for high-speed queue. |

# SAMA5D2 Series

## USB Host High Speed Port (UHPHS)

| Value | Description  |
|-------|--|
| 1     | Host controller supports the park feature for high-speed queue heads in the Asynchronous Schedule. |

### Bit 1 – PFLF Programmable Frame List Flag

| Value | Description   |
|-------|---|
| 0     | System software must use a frame list length of 1024 elements with this host controller. The UHPHS_USBCMD register Frame List Size field is a read-only register and must be set to 0.  |
| 1     | System software can specify and use a smaller frame list and configure the host controller via the UHPHS_USBCMD register Frame List Size field. The frame list must always be aligned on a 4-Kbyte page boundary. This requirement ensures that the frame list is always physically contiguous. |

### Bit 0 – AC 64-bit Addressing Capability

This field documents the addressing range capability of this implementation. The value of this field determines whether software should use 32-bit or 64-bit data structures.

This information is not tightly coupled with the UHPHS\_USBBASE address register mapping control. The 64-bit Addressing Capability bit indicates whether the host controller can generate 64-bit addresses as a master. The UHPHS\_USBBASE register indicates the host controller only needs to decode 32-bit addresses as a slave.

| Value | Description  |
|-------|--|
| 0     | Data structures using 32-bit address memory pointers |
| 1     | Data structures using 64-bit address memory pointers |

### 41.7.4 UHPHS USB Command Register

**Name:** UHPHS\_USBCMD  
**Offset:** 0x10  
**Reset:** 0x00080B00  
**Property:** Read/Write

The Command Register indicates the command to be executed by the serial bus host controller. Writing to the register causes a command to be executed.

|        |          |      |     |     |          |    |         |            |   |
|--------|----------|------|-----|-----|----------|----|---------|------------|---|
| Bit    | 31       | 30   | 29  | 28  | 27       | 26 | 25      | 24         |   |
| Access |          |      |     |     |          |    |         |            |   |
| Reset  |          |      |     |     |          |    |         |            |   |
| Bit    | 23       | 22   | 21  | 20  | 19       | 18 | 17      | 16         |   |
| Access | ITC[7:0] |      |     |     |          |    |         |            |   |
| Reset  | 0        | 0    | 0   | 0   | 1        | 0  | 0       | 0          |   |
| Bit    | 15       | 14   | 13  | 12  | 11       | 10 | 9       | 8          |   |
| Access |          |      |     |     | ASPME    |    |         | ASPM[C1:0] |   |
| Reset  |          |      |     |     | 1        |    |         | 1          | 1 |
| Bit    | 7        | 6    | 5   | 4   | 3        | 2  | 1       | 0          |   |
| Access | LHCR     | IAAD | ASE | PSE | FLS[1:0] |    | HCRESET | RS         |   |
| Reset  | 0        | 0    | 0   | 0   | 0        | 0  | 0       | 0          |   |

#### Bits 23:16 – ITC[7:0] Interrupt Threshold Control

This field is used by system software to select the maximum rate at which the host controller will issue interrupts. The only valid values are defined below. If software writes an invalid value to this register, the results are undefined.

| Value | Maximum Interrupt Interval |
|-------|----------------------------|
| 0     | Reserved                   |
| 1     | 1 microframe               |
| 2     | 2 microframes              |
| 4     | 4 microframes              |
| 8     | 8 microframes (1 ms)       |
| 16    | 16 microframes (2 ms)      |
| 32    | 32 microframes (4 ms)      |
| 64    | 64 microframes (8 ms)      |

Any other value in this register yields undefined results.

Software modifications to this field while HCHLT=0 results in undefined behavior.

**Bit 11 – ASPME** Asynchronous Schedule Park Mode Enable (optional)

If the Asynchronous Park Capability bit in the UHPHS\_HCCPARAMS register is set to 1, then this bit is set to 1 and is Read/Write. Otherwise the bit must be 0 and is read-only.

| Value | Description            |
|-------|------------------------|
| 0     | Park mode is enabled.  |
| 1     | Park mode is disabled. |

**Bits 9:8 – ASPMC[1:0]** Asynchronous Schedule Park Mode Count (optional)

If the Asynchronous Park Capability bit in the UHPHS\_HCCPARAMS register is set to 1, then this field defaults to 3 and is read/write. Otherwise it defaults to 0 and is read-only. It contains a count of the number of successive transactions the host controller is allowed to execute from a high-speed queue head on the Asynchronous schedule before continuing traversal of the Asynchronous schedule. Valid values are 1 to 3. Software must not write a 0 to this bit when Park Mode Enable is set to 1 as this will result in undefined behavior.

**Bit 7 – LHCR** Light Host Controller Reset (optional)

This control bit is not required. If implemented, it allows the driver to reset the EHCI controller without affecting the state of the ports or the relationship to the companion host controllers. For example, the UHPHS\_PORTSC registers should not be reset to their default values and the CF bit setting should not go to 0 (retaining port ownership relationships).

A host software read of this bit as 0 indicates the Light Host Controller Reset has completed and it is safe for host software to re-initialize the host controller. A host software read of this bit as 1 indicates the Light Host Controller Reset has not yet completed.

If not implemented, a read of this field will always return a 0.

**Bit 6 – IAAD** Interrupt on Async Advance Doorbell

This bit is used as a doorbell by software to tell the host controller to issue an interrupt the next time it advances asynchronous schedule. Software must write a 1 to this bit to ring the doorbell.

When the host controller has evicted all appropriate cached schedule state, it sets the Interrupt on Async Advance status bit in the UHPHS\_USBSTS register. If the Interrupt on Async Advance Enable bit in the UHPHS\_USBINTR register is set to 1, then the host controller will assert an interrupt at the next interrupt threshold.

The host controller sets this bit to 0 after it has set the Interrupt on Async Advance status bit in the UHPHS\_USBSTS register to 1.

Software should not write a 1 to this bit when the asynchronous schedule is disabled. Doing so will yield undefined results.

**Bit 5 – ASE** Asynchronous Schedule Enable

This bit controls whether the host controller skips processing the Asynchronous Schedule.

| Value | Description   |
|-------|---|
| 0     | Do not process the Asynchronous Schedule.                                 |
| 1     | Use the UHPHS_ASYNCLISTADDR register to access the Asynchronous Schedule. |

### Bit 4 – PSE Periodic Schedule Enable

This bit controls whether the host controller skips processing the Periodic Schedule.

| Value | Description  |
|-------|--|
| 0     | Do not process the Periodic Schedule.                                    |
| 1     | Use the UHPHS_PERIODICLISTBASE register to access the Periodic Schedule. |

### Bits 3:2 – FLS[1:0] Frame List Size

This field is read-only with one exception: it is read/write if the Programmable Frame List flag, in the UHPHS\_HCCPARAMS register, is set to 1. This field specifies the size of the frame list. The size of the frame list controls which bits in the Frame Index Register should be used for the Frame List Current index.

| Value | Description   |
|-------|---|
| 0     | 1024 elements (4096 bytes).                                       |
| 1     | 512 elements (2048 bytes).  |
| 2     | 256 elements (1024 bytes), for resource-constrained environments. |
| 3     | Reserved.   |

### Bit 1 – HCRESET Host Controller Reset

This control bit is used by software to reset the host controller. The effects of this on Root Hub registers are similar to a Chip Hardware Reset.

When software writes a 1 to this bit, the Host Controller resets its internal pipelines, timers, counters, state machines, etc. to their initial value. Any transaction currently in progress on USB is immediately terminated. A USB reset is not driven on downstream ports.

PCI Configuration registers are not affected by this reset. All operational registers, including port registers and port state machines, are set to their initial values. Port ownership reverts to the companion host controller(s) with side effects. Software must reinitialize the host controller in order to return the host controller to an operational state.

This bit is set to 0 by the Host Controller when the reset process is complete. Software cannot terminate the reset process early by writing a 0 to this register.

Software must not set this bit to 1 when HCHLT in the UHPHS\_USBSTS register is 0. Attempting to reset an actively running host controller results in undefined behavior.

### Bit 0 – RS Run/Stop

The Host Controller must halt within 16 microframes after software clears the bit RS. The HCHLT bit in the status register indicates when the Host Controller has finished its pending pipelined transactions and has entered the stopped state. Software must not write 1 to this field unless the host controller is in the halted state (i.e., HCHLT in the UHPHS\_USBSTS register is 1). Doing so yields undefined results.

| Value | Description  |
|-------|--|
| 0     | Host Controller completes the current and any actively pipelined transactions on the USB and then halts. |
| 1     | Host Controller proceeds with execution of the schedule.   |

### 41.7.5 UHPHS USB Status Register

**Name:** UHPHS\_USBSTS  
**Offset:** 0x14  
**Reset:** 0x00001000  
**Property:** Read/Write

This register indicates pending interrupts and various states of the Host Controller. The status resulting from a transaction on the serial bus is not indicated in this register. Software sets a bit to 0 in this register by writing a 1 to it.

|        |     |     |     |       |     |     |           |        |
|--------|-----|-----|-----|-------|-----|-----|-----------|--------|
| Bit    | 31  | 30  | 29  | 28    | 27  | 26  | 25        | 24     |
|        |     |     |     |       |     |     |           |        |
| Access |     |     |     |       |     |     |           |        |
| Reset  |     |     |     |       |     |     |           |        |
|        |     |     |     |       |     |     |           |        |
| Bit    | 23  | 22  | 21  | 20    | 19  | 18  | 17        | 16     |
|        |     |     |     |       |     |     |           |        |
| Access |     |     |     |       |     |     |           |        |
| Reset  |     |     |     |       |     |     |           |        |
|        |     |     |     |       |     |     |           |        |
| Bit    | 15  | 14  | 13  | 12    | 11  | 10  | 9         | 8      |
|        | ASS | PSS | RCM | HCHLT |     |     |           |        |
| Access | R   | R   | R   | R     |     |     |           |        |
| Reset  | 0   | 0   | 0   | 1     |     |     |           |        |
|        |     |     |     |       |     |     |           |        |
| Bit    | 7   | 6   | 5   | 4     | 3   | 2   | 1         | 0      |
|        |     |     | IAA | HSE   | FLR | PCD | USBERRINT | USBINT |
| Access |     |     | R/W | R/W   | R/W | R/W | R/W       | R/W    |
| Reset  |     |     | 0   | 0     | 0   | 0   | 0         | 0      |

#### Bit 15 – ASS Asynchronous Schedule Status

The bit reports the current real status of the Asynchronous Schedule.

The Host Controller is not required to immediately disable or enable the Asynchronous Schedule when software transitions the Asynchronous Schedule Enable bit in the UHPHS\_USBCMD register. When this bit and the Asynchronous Schedule Enable bit are the same value, the Asynchronous Schedule is either enabled or disabled.

| Value | Description                        |
|-------|------------------------------------|
| 0     | Asynchronous Schedule is disabled. |
| 1     | Asynchronous Schedule is enabled.  |

#### Bit 14 – PSS Periodic Schedule Status

The bit reports the current real status of the Periodic Schedule. If this bit is set to 0, then the status of the Periodic Schedule is disabled. If this bit is set to 1, then the status of the Periodic Schedule is enabled. The Host Controller is not required to immediately disable or enable the Periodic Schedule when software transitions the Periodic Schedule Enable bit in the UHPHS\_USBCMD register. When this bit and the Periodic Schedule Enable bit are the same value, the Periodic Schedule is either enabled or disabled.

**Bit 13 – RCM** Reclamation

This is a read-only status bit used to detect any empty asynchronous schedule.

**Bit 12 – HCHLT** HCHalted

This bit is 0 whenever the Run/Stop bit is 1. The Host Controller sets this bit to 1 after it has stopped executing as a result of the Run/Stop bit being set to 0, either by software or by the Host Controller hardware (e.g. internal error).

**Bit 5 – IAA** Interrupt on Async Advance (Cleared on write)

System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing 1 to the Interrupt on the Async Advance Doorbell bit in the UHPHS\_USBCMD register. This status bit indicates the assertion of that interrupt source.

**Bit 4 – HSE** Host System Error (Cleared on write)

The Host Controller sets this bit to 1 when a serious error occurs during a host system access involving the Host Controller module. In a PCI system, conditions that set this bit to 1 include PCI Parity error, PCI Master Abort, and PCI Target Abort. When this error occurs, the Host Controller clears the Run/Stop bit in the Command register to prevent further execution of the scheduled TDs.

**Bit 3 – FLR** Frame List Rollover (Cleared on write)

The Host Controller sets this bit to 1 when the Frame List Index (see [UHPHS USB Frame Index Register](#)) rolls over from its maximum value to 0. The exact value at which the rollover occurs depends on the frame list size. For example, if the frame list size (as programmed in the Frame List Size field of the UHPHS\_USBCMD register) is 1024, the Frame Index Register rolls over every time FRINDEX[13] toggles. Similarly, if the size is 512, the Host Controller sets this bit to 1 every time FRINDEX[12] toggles.

**Bit 2 – PCD** Port Change Detect (Cleared on write)

The Host Controller sets this bit to 1 when any port for which the Port Owner bit is set to 0 (see [UHPHS Port Status and Control Register](#)) has a change bit transition from 0 to 1 or a Force Port Resume bit transition from 0 to 1 as a result of a J-K transition detected on a suspended port. This bit will also be set as a result of the Connect Status Change being set to 1 after system software has relinquished ownership of a connected port by writing 1 to a port's Port Owner bit.

This bit is allowed to be maintained in the Auxiliary power well. Alternatively, it is also acceptable that on a D3 to D0 transition of the EHCI HC device, this bit is loaded with the OR of all of the PORTSC change bits (including: Force Port Resume, Overcurrent Change, Enable/Disable Change and Connect Status Change).

**Bit 1 – USBERRINT** USB Error Interrupt (Cleared on write)

The Host Controller sets this bit to 1 when completion of a USB transaction results in an error condition (e.g., error counter underflow). If the TD on which the error interrupt occurred also had its IOC bit set, both this bit and USBINT bit are set.

**Bit 0 – USBINT** USB Interrupt (Cleared on write)

The Host Controller sets this bit to 1 on the completion of a USB transaction, which results in the retirement of a Transfer Descriptor that had its IOC bit set.

The Host Controller also sets this bit to 1 when a short packet is detected (the actual number of bytes received was less than the expected number of bytes).

### 41.7.6 UHPHS USB Interrupt Enable Register

**Name:** UHPHS\_USBINTR  
**Offset:** 0x18  
**Reset:** 0x00000000  
**Property:** Read/Write

This register enables and disables reporting of the corresponding interrupt to the software. When a bit is set and the corresponding interrupt is active, an interrupt is generated to the host. Interrupt sources that are disabled in this register still appear in the UHPHS\_USBSTS to allow the software to poll for events.

For all bits, 1=Enabled, 0=Disabled.

|        |    |    |      |      |      |      |        |       |
|--------|----|----|------|------|------|------|--------|-------|
| Bit    | 31 | 30 | 29   | 28   | 27   | 26   | 25     | 24    |
|        |    |    |      |      |      |      |        |       |
| Access |    |    |      |      |      |      |        |       |
| Reset  |    |    |      |      |      |      |        |       |
|        |    |    |      |      |      |      |        |       |
| Bit    | 23 | 22 | 21   | 20   | 19   | 18   | 17     | 16    |
|        |    |    |      |      |      |      |        |       |
| Access |    |    |      |      |      |      |        |       |
| Reset  |    |    |      |      |      |      |        |       |
|        |    |    |      |      |      |      |        |       |
| Bit    | 15 | 14 | 13   | 12   | 11   | 10   | 9      | 8     |
|        |    |    |      |      |      |      |        |       |
| Access |    |    |      |      |      |      |        |       |
| Reset  |    |    |      |      |      |      |        |       |
|        |    |    |      |      |      |      |        |       |
| Bit    | 7  | 6  | 5    | 4    | 3    | 2    | 1      | 0     |
|        |    |    | IAAE | HSEE | FLRE | PCIE | USBEIE | USBIE |
| Access |    |    | R/W  | R/W  | R/W  | R/W  | R/W    | R/W   |
| Reset  |    |    | 0    | 0    | 0    | 0    | 0      | 0     |

**Bit 5 – IAAE** Interrupt on Async Advance Enable

The interrupt is acknowledged by software clearing the Interrupt on Async Advance bit UHPHS\_USBSTS.

**Bit 4 – HSEE** Host System Error Enable

The interrupt is acknowledged by software clearing the Host System Error bit in UHPHS\_USBSTS.

**Bit 3 – FLRE** Frame List Rollover Enable

The interrupt is acknowledged by software clearing the Frame List Rollover in UHPHS\_USBSTS.

**Bit 2 – PCIE** Port Change Interrupt Enable

The interrupt is acknowledged by software clearing the Port Change Detect bit in UHPHS\_USBSTS.

**Bit 1 – USBEIE** USB Error Interrupt Enable

The interrupt is acknowledged by software clearing the USBERRINT in UHPHS\_USBSTS.

**Bit 0 – USBIE** USB Interrupt Enable

The interrupt is acknowledged by software clearing the USBINT in UHPHS\_USBSTS.

### 41.7.7 UHPHS USB Frame Index Register

**Name:** UHPHS\_FRINDEX  
**Offset:** 0x1C  
**Reset:** 0x00000000  
**Property:** Read/Write

This register is used by the host controller to index into the periodic frame list. The register updates every 125  $\mu$ s (once each microframe). Bits [N:3] are used to select a particular entry in the Periodic Frame List during periodic schedule execution. The number of bits used for the index depends on the size of the frame list as set by system software in the Frame List Size field in the UHPHS\_USBCMD register).

This register must be written as a DWord. Byte writes produce undefined results. This register cannot be written unless the Host Controller is in the Halted state as indicated by the HCHLT bit (UHPHS\_USBSTS register). A write to this register while the Run/Stop bit is set to 1 (UHPHS\_USBCMD register) produces undefined results. Writes to this register also affect the SOF value.

#### Bits 13:0 – FI[13:0] Frame Index

The value in this register increments at the end of each time frame (e.g., microframe). Bits [N:3] are used for the Frame List current index. This means that each location of the frame list is accessed eight times (frames or microframes) before moving to the next index. The following illustrates values of N based on the value of FLS (Frame List Size) in the UHPHS\_USBCMD register.

| UHPHS_USBCMD.FLS | Number Elements | N  |
|------------------|-----------------|----|
| 0                | 1024            | 12 |
| 1                | 512             | 11 |
| 2                | 256             | 10 |
| 3                | Reserved        | –  |

# SAMA5D2 Series

## USB Host High Speed Port (UHPHS)

---

The SOF frame number value for the bus SOF token is derived or alternatively managed from this register. The value of FRINDEX must be 125  $\mu$ s (1 microframe) ahead of the SOF token value. The SOF value may be implemented as an 11-bit shadow register. For this discussion, this shadow register is 11 bits and is named SOFV. SOFV updates every eight microframes (1 millisecond). An example implementation to achieve this behavior is to increment SOFV each time the FRINDEX[2:0] increments from 0 to 1.

Software must use the value of FRINDEX to derive the current microframe number, both for high-speed isochronous scheduling purposes and to provide the “get microframe number” function required for client drivers. Therefore, the value of FRINDEX and the value of SOFV must be kept consistent if chip is reset or software writes to FRINDEX. Writes to FRINDEX must also write-through FRINDEX[13:3] to SOFV[10:0]. In order to keep the update as simple as possible, software should never write a FRINDEX value where the three least significant bits are 7 or 0.

### 41.7.8 UHPHS Periodic Frame List Base Address Register

**Name:** UHPHS\_PERIODICLISTBASE  
**Offset:** 0x24  
**Reset:** 0x00000000  
**Property:** Read/Write

This 32-bit register contains the beginning address of the Periodic Frame List in the system memory. If the host controller is in 64-bit mode (as indicated by a 1 in the 64-bit Addressing Capability field in the UHPHS\_HCCSPARAMS register), then the most significant 32 bits of every control data structure address comes from the UHPHS\_CTRLDSSEGMENT register. System software loads this register prior to starting the schedule execution by the Host Controller. The memory structure referenced by this physical memory pointer is assumed to be 4-Kbyte aligned. The contents of this register are combined with the Frame Index Register (UHPHS\_FRINDEX) to enable the Host Controller to step through the Periodic Frame List in sequence. This register must be written as a DWord. Byte writes produce undefined results.

|        |     |           |     |     |     |     |     |     |     |
|--------|-----|-----------|-----|-----|-----|-----|-----|-----|-----|
|        | Bit | 31        | 30  | 29  | 28  | 27  | 26  | 25  | 24  |

**Bits 31:12 – BA[19:0]** Base Address (Low)

These bits correspond to memory address signals [31:12], respectively.

### 41.7.9 UHPHS Asynchronous List Address Register

**Name:** UHPHS\_ASYNCLISTADDR  
**Offset:** 0x28  
**Reset:** 0x00000000  
**Property:** Read/Write

This 32-bit register contains the address of the next asynchronous queue head to be executed. If the host controller is in 64-bit mode (as indicated by a 1 in the 64-bit Addressing Capability field in the UHPHS\_HCCPARAMS register), then the most significant 32 bits of every control data structure address comes from the UHPHS\_CTRLDSSEGMENT register. Bits [4:0] of this register cannot be modified by system software and will always return a zero when read. The memory structure referenced by this physical memory pointer is assumed to be 32-byte (cache line) aligned. This register must be written as a DWord. Byte writes produce undefined results.

|        |     |            |     |     |     |     |     |     |     |  |
|--------|-----|------------|-----|-----|-----|-----|-----|-----|-----|--|
|        | Bit | 31         | 30  | 29  | 28  | 27  | 26  | 25  | 24  |  |

|        |     |            |     |     |     |     |     |     |     |  |
|        | Bit | 7          | 6   | 5   | 4   | 3   | 2   | 1   | 0   |  |
|        |     | LPL[2:0]   |     |     |     |     |     |     |     |  |
| Access |     | R/W        | R/W | R/W |     |     |     |     |     |  |
| Reset  |     | 0          | 0   | 0   |     |     |     |     |     |  |

**Bits 31:5 – LPL[26:0] Link Pointer Low**

These bits correspond to memory address signals [31:5], respectively. This field may only reference a Queue Head (QH).

### 41.7.10 UHPHS Configure Flag Register

**Name:** UHPHS\_CONFIGFLAG  
**Offset:** 0x50  
**Reset:** 0x00000000  
**Property:** Read/Write

This register is in the auxiliary power well. It is only reset by hardware when the auxiliary power is initially applied or in response to a host controller reset.

#### Bit 0 – CF Configure Flag

Host software sets this bit as the last action in its process of configuring the Host Controller. This bit controls the default port-routing control logic. Bit values and side-effects are listed below.

| Value | Description   |
|-------|---|
| 0     | Port routing control logic default-routes each port to an implementation-dependent classic host controller (default value). |
| 1     | Port routing control logic default-routes all ports to this host controller.  |

### 41.7.11 UHPHS Port Status and Control Register

**Name:** UHPHS\_PORTSCx  
**Offset:** 0x54 + x\*0x04 [x=0..2]  
**Reset:** 0x00002000  
**Property:** Read/Write

The number of port registers is documented in the UHPHS\_HCSPARAMS register. Software uses this information as an input parameter to determine how many ports need to be serviced. All ports have the structure defined below.

This register is in the auxiliary power well. It is only reset by hardware when the auxiliary power is initially applied or in response to a host controller reset. The initial conditions of a port are:

- No device connected
- Port disabled

If the port has port power control, software cannot change the state of the port until after it applies power to the port by setting port power to a 1. Software must not attempt to change the state of the port until after power is stable on the port. The host is required to have power stable to the port within 20 milliseconds of the 0 to 1 transition.

**Note:**

1. When a device is attached, the port state transitions to the connected state and system software will process this as with any status change notification.
2. If a port is being used as the Debug Port, then the port may report device connected and enabled when the Configured Flag is set to 0.

|        |          |     |        |            |           |          |     |     |
|--------|----------|-----|--------|------------|-----------|----------|-----|-----|
| Bit    | 31       | 30  | 29     | 28         | 27        | 26       | 25  | 24  |
|        |          |     |        |            |           |          |     |     |
| Access |          |     |        |            |           |          |     |     |
| Reset  |          |     |        |            |           |          |     |     |
| Bit    | 23       | 22  | 21     | 20         | 19        | 18       | 17  | 16  |

**Bit 22 – WKOC\_E** Wake on Overcurrent Enable  
 This field is 0 if Port Power is 0.

# SAMA5D2 Series

## USB Host High Speed Port (UHPHS)

| Value | Description  |
|-------|--|
| 0     | Disables the port to be sensitive to overcurrent conditions as wake-up events. |
| 1     | Enables the port to be sensitive to overcurrent conditions as wake-up events.  |

### Bit 21 – WKDSCNNT\_E Wake on Disconnect Enable

This field is 0 if Port Power is 0.

| Value | Description  |
|-------|--|
| 0     | Disables the port to be sensitive to device disconnects as wake-up events. |
| 1     | Enables the port to be sensitive to device disconnects as wake-up events.  |

### Bit 20 – WKCNT\_E Wake on Connect Enable

This field is 0 if Port Power is 0.

| Value | Description   |
|-------|---|
| 0     | Disables the port to be sensitive to device connects as wake-up events. |
| 1     | Enables the port to be sensitive to device connects as wake-up events.  |

### Bits 19:16 – PTC[3:0] Port Test Control

When this field is set to 0, the port is NOT operating in a test mode. A non-zero value indicates that it is operating in test mode and the specific test mode is indicated by the specific value.

Test mode bits are encoded as follows (6 to 15 are reserved):

| Value | Test Mode             |
|-------|-----------------------|
| 0     | Test mode not enabled |
| 1     | Test J_STATE          |
| 2     | Test K_STATE          |
| 3     | Test SE0_NAK          |
| 4     | Test Packet           |
| 5     | Test FORCE_ENABLE     |

Refer to the USB Specification Revision 2.0, Chapter 7, for details on each test mode.

### Bits 15:14 – PIC[1:0] Port Indicator Control

Writing to these bits has no effect if the P\_INDICATOR bit in the UHPHS\_HCSPARAMS register is set to 0. If the P\_INDICATOR bit is set to 1, then the bits are encoded as follows:

| Value | Meaning                 |
|-------|-------------------------|
| 0     | Port indicators are off |
| 1     | Amber                   |
| 2     | Green                   |
| 3     | Undefined               |

Refer to the USB Specification Revision 2.0 for a description of how these bits are to be used.

This field is 0 if Port Power is 0.

### Bit 13 – PO Port Owner

System software uses this field to release ownership of the port to a selected host controller (in the event that the attached device is not a high-speed device). Software writes 1 to this bit when the attached device is not a high-speed device. A 1 in this bit means that a companion host controller owns and controls the port.

| Value | Description  |
|-------|--|
| 0     | This bit unconditionally goes to a 0 when the bit UHPHS_CONFIGFLAG.CF makes a 0 to 1 transition. |
| 1     | This bit unconditionally goes to 1 whenever the bit UHPHS_CONFIGFLAG.CF=0.                       |

### Bit 12 – PP Port Power

The function of this bit depends on the value of the Port Power Control (PPC) field in the UHPHS\_HCSPARAMS register. When host controller has port power control switches (PPC=0), PP is in read-only mode:

| Value | Description                       |
|-------|-----------------------------------|
| 1     | Each port is hard-wired to power. |

When host controller has port power control switches (PPC=1), PP is in read/write mode:

| Value | Description  |
|-------|--|
| 0     | Host port power switch is OFF.<br><br>When power is not available on a port (i.e., PP at 0), the port is non-functional and does not report attaches, detaches, etc. |
| 1     | Host port power switch is ON.<br><br>When power is not available on a port (i.e., PP at 0), the port is non-functional and does not report attaches, detaches, etc.  |

When an overcurrent condition is detected on a powered port and PPC is set to 1, the PP bit in each affected port may be transitioned by the host controller from 1 to 0 (removing power from the port).

### Bits 11:10 – LS[1:0] Line Status

These bits reflect the current logical levels of the D+ (bit 11) and D- (bit 10) signal lines. These bits are used for detection of low-speed USB devices prior to the port reset and enable sequence. This field is valid only when the port enable bit is 0 and the current connect status bit is set to 1.

This value of this field is undefined if Port Power is 0.

| Value | Name      | Description                                 |
|-------|-----------|---|
| 0     | SE0       | Not a low-speed device, perform EHCI reset  |
| 1     | K-STATE   | Low-speed device, release ownership of port |
| 2     | J-STATE   | Not a low-speed device, perform EHCI reset  |
| 3     | Undefined | Not a low-speed device, perform EHCI reset  |

### Bit 8 – PR Port Reset

When software writes a 1 to this bit (from 0), the bus reset sequence as defined in the USB Specification Revision 2.0 is started. Software writes a 0 to this bit to terminate the bus reset sequence. Software must

keep this bit set to 1 long enough to ensure the reset sequence, as specified in the USB Specification Revision 2.0, completes.

**Note:** When software writes this bit to 1, it must also write 0 to the Port Enable bit.

When software writes a 0 to this bit, there may be a delay before the bit status changes to 0. The bit status will not read as 0 until after the reset has completed. If the port is in High-Speed mode after reset is complete, the host controller will automatically enable this port (e.g., set the Port Enable bit to 1). A host controller must terminate the reset and stabilize the state of the port within 2 milliseconds of software transitioning this bit from 1 to 0. For example: if the port detects that the attached device is high-speed during reset, then the host controller must have the port in the enabled state within 2 ms of software writing this bit to 0.

The HCHLT bit in the UHPHS\_USBSTS register should be set to 0 before software attempts to use this bit. The host controller may hold Port Reset asserted to 1 when the HCHLT bit is 1.

This field is 0 if Port Power is 0.

| Value | Description           |
|-------|-----------------------|
| 0     | Port is not in Reset. |
| 1     | Port is in Reset.     |

### Bit 7 – SUS Suspend

| Value | Description                |
|-------|----------------------------|
| 0     | Port not in suspend state. |
| 1     | Port in suspend state.     |

**Note:**

Port Enabled Bit and Suspend bit of this register define the port states as follows:

| Bits [Port Enabled, Suspend] | Port State |
|------------------------------|------------|
| 0X                           | Disable    |
| 10                           | Enable     |
| 11                           | Suspend    |

When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction, if a transaction was in progress when this bit was written to 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB.

A write of 0 to this bit is ignored by the host controller. The host controller will unconditionally set this bit to 0 when:

- Software sets the Force Port Resume bit to 0 (from 1).
- Software sets the Port Reset bit to 1 (from 0).

If host software sets this bit to 1 when the port is not enabled (i.e., Port Enabled bit set to 0), the results are undefined.

This field is 0 if Port Power is set to 0.

### Bit 6 – FPR Force Port Resume

This functionality defined for manipulating this bit depends on the value of the Suspend bit. For example, if the port is not suspended (Suspend and Enabled bits are set to 1) and software transitions this bit to 1, then the effects on the bus are undefined.

Software sets this bit to a 1 to drive resume signaling. The Host Controller sets this bit to 1 if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to 1 because a J-to-K transition is detected, the Port Change Detect bit in the UHPHS\_USBSTS register is also set to 1. If software sets this bit to 1, the host controller must not set the Port Change Detect bit.

Note that when the EHCI controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains set to 1. Software must appropriately time the Resume and set this bit to 0 when the appropriate amount of time has elapsed. Writing a 0 (from 1) causes the port to return to High-Speed mode (forcing the bus below the port into a high-speed idle). This bit will remain set to 1 until the port has switched to the high-speed idle. The host controller must complete this transition within 2 milliseconds of software setting this bit to 0.

This field is 0 if Port Power is 0.

| Value | Description                                  |
|-------|--|
| 0     | No resume (K-state) detected/driven on port. |
| 1     | Resume detected/driven on port.              |

### Bit 5 – OCC Overcurrent Change (Cleared on write)

Software clears this bit by writing 1.

| Value | Description                      |
|-------|----------------------------------|
| 0     | No change to Overcurrent Active. |
| 1     | Changes to Overcurrent Active.   |

### Bit 4 – OCA Overcurrent Active

This bit will automatically transition from 1 to 0 when the overcurrent condition is removed.

| Value | Description                                       |
|-------|---|
| 0     | This port does not have an overcurrent condition. |
| 1     | This port currently has an overcurrent condition. |

### Bit 3 – PEDC Port Enable/Disable Change (Cleared on write)

For the root hub, this bit gets set to 1 only when a port is disabled due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification for the definition of a Port Error). Software clears this bit by writing a 1 to it.

This field is 0 if Port Power bit is 0.

| Value | Description                                |
|-------|--|
| 0     | No change in port enabled/disabled status. |
| 1     | Port enabled/disabled status has changed.  |

### Bit 2 – PED Port Enabled/Disabled

Ports can only be enabled by the host controller as a part of the reset and enable. Software cannot enable a port by writing a 1 to this field. The host controller will only set this bit to 1 when the reset sequence determines that the attached device is a high-speed device.

# SAMA5D2 Series

## USB Host High Speed Port (UHPHS)

Ports can be disabled by either a fault condition (disconnect event or other fault condition) or by host software. Note that the bit status does not change until the port state actually changes. There may be a delay in disabling or enabling a port due to other host controller and bus events.

When the port is disabled (0b), downstream propagation of data is blocked on this port, except for reset.

This field is 0 if Port Power bit is 0.

| Value | Description |
|-------|-------------|
| 0     | Disable.    |
| 1     | Enable.     |

### Bit 1 – CSC Connect Status Change (Cleared on write)

Indicates a change has occurred in the port's Current Connect Status. The host controller sets this bit for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the insertion status changes twice before system software has cleared the changed condition, hub hardware will be "setting" an already-set bit (i.e., the bit remains set). Software sets this bit to 0 by writing a 1 to it.

This field is 0 if Port Power bit is 0.

| Value | Description                       |
|-------|-----------------------------------|
| 0     | No change.                        |
| 1     | Change in Current Connect Status. |

### Bit 0 – CCS Current Connect Status

This value reflects the current state of the port, and may not correspond directly to the event that caused the CSC bit to be 1.

This bit is 0 if Port Power is 0.

| Value | Description                |
|-------|----------------------------|
| 0     | No device is present.      |
| 1     | Device is present on port. |

### 41.7.12 EHCI: REG06 - AHB Error Status

**Name:** UHPHS\_INSNREG06  
**Offset:** 0xA8  
**Reset:** 0x00000000  
**Property:** Read/Write

Control and Status Register, used to read the UTMI registers from the signals below.

|        |               |    |    |    |                       |    |    |               |  |

#### Bit 31 – AHB\_ERR AHB Error

System bus error was encountered and erroneous burst characteristics are captured. To clear this field the application must write a 0.

EHCI:

- When no error, 0 is written to INSNREG06[8:4].
- When INCR4 and an error occurs, 4 is written to INSNREG06[8:4].
- When INCR8 and an error occurs, 8 is written to INSNREG06[8:4].
- When INCR16 and an error occurs, 16 is written to INSNREG06[8:4].
- Other values except 4, 8, and 16 are not written to INSNREG06[8:4].

OHCI:

- When no error, 0 is written to INSNREG06[8:4].
- When INCR4 and error occurs, 4 is written to INSNREG06[8:4].
- Other values except 4 are not written to INSNREG06[8:4].

#### Bits 11:9 – HBURST[2:0] Burst Value

Value of the control phase at which the AHB error occurred.

This field applies to enabled incremental bursts only.

**Bits 8:4 – Nb\_Burst[4:0]** Number of Bursts

Number of beats expected in the burst at which the AHB error occurred. Valid values are 0 to 16.

This field applies to enabled incremental bursts only.

**Bits 3:0 – Nb\_Success\_Burst[3:0]** Number of Successful Bursts

Number of successfully completed beats in the current burst before the AHB error occurred.

This field applies to enabled incremental bursts only.

**41.7.13 EHCI: REG07 - AHB Master Error Address**

**Name:** UHPHS\_INSNREG07  
**Offset:** 0xAC

**Bits 31:0 – AHB\_ADDR[31:0] AHB Address**

System bus address of the control phase at which the system bus error occurred.

### 41.7.14 EHCI: REG08 - HSIC Enable/Disable

**Name:** UHPHS\_INSNREG08  
**Offset:** 0xB0  
**Reset:** 0x00000000  
**Property:** Read/Write

**Bit 2 – HSIC\_EN** HSIC Enable/Disable

This register has R/W access to the host driver and gives control to the host driver to enable/disable the HSIC interface of Port C.

| Value | Description   |
|-------|---|
| 0     | Port C is in the HSIC Disable state (see High-Speed Inter-Chip USB Electrical Specification, Version 1.0, Section 3.1.2). HSIC is in the Disabled state after a power-on reset. |
| 1     | Port C is in the HSIC Enable state (see High-Speed Inter-Chip USB Electrical Specification, Version 1.0, Section 3.1.2).  |

## **42. Audio Class D Amplifier (CLASSD)**

### **42.1 Description**

The Audio Class D Amplifier (CLASSD) is a digital input, Pulse Width Modulated (PWM) output stereo Class D amplifier. It features a high quality interpolation filter embedding a digitally controlled gain, an equalizer and a de-emphasis filter.

On its input side, the CLASSD is compatible with most common audio data rates. On the output side, its PWM output can drive either:

- high-impedance single-ended or differential output loads (Audio DAC application) or,
- external MOSFETs through an integrated non-overlapping circuit (Class D power amplifier application).

### **42.2 Embedded Characteristics**

- Stereo PWM Class D Amplifier
- 16-bit Audio Data
- DSP clocks: 12.288 and 11.2896 MHz
- Input Sampling Rates: 8, 16, 32, 48, 96, 22.05, 44.1, 88.2 kHz
- 3-band Equalizer
- De-emphasis Filter
- Digital Volume Control
- Differential or Single-ended Outputs
- Non-overlapping Circuit to Control External MOSFETs
- Supports DMA

### 42.3 Block Diagram

## 42.5 Product Dependencies

### 42.5.1 I/O Lines

The pins used for interfacing the compliant external devices may be multiplexed with PIO lines. The programmer must first program the PIO controllers to assign the CLASSD pins to their peripheral functions.

### 42.5.2 Power Management

The CLASSD is clocked through the Power Management Controller (PMC), thus the programmer must first configure the PMC to enable the CLASSD Peripheral Clock and provide a generic clock (GCLK).

The fields NOVRVAL, NON\_OVERLAP and PWMTYP in CLASSD\_MR, and DSPCLKFREQ and FREQ in CLASSD\_INTPMR, must be configured prior to applying the GCLK.

### 42.5.3 Interrupt

The CLASSD has an interrupt line connected to the interrupt controller. Handling the CLASSD interrupt requires programming the interrupt controller before configuring the CLASSD.

## 42.6 Functional Description

### 42.6.1 Interpolator

#### 42.6.1.1 Clock Configuration

The interpolator accepts input sampling frequencies ( $f_s$ ) and the input DSP clock (DSPCLK) that can be configured in the CLASSD Interpolator Mode Register. GCLK must be configured in the PMC according to the desired DSPCLK so that  $DSPCLK = GCLK / 8$ .

The following table provides authorized DSPCLK /  $f_s$  ratios and associated filter types.

**Table 42-2. Authorized DSPCLK /  $f_s$  Ratios & Filter Types**

| $f_s$     | DSPCLK     |             |
|-----------|------------|-------------|
|           | 12.288 MHz | 11.2896 MHz |
| 8 kHz     | 2          | –           |
| 16 kHz    | 2          | –           |
| 32 kHz    | 2          | –           |
| 48 kHz    | 1          | –           |
| 96 kHz    | 3          | –           |
| 22.05 kHz | –          | 1           |
| 44.1 kHz  | –          | 1           |
| 88.2 kHz  | –          | 3           |

**Note:** Each dash (–) indicates a configuration that is not authorized and that raises the CFGERR flag in the CLASSD Interpolator Status Register.

### 42.6.1.2 CLASSD Frequency Response

Interpolation is performed with a combination of Infinite Impulse Response (IIR) and Cascaded Integrator-Comb (CIC) filters. Given the input configuration, the coefficients of the filters are redefined to optimize their transfer function to optimize the audio bandwidth. The different types of filters are defined in section [Clock Configuration](#).

**Figure 42-2. Type 1 Frequency Response**

**Figure 42-3. Type 2 Frequency Response**

**Figure 42-4. Type 3 Frequency Response**

### 42.6.2 Equalizer

The CLASSD offers 12 pre-programmed equalization filters.

A zero-cross detection system is used to modify the equalizer on-the-fly with minimum disturbance on the output signal.

Programming of the equalization filter is detailed in section [CLASSD Interpolator Mode Register](#).

The following figures show the frequency response of the equalizer function implemented in the D/A channels.

**Figure 42-5. Bass Filters Response**

**Figure 42-6. Medium Filters Response**

**Figure 42-7. Treble Filters Response**

**42.6.3 De-emphasis Filter Frequency Response**

The CLASSD includes a de-emphasis filter which can be enabled for 32, 44.1 or 48 kHz sampling frequencies.

The response and the error generated by the digital approximation of the filter are illustrated in the following figures.

**Figure 42-8. De-emphasis Filter: Frequency Response & Error ( $f_s = 32$  kHz)**

**Figure 42-9. De-emphasis Filter: Frequency Response & Error ( $f_s = 44.1$  kHz)**

**Figure 42-10. De-emphasis Filter: Frequency Response & Error ( $f_s = 48 \text{ kHz}$ )**

#### 42.6.4 Attenuator and Recommended Input Levels

The CLASSD features a digital attenuator with an attenuation range of 0–77 dB and a step size of 1 dB. When attenuation greater than 77 dB is programmed, the attenuator mutes the channel.

To avoid saturations in the PWM stage, it is recommended to avoid input levels greater than 1 dB below the digital full scale (-1 dBFS). This can be done by programming a minimum attenuation of 1 dB.

#### 42.6.5 Pulse Width Modulator (PWM)

The CLASSD Pulse Width Modulator generates fixed frequency pulse width modulated output signals. For the 44.1 kS/s and 48 kS/s standard audio sample rates, the PWM output frequency is set to  $16 \times f_s$ : 705.6 kHz and 768 kHz respectively. For 8, 16, 24 and 96 kS/s, the 16 $\times$  (interpolation) ratio is adapted to keep the output frequency at 768 kHz. In the same way, the output frequency is 705.6 kHz for the 22.05 and 88.2 kS/s cases.

The CLASSD functions either as a DAC loaded by a medium-to-high resistive load (e.g., 1 k $\Omega$  to 100 k $\Omega$ ) or as a Class D power amplifier controller driving an external power stage. Depending on the value of CLASSD\_MR.NON\_OVERLAP, the CLASSD drives:

- Single-ended or differential resistive loads (NON\_OVERLAP = 0)
- Full or Half MOSFET H-bridges (NON\_OVERLAP = 1)

When driving an external power stage (NON\_OVERLAP = 1), the CLASSD generates the signals to control complementary MOSFET pairs (PMOS and NMOS) with a non-overlapping delay between the NMOS and PMOS controls to avoid short circuit current. The non-overlapping delay can be adjusted in the CLASSD\_MR.NOVRVAL field.

The CLASSD can have a single-ended or a differential output. A specific pulse width modulation type is associated to each case. For single-ended output (CLASSD\_MR.PWMTYP = 0), the PWM acts only on the falling edge of the PWM waveform (trailing edge PWM). For differential output (CLASSD\_MR.PWMTYP = 1), both the rising and the falling edges of the PWM waveform are modulated (symmetric PWM). Modulation principles are illustrated in the following figures for both types of PWM. In particular, when describing a null input, if PWMTYP = 0 (trailing edge PWM), the output waveform is a square wave with 50% duty cycle. With the same input and PWMTYP = 1, the differential output waveform is zero. This difference removes the classical L-C low pass filter when PWMTYP = 1.

**Figure 42-11. Output Waveform Modulation Principle for PWMTYP = 0**

**Figure 42-12. Output Waveform Modulation Principle for PWMTYP = 1 (Only Left Channel Pins Shown)**

# SAMA5D2 Series

## Audio Class D Amplifier (CLASSD)

### 42.6.6 Application Schematics For Use Case Examples

Figure 42-13. Use Case 1: Stereo Class D Amplifier With External Differential Power Stage

Use case example:

- D1..D4 = e.g., 1N4148
- Q1..Q4 = e.g., DMC2400UV
- R1..R8 = 10 ohm
- R9..R16 = 10 kohm
- C1..C4 = 10 nF
- C5..C6 = 10  $\mu$ F
- C7 = 1  $\mu$ F

**Figure 42-14. Use Case 1: Waveforms**

CLASSD\_MR.PWM\_TYP = 1, CLASSD\_MR.NON\_OVERLAP = 1

In Use Case 1, the external power stages are made of complementary low-cost MOSFETs. In addition to the  $R_{DS(ON)}$  and drain breakdown voltage characteristics, the choice of these components is driven by a low gate threshold voltage, a low input capacitance, a low total gate charge and a fast turn-on time characteristics. Series resistance ( $10\ \Omega$ ) added to the gates of the MOSFETs are optional and may be adjusted to optimize the gate drive. They help to limit the output current peaks driven by the I/Os into the MOSFET gates in some cases. The  $10k$  resistors ensure an OFF condition when not driven and the capacitor / diode network (C1..C2 / D1..D2) shifts the PMOS drive from the typical  $V_{DDIO}$  level (3.3V) to a higher supply voltage (e.g., a 5V power domain).

# SAMA5D2 Series

## Audio Class D Amplifier (CLASSD)

Figure 42-15. Use Case 2: Stereo Class D Amplifier With External Single-ended Power Stage

Use case example:

- D1..D2 = e.g., 1N4148
- Q1..Q2 = e.g., DMC2400UV
- R1..R4 = 10 ohm
- R5..R8 = 10 kohm
- C1..C2 = 10 nF
- C3 = 10  $\mu$ F
- C4 = 1  $\mu$ F

In the Use Case 2 application schematic, the drive network of the MOSFETs gates follows the principles described in Use Case 1.

**Figure 42-16. Use Case 2: Waveforms**

CLASSD\_MR.PWMTYP = 0, CLASSD\_MR.NON\_OVERLAP = 1

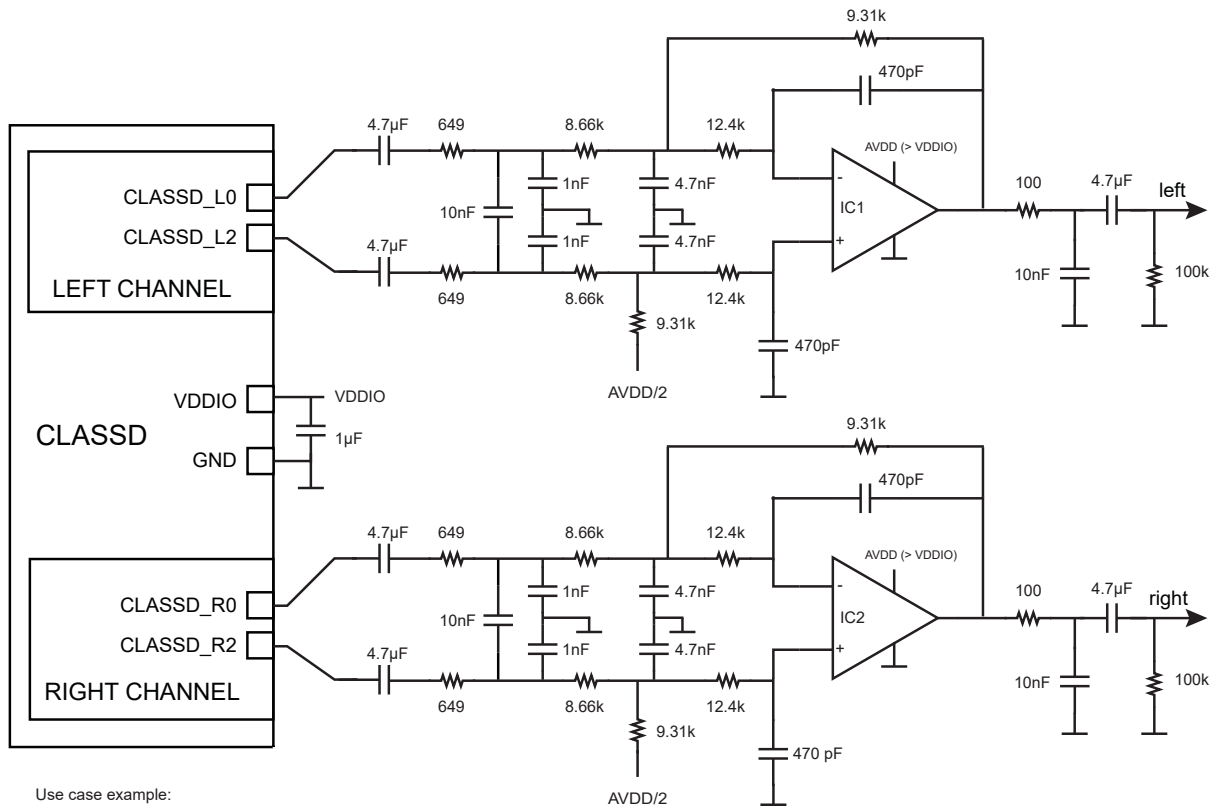

A coupling capacitor ( $C_C$ ) and an L-C low pass filter ( $L_F$ ,  $C_F$ ) are added to the output of the power stage to remove both the DC and the high frequency components of the PWM signal.  $C_C$  with the resistive part of the speaker ( $R_{SPK}$ ) forms a C-R high pass filter with a corner frequency of  $f_{HP} = 1 / (2 \times \text{PI} \times C_C \times R_{SPK})$ .

$L_F$ ,  $C_F$  and  $R_{SPK}$  form a second-order low pass filter of corner frequency  $f_C = 1 / (2 \times \text{PI} \times \text{sqrt}(L_F \times C_F))$  and of quality factor  $Q = R_{SPK} \times \text{sqrt}(C_F / L_F)$ . As a numerical example, consider the case  $f_{HP} = 200$  Hz,  $f_C = 30$  kHz,  $Q = 0.707$  (maximum flat response) with  $R_{SPK} = 8 \Omega$ . This leads to  $C_C = 100 \mu\text{F}$ ,  $L_F = 60 \mu\text{H}$ ,  $C_F = 470$  nF.

## Audio Class D Amplifier (CLASSD)

**Figure 42-17. Use Case 3A: Stereo Audio DAC With Active differential to single low pass filter**

Use case example:

IC1..IC2 = e.g., 1/2 LMV356

**Figure 42-18. Use Case 3B: Stereo Audio DAC With Simple Passive Low Pass Filter and Differential Outputs**

# SAMA5D2 Series

## Audio Class D Amplifier (CLASSD)

**Figure 42-19. Use Cases 3A and 3B: Waveforms**

CLASSD\_MR.PWMTYP = 1, CLASSD\_MR.NON\_OVERLAP = 0

In Use Case 3A, the CLASSD is used as an audio DAC. In this case, the differential outputs of the CLASSD are used. The application schematic suggested in figure "Use Case 3A: Stereo Audio DAC With Active differential to single low pass filter" above implements a third order 10 kHz low pass Butterworth filter and makes the differential to single-ended conversion. Note that in this schematic, the AVDD/2 point needs to be fed at low impedance (e.g., a buffered voltage). A simpler schematic (Use Case 3B) may also be possible, as shown in figure "Use Case 3B: Stereo Audio DAC With Simple Passive Low Pass Filter and Differential Outputs" above, at the cost of higher out-of-band noise and differential outputs which may be acceptable in some applications.

**Figure 42-20. Use Case 4A: Stereo Audio DAC With Active Low Pass Filter and Single-ended Outputs**

**Figure 42-21. Use Case 4B: Stereo Audio DAC With Passive Low Pass Filter and Single-ended Outputs**

**Figure 42-22. Use Cases 4A and 4B: Waveforms**

CLASSD\_MR.PWMTYP = 0, CLASSD\_MR.NON\_OVERLAP = 0

In Use Case 4A, the CLASSD is used as an audio DAC with active low pass filter. In this case, the single-ended outputs of the CLASSD are selected (PWMTYP = 0, trailing edge PWM) which leaves more I/Os to the application. A third order 30 kHz low pass Butterworth filter is shown in figure "Use Case 4A: Stereo Audio DAC With Active Low Pass Filter and Single-ended Outputs". The AVDD/2 point can be fed at relatively high impedance as no current is drawn from this point (a simple resistive divider properly decoupled is acceptable). A reduced complexity schematic is presented in figure "Use Case 4B: Stereo Audio DAC With Passive Low Pass Filter and Single-ended Outputs" above for less constrained applications.

### 42.6.7 Register Write Protection

To prevent any single software error from corrupting CLASSD behavior, certain registers in the address space can be write-protected by setting the WPEN bit in the CLASSD Write Protection Mode Register (CLASSD\_WPMR).

The following registers can be write-protected:

- CLASSD Mode Register
- CLASSD Interpolator Mode Register

# SAMA5D2 Series

## Audio Class D Amplifier (CLASSD)

### 42.7 Register Summary

| Offset              | Name          | Bit Pos. |  |               |              |      |            |  |       |            |             |
|---------------------|---------------|----------|--|---------------|--------------|------|------------|--|-------|------------|-------------|
| 0x00                | CLASSD_CR     | 7:0      |  |               |              |      |            |  | SWRST |            |             |
|                     |               | 15:8     |  |               |              |      |            |  |       |            |             |

### 42.7.1 CLASSD Control Register

**Name:** CLASSD\_CR  
**Offset:** 0x00  
**Reset:** –  
**Property:** Write-only

**Bit 0 – SWRST** Software Reset

| Value | Description                                 |
|-------|---|
| 0     | No effect.                                  |
| 1     | Resets CLASSD, simulating a hardware reset. |

### 42.7.2 CLASSD Mode Register

**Name:** CLASSD\_MR  
**Offset:** 0x04  
**Reset:** 0x00010022  
**Property:** Read/Write

This register can only be written if the WPEN bit is cleared in the CLASSD Write Protection Mode Register.

| Access |    |    | R/W          | R/W |    |    | R/W   | R/W    |             |
| Reset  |    |    | 1            | 0   |    |    | 1     | 0      |             |

**Bits 21:20 – NOVRVAL[1:0]** Non-Overlapping Value  
 This field has no effect when NON\_OVERLAP = 0.

| Value | Name | Description                   |
|-------|------|-------------------------------|
| 0     | 5NS  | Non-overlapping time is 5 ns  |
| 1     | 10NS | Non-overlapping time is 10 ns |
| 2     | 15NS | Non-overlapping time is 15 ns |
| 3     | 20NS | Non-overlapping time is 20 ns |

**Bit 16 – NON\_OVERLAP** Non-Overlapping Enable

| Value | Description                          |
|-------|--------------------------------------|
| 0     | Non-overlapping circuit is disabled. |
| 1     | Non-overlapping circuit is enabled.  |

**Bit 8 – PWMTYP** PWM Modulation Type  
 0 (TRAILING\_EDGE): The signal is single-ended.

# SAMA5D2 Series

## Audio Class D Amplifier (CLASSD)

If NON\_OVERLAP is cleared, the signal is sent to CLASSD\_L0 and CLASSD\_R0 (see figure [Use Case 4A](#) or figure [Use Case 4B](#)).

If NON\_OVERLAP is set, the signal is sent to CLASSD\_L0/L1 and CLASSD\_R0/R1 (see figure [Use Case 2](#)).

1 (UNIFORM): The signal is differential.

If NON\_OVERLAP is cleared, the signal is sent to CLASSD\_L0/L2 and CLASSD\_R0/R2 (see figure [Use Case 3A](#) or figure [Use Case 3B](#)).

If NON\_OVERLAP is set, the signal is sent to CLASSD\_L0/L1/L2/L3 and CLASSD\_R0/R1/R2/R3 (see figure [Use Case 1](#)).

### Bit 5 – RMUTE Right Channel Mute

| Value | Description               |
|-------|---------------------------|
| 0     | Right channel is unmuted. |
| 1     | Right channel is muted.   |

### Bit 4 – REN Right Channel Enable

| Value | Description                |
|-------|----------------------------|
| 0     | Right channel is disabled. |
| 1     | Right channel is enabled.  |

### Bit 1 – LMUTE Left Channel Mute

| Value | Description              |
|-------|--------------------------|
| 0     | Left channel is unmuted. |
| 1     | Left channel is muted.   |

### Bit 0 – LEN Left Channel Enable

| Value | Description               |
|-------|---------------------------|
| 0     | Left channel is disabled. |
| 1     | Left channel is enabled.  |

### 42.7.3 CLASSD Interpolator Mode Register

**Name:** CLASSD\_INTPMR  
**Offset:** 0x08  
**Reset:** 0x00304E4E  
**Property:** Read/Write

This register can only be written if the WPEN bit is cleared in the CLASSD Write Protection Mode Register.

|        |               |     |      |            |       |     |     |            |

#### Bits 30:29 – MONOMODE[1:0] Mono Mode Selection

This field defines which signal is sent to both channels when the MONO bit is set.

| Value | Name      | Description   |
|-------|-----------|---|
| 0     | MONOMIX   | (left + right) / 2 is sent to both channels   |
| 1     | MONOSAT   | (left + right) is sent to both channels. If the sum is too high, the result is saturated. |
| 2     | MONOLEFT  | THR[15:0] is sent to both the left and the right channels                                 |
| 3     | MONORIGHT | THR[31:16] is sent to both the left and the right channels                                |

#### Bit 28 – MONO Mono Signal

0 (DISABLED): The signal is sent stereo to the left and right channels.

1 (ENABLED): The same signal is sent to both the left and the right channels. The sent signal is defined by the MONOMODE field value.

#### Bits 27:24 – EQCFG[3:0] Equalization Selection

EQCFG field values 13–15 = flat response

# SAMA5D2 Series

## Audio Class D Amplifier (CLASSD)

| Value | Name     | Description         |
|-------|----------|---------------------|
| 0     | FLAT     | Flat response       |
| 1     | BBOOST12 | Bass boost +12 dB   |
| 2     | BBOOST6  | Bass boost +6 dB    |
| 3     | BCUT12   | Bass cut -12 dB     |
| 4     | BCUT6    | Bass cut -6 dB      |
| 5     | MBOOST3  | Medium boost +3 dB  |
| 6     | MBOOST8  | Medium boost +8 dB  |
| 7     | MCUT3    | Medium cut -3 dB    |
| 8     | MCUT8    | Medium cut -8 dB    |
| 9     | TBOOST12 | Treble boost +12 dB |
| 10    | TBOOST6  | Treble boost +6 dB  |
| 11    | TCUT12   | Treble cut -12 dB   |
| 12    | TCUT6    | Treble cut -6 dB    |

### Bits 22:20 – FRAME[2:0] CLASSD Incoming Data Sampling Frequency

| Value | Name      | Description |
|-------|-----------|-------------|
| 0     | FRAME_8K  | 8 kHz       |
| 1     | FRAME_16K | 16 kHz      |
| 2     | FRAME_32K | 32 kHz      |
| 3     | FRAME_48K | 48 kHz      |
| 4     | FRAME_96K | 96 kHz      |
| 5     | FRAME_22K | 22.05 kHz   |
| 6     | FRAME_44K | 44.1 kHz    |
| 7     | FRAME_88K | 88.2 kHz    |

### Bit 19 – SWAP Swap Left and Right Channels

0 (LEFT\_ON\_LSB): Left channel is on CLASSD\_THR[15:0], right channel is on CLASSD\_THR[31:16].

1 (RIGHT\_ON\_LSB): Right channel is on CLASSD\_THR[15:0], left channel is on CLASSD\_THR[31:16].

### Bit 18 – DEEMP Enable De-emphasis Filter

0 (DISABLED): De-emphasis filter is disabled.

1 (ENABLED): De-emphasis filter is enabled.

### Bit 16 – DSPCLKFREQ DSP Clock Frequency

0 (12M288): DSP Clock (DSPCLK) is 12.288 MHz.

1 (11M2896): DSP Clock (DSPCLK) is 11.2896 MHz.

### Bits 14:8 – ATTR[6:0] Right Channel Attenuation

Right channel attenuation is defined as follows:

– if  $ATTR \leq 77$  the attenuation is  $-ATTR$  dB

– else the right signal is muted

### Bits 6:0 – ATTL[6:0] Left Channel Attenuation

Left channel attenuation is defined as follows:

– if  $ATTL \leq 77$  the attenuation is  $-ATTL$  dB

– else the left signal is muted

#### 42.7.4 CLASSD Interpolator Status Register

**Name:** CLASSD\_INTSR  
**Offset:** 0x0C  
**Reset:** 0x00000000  
**Property:** Read-only

**Bit 0 – CFGERR** Configuration Error

| Value | Description  |
|-------|--|
| 0     | The frame and clock configurations are correct.  |
| 1     | The frame and clock configurations are wrong (see <a href="#">Clock Configuration</a> for information about allowed configurations). |

### 42.7.5 CLASSD Transmit Holding Register

**Name:** CLASSD\_THR  
**Offset:** 0x10  
**Reset:** 0x00000000  
**Property:** Read/Write

|             |     |     |     |     |     |     |     |     |
|-------------|-----|-----|-----|-----|-----|-----|-----|-----|

| Reset       | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

**Bits 31:16 – RDATA[15:0]** Right Channel Data

**Bits 15:0 – LDATA[15:0]** Left Channel Data

### 42.7.6 CLASSD Interrupt Enable Register

**Name:** CLASSD\_IER  
**Offset:** 0x14  
**Reset:** –  
**Property:** Write-only

#### Bit 0 – DATRDY Data Ready

| Value | Description  |
|-------|--|
| 0     | No effect.   |
| 1     | Enables the interrupt when CLASSD is ready to receive new data to convert. |

### 42.7.7 CLASSD Interrupt Disable Register

**Name:** CLASSD\_IDR  
**Offset:** 0x18  
**Reset:** –  
**Property:** Write-only

#### Bit 0 – DATRDY Data Ready

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | Disables the interrupt when CLASSD is ready to receive new data to convert. |

### 42.7.8 CLASSD Interrupt Mask Register

**Name:** CLASSD\_IMR  
**Offset:** 0x1C  
**Reset:** 0x00000000  
**Property:** Read-only

**Bit 0 – DATRDY** Data Ready

| Value | Description                |
|-------|----------------------------|
| 0     | The interrupt is disabled. |
| 1     | The interrupt is enabled.  |

### 42.7.9 CLASSD Interrupt Status Register

**Name:** CLASSD\_ISR  
**Offset:** 0x20  
**Reset:** 0x00000000  
**Property:** Read-only

#### Bit 0 – DATRDY Data Ready

| Value | Description   |
|-------|---|
| 0     | CLASSD has not been ready to convert a value since the last read of CLASSD_ISR. |
| 1     | CLASSD has been ready to convert a value since the last read of CLASSD_ISR.     |

### 42.7.10 CLASSD Write Protection Mode Register

**Name:** CLASSD\_WPMR  
**Offset:** 0xE4  
**Reset:** 0x00000000  
**Property:** Read/Write

|        |     |              |    |    |    |    |    |    |     |
|--------|-----|--------------|----|----|----|----|----|----|-----|
|        | Bit | 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24  |
|        |     | WPKEY[23:16] |    |    |    |    |    |    |     |
| Access |     | W            | W  | W  | W  | W  | W  | W  | W   |
| Reset  |     | 0            | 0  | 0  | 0  | 0  | 0  | 0  | 0   |
|        | Bit | 23           | 22 | 21 | 20 | 19 | 18 | 17 | 16  |
|        |     | WPKEY[15:8]  |    |    |    |    |    |    |     |
| Access |     | W            | W  | W  | W  | W  | W  | W  | W   |
| Reset  |     | 0            | 0  | 0  | 0  | 0  | 0  | 0  | 0   |
|        | Bit | 15           | 14 | 13 | 12 | 11 | 10 | 9  | 8   |
|        |     | WPKEY[7:0]   |    |    |    |    |    |    |     |
| Access |     | W            | W  | W  | W  | W  | W  | W  | W   |
| Reset  |     | 0            | 0  | 0  | 0  | 0  | 0  | 0  | 0   |
|        | Bit | 7            | 6  | 5  | 4  | 3  | 2  | 1  | 0   |
|        |     | WPEN         |    |    |    |    |    |    |     |
| Access |     |              |    |    |    |    |    |    | R/W |
| Reset  |     |              |    |    |    |    |    |    | 0   |

#### Bits 31:8 – WPKEY[23:0] Write Protection Key

| Value    | Name   | Description   |
|----------|--------|---|
| 0x434C44 | PASSWD | Writing any other value in this field aborts the write operation of the WPEN bit. |
| 4        |        | Always reads as 0.  |

#### Bit 0 – WPEN Write Protection Enable

See [Register Write Protection](#) for the list of registers that can be write-protected.

| Value | Description  |
|-------|--|
| 0     | Disables the write protection if WPKEY corresponds to 0x434C44 (“CLD” in ASCII). |
| 1     | Enables the write protection if WPKEY corresponds to 0x434C44 (“CLD” in ASCII).  |

## 43. Inter-IC Sound Controller (I2SC)

### 43.1 Description

The Inter-IC Sound Controller (I2SC) provides a 5-wire, bidirectional, synchronous, digital audio link to external audio devices: I2SC\_DI, I2SC\_DO, I2SC\_WS, I2SC\_CK, and I2SC\_MCK pins.

The I2SC is compliant with the Inter-IC Sound (I<sup>2</sup>S) bus specification.

The I2SC consists of a receiver, a transmitter and a common clock generator that can be enabled separately to provide Master, Slave or Controller modes with receiver and/or transmitter active.

DMA Controller channels, separate for the receiver and for the transmitter, allow a continuous high bit rate data transfer without processor intervention to the following:

- Audio CODECs in Master, Slave, or Controller mode
- Stereo DAC or ADC through a dedicated I<sup>2</sup>S serial interface

The I2SC uses a single DMA Controller channel for both audio channels.

The 8- and 16-bit compact stereo format reduces the required DMA Controller bandwidth by transferring the left and right samples within the same data word.

In Master mode, the I2SC can produce a  $32 f_s$  to  $1024 f_s$  master clock that provides an over-sampling clock to an external audio codec or digital signal processor (DSP).

### 43.2 Embedded Characteristics

- Compliant with Inter-IC Sound (I<sup>2</sup>S) Bus Specification
- Master, Slave, and Controller Modes
  - Slave: Data Received/Transmitted
  - Master: Data Received/Transmitted And Clocks Generated
  - Controller: Clocks Generated
- Individual Enable and Disable of Receiver, Transmitter and Clocks
- Configurable Clock Generator Common to Receiver and Transmitter
  - Suitable for a Wide Range of Sample Frequencies ( $f_s$ ), Including 32 kHz, 44.1 kHz, 48 kHz, 88.2 kHz, 96 kHz, and 192 kHz
  - $32 f_s$  to  $1024 f_s$  Master Clock Generated for External Oversampling Data Converters
- Support for Multiple Data Formats
  - 32-, 24-, 20-, 18-, 16-, and 8-bit Mono or Stereo Format
  - 16- and 8-bit Compact Stereo Format, with Left and Right Samples Packed in the Same Word to Reduce Data Transfers
- DMA Controller Interfaces the Receiver and Transmitter to Reduce Processor Overhead
  - One DMA Controller Channel for Both Audio Channels
- Smart Holding Registers Management to Avoid Audio Channels Mix After Overrun or Underrun

### 43.3 Block Diagram

Figure 43-1. I2SC Block Diagram

(1) For the value of 'PID', refer to I2SCx in the table "Peripheral Identifiers".

### 43.4 I/O Lines Description

Table 43-1. I/O Lines Description

| Pin Name | Pin Description              | Type         |
|----------|------------------------------|--------------|
| I2SC_MCK | Master Clock                 | Output       |
| I2SC_CK  | Serial Clock                 | Input/Output |
| I2SC_WS  | I <sup>2</sup> S Word Select | Input/Output |
| I2SC_DI  | Serial Data Input            | Input        |
| I2SC_DO  | Serial Data Output           | Output       |

### 43.5 Product Dependencies

To use the I2SC, other parts of the system must be configured correctly, as described below.

#### 43.5.1 I/O Lines

The I2SC pins may be multiplexed with I/O Controller lines. The user must first program the PIO Controller to assign the required I2SC pins to their peripheral function. If the I2SC I/O lines are not used by the application, they can be used for other purposes by the PIO Controller. The user must enable the I2SC inputs and outputs that are used.

### 43.5.2 Power Management

If the CPU enters a Sleep mode that disables clocks used by the I2SC, the I2SC stops functioning and resumes operation after the system wakes up from Sleep mode.

### 43.5.3 Clocks

The clock for the I2SC bus interface is generated by the Power Management Controller (PMC). I2SC must be disabled before disabling the clock to avoid freezing the I2SC in an undefined state.

### 43.5.4 DMA Controller

The I2SC interfaces to the DMA Controller. Using the I2SC DMA functionality requires the DMA Controller to be programmed first.

### 43.5.5 Interrupt Sources

The I2SC interrupt line is connected to the Interrupt Controller. Using the I2SC interrupt requires the Interrupt Controller to be programmed first.

## 43.6 Functional Description

### 43.6.1 Initialization

The I2SC features a receiver, a transmitter and a clock generator for Master and Controller modes. Receiver and transmitter share the same serial clock and word select.

Before enabling the I2SC, the selected configuration must be written to the I2SC Mode Register (I2SC\_MR) and to the I2S Clock Source Selection register (SFR\_I2SCLKSEL) described in the section “Special Function Registers (SFR)”.

If the I2SC\_MR.IMCKMODE bit is set, the I2SC\_MR.IMCKFS field must be configured as described in section “[Serial Clock and Word Select Generation](#)”.

Once the I2SC\_MR has been written, the I2SC clock generator, receiver, and transmitter can be enabled by writing a '1' to the CKEN, RXEN, and TXEN bits in the Control Register (I2SC\_CR). The clock generator can be enabled alone in Controller mode to output clocks to the I2SC\_MCK, I2SC\_CK, and I2SC\_WS pins. The clock generator must also be enabled if the receiver or the transmitter is enabled.

The clock generator, receiver, and transmitter can be disabled independently by writing a '1' to I2SC\_CR.CXDIS, I2SC\_CR.RXDIS and/or I2SC\_CR.TXDIS, respectively. Once requested to stop, they stop only when the transmission of the pending frame transmission is completed.

### 43.6.2 Basic Operation

The receiver can be operated by reading the Receiver Holding Register (I2SC\_RHR), whenever the Receive Ready (RXRDY) bit in the Status Register (I2SC\_SR) is set. Successive values read from RHR correspond to the samples from the left and right audio channels for the successive frames.

The transmitter can be operated by writing to the Transmitter Holding Register (I2SC\_THR), whenever the Transmit Ready (TXRDY) bit in the I2SC\_SR is set. Successive values written to THR correspond to the samples from the left and right audio channels for the successive frames.

The RXRDY and TXRDY bits can be polled by reading the I2SC\_SR.

The I2SC processor load can be reduced by enabling interrupt-driven operation. The RXRDY and/or TXRDY interrupt requests can be enabled by writing a '1' to the corresponding bit in the Interrupt Enable Register (I2SC\_IER). The interrupt service routine associated to the I2SC interrupt request is executed whenever the Receive Ready or the Transmit Ready status bit is set.

### 43.6.3 Master, Controller and Slave Modes

In Master and Controller modes, the I2SC provides the master clock, the serial clock and the word select. I2SC\_MCK, I2SC\_CK, and I2SC\_WS pins are outputs.

In Controller mode, the I2SC receiver and transmitter are disabled. Only the clocks are enabled and used by an external receiver and/or transmitter.

In Slave mode, the I2SC receives the serial clock and the word select from an external master. I2SC\_CK and I2SC\_WS pins are inputs.

The mode is selected by writing the MODE field in the I2SC\_MR. Since the MODE field changes the direction of the I2SC\_WS and I2SC\_SCK pins, the I2SC\_MR must be written when the I2SC is stopped.

### 43.6.4 I<sup>2</sup>S Reception and Transmission Sequence

As specified in the I<sup>2</sup>S protocol, data bits are left-justified in the word select time slot, with the MSB transmitted first, starting one clock period after the transition on the word select line.

**Figure 43-2. I<sup>2</sup>S Reception and Transmission Sequence**

Data bits are sent on the falling edge of the serial clock and sampled on the rising edge of the serial clock. The word select line indicates the channel in transmission, a low level for the left channel and a high level for the right channel.

The length of transmitted words can be chosen among 8, 16, 18, 20, 24, and 32 bits by writing the I2SC\_MR.DATALENGTH field.

If the time slot allows for more data bits than written in the I2SC\_MR.DATALENGTH field, zeroes are appended to the transmitted data word or extra received bits are discarded.

### 43.6.5 Serial Clock and Word Select Generation

The generation of clocks in the I2SC is described in figure "[I2SC Clock Generation](#)".

In Slave mode, the serial clock and word select clock are driven by an external master. I2SC\_CK and I2SC\_WS pins are inputs.

# SAMA5D2 Series

## Inter-IC Sound Controller (I2SC)

In Master mode, the user can configure the master clock, serial clock, and word select clock through the I2SC\_MR. I2SC\_MCK, I2SC\_CK, and I2SC\_WS pins are outputs and MCK is used to derive the I2SC clocks.

In Master mode, if the peripheral clock frequency is higher than 96 MHz, GCLK[PID] from the PMC must be selected as the I2SC input clock by writing a '1' in the CLKSELx bit of the SFR\_I2SCLKSEL register located in SFR.

Audio codecs connected to the I2SC pins may require a master clock (I2SC\_MCK) signal with a frequency multiple of the audio sample frequency ( $f_s$ ), such as  $256f_s$ . When the I2SC is in Master mode, writing a '1' to I2SC\_MR.IMCKMODE outputs MCK as master clock to the I2SC\_MCK pin, and divides MCK to create the internal bit clock, output on the I2SC\_CK pin. The clock division factor is defined by writing to I2SC\_MR.IMCKFSS and I2SC\_MR.DATALENGTH, as described in the I2SC\_MR.IMCKFSS field description.

The master clock (I2SC\_MCK) frequency is  $(2 \times 16 \times (\text{IMCKFSS} + 1)) / (\text{IMCKDIV} + 1)$  times the sample frequency ( $f_s$ ), i.e., I2SC\_WS frequency.

Example: If the sampling rate is 44.1 kHz with an I2S master clock (I2SC\_MCK) ratio of 256, the core frequency must be an integer multiple of 11.2896 MHz. Assuming an integer multiple of 4, the IMCKDIV field must be configured to 4; the field IMCKFSS must then be set to 31.

The serial clock (I2SC\_CK) frequency is  $2 \times \text{Slot Length}$  times the sample frequency ( $f_s$ ), where Slot Length is defined in table [Slot Length](#).

**Table 43-2. Slot Length**

| I2SC_MR.DATALENGTH | Word Length            | Slot Length                                    |
|--------------------|------------------------|--|
| 0                  | 32 bits                | 32   |
| 1                  | 24 bits                | 32 if I2SC_MR.IWS = 0<br>24 if I2SC_MR.IWS = 1 |
| 2                  | 20 bits                |  |
| 3                  | 18 bits                |  |
| 4                  | 16 bits                | 16   |
| 5                  | 16 bits compact stereo |  |
| 6                  | 8 bits                 | 8  |
| 7                  | 8 bits compact stereo  |  |

 I2SC\_MR.IMCKMODE must be written to '1' if the master clock frequency is strictly higher than the serial clock.

If a master clock output is not required, the MCK clock is used as I2SC\_CK by clearing I2SC\_MR.IMCKMODE. Alternatively, if the frequency of the MCK clock used is a multiple of the required I2SC\_CK frequency, the I2SC\_MCK to I2SC\_CK divider can be used with the ratio defined by writing the I2SC\_MR.IMCKFSS field.

The I2SC\_WS pin is used as word select as described in section [“I2S Reception and Transmission Sequence”](#).

SFR.SFR\_I2SCLKSEL.CLKSELx

### 43.6.6 Mono

When the Transmit Mono bit (TXMONO) in I2SC\_MR is set, data written to the left channel is duplicated to the right output channel.

When the Receive Mono bit (RXMONO) in I2SC\_MR is set, data received from the left channel is duplicated to the right channel.

### 43.6.7 Holding Registers

The I2SC user interface includes a Receive Holding Register (I2SC\_RHR) and a Transmit Holding Register (I2SC\_THR). These registers are used to access audio samples for both audio channels.

When a new data word is available in I2SC\_RHR, the Receive Ready bit (RXRDY) in I2SC\_SR is set. Reading I2SC\_RHR clears this bit.

A receive overrun condition occurs if a new data word becomes available before the previous data word has been read from I2SC\_RHR. In this case, the Receive Overrun bit in I2SC\_SR and bit *i* of the RXORCH field in I2SC\_SR are set, where *i* is the current receive channel number.

When I2SC\_THR is empty, the Transmit Ready bit (TXRDY) in I2SC\_SR is set. Writing to I2SC\_THR clears this bit.

A transmit underrun condition occurs if a new data word needs to be transmitted before it has been written to I2SC\_THR. In this case, the Transmit Underrun (TXUR) bit and bit *i* of the TXORCH field in I2SC\_SR are set, where *i* is the current transmit channel number. If the TXSAME bit in I2SC\_MR is '0', then a zero data word is transmitted in case of underrun. If I2SC\_MR.TXSAME is '1', then the previous data word for the current transmit channel number is transmitted.

Data words are right-justified in I2SC\_RHR and I2SC\_THR. For the 16-bit compact stereo data format, the left sample uses bits 15:0 and the right sample uses bits 31:16 of the same data word. For the 8-bit compact stereo data format, the left sample uses bits 7:0 and the right sample uses bits 15:8 of the same data word.

### 43.6.8 DMA Controller Operation

All receiver audio channels are assigned to a single DMA Controller.

The DMA Controller reads from the I2SC\_RHR and writes to the I2SC\_THR for both audio channels successively.

The DMA Controller transfers may use 32-bit word, 16-bit halfword, or 8-bit byte depending on the value of the I2SC\_MR.DATALength field.

### 43.6.9 Loopback Mode

For debug purposes, the I2SC can be configured to loop back the transmitter to the Receiver. Writing a '1' to the I2SC\_MR.LOOP bit internally connects I2SC\_DO to I2SC\_DI, so that the transmitted data is also received. Writing a '0' to I2SC\_MR.LOOP restores the normal behavior with independent Receiver and Transmitter. As for other changes to the Receiver or Transmitter configuration, the I2SC Receiver and Transmitter must be disabled before writing to I2SC\_MR to update I2SC\_MR.LOOP.

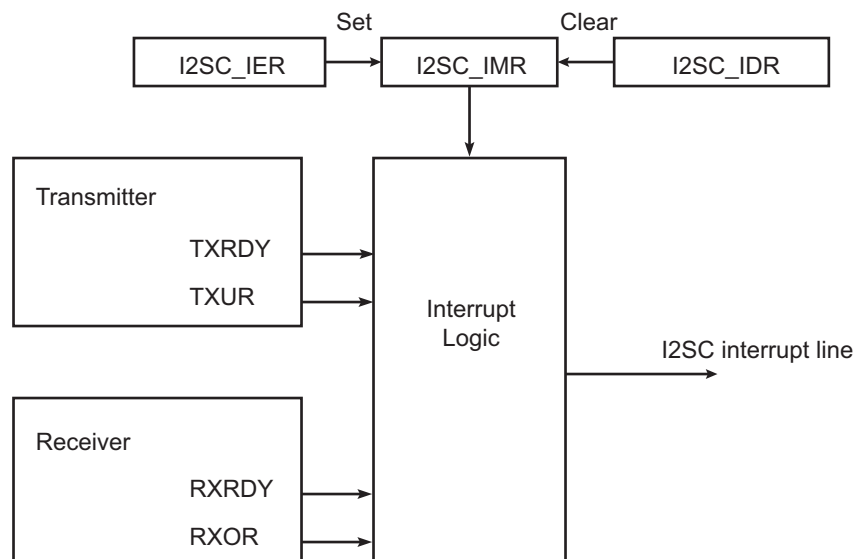

### 43.6.10 Interrupts

An I2SC interrupt request can be triggered whenever one or several of the following bits are set in I2SC\_SR: Receive Ready (RXRDY), Receive Overrun (RXOR), Transmit Ready (TXRDY) or Transmit Underrun (TXUR).

The interrupt request is generated if the corresponding bit in the Interrupt Mask Register (I2SC\_IMR) is set. Bits in I2SC\_IMR are set by writing a '1' to the corresponding bit in I2SC\_IER and cleared by writing a '1' to the corresponding bit in the Interrupt Disable Register (I2SC\_IDR). The interrupt request remains active until the corresponding bit in I2SC\_SR is cleared by writing a '1' to the corresponding bit in the Status Clear Register (I2SC\_SCR).

For debug purposes, interrupt requests can be simulated by writing a '1' to the corresponding bit in the Status Set Register (I2SC\_SSR).

**Figure 43-4. Interrupt Block Diagram**

### 43.7 I2SC Application Examples

The I2SC supports several serial communication modes used in audio or high-speed serial links. Examples of standard applications are shown in the following figures. All serial link applications supported by the I2SC are not listed here.

**Figure 43-5. Slave Transmitter I2SC Application Example**

| Bit    | 7     | 6  | 5     | 4    | 3     | 2    | 1     | 0    |
|        | SWRST |    | TXDIS | TXEN | CKDIS | CKEN | RXDIS | RXEN |
| Access | W     |    | W     | W    | W     | W    | W     | W    |
| Reset  | -     |    | -     | -    | -     | -    | -     | -    |

#### Bit 7 – SWRST Software Reset

| Value | Description   |
|-------|---|
| 0     | Writing a '0' to this bit has no effect.  |
| 1     | Writing a '1' to this bit resets all the registers in the I2SC. The I2SC is disabled after the reset. |

#### Bit 5 – TXDIS Transmitter Disable

| Value | Description   |
|-------|---|
| 0     | Writing a '0' to this bit has no effect.  |
| 1     | Writing a '1' to this bit disables the I2SC transmitter. Bit I2SC_SR.TXEN is cleared when the Transmitter is stopped. |

#### Bit 4 – TXEN Transmitter Enable

| Value | Description   |
|-------|---|
| 0     | Writing a '0' to this bit has no effect.  |
| 1     | Writing a '1' to this bit enables the I2SC transmitter, if TXDIS is not one. Bit I2SC_SR.TXEN is set when the Transmitter is started. |

#### Bit 3 – CKDIS Clocks Disable

# SAMA5D2 Series

## Inter-IC Sound Controller (I2SC)

| Value | Description  |
|-------|--|
| 0     | Writing a '0' to this bit has no effect.                       |
| 1     | Writing a zone to this bit disables the I2SC clock generation. |

### Bit 2 – CKEN Clocks Enable

| Value | Description  |
|-------|--|
| 0     | Writing a '0' to this bit has no effect.   |
| 1     | Writing a '1' to this bit enables the I2SC clocks generation, if CKDIS is not one. |

### Bit 1 – RXDIS Receiver Disable

| Value | Description   |
|-------|---|
| 0     | Writing a '0' to this bit has no effect.  |
| 1     | Writing a '1' to this bit disables the I2SC receiver. Bit I2SC_SR.RXEN is cleared when the receiver is stopped. |

### Bit 0 – RXEN Receiver Enable

| Value | Description   |
|-------|---|
| 0     | Writing a '0' to this bit has no effect.  |
| 1     | Writing a '1' to this bit enables the I2SC receiver, if RXDIS is not one. Bit I2SC_SR.RXEN is set when the receiver is activated. |

### 43.8.2 I2SC Mode Register

**Name:** I2SC\_MR  
**Offset:** 0x04  
**Reset:** 0x00000000  
**Property:** Read/Write

The I2SC\_MR must be written when the I2SC is stopped. The proper sequence is to write to I2SC\_MR, then write to I2SC\_CR to enable the I2SC or to disable the I2SC before writing a new value to I2SC\_MR.

|        |             |          |                 |     |        |     |        |     |
|--------|-------------|----------|-----------------|-----|--------|-----|--------|-----|
| Bit    | 31          | 30       | 29              | 28  | 27     | 26  | 25     | 24  |
|        | IWS         | IMCKMODE | IMCKFS[5:0]     |     |        |     |        |     |

| Reset  | 0           | 0        | 0               | 0   | 0      | 0   | 0      | 0   |
|        |             |          |                 |     |        |     |        |     |
| Bit    | 23          | 22       | 21              | 20  | 19     | 18  | 17     | 16  |
|        |             |          | IMCKDIV[5:0]    |     |        |     |        |     |
| Access |             |          | R/W             | R/W | R/W    | R/W | R/W    | R/W |
| Reset  |             |          | 0               | 0   | 0      | 0   | 0      | 0   |
|        |             |          |                 |     |        |     |        |     |
| Bit    | 15          | 14       | 13              | 12  | 11     | 10  | 9      | 8   |
|        | TXSAME      |          | TXMONO          |     | RXLOOP |     | RXMONO |     |
| Access | R/W         |          | R/W             |     | R/W    |     | R/W    |     |
| Reset  | 0           |          | 0               |     | 0      |     | 0      |     |
|        |             |          |                 |     |        |     |        |     |
| Bit    | 7           | 6        | 5               | 4   | 3      | 2   | 1      | 0   |
|        | FORMAT[1:0] |          | DATALENGTH[2:0] |     |        |     | MODE   |     |
| Access | R/W         | R/W      | R/W             |     |        |     | R/W    |     |
| Reset  | 0           | 0        | 0               |     |        |     | 0      |     |

**Bit 31 – IWS** I2SC\_WS Slot Width  
 Refer to table [Slot Length \(I2S format\)](#).

| Value | Description  |
|-------|--|
| 0     | I2SC_WS slot is 32 bits wide for DATALENGTH = 18/20/24 bits. |
| 1     | I2SC_WS slot is 24 bits wide for DATALENGTH = 18/20/24 bits. |

**Bit 30 – IMCKMODE** Master Clock Mode

**WARNING** If I2SC\_MCK frequency is the same as I2SC\_CK, IMCKMODE must be cleared. Refer to section [Serial Clock and Word Select Generation](#) and table [Slot Length](#).

| Value | Description   |
|-------|---|
| 0     | No master clock generated (Selected Clock drives I2SC_CK output).               |
| 1     | Master clock generated (internally generated clock is used as I2SC_MCK output). |

**Bits 29:24 – IMCKFS[5:0]** Master Clock to  $f_s$  Ratio

Master clock frequency is  $[2 \times 16 \times (\text{IMCKFS} + 1)] / (\text{IMCKDIV} + 1)$  times the sample rate, i.e., I2SC\_WS frequency.

| Value | Name     | Description                        |
|-------|----------|------------------------------------|
| 0     | M2SF32   | Sample frequency ratio set to 32   |
| 1     | M2SF64   | Sample frequency ratio set to 64   |
| 2     | M2SF96   | Sample frequency ratio set to 96   |
| 3     | M2SF128  | Sample frequency ratio set to 128  |
| 5     | M2SF192  | Sample frequency ratio set to 192  |
| 7     | M2SF256  | Sample frequency ratio set to 256  |
| 11    | M2SF384  | Sample frequency ratio set to 384  |
| 15    | M2SF512  | Sample frequency ratio set to 512  |
| 23    | M2SF768  | Sample frequency ratio set to 768  |
| 31    | M2SF1024 | Sample frequency ratio set to 1024 |
| 47    | M2SF1536 | Sample frequency ratio set to 1536 |
| 63    | M2SF2048 | Sample frequency ratio set to 2048 |

**Bits 21:16 – IMCKDIV[5:0]** Selected Clock to I2SC Master Clock Ratio

I2SC\_MCK Master clock output frequency is Selected Clock divided by  $(\text{IMCKDIV} + 1)$ . Refer to the IMCKFS field description.

**Note:**

1. This field is write-only. Always read as '0'.
2. Do not write a '0' to this field.

**Bit 14 – TXSAME** Transmit Data when Underrun

| Value | Description                               |
|-------|---|
| 0     | Zero sample transmitted when underrun.    |
| 1     | Previous sample transmitted when underrun |

**Bit 12 – TXMONO** Transmit Mono

| Value | Description  |
|-------|--|
| 0     | Stereo   |
| 1     | Mono, with left audio samples duplicated to right audio channel by the I2SC. |

**Bit 10 – RXLOOP** Loopback Test Mode

| Value | Description  |
|-------|--|
| 0     | Normal mode  |
| 1     | I2SC_DO output of I2SC is internally connected to I2SC_DI input. |

**Bit 8 – RXMONO** Receive Mono

| Value | Description  |
|-------|--|
| 0     | Stereo   |
| 1     | Mono, with left audio samples duplicated to right audio channel by the I2SC. |

**Bits 7:6 – FORMAT[1:0]** Data Format

# SAMA5D2 Series

## Inter-IC Sound Controller (I2SC)

| Value | Name | Description   |
|-------|------|---|
| 0     | I2S  | I <sup>2</sup> S format, stereo with I2SC_WS low for left channel, and MSB of sample starting one I2SC_CK period after I2SC_WS edge |
| 1     | LJ   | Left-justified format, stereo with I2SC_WS high for left channel, and MSB of sample starting on I2SC_WS edge                        |
| 2     | –    | Reserved  |
| 3     | –    | Reserved  |

### Bits 4:2 – DATALENGTH[2:0] Data Word Length

| Value | Name            | Description   |
|-------|-----------------|---|
| 0     | 32_BITS         | Data length is set to 32 bits.  |
| 1     | 24_BITS         | Data length is set to 24 bits.  |
| 2     | 20_BITS         | Data length is set to 20 bits.  |
| 3     | 18_BITS         | Data length is set to 18 bits.  |
| 4     | 16_BITS         | Data length is set to 16 bits.  |
| 5     | 16_BITS_COMPACT | Data length is set to 16-bit compact stereo. Left sample in bits 15:0 and right sample in bits 31:16 of same word.  |
| 6     | 8_BITS          | Data length is set to 8 bits.   |
| 7     | 8_BITS_COMPACT  | Data length is set to 8-bit compact stereo. Left sample in bits 7:0 and right sample in bits 15:8 of the same word. |

### Bit 0 – MODE Inter-IC Sound Controller Mode

| Value | Name   | Description   |
|-------|--------|---|
| 0     | SLAVE  | I2SC_CK and I2SC_WS pin inputs used as bit clock and word select/frame synchronization.   |
| 1     | MASTER | Bit clock and word select/frame synchronization generated by I2SC from MCK and output to I2SC_CK and I2SC_WS pins. Peripheral clock or GCLK is output as master clock on I2SC_MCK if I2SC_MR.IMCKMODE is set. |

### 43.8.3 I2SC Status Register

**Name:** I2SC\_SR  
**Offset:** 0x08  
**Reset:** 0x00000000  
**Property:** Read-only

|        |    |      |             |      |    |      |             |      |
|--------|----|------|-------------|------|----|------|-------------|------|
| Bit    | 31 | 30   | 29          | 28   | 27 | 26   | 25          | 24   |
|        |    |      |             |      |    |      |             |      |
| Access |    |      |             |      |    |      |             |      |
| Reset  |    |      |             |      |    |      |             |      |
|        |    |      |             |      |    |      |             |      |
| Bit    | 23 | 22   | 21          | 20   | 19 | 18   | 17          | 16   |
|        |    |      | TXURCH[1:0] |      |    |      |             |      |
| Access |    |      | R           | R    |    |      |             |      |
| Reset  |    |      | 0           | 0    |    |      |             |      |
|        |    |      |             |      |    |      |             |      |
| Bit    | 15 | 14   | 13          | 12   | 11 | 10   | 9           | 8    |
|        |    |      |             |      |    |      | RXORCH[1:0] |      |
| Access |    |      |             |      |    |      | R           | R    |
| Reset  |    |      |             |      |    |      | 0           | 0    |
|        |    |      |             |      |    |      |             |      |
| Bit    | 7  | 6    | 5           | 4    | 3  | 2    | 1           | 0    |
|        |    | TXUR | TXRDY       | TXEN |    | RXOR | RXRDY       | RXEN |
| Access |    | R    | R           | R    |    | R    | R           | R    |
| Reset  |    | 0    | 0           | 0    |    | 0    | 0           | 0    |

#### Bits 21:20 – TXURCH[1:0] Transmit Underrun Channel

| Value | Description   |
|-------|---|
| 0     | This field is cleared when I2SC_SCR.TXUR is written to '1'.   |
| 1     | Bit i of this field is set when a transmit underrun error occurred in channel i (i = 0 for first channel of the frame). |

#### Bits 9:8 – RXORCH[1:0] Receive Overrun Channel

This field is cleared when I2SC\_SCR.RXOR is written to '1'.

Bit i of this field is set when a receive overrun error occurred in channel i (i = 0 for first channel of the frame).

#### Bit 6 – TXUR Transmit Underrun

| Value | Description  |
|-------|--|
| 0     | This bit is cleared when the corresponding bit in I2SC_SCR is written to '1'.  |
| 1     | This bit is set when an underrun error occurs on I2SC_THR or when the corresponding bit in I2SC_SSR is written to '1'. |

#### Bit 5 – TXRDY Transmit Ready

# SAMA5D2 Series

## Inter-IC Sound Controller (I2SC)

| Value | Description  |
|-------|--|
| 0     | This bit is cleared when data is written to I2SC_THR.                                      |
| 1     | This bit is set when I2SC_THR is empty and can be written with new data to be transmitted. |

### Bit 4 – TXEN Transmitter Enabled

| Value | Description   |
|-------|---|
| 0     | This bit is cleared when the transmitter is disabled, following a I2SC_CR.TXDIS or I2SC_CR.SWRST request. |
| 1     | This bit is set when the transmitter is enabled, following a I2SC_CR.TXEN request.                        |

### Bit 2 – RXOR Receive Overrun

| Value | Description   |
|-------|---|
| 0     | This bit is cleared when the corresponding bit in I2SC_SCR is written to '1'.   |
| 1     | This bit is set when an overrun error occurs on I2SC_RHR or when the corresponding bit in I2SC_SSR is written to '1'. |

### Bit 1 – RXRDY Receive Ready

| Value | Description  |
|-------|--|
| 0     | This bit is cleared when I2SC_RHR is read.                 |
| 1     | This bit is set when received data is present in I2SC_RHR. |

### Bit 0 – RXEN Receiver Enabled

| Value | Description   |
|-------|---|
| 0     | This bit is cleared when the receiver is disabled, following a RXDIS or SWRST request in I2SC_CR. |
| 1     | This bit is set when the receiver is enabled, following a RXEN request in I2SC_CR.                |

#### 43.8.4 I2SC Status Clear Register

**Name:** I2SC\_SCR  
**Offset:** 0x0C  
**Reset:** –  
**Property:** Write-only

|        |    |    |             |    |    |    |             |    |
|--------|----|----|-------------|----|----|----|-------------|----|
| Bit    | 31 | 30 | 29          | 28 | 27 | 26 | 25          | 24 |

| Access |    |    | W           |    |    |    | W           |    |
| Reset  |    |    | –           |    |    |    | –           |    |

**Bits 21:20 – TXURCH[1:0]** Transmit Underrun Per Channel Status Clear

Writing a '0' has no effect.

Writing a '1' to any bit in this field clears the corresponding bit in the I2SC\_SR and the corresponding interrupt request.

**Bits 9:8 – RXORCH[1:0]** Receive Overrun Per Channel Status Clear

Writing a '0' has no effect.

Writing a '1' to any bit in this field clears the corresponding bit in the I2SC\_SR and the corresponding interrupt request.

**Bit 6 – TXUR** Transmit Underrun Status Clear

Writing a '0' to this bit has no effect.

Writing a '1' to this bit clears the status bit.

**Bit 2 – RXOR** Receive Overrun Status Clear

Writing a '0' to this bit has no effect.

Writing a '1' to this bit clears the status bit.

### 43.8.5 I2SC Status Set Register

**Name:** I2SC\_SSR  
**Offset:** 0x10  
**Property:** Write-only

**Bits 21:20 – TXURCH[1:0]** Transmit Underrun Per Channel Status Set

Writing a '0' has no effect.

Writing a '1' to any bit in this field sets the corresponding bit in I2SC\_SR and the corresponding interrupt request.

**Bits 9:8 – RXORCH[1:0]** Receive Overrun Per Channel Status Set

Writing a '0' has no effect.

Writing a '1' to any bit in this field sets the corresponding bit in I2SC\_SR and the corresponding interrupt request.

**Bit 6 – TXUR** Transmit Underrun Status Set

Writing a '0' to this bit has no effect.

Writing a '1' to this bit sets the status bit.

**Bit 2 – RXOR** Receive Overrun Status Set

Writing a '0' to this bit has no effect.

Writing a '1' to this bit sets the status bit.

### 43.8.6 I2SC Interrupt Enable Register

**Name:** I2SC\_IER  
**Offset:** 0x14  
**Property:** Write-only

**Bit 6 – TXUR** Transmit Underflow Interrupt Enable

| Value | Description   |
|-------|---|
| 0     | Writing a '0' to this bit has no effect.                          |
| 1     | Writing a '1' to this bit sets the corresponding bit in I2SC_IMR. |

**Bit 5 – TXRDY** Transmit Ready Interrupt Enable

| Value | Description   |
|-------|---|
| 0     | Writing a '0' to this bit as no effect.                           |
| 1     | Writing a '1' to this bit sets the corresponding bit in I2SC_IMR. |

**Bit 2 – RXOR** Receiver Overrun Interrupt Enable

| Value | Description   |
|-------|---|
| 0     | Writing a '0' to this bit has no effect.                          |
| 1     | Writing a '1' to this bit sets the corresponding bit in I2SC_IMR. |

**Bit 1 – RXRDY** Receiver Ready Interrupt Enable

| Value | Description   |
|-------|---|
| 0     | Writing a '0' to this bit has no effect.                          |
| 1     | Writing a '1' to this bit sets the corresponding bit in I2SC_IMR. |

### 43.8.7 I2SC Interrupt Disable Register

**Name:** I2SC\_IDR  
**Offset:** 0x18  
**Property:** Write-only

**Bit 6 – TXUR** Transmit Underflow Interrupt Disable

| Value | Description   |
|-------|---|
| 0     | Writing a '0' to this bit has no effect.                            |
| 1     | Writing a '1' to this bit clears the corresponding bit in I2SC_IMR. |

**Bit 5 – TXRDY** Transmit Ready Interrupt Disable

| Value | Description   |
|-------|---|
| 0     | Writing a '0' to this bit has no effect.                            |
| 1     | Writing a '1' to this bit clears the corresponding bit in I2SC_IMR. |

**Bit 2 – RXOR** Receiver Overrun Interrupt Disable

| Value | Description   |
|-------|---|
| 0     | Writing a '0' to this bit has no effect.                            |
| 1     | Writing a '1' to this bit clears the corresponding bit in I2SC_IMR. |

**Bit 1 – RXRDY** Receiver Ready Interrupt Disable

| Value | Description   |
|-------|---|
| 0     | Writing a '0' to this bit has no effect.                            |
| 1     | Writing a '1' to this bit clears the corresponding bit in I2SC_IMR. |

### 43.8.8 I2SC Interrupt Mask Register

**Name:** I2SC\_IMR  
**Offset:** 0x1C  
**Reset:** 0x00000000  
**Property:** Read-only

|        |    |  |    |  |    |  |    |  |    |  |    |  |    |  |    |
|--------|----|--|----|--|----|--|----|--|----|--|----|--|----|--|----|
| Bit    | 31 |  | 30 |  | 29 |  | 28 |  | 27 |  | 26 |  | 25 |  | 24 |
|        |    |  |    |  |    |  |    |  |    |  |    |  |    |  |    |
| Access |    |  |    |  |    |  |    |  |    |  |    |  |    |  |    |
| Reset  |    |  |    |  |    |  |    |  |    |  |    |  |    |  |    |
|        |    |  |    |  |    |  |    |  |    |  |    |  |    |  |    |

| Access |    |  |    |  |    |  |    |  |    |  |    |  |    |  |    |
| Reset  |    |  |    |  |    |  |    |  |    |  |    |  |    |  |    |
|        |    |  |    |  |    |  |    |  |    |  |    |  |    |  |    |
| Bit    | 15 |  | 14 |  | 13 |  | 12 |  | 11 |  | 10 |  | 9  |  | 8  |
|        |    |  |    |  |    |  |    |  |    |  |    |  |    |  |    |
| Access |    |  |    |  |    |  |    |  |    |  |    |  |    |  |    |
| Reset  |    |  |    |  |    |  |    |  |    |  |    |  |    |  |    |
|        |    |  |    |  |    |  |    |  |    |  |    |  |    |  |    |
| Bit    | 7  |  | 6  |  | 5  |  | 4  |  | 3  |  | 2  |  | 1  |  | 0  |
|        |    |  |    |  |    |  |    |  |    |  |    |  |    |  |    |
| Access |    |  | R  |  | R  |  |    |  |    |  | R  |  | R  |  |    |
| Reset  |    |  | 0  |  | 0  |  |    |  |    |  | 0  |  | 0  |  |    |

#### Bit 6 – TXUR Transmit Underflow Interrupt Disable

| Value | Description  |
|-------|--|
| 0     | The corresponding interrupt is disabled. This bit is cleared when the corresponding bit in I2SC_IDR is written to '1'. |
| 1     | The corresponding interrupt is enabled. This bit is set when the corresponding bit in I2SC_IER is written to '1'.      |

#### Bit 5 – TXRDY Transmit Ready Interrupt Disable

| Value | Description  |
|-------|--|
| 0     | The corresponding interrupt is disabled. This bit is cleared when the corresponding bit in I2SC_IDR is written to '1'. |
| 1     | The corresponding interrupt is enabled. This bit is set when the corresponding bit in I2SC_IER is written to '1'.      |

#### Bit 2 – RXOR Receiver Overrun Interrupt Disable

| Value | Description  |
|-------|--|
| 0     | The corresponding interrupt is disabled. This bit is cleared when the corresponding bit in I2SC_IDR is written to '1'. |

# SAMA5D2 Series

## Inter-IC Sound Controller (I2SC)

---

---

| Value | Description   |
|-------|---|
| 1     | The corresponding interrupt is enabled. This bit is set when the corresponding bit in I2SC_IER is written to '1'. |

### Bit 1 – RXRDY Receiver Ready Interrupt Disable

| Value | Description  |
|-------|--|
| 0     | The corresponding interrupt is disabled. This bit is cleared when the corresponding bit in I2SC_IDR is written to '1'. |
| 1     | The corresponding interrupt is enabled. This bit is set when the corresponding bit in I2SC_IER is written to '1'.      |

### 43.8.9 I2SC Receiver Holding Register

**Name:** I2SC\_RHR  
**Offset:** 0x20  
**Reset:** 0x00000000  
**Property:** Read-only

|        |            |    |    |    |    |    |    |    |
|--------|------------|----|----|----|----|----|----|----|
| Bit    | 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 |
|        | RHR[31:24] |    |    |    |    |    |    |    |
| Access | R          | R  | R  | R  | R  | R  | R  | R  |
| Reset  | 0          | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| Bit    | 23         | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|        | RHR[23:16] |    |    |    |    |    |    |    |
| Access | R          | R  | R  | R  | R  | R  | R  | R  |
| Reset  | 0          | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| Bit    | 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  |
|        | RHR[15:8]  |    |    |    |    |    |    |    |
| Access | R          | R  | R  | R  | R  | R  | R  | R  |
| Reset  | 0          | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| Bit    | 7          | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|        | RHR[7:0]   |    |    |    |    |    |    |    |
| Access | R          | R  | R  | R  | R  | R  | R  | R  |
| Reset  | 0          | 0  | 0  | 0  | 0  | 0  | 0  | 0  |

**Bits 31:0 – RHR[31:0] Receiver Holding Register**

This field is set by hardware to the last received data word. If I2SC\_MR.DATALength specifies fewer than 32 bits, data is right-justified in the RHR field.

### 43.8.10 I2SC Transmitter Holding Register

**Name:** I2SC\_THR  
**Offset:** 0x24  
**Property:** Write-only

|        |            |    |    |    |    |    |    |    |
|--------|------------|----|----|----|----|----|----|----|
| Bit    | 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 |
|        | THR[31:24] |    |    |    |    |    |    |    |
| Access | W          | W  | W  | W  | W  | W  | W  | W  |
| Reset  | –          | –  | –  | –  | –  | –  | –  | –  |
| Bit    | 23         | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|        | THR[23:16] |    |    |    |    |    |    |    |
| Access | W          | W  | W  | W  | W  | W  | W  | W  |
| Reset  | –          | –  | –  | –  | –  | –  | –  | –  |
| Bit    | 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  |
|        | THR[15:8]  |    |    |    |    |    |    |    |
| Access | W          | W  | W  | W  | W  | W  | W  | W  |
| Reset  | –          | –  | –  | –  | –  | –  | –  | –  |
| Bit    | 7          | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|        | THR[7:0]   |    |    |    |    |    |    |    |
| Access | W          | W  | W  | W  | W  | W  | W  | W  |
| Reset  | –          | –  | –  | –  | –  | –  | –  | –  |

**Bits 31:0 – THR[31:0]** Transmitter Holding Register

Next data word to be transmitted after the current word if TXRDY is not set. If I2SC\_MR.DATALength specifies fewer than 32 bits, data is right-justified in the THR field.

## **44. Synchronous Serial Controller (SSC)**

### **44.1 Description**

The Synchronous Serial Controller (SSC) provides a synchronous communication link with external devices. It supports many serial synchronous communication protocols generally used in audio and telecom applications such as I2S, Short Frame Sync, Long Frame Sync, etc.

The SSC contains an independent receiver and transmitter and a common clock divider. The receiver and the transmitter each interface with three signals: the TD/RD signal for data, the TK/RK signal for the clock and the TF/RF signal for the Frame Sync. The transfers can be programmed to start automatically or on different events detected on the Frame Sync signal.

The SSC high-level of programmability and its use of DMA enable a continuous high bit rate data transfer without processor intervention.

Featuring connection to the DMA, the SSC enables interfacing with low processor overhead to:

- Codecs in Master or Slave mode
- DAC through dedicated serial interface, particularly I2S
- Magnetic card reader

### **44.2 Embedded Characteristics**

- Provides Serial Synchronous Communication Links Used in Audio and Telecom Applications
- Contains an Independent Receiver and Transmitter and a Common Clock Divider
- Interfaced with the DMA Controller (DMAC) to Reduce Processor Overhead
- Offers a Configurable Frame Sync and Data Length
- Receiver and Transmitter Can be Programmed to Start Automatically or on Detection of Different Events on the Frame Sync Signal
- Receiver and Transmitter Include a Data Signal, a Clock Signal and a Frame Sync Signal

### 44.3 Block Diagram

Figure 44-1. Block Diagram

### 44.4 Application Block Diagram

Figure 44-2. Application Block Diagram

### 44.5 SSC Application Examples

The SSC can support several serial communication modes used in audio or high speed serial links. Some standard applications are shown in the following figures. All serial link applications supported by the SSC are not listed here.

**Figure 44-3. Audio Application Block Diagram**

**Figure 44-4. Codec Application Block Diagram**

**Figure 44-5. Time Slot Application Block Diagram**

## 44.6 Pin Name List

**Table 44-1. I/O Lines Description**

| Pin Name | Pin Description                | Type         |
|----------|--------------------------------|--------------|
| RF       | Receive Frame Synchronization  | Input/Output |
| RK       | Receive Clock                  | Input/Output |
| RD       | Receive Data                   | Input        |
| TF       | Transmit Frame Synchronization | Input/Output |
| TK       | Transmit Clock                 | Input/Output |
| TD       | Transmit Data                  | Output       |

## 44.7 Product Dependencies

### 44.7.1 I/O Lines

The pins used for interfacing the compliant external devices may be multiplexed with PIO lines.

Before using the SSC receiver, the PIO controller must be configured to dedicate the SSC receiver I/O lines to the SSC Peripheral mode.

Before using the SSC transmitter, the PIO controller must be configured to dedicate the SSC transmitter I/O lines to the SSC Peripheral mode.

### 44.7.2 Power Management

The SSC is not continuously clocked. The SSC interface may be clocked through the Power Management Controller (PMC), therefore the programmer must first configure the PMC to enable the SSC clock.

### 44.7.3 Interrupt

The SSC interface has an interrupt line connected to the interrupt controller. Handling interrupts requires programming the interrupt controller before configuring the SSC.

All SSC interrupts can be enabled/disabled configuring the SSC Interrupt Mask Register. Each pending and unmasked SSC interrupt asserts the SSC interrupt line. The SSC interrupt service routine can get the interrupt origin by reading the SSC Interrupt Status Register.

## 44.8 Functional Description

This section contains the functional description of the following: SSC Functional Block, Clock Management, Data Format, Start, Transmit, Receive and Frame Synchronization.

The receiver and transmitter operate separately. However, they can work synchronously by programming the receiver to use the transmit clock and/or to start a data transfer when transmission starts.

Alternatively, this can be done by programming the transmitter to use the receive clock and/or to start a data transfer when reception starts. The transmitter and the receiver can be programmed to operate with the clock signals provided on either the TK or RK pins. This allows the SSC to support many Slave mode data transfers. The maximum clock speed allowed on the TK and RK pins is the peripheral clock divided by 2.

**Figure 44-6. SSC Functional Block Diagram**

### 44.8.1 Clock Management

The transmit clock can be generated by:

- an external clock received on the TK I/O pad
- the receive clock
- the internal clock divider

The receive clock can be generated by:

- an external clock received on the RK I/O pad
- the transmit clock
- the internal clock divider

Furthermore, the transmitter block can generate an external clock on the TK I/O pad, and the receive block can generate an external clock on the RK I/O pad.

This allows the SSC to support many Master and Slave mode data transfers.

### 44.8.1.1 Clock Divider

**Figure 44-7. Divided Clock Block Diagram**

The peripheral clock divider is determined by the 12-bit field DIV counter and comparator (so its maximal value is 4095) in the Clock Mode Register (SSC\_CMCR), allowing a peripheral clock division by up to 8190. The Divided Clock is provided to both the receiver and the transmitter. When this field is programmed to 0, the Clock Divider is not used and remains inactive.

When DIV is set to a value equal to or greater than 1, the Divided Clock has a frequency of peripheral clock divided by 2 times DIV. Each level of the Divided Clock has a duration of the peripheral clock multiplied by DIV. This ensures a 50% duty cycle for the Divided Clock regardless of whether the DIV value is even or odd.

**Figure 44-8. Divided Clock Generation**

### 44.8.1.2 Transmit Clock Management

The transmit clock is generated from the receive clock or the divider clock or an external clock scanned on the TK I/O pad. The transmit clock is selected by the CKS field in the Transmit Clock Mode Register (SSC\_TCMR). Transmit Clock can be inverted independently by the CKI bits in the SSC\_TCMR.

The transmitter can also drive the TK I/O pad continuously or be limited to the current data transfer. The clock output is configured by the SSC\_TCMR. The Transmit Clock Inversion (CKI) bits have no effect on the clock outputs. Programming the SSC\_TCMR to select TK pin (CKS field) and at the same time Continuous Transmit Clock (CKO field) can lead to unpredictable results.

**Figure 44-9. Transmit Clock Management**

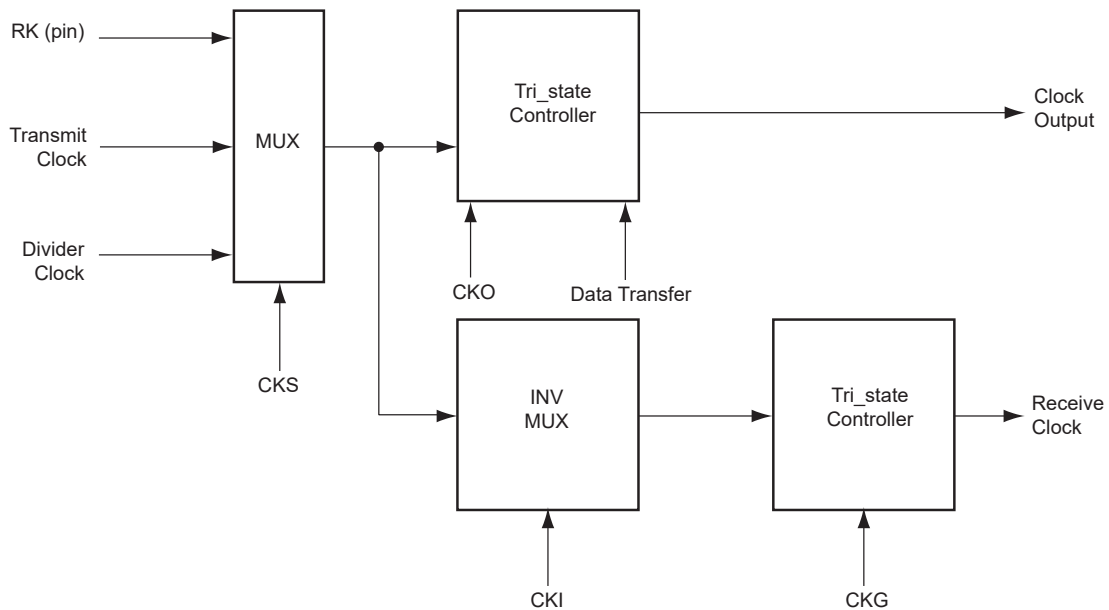

**44.8.1.3 Receive Clock Management**

The receive clock is generated from the transmit clock or the divider clock or an external clock scanned on the RK I/O pad. The Receive Clock is selected by the CKS field in SSC\_RCMR (Receive Clock Mode Register). Receive Clocks can be inverted independently by the CKI bits in SSC\_RCMR.

The receiver can also drive the RK I/O pad continuously or be limited to the current data transfer. The clock output is configured by the SSC\_RCMR. The Receive Clock Inversion (CKI) bits have no effect on the clock outputs. Programming the SSC\_RCMR to select RK pin (CKS field) and at the same time Continuous Receive Clock (CKO field) can lead to unpredictable results.

**Figure 44-10. Receive Clock Management**

### 44.8.1.4 Serial Clock Ratio Considerations

The transmitter and the receiver can be programmed to operate with the clock signals provided on either the TK or RK pins. This allows the SSC to support many Slave mode data transfers. In this case, the maximum clock speed allowed on the RK pin is:

- Peripheral clock divided by 2 if Receive Frame Synchronization is input
- Peripheral clock divided by 3 if Receive Frame Synchronization is output

In addition, the maximum clock speed allowed on the TK pin is:

- Peripheral clock divided by 6 if Transmit Frame Synchronization is input
- Peripheral clock divided by 2 if Transmit Frame Synchronization is output

These are only theoretical speed limits for first order calculations. Exact speed limits on TK and RK are provided in the "Electrical Characteristics" chapter.

### 44.8.2 Transmit Operations

A transmit frame is triggered by a start event and can be followed by synchronization data before data transmission.

The start event is configured by setting the SSC\_TCMR. See [Start](#).

The frame synchronization is configured setting the Transmit Frame Mode Register (SSC\_TFMR). See [Frame Synchronization](#).

To transmit data, the transmitter uses a shift register clocked by the transmit clock signal and the start mode selected in the SSC\_TCMR. Data is written by the application to the Transmit Holding register (SSC\_THR) then transferred to the transmit shift register according to the data format selected.

When both the SSC\_THR and the transmit shift register are empty, the status flag TXEMPTY is set in the Status register (SSC\_SR). When the Transmit Holding register is transferred in the transmit shift register, the status flag TXRDY is set in the SSC\_SR and additional data can be loaded in the Transmit Holding register.

**Figure 44-11. Transmit Block Diagram**

### 44.8.3 Receive Operations

A receive frame is triggered by a start event and can be followed by synchronization data before data transmission.

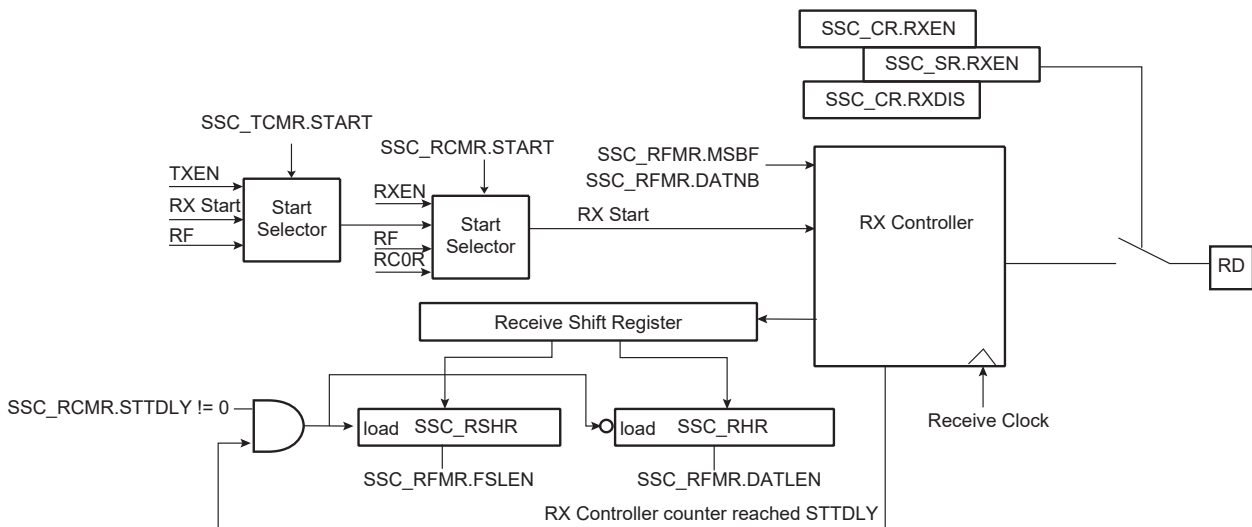

The start event is configured by setting the Receive Clock Mode Register (SSC\_RCMR). See [Start](#).

The frame synchronization is configured by setting the Receive Frame Mode Register (SSC\_RFMR). See [Frame Synchronization](#).

The receiver uses a shift register clocked by the receive clock signal and the start mode selected in the SSC\_RCMR. The data is transferred from the shift register depending on the data format selected.

When the receive shift register is full, the SSC transfers the data into the Receive Holding register (SSC\_RHR), the status flag RXRDY is set in the SSC\_SR and the data can be read in the Receive Holding register. If another transfer occurs before read of the Receive Holding register, the status flag OVRUN is set in the SSC\_SR and the receive shift register is transferred in the SSC\_RHR. The old unread data is then lost.

**Figure 44-12. Receive Block Diagram**

### 44.8.4 Start

The transmitter and receiver can both be programmed to start their operations when an event occurs, respectively in the Transmit Start Selection (START) field of SSC\_TCMR and in the Receive Start Selection (START) field of SSC\_RCMR.

Under the following conditions the start event is independently programmable:

- Continuous. In this case, the transmission starts as soon as a word is written in SSC\_THR and the reception starts as soon as the receiver is enabled.
- Synchronously with the transmitter/receiver
- On detection of a falling/rising edge on TF/RF
- On detection of a low level/high level on TF/RF
- On detection of a level change or an edge on TF/RF

A start can be programmed in the same manner on either side of the Transmit/Receive Clock Register (SSC\_RCMR/SSC\_TCMR). Thus, the start could be on TF (Transmit) or RF (Receive).

Moreover, the receiver can start when data is detected in the bit stream with the Compare Functions.

Detection on TF/RF input/output is done by the field FSOS of the Transmit/Receive Frame Mode Register (SSC\_TFMR/SSC\_RFMR).

**Figure 44-13. Transmit Start Mode**

**Figure 44-14. Receive Pulse/Edge Start Modes**

### 44.8.5 Frame Synchronization

The Transmit and Receive Frame Sync pins, TF and RF, can be programmed to generate different kinds of Frame Sync signals. The Frame Sync Output Selection (FSOS) field in the Receive Frame Mode Register (SSC\_RFMR) and in the Transmit Frame Mode Register (SSC\_TFMR) are used to select the required waveform.

- Programmable low or high levels during data transfer are supported.
- Programmable high levels before the start of data transfers or toggling are also supported.

If a pulse waveform is selected, the Frame Sync Length (FSLEN) field in SSC\_RFMR and SSC\_TFMR programs the length of the pulse, from 1 bit time up to 256 bit times.

The periodicity of the Receive and Transmit Frame Sync pulse output can be programmed through the Period Divider Selection (PERIOD) field in SSC\_RCMR and SSC\_TCMR.

### 44.8.5.1 Frame Sync Data

Frame Sync Data transmits or receives a specific tag during the Frame Sync signal.

During the Frame Sync signal, the receiver can sample the RD line and store the data in the Receive Sync Holding Register and the transmitter can transfer Transmit Sync Holding Register in the shift register. The data length to be sampled/shifted out during the Frame Sync signal is programmed by the FSLEN field in SSC\_RFMR/SSC\_TFMR and has a maximum value of 256.

Concerning the Receive Frame Sync Data operation, if the Frame Sync Length is equal to or lower than the delay between the start event and the current data reception, the data sampling operation is performed in the Receive Sync Holding Register through the receive shift register.

The Transmit Frame Sync Operation is performed by the transmitter only if the bit Frame Sync Data Enable (FSDEN) in SSC\_TFMR is set. If the Frame Sync length is equal to or lower than the delay between the start event and the current data transmission, the normal transmission has priority and the data contained in the Transmit Sync Holding Register is transferred in the Transmit Register, then shifted out.

### 44.8.5.2 Frame Sync Edge Detection

The Frame Sync Edge detection is programmed by the FSEDGE field in SSC\_RFMR/SSC\_TFMR. This sets the corresponding flags RXSYN/TXSYN in the SSC Status Register (SSC\_SR) on Frame Sync Edge detection (signals RF/TF).

### 44.8.6 Receive Compare Modes

**Figure 44-15. Receive Compare Modes**

#### 44.8.6.1 Compare Functions

The length of the comparison patterns (Compare 0, Compare 1) and thus the number of bits they are compared to is defined by FSLEN, but with a maximum value of 256 bits. Comparison is always done by comparing the last bits received with the comparison pattern. Compare 0 can be one start event of the receiver. In this case, the receiver compares at each new sample the last bits received at the Compare 0 pattern contained in the Compare 0 Register (SSC\_RC0R). When this start event is selected, the user can program the receiver to start a new data transfer either by writing a new Compare 0, or by receiving continuously until Compare 1 occurs. This selection is done with the STOP bit in the SSC\_RCMR.

### 44.8.7 Data Format

The data framing format of both the transmitter and the receiver are programmable through the Transmitter Frame Mode Register (SSC\_TFMR) and the Receive Frame Mode Register (SSC\_RFMR). In either case, the user can independently select the following parameters:

- Event that starts the data transfer (START)
- Delay in number of bit periods between the start event and the first data bit (STTDLY)

# SAMA5D2 Series

## Synchronous Serial Controller (SSC)

- Length of the data (DATLEN)
- Number of data to be transferred for each start event (DATNB)
- Length of synchronization transferred for each start event (FSLEN)
- Bit sense: most or least significant bit first (MSBF)

Additionally, the transmitter can be used to transfer synchronization and select the level driven on the TD pin while not in data transfer operation. This is done respectively by the Frame Sync Data Enable (FSDEN) and by the Data Default Value (DATDEF) bits in SSC\_TFMR.

**Table 44-2. Data Frame Registers**

| Transmitter | Receiver | Field  | Length    | Comment                              |
|-------------|----------|--------|-----------|--------------------------------------|
| SSC_TFMR    | SSC_RFMR | DATLEN | Up to 32  | Size of word                         |
| SSC_TFMR    | SSC_RFMR | DATNB  | Up to 16  | Number of words transmitted in frame |
| SSC_TFMR    | SSC_RFMR | MSBF   | –         | Most significant bit first           |
| SSC_TFMR    | SSC_RFMR | FSLEN  | Up to 256 | Size of Synchro data register        |
| SSC_TFMR    | –        | DATDEF | 0 or 1    | Data default value ended             |
| SSC_TFMR    | –        | FSDEN  | –         | Enable send SSC_TSHR                 |
| SSC_TCMR    | SSC_RCMR | PERIOD | Up to 512 | Frame size                           |
| SSC_TCMR    | SSC_RCMR | STTDLY | Up to 255 | Size of transmit start delay         |

**Figure 44-16. Transmit and Receive Frame Format in Edge/Pulse Start Modes**

Note: 1. Example of input on falling edge of TF/RF.

In the example illustrated above, the SSC\_THR is loaded twice. The FSDEN value has no effect on the transmission. SyncData cannot be output in Continuous mode.

**Figure 44-17. Transmit Frame Format in Continuous Mode (STTDLY = 0)**

**Figure 44-18. Receive Frame Format in Continuous Mode (STTDLY = 0)**

#### 44.8.8 Loop Mode

The receiver can be programmed to receive transmissions from the transmitter. This is done by setting the Loop Mode (LOOP) bit in the SSC\_RFMR. In this case, RD is connected to TD, RF is connected to TF and RK is connected to TK.

#### 44.8.9 Interrupt

Most bits in the SSC\_SR have a corresponding bit in interrupt management registers.

The SSC can be programmed to generate an interrupt when it detects an event. The interrupt is controlled by writing the Interrupt Enable Register (SSC\_IER) and Interrupt Disable Register (SSC\_IDR). These registers enable and disable, respectively, the corresponding interrupt by setting and clearing the corresponding bit in the Interrupt Mask Register (SSC\_IMR), which controls the generation of interrupts by asserting the SSC interrupt line connected to the interrupt controller.

**Figure 44-19. Interrupt Block Diagram**

#### 44.8.10 Register Write Protection

To prevent any single software error from corrupting SSC behavior, certain registers in the address space can be write-protected by setting the WPEN bit in the [SSC Write Protection Mode Register](#) (SSC\_WPMR).

If a write access to a write-protected register is detected, the WPVS flag in the [SSC Write Protection Status Register](#) (SSC\_WPSR) is set and the field WPVSR indicates the register in which the write access has been attempted.

The WPVS bit is automatically cleared after reading the SSC\_WPSR.

The following registers can be write-protected:

- [SSC Clock Mode Register](#)
- [SSC Receive Clock Mode Register](#)
- [SSC Receive Frame Mode Register](#)
- [SSC Transmit Clock Mode Register](#)
- [SSC Transmit Frame Mode Register](#)
- [SSC Receive Compare 0 Register](#)
- [SSC Receive Compare 1 Register](#)

#### Bit 15 – SWRST Software Reset

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | Performs a software reset. Has priority on any other bit in SSC_CR. |

#### Bit 9 – TXDIS Transmit Disable

| Value | Description  |
|-------|--|
| 0     | No effect.   |
| 1     | Disables Transmit. If a character is currently being transmitted, disables at end of current character transmission. |

#### Bit 8 – TXEN Transmit Enable

| Value | Description                           |
|-------|---------------------------------------|
| 0     | No effect.                            |
| 1     | Enables Transmit if TXDIS is not set. |

#### Bit 1 – RXDIS Receive Disable

| Value | Description |
|-------|-------------|
| 0     | No effect.  |

# SAMA5D2 Series

## Synchronous Serial Controller (SSC)

---

---

| Value | Description   |
|-------|---|
| 1     | Disables Receive. If a character is currently being received, disables at end of current character reception. |

### Bit 0 – RXEN Receive Enable

| Value | Description                          |
|-------|--------------------------------------|
| 0     | No effect.                           |
| 1     | Enables Receive if RXDIS is not set. |

### 44.9.2 SSC Clock Mode Register

**Name:** SSC\_CMCR  
**Offset:** 0x4  
**Reset:** 0x00000000  
**Property:** Read/Write

This register can only be written if the WPEN bit is cleared in the [SSC Write Protection Mode Register](#).

|        |          |     |     |     |           |     |     |     |
|--------|----------|-----|-----|-----|-----------|-----|-----|-----|
| Bit    | 31       | 30  | 29  | 28  | 27        | 26  | 25  | 24  |
|        |          |     |     |     |           |     |     |     |
| Access |          |     |     |     |           |     |     |     |
| Reset  |          |     |     |     |           |     |     |     |
| Bit    | 23       | 22  | 21  | 20  | 19        | 18  | 17  | 16  |
|        |          |     |     |     |           |     |     |     |
| Access |          |     |     |     |           |     |     |     |
| Reset  |          |     |     |     |           |     |     |     |
| Bit    | 15       | 14  | 13  | 12  | 11        | 10  | 9   | 8   |
|        |          |     |     |     | DIV[11:8] |     |     |     |
| Access |          |     |     |     | R/W       | R/W | R/W | R/W |
| Reset  |          |     |     |     | 0         | 0   | 0   | 0   |
| Bit    | 7        | 6   | 5   | 4   | 3         | 2   | 1   | 0   |
|        | DIV[7:0] |     |     |     |           |     |     |     |
| Access | R/W      | R/W | R/W | R/W | R/W       | R/W | R/W | R/W |
| Reset  | 0        | 0   | 0   | 0   | 0         | 0   | 0   | 0   |

#### Bits 11:0 – DIV[11:0] Clock Divider

| Value           | Description  |
|-----------------|--|
| 0               | The Clock Divider is not active.   |
| Any other value | The divided clock equals the peripheral clock divided by 2 times DIV. The maximum bit rate is $f_{\text{peripheral clock}}/2$ . The minimum bit rate is $f_{\text{peripheral clock}}/2 \times 4095 = f_{\text{peripheral clock}}/8190$ . |

### 44.9.3 SSC Receive Clock Mode Register

**Name:** SSC\_RCMR  
**Offset:** 0x10  
**Reset:** 0x00000000  
**Property:** Read/Write

This register can only be written if the WPEN bit is cleared in the [SSC Write Protection Mode Register](#).

| Access | R/W         | R/W | R/W | R/W      | R/W        | R/W | R/W      | R/W |
| Reset  | 0           | 0   | 0   | 0        | 0          | 0   | 0        | 0   |

#### Bits 31:24 – PERIOD[7:0] Receive Period Divider Selection

This field selects the divider to apply to the selected Receive Clock in order to generate a new Frame Sync signal. If 0, no PERIOD signal is generated. If not 0, a PERIOD signal is generated each 2 x (PERIOD + 1) Receive Clock.

#### Bits 23:16 – STTDLY[7:0] Receive Start Delay

If STTDLY is not 0, a delay of STTDLY clock cycles is inserted between the start event and the current start of reception. When the receiver is programmed to start synchronously with the transmitter, the delay is also applied.

#### Note:

STTDLY must be configured in relation to the receive synchronization data to be stored in SSC\_RSHR.

#### Bit 12 – STOP Receive Stop Selection

| Value | Description   |
|-------|---|
| 0     | After completion of a data transfer when starting with a Compare 0, the receiver stops the data transfer and waits for a new compare 0. |
| 1     | After starting a receive with a Compare 0, the receiver operates in a continuous mode until a Compare 1 is detected.                    |

# SAMA5D2 Series

## Synchronous Serial Controller (SSC)

### Bits 11:8 – START[3:0] Receive Start Selection

| Value | Name       | Description   |
|-------|------------|---|
| 0     | CONTINUOUS | Continuous, as soon as the receiver is enabled, and immediately after the end of transfer of the previous data. |
| 1     | TRANSMIT   | Transmit start  |
| 2     | RF_LOW     | Detection of a low level on RF signal   |
| 3     | RF_HIGH    | Detection of a high level on RF signal  |
| 4     | RF_FALLING | Detection of a falling edge on RF signal  |
| 5     | RF_RISING  | Detection of a rising edge on RF signal   |
| 6     | RF_LEVEL   | Detection of any level change on RF signal  |
| 7     | RF_EDGE    | Detection of any edge on RF signal  |
| 8     | CMP_0      | Compare 0   |

### Bits 7:6 – CKG[1:0] Receive Clock Gating Selection

| Value | Name       | Description                           |
|-------|------------|---------------------------------------|
| 0     | CONTINUOUS | None                                  |
| 1     | EN_RF_LOW  | Receive Clock enabled only if RF Low  |
| 2     | EN_RF_HIGH | Receive Clock enabled only if RF High |

### Bit 5 – CKI Receive Clock Inversion

CKI affects only the Receive Clock and not the output clock signal.

| Value | Description  |
|-------|--|
| 0     | The data inputs (Data and Frame Sync signals) are sampled on Receive Clock falling edge. The Frame Sync signal output is shifted out on Receive Clock rising edge. |
| 1     | The data inputs (Data and Frame Sync signals) are sampled on Receive Clock rising edge. The Frame Sync signal output is shifted out on Receive Clock falling edge. |

### Bits 4:2 – CKO[2:0] Receive Clock Output Mode Selection

| Value | Name       | Description   |
|-------|------------|---|
| 0     | NONE       | None, RK pin is an input                                      |
| 1     | CONTINUOUS | Continuous Receive Clock, RK pin is an output                 |
| 2     | TRANSFER   | Receive Clock only during data transfers, RK pin is an output |

### Bits 1:0 – CKS[1:0] Receive Clock Selection

| Value | Name | Description     |
|-------|------|-----------------|
| 0     | MCK  | Divided Clock   |
| 1     | TK   | TK Clock signal |
| 2     | RK   | RK pin          |

### 44.9.4 SSC Receive Frame Mode Register

**Name:** SSC\_RFMR  
**Offset:** 0x14  
**Reset:** 0x00000000  
**Property:** Read/Write

This register can only be written if the WPEN bit is cleared in the [SSC Write Protection Mode Register](#).

|        |                |           |      |             |            |     |     |        |
|--------|----------------|-----------|------|-------------|------------|-----|-----|--------|
| Bit    | 31             | 30        | 29   | 28          | 27         | 26  | 25  | 24     |
|        | FSLEN_EXT[3:0] |           |      |             |            |     |     | FSEDGE |
| Access | R/W            | R/W       | R/W  | R/W         |            |     |     | R/W    |
| Reset  | 0              | 0         | 0    | 0           |            |     |     | 0      |
|        |                |           |      |             |            |     |     |        |
| Bit    | 23             | 22        | 21   | 20          | 19         | 18  | 17  | 16     |
|        |                | FSOS[2:0] |      |             | FSLEN[3:0] |     |     |        |
| Access |                | R/W       | R/W  | R/W         | R/W        | R/W | R/W | R/W    |

| Access |                |           |      |             | R/W        | R/W | R/W | R/W    |
| Reset  |                |           |      |             | 0          | 0   | 0   | 0      |
|        |                |           |      |             |            |     |     |        |
| Bit    | 7              | 6         | 5    | 4           | 3          | 2   | 1   | 0      |
|        | MSBF           |           | LOOP | DATLEN[4:0] |            |     |     |        |
| Access | R/W            |           | R/W  | R/W         | R/W        | R/W | R/W | R/W    |
| Reset  | 0              |           | 0    | 0           | 0          | 0   | 0   | 0      |

**Bits 31:28 – FSLEN\_EXT[3:0]** FSLEN Field Extension  
 Extends FSLEN field. For details, see [FSLEN: Receive Frame Sync Length](#).

**Bit 24 – FSEDGE** Frame Sync Edge Detection  
 Determines which edge on Frame Sync will generate the interrupt RXSYN in the SSC Status Register.

| Value | Name     | Description             |
|-------|----------|-------------------------|
| 0     | POSITIVE | Positive Edge Detection |
| 1     | NEGATIVE | Negative Edge Detection |

**Bits 22:20 – FSOS[2:0]** Receive Frame Sync Output Selection

| Value | Name     | Description  |
|-------|----------|--|
| 0     | NONE     | None, RF pin is an input                                     |
| 1     | NEGATIVE | Negative Pulse, RF pin is an output                          |
| 2     | POSITIVE | Positive Pulse, RF pin is an output                          |
| 3     | LOW      | Driven Low during data transfer, RF pin is an output         |
| 4     | HIGH     | Driven High during data transfer, RF pin is an output        |
| 5     | TOGGLING | Toggling at each start of data transfer, RF pin is an output |

# SAMA5D2 Series

## Synchronous Serial Controller (SSC)

### Bits 19:16 – FSLEN[3:0] Receive Frame Sync Length

This field defines the number of bits sampled and stored in the Receive Sync Data Register. When this mode is selected by the START field in the Receive Clock Mode Register, it also determines the length of the sampled data to be compared to the Compare 0 or Compare 1 register.

This field is used with FSLEN\_EXT to determine the pulse length of the Receive Frame Sync signal.

Pulse length is equal to  $FSLEN + (FSLEN\_EXT \times 16) + 1$  Receive Clock periods.

### Bits 11:8 – DATNB[3:0] Data Number per Frame

This field defines the number of data words to be received after each transfer start, which is equal to  $(DATNB + 1)$ .

### Bit 7 – MSBF Most Significant Bit First

| Value | Description   |
|-------|---|
| 0     | The lowest significant bit of the data register is sampled first in the bit stream. |
| 1     | The most significant bit of the data register is sampled first in the bit stream.   |

### Bit 5 – LOOP Loop Mode

| Value | Description  |
|-------|--|
| 0     | Normal operating mode.                                   |
| 1     | RD is driven by TD, RF is driven by TF and TK drives RK. |

### Bits 4:0 – DATLEN[4:0] Data Length

| Value           | Description  |
|-----------------|--|
| 0               | Forbidden value (1-bit data length not supported). |
| Any other value | The bit stream contains $DATLEN + 1$ data bits.    |

### 44.9.5 SSC Transmit Clock Mode Register

**Name:** SSC\_TCMR  
**Offset:** 0x18  
**Reset:** 0x00000000  
**Property:** Read/Write

This register can only be written if the WPEN bit is cleared in the [SSC Write Protection Mode Register](#).

|        |             |     |     |          |     |     |          |     |
|--------|-------------|-----|-----|----------|-----|-----|----------|-----|
| Bit    | 31          | 30  | 29  | 28       | 27  | 26  | 25       | 24  |
|        | PERIOD[7:0] |     |     |          |     |     |          |     |
| Access | R/W         | R/W | R/W | R/W      | R/W | R/W | R/W      | R/W |
| Reset  | 0           | 0   | 0   | 0        | 0   | 0   | 0        | 0   |
| Bit    | 23          | 22  | 21  | 20       | 19  | 18  | 17       | 16  |
|        | STTDLY[7:0] |     |     |          |     |     |          |     |
| Access | R/W         | R/W | R/W | R/W      | R/W | R/W | R/W      | R/W |
| Reset  | 0           | 0   | 0   | 0        | 0   | 0   | 0        | 0   |
| Bit    | 15          | 14  | 13  | 12       | 11  | 10  | 9        | 8   |
|        | START[3:0]  |     |     |          |     |     |          |     |
| Access |             |     |     |          | R/W | R/W | R/W      | R/W |
| Reset  |             |     |     |          | 0   | 0   | 0        | 0   |
| Bit    | 7           | 6   | 5   | 4        | 3   | 2   | 1        | 0   |
|        | CKG[1:0]    |     | CKI | CKO[2:0] |     |     | CKS[1:0] |     |
| Access | R/W         | R/W | R/W | R/W      | R/W | R/W | R/W      | R/W |
| Reset  | 0           | 0   | 0   | 0        | 0   | 0   | 0        | 0   |

#### Bits 31:24 – PERIOD[7:0] Transmit Period Divider Selection

This field selects the divider to apply to the selected Transmit Clock to generate a new Frame Sync signal. If 0, no period signal is generated. If not 0, a period signal is generated at each  $2 \times (\text{PERIOD} + 1)$  Transmit Clock.

#### Bits 23:16 – STTDLY[7:0] Transmit Start Delay

If STTDLY is not 0, a delay of STTDLY clock cycles is inserted between the start event and the current start of transmission of data. When the transmitter is programmed to start synchronously with the receiver, the delay is also applied.

#### Note:

If STTDLY is too short with respect to transmit synchronization data (SSC\_TSHR), SSC\_THR.TDAT is transmitted instead of the end of SSC\_TSHR.

#### Bits 11:8 – START[3:0] Transmit Start Selection

| Value | Name       | Description  |
|-------|------------|--|
| 0     | CONTINUOUS | Continuous, as soon as a word is written in the SSC_THR (if Transmit is enabled), and immediately after the end of transfer of the previous data |
| 1     | RECEIVE    | Receive start  |
| 2     | TF_LOW     | Detection of a low level on TF signal  |

# SAMA5D2 Series

## Synchronous Serial Controller (SSC)

| Value | Name       | Description                                |
|-------|------------|--|
| 3     | TF_HIGH    | Detection of a high level on TF signal     |
| 4     | TF_FALLING | Detection of a falling edge on TF signal   |
| 5     | TF_RISING  | Detection of a rising edge on TF signal    |
| 6     | TF_LEVEL   | Detection of any level change on TF signal |
| 7     | TF_EDGE    | Detection of any edge on TF signal         |

### Bits 7:6 – CKG[1:0] Transmit Clock Gating Selection

| Value | Name       | Description                            |
|-------|------------|--|
| 0     | CONTINUOUS | None                                   |
| 1     | EN_TF_LOW  | Transmit Clock enabled only if TF Low  |
| 2     | EN_TF_HIGH | Transmit Clock enabled only if TF High |

### Bit 5 – CKI Transmit Clock Inversion

CKI affects only the Transmit Clock and not the Output Clock signal.

| Value | Description  |
|-------|--|
| 0     | The data outputs (Data and Frame Sync signals) are shifted out on Transmit Clock falling edge. The Frame Sync signal input is sampled on Transmit Clock rising edge. |
| 1     | The data outputs (Data and Frame Sync signals) are shifted out on Transmit Clock rising edge. The Frame Sync signal input is sampled on Transmit Clock falling edge. |

### Bits 4:2 – CKO[2:0] Transmit Clock Output Mode Selection

| Value | Name       | Description  |
|-------|------------|--|
| 0     | NONE       | None, TK pin is an input                                       |
| 1     | CONTINUOUS | Continuous Transmit Clock, TK pin is an output                 |
| 2     | TRANSFER   | Transmit Clock only during data transfers, TK pin is an output |

### Bits 1:0 – CKS[1:0] Transmit Clock Selection

| Value | Name | Description     |
|-------|------|-----------------|
| 0     | MCK  | Divided Clock   |
| 1     | RK   | RK Clock signal |
| 2     | TK   | TK pin          |

### 44.9.6 SSC Transmit Frame Mode Register

**Name:** SSC\_TFMR  
**Offset:** 0x1C  
**Reset:** 0x00000000  
**Property:** Read/Write

This register can only be written if the WPEN bit is cleared in the [SSC Write Protection Mode Register](#).

|        |                |           |        |             |            |     |     |        |
|--------|----------------|-----------|--------|-------------|------------|-----|-----|--------|
| Bit    | 31             | 30        | 29     | 28          | 27         | 26  | 25  | 24     |
|        | FSLEN_EXT[3:0] |           |        |             |            |     |     | FSEDGE |
| Access | R/W            | R/W       | R/W    | R/W         |            |     |     | R/W    |
| Reset  | 0              | 0         | 0      | 0           |            |     |     | 0      |
| Bit    | 23             | 22        | 21     | 20          | 19         | 18  | 17  | 16     |
|        | FSDEN          | FSOS[2:0] |        |             | FSLEN[3:0] |     |     |        |
| Access | R/W            | R/W       | R/W    | R/W         |            |     |     |        |
| Reset  | 0              | 0         | 0      | 0           | 0          | 0   | 0   | 0      |
| Bit    | 15             | 14        | 13     | 12          | 11         | 10  | 9   | 8      |
|        |                |           |        |             | DATNB[3:0] |     |     |        |
| Access |                |           |        |             | R/W        | R/W | R/W | R/W    |
| Reset  |                |           |        |             | 0          | 0   | 0   | 0      |
| Bit    | 7              | 6         | 5      | 4           | 3          | 2   | 1   | 0      |
|        | MSBF           |           | DATDEF | DATLEN[4:0] |            |     |     |        |
| Access | R/W            |           | R/W    | R/W         | R/W        | R/W | R/W | R/W    |
| Reset  | 0              |           | 0      | 0           | 0          | 0   | 0   | 0      |

**Bits 31:28 – FSLEN\_EXT[3:0]** FSLEN Field Extension  
 Extends FSLEN field. For details, see FSLEN bit description below.

**Bit 24 – FSEDGE** Frame Sync Edge Detection  
 Determines which edge on frame synchronization will generate the interrupt TXSYN (Status Register).

| Value | Name     | Description             |
|-------|----------|-------------------------|
| 0     | POSITIVE | Positive Edge Detection |
| 1     | NEGATIVE | Negative Edge Detection |

**Bit 23 – FSDEN** Frame Sync Data Enable

| Value | Description  |
|-------|--|
| 0     | The TD line is driven with the default value during the Transmit Frame Sync signal.      |
| 1     | SSC_TSHR value is shifted out during the transmission of the Transmit Frame Sync signal. |

**Bits 22:20 – FSOS[2:0]** Transmit Frame Sync Output Selection

| Value | Name     | Description                         |
|-------|----------|-------------------------------------|
| 0     | NONE     | None, TF pin is an input            |
| 1     | NEGATIVE | Negative Pulse, TF pin is an output |

# SAMA5D2 Series

## Synchronous Serial Controller (SSC)

| Value | Name     | Description                             |
|-------|----------|---|
| 2     | POSITIVE | Positive Pulse, TF pin is an output     |
| 3     | LOW      | Driven Low during data transfer         |
| 4     | HIGH     | Driven High during data transfer        |
| 5     | TOGGLING | Toggling at each start of data transfer |

### Bits 19:16 – FSLEN[3:0] Transmit Frame Sync Length

This field defines the length of the Transmit Frame Sync signal and the number of bits shifted out from SSC\_TSHR if FSDEN is 1.

This field is used with FSLEN\_EXT to determine the pulse length of the Transmit Frame Sync signal.

Pulse length is equal to  $FSLEN + (FSLEN\_EXT \times 16) + 1$  Transmit Clock period.

### Bits 11:8 – DATNB[3:0] Data Number per Frame

This field defines the number of data words to be transferred after each transfer start, which is equal to  $(DATNB + 1)$ .

### Bit 7 – MSBF Most Significant Bit First

| Value | Description   |
|-------|---|
| 0     | The lowest significant bit of the data register is shifted out first in the bit stream. |
| 1     | The most significant bit of the data register is shifted out first in the bit stream.   |

### Bit 5 – DATDEF Data Default Value

This bit defines the level driven on the TD pin while out of transmission. Note that if the pin is defined as multi-drive by the PIO Controller, the pin is enabled only if the SCC TD output is 1.

### Bits 4:0 – DATLEN[4:0] Data Length

| Value           | Description  |
|-----------------|--|
| 0               | Forbidden value (1-bit data length not supported). |
| Any other value | The bit stream contains $DATLEN + 1$ data bits.    |

|-------|----------------------|
| 0     | Receive is disabled. |
| 1     | Receive is enabled.  |

#### Bit 16 – TXEN Transmit Enable

| Value | Description           |
|-------|-----------------------|
| 0     | Transmit is disabled. |
| 1     | Transmit is enabled.  |

#### Bit 11 – RXSYN Receive Sync

| Value | Description   |
|-------|---|
| 0     | An Rx Sync has not occurred since the last read of the Status Register. |
| 1     | An Rx Sync has occurred since the last read of the Status Register.     |

#### Bit 10 – TXSYN Transmit Sync

| Value | Description  |
|-------|--|
| 0     | A Tx Sync has not occurred since the last read of the Status Register. |
| 1     | A Tx Sync has occurred since the last read of the Status Register.     |

# SAMA5D2 Series

## Synchronous Serial Controller (SSC)

### Bit 9 – CP1 Compare 1

| Value | Description  |
|-------|--|
| 0     | A compare 1 has not occurred since the last read of the Status Register. |
| 1     | A compare 1 has occurred since the last read of the Status Register.     |

### Bit 8 – CP0 Compare 0

| Value | Description  |
|-------|--|
| 0     | A compare 0 has not occurred since the last read of the Status Register. |
| 1     | A compare 0 has occurred since the last read of the Status Register.     |

### Bit 5 – OVRUN Receive Overrun

| Value | Description   |
|-------|---|
| 0     | No data has been loaded in SSC_RHR while previous data has not been read since the last read of the Status Register.  |
| 1     | Data has been loaded in SSC_RHR while previous data has not yet been read since the last read of the Status Register. |

### Bit 4 – RXRDY Receive Ready

| Value | Description                                   |
|-------|---|
| 0     | SSC_RHR is empty.                             |
| 1     | Data has been received and loaded in SSC_RHR. |

### Bit 1 – TXEMPTY Transmit Empty

| Value | Description   |
|-------|---|
| 0     | Data remains in SSC_THR or is currently transmitted from TSR.   |
| 1     | Last data written in SSC_THR has been loaded in TSR and last data loaded in TSR has been transmitted. |

### Bit 0 – TXRDY Transmit Ready

| Value | Description   |
|-------|---|
| 0     | Data has been loaded in SSC_THR and is waiting to be loaded in the transmit shift register (TSR). |
| 1     | SSC_THR is empty.   |

### 44.9.14 SSC Interrupt Enable Register

**Name:** SSC\_IER  
**Offset:** 0x44  
**Reset:** –  
**Property:** Write-only

|        |    |    |       |       |       |       |         |       |
|--------|----|----|-------|-------|-------|-------|---------|-------|
| Bit    | 31 | 30 | 29    | 28    | 27    | 26    | 25      | 24    |
|        |    |    |       |       |       |       |         |       |
| Access |    |    |       |       |       |       |         |       |
| Reset  |    |    |       |       |       |       |         |       |
| Bit    | 23 | 22 | 21    | 20    | 19    | 18    | 17      | 16    |
|        |    |    |       |       |       |       |         |       |
| Access |    |    |       |       |       |       |         |       |
| Reset  |    |    |       |       |       |       |         |       |
| Bit    | 15 | 14 | 13    | 12    | 11    | 10    | 9       | 8     |
|        |    |    |       |       | RXSYN | TXSYN | CP1     | CP0   |
| Access |    |    |       |       | W     | W     | W       | W     |
| Reset  |    |    |       |       | –     | –     | –       | –     |
| Bit    | 7  | 6  | 5     | 4     | 3     | 2     | 1       | 0     |
|        |    |    | OVRUN | RXRDY |       |       | TXEMPTY | TXRDY |
| Access |    |    | W     | W     |       |       | W       | W     |
| Reset  |    |    | –     | –     |       |       | –       | –     |

#### Bit 11 – RXSYN Rx Sync Interrupt Enable

| Value | Description                    |
|-------|--------------------------------|
| 0     | No effect.                     |
| 1     | Enables the Rx Sync Interrupt. |

#### Bit 10 – TXSYN Tx Sync Interrupt Enable

| Value | Description                    |
|-------|--------------------------------|
| 0     | No effect.                     |
| 1     | Enables the Tx Sync Interrupt. |

#### Bit 9 – CP1 Compare 1 Interrupt Enable

| Value | Description                      |
|-------|----------------------------------|
| 0     | No effect.                       |
| 1     | Enables the Compare 1 Interrupt. |

#### Bit 8 – CP0 Compare 0 Interrupt Enable

| Value | Description                      |
|-------|----------------------------------|
| 0     | No effect.                       |
| 1     | Enables the Compare 0 Interrupt. |

---

---

**Bit 5 – OVRUN** Receive Overrun Interrupt Enable

| Value | Description                            |
|-------|--|
| 0     | No effect.                             |
| 1     | Enables the Receive Overrun Interrupt. |

**Bit 4 – RXRDY** Receive Ready Interrupt Enable

| Value | Description                          |
|-------|--------------------------------------|
| 0     | No effect.                           |
| 1     | Enables the Receive Ready Interrupt. |

**Bit 1 – TXEMPTY** Transmit Empty Interrupt Enable

| Value | Description                           |
|-------|---------------------------------------|
| 0     | No effect.                            |
| 1     | Enables the Transmit Empty Interrupt. |

**Bit 0 – TXRDY** Transmit Ready Interrupt Enable

| Value | Description                           |
|-------|---------------------------------------|
| 0     | No effect.                            |
| 1     | Enables the Transmit Ready Interrupt. |

### 44.9.15 SSC Interrupt Disable Register

**Name:** SSC\_IDR  
**Offset:** 0x48  
**Reset:** –  
**Property:** Write-only

|        |    |    |       |       |       |       |         |       |
|--------|----|----|-------|-------|-------|-------|---------|-------|
| Bit    | 31 | 30 | 29    | 28    | 27    | 26    | 25      | 24    |
|        |    |    |       |       |       |       |         |       |
| Access |    |    |       |       |       |       |         |       |
| Reset  |    |    |       |       |       |       |         |       |
| Bit    | 23 | 22 | 21    | 20    | 19    | 18    | 17      | 16    |
|        |    |    |       |       |       |       |         |       |
| Access |    |    |       |       |       |       |         |       |
| Reset  |    |    |       |       |       |       |         |       |
| Bit    | 15 | 14 | 13    | 12    | 11    | 10    | 9       | 8     |
|        |    |    |       |       | RXSYN | TXSYN | CP1     | CP0   |
| Access |    |    |       |       | W     | W     | W       | W     |
| Reset  |    |    |       |       | –     | –     | –       | –     |
| Bit    | 7  | 6  | 5     | 4     | 3     | 2     | 1       | 0     |
|        |    |    | OVRUN | RXRDY |       |       | TXEMPTY | TXRDY |
| Access |    |    | W     | W     |       |       | W       | W     |
| Reset  |    |    | –     | –     |       |       | –       | –     |

#### Bit 11 – RXSYN Rx Sync Interrupt Enable

| Value | Description                     |
|-------|---------------------------------|
| 0     | No effect.                      |
| 1     | Disables the Rx Sync Interrupt. |

#### Bit 10 – TXSYN Tx Sync Interrupt Enable

| Value | Description                     |
|-------|---------------------------------|
| 0     | No effect.                      |
| 1     | Disables the Tx Sync Interrupt. |

#### Bit 9 – CP1 Compare 1 Interrupt Disable

| Value | Description                       |
|-------|-----------------------------------|
| 0     | No effect.                        |
| 1     | Disables the Compare 1 Interrupt. |

#### Bit 8 – CP0 Compare 0 Interrupt Disable

| Value | Description                       |
|-------|-----------------------------------|
| 0     | No effect.                        |
| 1     | Disables the Compare 0 Interrupt. |

**Bit 5 – OVRUN** Receive Overrun Interrupt Disable

| Value | Description                             |
|-------|---|
| 0     | No effect.                              |
| 1     | Disables the Receive Overrun Interrupt. |

**Bit 4 – RXRDY** Receive Ready Interrupt Disable

| Value | Description                           |
|-------|---------------------------------------|
| 0     | No effect.                            |
| 1     | Disables the Receive Ready Interrupt. |

**Bit 1 – TXEMPTY** Transmit Empty Interrupt Disable

| Value | Description                            |
|-------|--|
| 0     | No effect.                             |
| 1     | Disables the Transmit Empty Interrupt. |

**Bit 0 – TXRDY** Transmit Ready Interrupt Disable

| Value | Description                            |
|-------|--|
| 0     | No effect.                             |
| 1     | Disables the Transmit Ready Interrupt. |

#### 44.9.16 SSC Interrupt Mask Register

**Name:** SSC\_IMR  
**Offset:** 0x4C  
**Reset:** 0x00000000  
**Property:** Read-only

|        |    |    |       |       |       |       |         |       |
|--------|----|----|-------|-------|-------|-------|---------|-------|
| Bit    | 31 | 30 | 29    | 28    | 27    | 26    | 25      | 24    |
|        |    |    |       |       |       |       |         |       |
| Access |    |    |       |       |       |       |         |       |
| Reset  |    |    |       |       |       |       |         |       |
| Bit    | 23 | 22 | 21    | 20    | 19    | 18    | 17      | 16    |
|        |    |    |       |       |       |       |         |       |
| Access |    |    |       |       |       |       |         |       |
| Reset  |    |    |       |       |       |       |         |       |
| Bit    | 15 | 14 | 13    | 12    | 11    | 10    | 9       | 8     |
|        |    |    |       |       | RXSYN | TXSYN | CP1     | CP0   |
| Access |    |    |       |       | R     | R     | R       | R     |
| Reset  |    |    |       |       | 0     | 0     | 0       | 0     |
| Bit    | 7  | 6  | 5     | 4     | 3     | 2     | 1       | 0     |
|        |    |    | OVRUN | RXRDY |       |       | TXEMPTY | TXRDY |
| Access |    |    | R     | R     |       |       | R       | R     |
| Reset  |    |    | 0     | 0     |       |       | 0       | 0     |

##### Bit 11 – RXSYN Rx Sync Interrupt Mask

| Value | Description                        |
|-------|------------------------------------|
| 0     | The Rx Sync Interrupt is disabled. |
| 1     | The Rx Sync Interrupt is enabled.  |

##### Bit 10 – TXSYN Tx Sync Interrupt Mask

| Value | Description                        |
|-------|------------------------------------|
| 0     | The Tx Sync Interrupt is disabled. |
| 1     | The Tx Sync Interrupt is enabled.  |

##### Bit 9 – CP1 Compare 1 Interrupt Mask

| Value | Description                          |
|-------|--------------------------------------|
| 0     | The Compare 1 Interrupt is disabled. |
| 1     | The Compare 1 Interrupt is enabled.  |

##### Bit 8 – CP0 Compare 0 Interrupt Mask

| Value | Description                          |
|-------|--------------------------------------|
| 0     | The Compare 0 Interrupt is disabled. |
| 1     | The Compare 0 Interrupt is enabled.  |

**Bit 5 – OVRUN** Receive Overrun Interrupt Mask

| Value | Description                                |
|-------|--|
| 0     | The Receive Overrun Interrupt is disabled. |
| 1     | The Receive Overrun Interrupt is enabled.  |

**Bit 4 – RXRDY** Receive Ready Interrupt Mask

| Value | Description                              |
|-------|--|
| 0     | The Receive Ready Interrupt is disabled. |
| 1     | The Receive Ready Interrupt is enabled.  |

**Bit 1 – TXEMPTY** Transmit Empty Interrupt Mask

| Value | Description                               |
|-------|---|
| 0     | The Transmit Empty Interrupt is disabled. |
| 1     | The Transmit Empty Interrupt is enabled.  |

**Bit 0 – TXRDY** Transmit Ready Interrupt Mask

| Value | Description                               |
|-------|---|
| 0     | The Transmit Ready Interrupt is disabled. |
| 1     | The Transmit Ready Interrupt is enabled.  |

# SAMA5D2 Series

## Synchronous Serial Controller (SSC)

### 44.9.17 SSC Write Protection Mode Register

**Name:** SSC\_WPMR  
**Offset:** 0xE4  
**Reset:** 0x00000000  
**Property:** Read/Write

|        |     |              |    |    |    |    |    |    |     |

|        |     | WPKEY[7:0]   |    |    |    |    |    |    |     |
| Access |     | W            | W  | W  | W  | W  | W  | W  | W   |
| Reset  |     | 0            | 0  | 0  | 0  | 0  | 0  | 0  | 0   |
|        | Bit | 7            | 6  | 5  | 4  | 3  | 2  | 1  | 0   |
|        |     | WPEN         |    |    |    |    |    |    |     |
| Access |     |              |    |    |    |    |    |    | R/W |
| Reset  |     |              |    |    |    |    |    |    | 0   |

#### Bits 31:8 – WPKEY[23:0] Write Protection Key

| Value    | Name   | Description   |
|----------|--------|---|
| 0x535343 | PASSWD | Writing any other value in this field aborts the write operation of the WPEN bit. |
| 3        |        | Always reads as 0.  |

#### Bit 0 – WPEN Write Protection Enable

See [Register Write Protection](#) for the list of registers that can be protected.

| Value | Description  |
|-------|--|
| 0     | Disables the write protection if WPKEY corresponds to 0x535343 (“SSC” in ASCII). |
| 1     | Enables the write protection if WPKEY corresponds to 0x535343 (“SSC” in ASCII).  |

### 44.9.18 SSC Write Protection Status Register

**Name:** SSC\_WPSR  
**Offset:** 0xE8  
**Reset:** 0x00000000  
**Property:** Read-only

|        |                   |    |    |    |    |    |    |      |
|--------|-------------------|----|----|----|----|----|----|------|

| Access | R                 | R  | R  | R  | R  | R  | R  | R    |
| Reset  | 0                 | 0  | 0  | 0  | 0  | 0  | 0  | 0    |
| Bit    | 15                | 14 | 13 | 12 | 11 | 10 | 9  | 8    |
|        | WPVSR[7:0]        |    |    |    |    |    |    |      |
| Access | R                 | R  | R  | R  | R  | R  | R  | R    |
| Reset  | 0                 | 0  | 0  | 0  | 0  | 0  | 0  | 0    |
| Bit    | 7                 | 6  | 5  | 4  | 3  | 2  | 1  | 0    |
|        | [Greyed out bits] |    |    |    |    |    |    | WPVS |
| Access |                   |    |    |    |    |    |    | R    |
| Reset  |                   |    |    |    |    |    |    | 0    |

**Bits 23:8 – WPVSR[15:0]** Write Protect Violation Source

When WPVS = 1, WPVSR indicates the register address offset at which a write access has been attempted.

**Bit 0 – WPVS** Write Protection Violation Status

| Value | Description   |
|-------|---|
| 0     | No write protection violation has occurred since the last read of the SSC_WPSR.   |
| 1     | A write protection violation has occurred since the last read of the SSC_WPSR. If this violation is an unauthorized attempt to write a protected register, the associated violation is reported into field WPVSR. |

## 45. Two-wire Interface (TWIHS)

### 45.1 Description

The Two-wire Interface (TWIHS) interconnects components on a unique two-wire bus, made up of one clock line and one data line with speeds of up to 400 kbit/s in Fast mode and up to 3.4 Mbit/s in High-speed slave mode only, based on a byte-oriented transfer format. It can be used with any Two-wire Interface bus Serial EEPROM and I<sup>2</sup>C-compatible devices, such as a Real-Time Clock (RTC), Dot Matrix/Graphic LCD Controller and temperature sensor. The TWIHS is programmable as a master or a slave with sequential or single-byte access. Multiple master capability is supported.

A configurable baud rate generator permits the output data rate to be adapted to a wide range of core clock frequencies.

The table below lists the compatibility level of the Two-wire Interface in Master mode and a full I<sup>2</sup>C compatible device.

**Table 45-1. TWI Compatibility with I<sup>2</sup>C Standard**

| I <sup>2</sup> C Standard                    | TWI           |
|--|---------------|
| Standard Mode Speed (100 kHz)                | Supported     |
| Fast Mode Speed (400 kHz)                    | Supported     |
| High-speed Mode (Slave only, 3.4 MHz)        | Supported     |
| 7- or 10-bit <sup>(1)</sup> Slave Addressing | Supported     |
| START Byte <sup>(2)</sup>                    | Not Supported |
| Repeated Start (Sr) Condition                | Supported     |
| ACK and NACK Management                      | Supported     |
| Input Filtering                              | Supported     |
| Slope Control                                | Not Supported |
| Clock Stretching                             | Supported     |
| Multi Master Capability                      | Supported     |

**Note:**

1. 10-bit support in Master mode only.
2. START + 00000001 + Ack + Sr

### 45.2 Embedded Characteristics

- 2 TWIHSs
- 16-byte Transmit and Receive FIFOs
- Compatible with Two-wire Interface Serial Memory and I<sup>2</sup>C Compatible Devices<sup>(1)</sup>
- One, Two or Three Bytes for Slave Address
- Sequential Read/Write Operations

- Master and Multimaster Operation (Standard and Fast Modes Only)
- Slave Mode Operation (Standard, Fast and High-Speed Modes)
- Bit Rate: Up to 400 Kbit/s in Fast Mode and 3.4 Mbit/s in High-Speed Mode (Slave Mode Only)
- General Call Supported in Slave Mode
- SleepWalking (Asynchronous and Partial Wakeup)
- SMBus Support
- Connection to DMA Controller (DMA) Channel Capabilities Optimizes Data Transfers
- Register Write Protection

**Note:**

See [TWI Compatibility with I2C Standard](#) for details on compatibility with I<sup>2</sup>C Standard.

### 45.3 List of Abbreviations

**Table 45-2. Abbreviations**

| Abbreviation | Description             |
|--------------|-------------------------|
| TWI          | Two-wire Interface      |
| A            | Acknowledge             |
| NA           | Non Acknowledge         |
| P            | Stop                    |
| S            | Start                   |
| Sr           | Repeated Start          |
| SADR         | Slave Address           |
| ADR          | Any address except SADR |
| R            | Read                    |
| W            | Write                   |

### 45.4 Block Diagram

**Figure 45-1. Block Diagram**

### 45.4.1 I/O Lines Description

**Table 45-3. I/O Lines Description**

| Pin Name | Pin Description       | Type         |
|----------|-----------------------|--------------|
| TWD      | Two-wire Serial Data  | Input/Output |
| TWCK     | Two-wire Serial Clock | Input/Output |

## 45.5 Product Dependencies

### 45.5.1 I/O Lines

Both TWD and TWCK are bidirectional lines, connected to a positive supply voltage via a current source or pullup resistor. When the bus is free, both lines are high. The output stages of devices connected to the bus must have an open-drain or open-collector to perform the wired-AND function.

TWD and TWCK pins may be multiplexed with PIO lines. To enable the TWIHS, the user must program the PIO Controller to dedicate TWD and TWCK as peripheral lines. When High-speed Slave mode is enabled, the analog pad filter must be enabled.

The user must not program TWD and TWCK as open-drain. This is already done by the hardware.

### 45.5.2 Power Management

Enable the peripheral clock.

The TWIHS may be clocked through the Power Management Controller (PMC), thus the user must first configure the PMC to enable the TWIHS clock.

### 45.5.3 Interrupt Sources

The TWIHS has an interrupt line connected to the Interrupt Controller. In order to handle interrupts, the Interrupt Controller must be programmed before configuring the TWIHS.

## 45.6 Functional Description

### 45.6.1 Transfer Format

The data put on the TWD line must be 8 bits long. Data is transferred MSB first; each byte must be followed by an acknowledgement. The number of bytes per transfer is unlimited, shown in [Transfer Format](#).

Each transfer begins with a START condition and terminates with a STOP condition, as shown in [START and STOP Conditions](#).

- A high-to-low transition on the TWD line while TWCK is high defines the START condition.
- A low-to-high transition on the TWD line while TWCK is high defines the STOP condition.

**Figure 45-2. START and STOP Conditions**

**Figure 45-3. Transfer Format**

## 45.6.2 Modes of Operation

The TWIHS has different modes of operation:

- Master Transmitter mode (Standard and Fast modes only)
- Master Receiver mode (Standard and Fast modes only)
- Multimaster Transmitter mode (Standard and Fast modes only)
- Multimaster Receiver mode (Standard and Fast modes only)
- Slave Transmitter mode (Standard, Fast and High-speed modes)
- Slave Receiver mode (Standard, Fast and High-speed modes)

These modes are described in the following sections.

## 45.6.3 Master Mode

### 45.6.3.1 Definition

The master is the device that starts a transfer, generates a clock and stops it. This operating mode is not available if High-speed mode is selected.

### 45.6.3.2 Programming Master Mode

The following registers must be programmed before entering Master mode:

1. TWIHS\_MMR.DADR (+ IADRSZ + IADR if a 10-bit device is addressed): The device address is used to access slave devices in Read or Write mode.
2. TWIHS\_CWGR.CKDIV + CHDIV + CLDIV: Clock Waveform register
3. TWIHS\_CR.SVDIS: Disables the Slave mode
4. TWIHS\_CR.MSEN: Enables the Master mode

**Note:** If the TWIHS is already in Master mode, the device address (DADR) can be configured without disabling the Master mode.

### 45.6.3.3 Transfer Rate Clock Source

The TWIHS speed is defined in the TWIHS\_CWGR. The TWIHS baud rate can be based either on the peripheral clock if the CKSRC bit value is '0' or on a GCLK clock if the CKSRC bit value is '1'.

If CKSRC = 1, the baud rate is independent of the system/core clock (MCK) and thus the MCK frequency can be changed without affecting the TWIHS transfer rate.

The GCLK frequency must always be three times lower than the peripheral clock frequency.

### 45.6.3.4 Master Transmitter Mode

This operating mode is not available if High-speed mode is selected.

After the master initiates a START condition when writing into the Transmit Holding register (TWIHS\_THR), it sends a 7-bit slave address, configured in the Master Mode register (DADR in TWIHS\_MMR), to notify the slave device. The bit following the slave address indicates the transfer direction, 0 in this case (MREAD = 0 in TWIHS\_MMR).

The TWIHS transfers require the slave to acknowledge each received byte. During the acknowledge clock pulse (9th pulse), the master releases the data line (HIGH), enabling the slave to pull it down in order to generate the acknowledge. If the slave does not acknowledge the byte, then the Not Acknowledge flag (NACK) is set in the TWIHS Status Register (TWIHS\_SR) of the master and a STOP condition is sent. The NACK flag must be clear by reading TWIHS\_SR before the next write into TWIHS\_THR. As with the other status bits, an interrupt can be generated if enabled in the Interrupt Enable register (TWIHS\_IER). If the slave acknowledges the byte, the data written in the TWIHS\_THR is then shifted in the internal shifter and transferred. When an acknowledge is detected, the TXRDY bit is set until a new write in the TWIHS\_THR.

TXRDY is used as Transmit Ready for the DMA transmit channel.

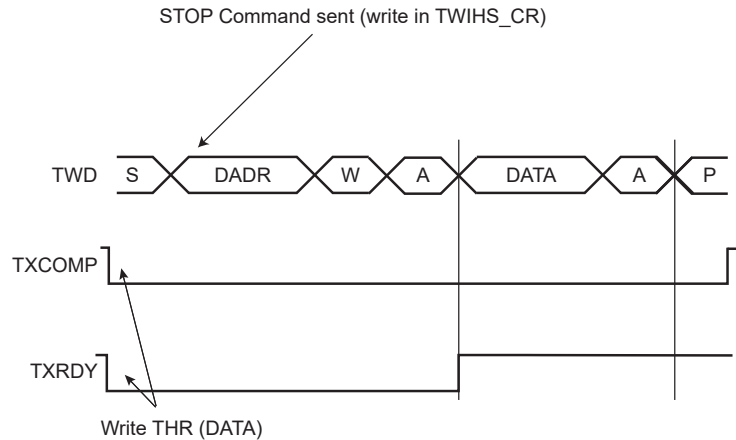

While no new data is written in the TWIHS\_THR, the serial clock line is tied low. When new data is written in the TWIHS\_THR, the SCL is released and the data is sent. Setting the STOP bit in TWIHS\_CR generates a STOP condition.

After a master write transfer, the serial clock line is stretched (tied low) as long as no new data is written in the TWIHS\_THR or until a STOP command is performed.

To clear the TXRDY flag, first set the bit TWIHS\_CR.MSDIS, then set the bit TWIHS\_CR.MSEN.

See the figures below.

**Figure 45-4. Master Write with One Data Byte**

**Figure 45-5. Master Write with Multiple Data Bytes**

**Figure 45-6. Master Write with One-Byte Internal Address and Multiple Data Bytes**

### 45.6.3.5 Master Receiver Mode

Master Receiver mode is not available if High-speed mode is selected.

The read sequence begins by setting the START bit. After the START condition has been sent, the master sends a 7-bit slave address to notify the slave device. The bit following the slave address indicates the transfer direction, 1 in this case (MREAD = 1 in TWIHS\_MMR). During the acknowledge clock pulse (9th pulse), the master releases the data line (HIGH), enabling the slave to pull it down in order to generate the acknowledge. The master polls the data line during this clock pulse and sets TWIHS\_SR.NACK if the slave does not acknowledge the byte.

If an acknowledge is received, the master is then ready to receive data from the slave. After data has been received, the master sends an acknowledge condition to notify the slave that the data has been received except for the last data (see [Master Read with One Data Byte](#)). When TWIHS\_SR.RXRDY is set, a character has been received in the Receive Holding register (TWIHS\_RHR). The RXRDY bit is reset when reading the TWIHS\_RHR.

When a single data byte read is performed, with or without internal address (IADR), the START and STOP bits must be set at the same time. See [Master Read with One Data Byte](#). When a multiple data byte read is performed, with or without internal address (IADR), the STOP bit must be set after the next-

to-last data received (same condition applies for START bit to generate a REPEATED START). See [Master Read with Multiple Data Bytes](#). For internal address usage, see [Internal Address](#).

If TWIHS\_RHR is full (RXRDY high) and the master is receiving data, the serial clock line is tied low before receiving the last bit of the data and until the TWIHS\_RHR is read. Once the TWIHS\_RHR is read, the master stops stretching the serial clock line and ends the data reception. See [Master Read Clock Stretching with Multiple Data Bytes](#).

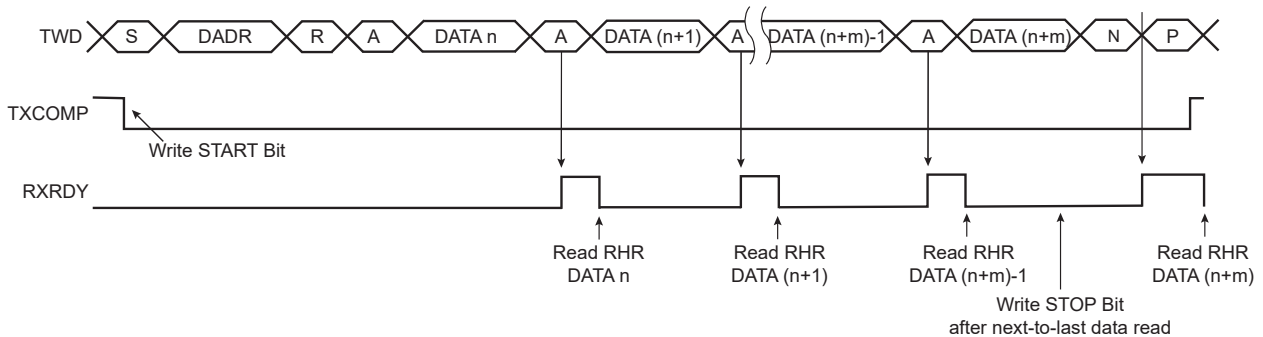

**WARNING** When receiving multiple bytes in Master Read mode, if the next-to-last access is not read (the RXRDY flag remains high), the last access is not completed until TWIHS\_RHR is read. The last access stops on the next-to-last bit (clock stretching). When the TWIHS\_RHR is read, there is only half a bit period to send the STOP (or START) command, else another read access might occur (spurious access).

A possible workaround is to set the STOP (or START) bit before reading the TWIHS\_RHR on the next-to-last access (within IT handler).

**Figure 45-7. Master Read with One Data Byte**

**Figure 45-8. Master Read with Multiple Data Bytes**

**Figure 45-9. Master Read Clock Stretching with Multiple Data Bytes**

RXRDY is used as receive ready for the DMA receive channel.

### 45.6.3.6 Internal Address

The TWIHS can perform transfers with 7-bit slave address devices and with 10-bit slave address devices.

#### 45.6.3.6.1 7-bit Slave Addressing

When addressing 7-bit slave devices, the internal address bytes are used to perform random address (read or write) accesses to reach one or more data bytes, e.g. within a memory page location in a serial memory. When performing read operations with an internal address, the TWIHS performs a write operation to set the internal address into the slave device, and then switch to Master Receiver mode. Note that the second START condition (after sending the IADR) is sometimes called “repeated start” (Sr) in I<sup>2</sup>C fully-compatible devices. See [Master Read with One-, Two- or Three-Byte Internal Address and One Data Byte](#).

See [Master Write with One-, Two- or Three-Byte Internal Address and One Data Byte](#) and [Internal Address Usage](#) for the master write operation with internal address.

The three internal address bytes are configurable through TWIHS\_MMR.

If the slave device supports only a 7-bit address, i.e., no internal address, IADRSZ must be set to 0.

The table below shows the abbreviations used in the figures below.

**Table 45-4. Abbreviations**

| Abbreviation | Definition      |
|--------------|-----------------|
| S            | Start           |
| Sr           | Repeated Start  |
| P            | Stop            |
| W            | Write           |
| R            | Read            |
| A            | Acknowledge     |
| NA           | Not Acknowledge |
| DADR         | Device Address  |

.....continued

| Abbreviation | Definition       |
|--------------|------------------|
| IADR         | Internal Address |

**Figure 45-10. Master Write with One-, Two- or Three-Byte Internal Address and One Data Byte**

**Figure 45-11. Master Read with One-, Two- or Three-Byte Internal Address and One Data Byte**

### 45.6.3.6.2 10-bit Slave Addressing

For a slave address higher than seven bits, configure the address size (IADRSZ) and set the other slave address bits in the Internal Address register (TWIHS\_IADR). The two remaining internal address bytes, IADR[15:8] and IADR[23:16], can be used the same way as in 7-bit slave addressing.

Example: Address a 10-bit device (10-bit device address is b1 b2 b3 b4 b5 b6 b7 b8 b9 b10)

1. Program IADRSZ = 1,
2. Program DADR with 1 1 1 1 0 b1 b2 (b1 is the MSB of the 10-bit address, b2, etc.)
3. Program TWIHS\_IADR with b3 b4 b5 b6 b7 b8 b9 b10 (b10 is the LSB of the 10-bit address)

The figure below shows a byte write to a memory device. This demonstrates the use of internal addresses to access the device.

**Figure 45-12. Internal Address Usage**

### 45.6.3.7 Repeated Start

In addition to Internal Address mode, REPEATED START (Sr) can be generated manually by writing the START bit at the end of a transfer instead of the STOP bit. In such case, the parameters of the next transfer (direction, SADR, etc.) need to be set before writing the START bit at the end of the previous transfer.

See [Read/Write Flowcharts](#) for detailed flowcharts.

Note that generating a REPEATED START after a single data read is not supported.

#### 45.6.3.8 Bus Clear Command

The TWIHS can perform a Bus Clear command:

1. Configure the Master mode (DADR, CKDIV, etc).
2. Start the transfer by setting TWIHS\_CR.CLEAR.

**Note:** If alternative command is used (ACMEN bit set to '1'), DATAL field must be set to 0.

#### 45.6.3.9 Using the DMA Controller (DMAC) in Master Mode

The use of the DMA significantly reduces the CPU load.

To ensure correct implementation, follow the programming sequences below:

##### 45.6.3.9.1 Data Transmit with the DMA in Master Mode

If Alternative Command mode is disabled (ACMEN bit set to '0'):

The DMA transfer size must be defined with the buffer size minus 1. The remaining character must be managed without DMA to ensure that the exact number of bytes are transmitted regardless of system bus latency conditions during the end of the buffer transfer period.

1. Initialize the DMA (channels, memory pointers, size - 1, etc.);
2. Configure the Master mode (DADR, CKDIV, MREAD = 0, etc.) or Slave mode.
3. Enable the DMA.
4. Wait for the DMA status flag indicating that the buffer transfer is complete.
5. Disable the DMA.
6. Wait for the TXRDY flag in TWIHS\_SR.
7. Set TWIHS\_CR.STOP.
8. Write the last character in TWIHS\_THR.
9. (Only if peripheral clock must be disabled) Wait for the TXCOMP flag to be raised in TWIHS\_SR.

If Alternative Command mode is enabled (ACMEN bit set to '1'):

1. Initialize the transmit DMA (memory pointers, transfer size).
2. Configure the Master mode (DADR, CKDIV, etc.) and TWIHS\_ACR.
3. Start the transfer by setting the DMA TXTEN bit.
4. Wait for the DMA ENDTX flag either by using the polling method or ENDTX interrupt.
5. Disable the DMA by setting the DMA TXTDIS bit.
6. (Only if peripheral clock must be disabled) Wait for the TXCOMP flag to be raised in TWIHS\_SR.

##### 45.6.3.9.2 Data Receive with the DMA in Master Mode

If Alternative Command mode is disabled (ACMEN bit set to '0'):

The DMA transfer size must be defined with the buffer size minus 2. The two remaining characters must be managed without DMA to ensure that the exact number of bytes are received regardless of system bus latency conditions encountered during the end of buffer transfer period.

1. Initialize the DMA (channels, memory pointers, size - 2, etc.);
2. Configure the Master mode (DADR, CKDIV, MREAD = 1, etc.) or Slave mode.
3. Enable the DMA.
4. (Master Only) Write TWIHS\_CR.START to start the transfer.
5. Wait for the DMA status flag indicating that the buffer transfer is complete.
6. Disable the DMA.
7. Wait for the RXRDY flag in the TWIHS\_SR.

8. Set TWIHS\_CR.STOP.
9. Read the penultimate character in TWIHS\_RHR.
10. Wait for the RXRDY flag in the TWIHS\_SR.
11. Read the last character in TWIHS\_RHR.
12. (Only if peripheral clock must be disabled) Wait for the TXCOMP flag to be raised in TWIHS\_SR.

If Alternative Command mode is enabled (ACMEN bit set to '1'):

1. Initialize the transmit DMA (memory pointers, transfer size).
2. Configure the Master mode (DADR, CKDIV, etc.) and TWIHS\_ACR.
3. Set the DMA RXTEN bit.
4. (Master Only) Write TWIHS\_CR.START to start the transfer.
5. Wait for the DMA ENDTX Flag either by using the polling method or ENDTX interrupt.
6. Disable the DMA by setting the DMA TXTDIS bit.
7. (Only if peripheral clock must be disabled) Wait for the TXCOMP flag to be raised in TWIHS\_SR.

#### 45.6.3.10 SMBus Mode

SMBus mode is enabled when a one is written to TWIHS\_CR.SMBEN. SMBus mode operation is similar to I<sup>2</sup>C operation with the following exceptions:

- Only 7-bit addressing can be used.
- The SMBus standard describes a set of timeout values to ensure progress and throughput on the bus. These timeout values must be programmed into TWIHS\_SMBTR.
- Transmissions can optionally include a CRC byte, called Packet Error Check (PEC).
- A set of addresses has been reserved for protocol handling, such as alert response address (ARA) and host header (HH) address. Address matching on these addresses can be enabled by configuring TWIHS\_CR.

##### 45.6.3.10.1 Packet Error Checking

Each SMBus transfer can optionally end with a CRC byte, called the PEC byte. Writing a one to TWIHS\_CR.PECEN enables automatic PEC handling in the current transfer. Transfers with and without PEC can be intermixed in the same system, since some slaves may not support PEC. The PEC LFSR is always updated on every bit transmitted or received, so that PEC handling on combined transfers is correct.

In Master Transmitter mode, the master calculates a PEC value and transmits it to the slave after all data bytes have been transmitted. Upon reception of this PEC byte, the slave compares it to the PEC value it has computed itself. If the values match, the data was received correctly, and the slave returns an ACK to the master. If the PEC values differ, data was corrupted, and the slave returns a NACK value. Some slaves may not be able to check the received PEC in time to return a NACK if an error occurred. In this case, the slave should always return an ACK after the PEC byte, and another method must be used to verify that the transmission was received correctly.

In Master Receiver mode, the slave calculates a PEC value and transmits it to the master after all data bytes have been transmitted. Upon reception of this PEC byte, the master compares it to the PEC value it has computed itself. If the values match, the data was received correctly. If the PEC values differ, data was corrupted, and TWIHS\_SR.PECERR is set. In Master Receiver mode, the PEC byte is always followed by a NACK transmitted by the master, since it is the last byte in the transfer.

In combined transfers, the PECRQ bit should only be set in the last of the combined transfers.

If the Alternative Command mode is enabled, only the NPEC bit should be set.

Consider the following transfer:

S, ADR+W, COMMAND\_BYTE, ACK, SR, ADR+R, DATA\_BYTE, ACK, PEC\_BYTE, NACK, P

See [Read/Write Flowcharts](#) for detailed flowcharts.

### 45.6.3.10.2 Timeouts

The TLOWS and TLOWM fields in TWIHS\_SMBTR configure the SMBus timeout values. If a timeout occurs, the master transmits a STOP condition and leaves the bus. The TOUT bit is also set in TWIHS\_SR.

### 45.6.3.11 SMBus Quick Command (Master Mode Only)

The TWIHS can perform a quick command by following these steps:

1. Configure the Master mode (DADR, CKDIV, etc).
2. Write TWIHS\_MMR.MREAD at the value of the one-bit command to be sent.
3. Start the transfer by setting TWIHS\_CR.QUICK.

If alternative command is used (ACMEN bit set to '1'), DATAL field must be set to 0.

**Figure 45-13. SMBus Quick Command**

### 45.6.3.12 Alternative Command

Another way to configure the transfer is to enable the Alternative Command mode with the ACMEN bit of the [TWIHS Control Register](#).

In this mode, the transfer is configured through the [TWIHS Alternative Command Register](#). It is possible to define a simple read or write transfer or a combined transfer with a repeated start.

In order to set a simple transfer, the DATAL field and the DIR field of the [TWIHS Alternative Command Register](#) must be filled accordingly and the NDATAL field must be cleared. To begin the transfer, either set the START bit in the [TWIHS Control Register](#) in case of a read transfer, or write the [TWIHS Transmit Holding Register](#) in case of a write transfer.

For a combined transfer linked by a repeated start, the NDATAL field must be filled with the length of the second transfer and NDIR with the corresponding direction.

The PEC and NPEC bits are used to set a PEC field. In the case of a single transfer with PEC, the PEC bit must be set. In the case of a combined transfer, the NPEC bit must be set.

**Note:** If Alternative Command mode is used, TWIHS\_MMR.IADRSZ must be set to 0.

See [Read/Write Flowcharts](#) for detailed flowcharts.

### 45.6.3.13 Handling Errors in Alternative Command

If a NACK is generated by a slave device or SMBus timeout error, the TWIHS stops the frame immediately, although the DMA transfer may still be active. To prevent a new frame from being restarted

with the remaining DMA data (transmit), the TWIHS prevents any start of frame until the LOCK flag is cleared in the TWIHS\_SR.

TWIHS\_SR.LOCK indicates the state of the TWIHS (locked or not locked).

When the TWIHS is locked, no transfer begins until the LOCK is cleared by TWIHS\_CR.LOCKCLR and error flags are cleared by reading the TWIHS\_SR.

In case of error, the TWIHS\_THR may have been loaded with a new data. TWIHS\_CR.THRCLR can be used to flush the TWIHS\_THR. If THRCLR is set, the TXRDY and TXCOMP flags are set.

#### 45.6.3.14 Read/Write Flowcharts

The flowcharts give examples for read and write operations. A polling or interrupt method can be used to check the status bits. The interrupt method requires that TWIHS\_IER be configured first.

### 45.6.4 Multimaster Mode

#### 45.6.4.1 Definition

In Multimaster mode, more than one master may handle the bus at the same time without data corruption by using arbitration.

Arbitration starts as soon as two or more masters place information on the bus at the same time, and stops (arbitration is lost) for the master that intends to send a logical one while the other master sends a logical zero.

As soon as arbitration is lost by a master, it stops sending data and listens to the bus in order to detect a stop. When the stop is detected, the master that has lost arbitration may put its data on the bus by respecting arbitration.

Arbitration is illustrated in [Arbitration Cases](#).

### 45.6.4.2 Different Multimaster Modes

Two Multimaster modes may be distinguished:

1. The TWIHS is considered as a master only and is never addressed.
2. The TWIHS may be either a master or a slave and may be addressed.

**Note:** Arbitration is supported in both Multimaster modes.

#### 45.6.4.2.1 TWIHS as Master Only

In this mode, the TWIHS is considered as a master only (MSEN is always at one) and must be driven like a master with the ARBLST (Arbitration Lost) flag in addition.

If arbitration is lost (ARBLST = 1), the user must reinitiate the data transfer.

If starting a transfer (ex.: DADR + START + W + Write in THR) and if the bus is busy, the TWIHS automatically waits for a STOP condition on the bus to initiate the transfer (see [User Sends Data While the Bus is Busy](#)).

**Note:** The state of the bus (busy or free) is not indicated in the user interface.

#### 45.6.4.2.2 TWIHS as Master or Slave

The automatic reversal from master to slave is not supported in case of a lost arbitration.

Then, in the case where TWIHS may be either a master or a slave, the user must manage the pseudo Multimaster mode described in the steps below:

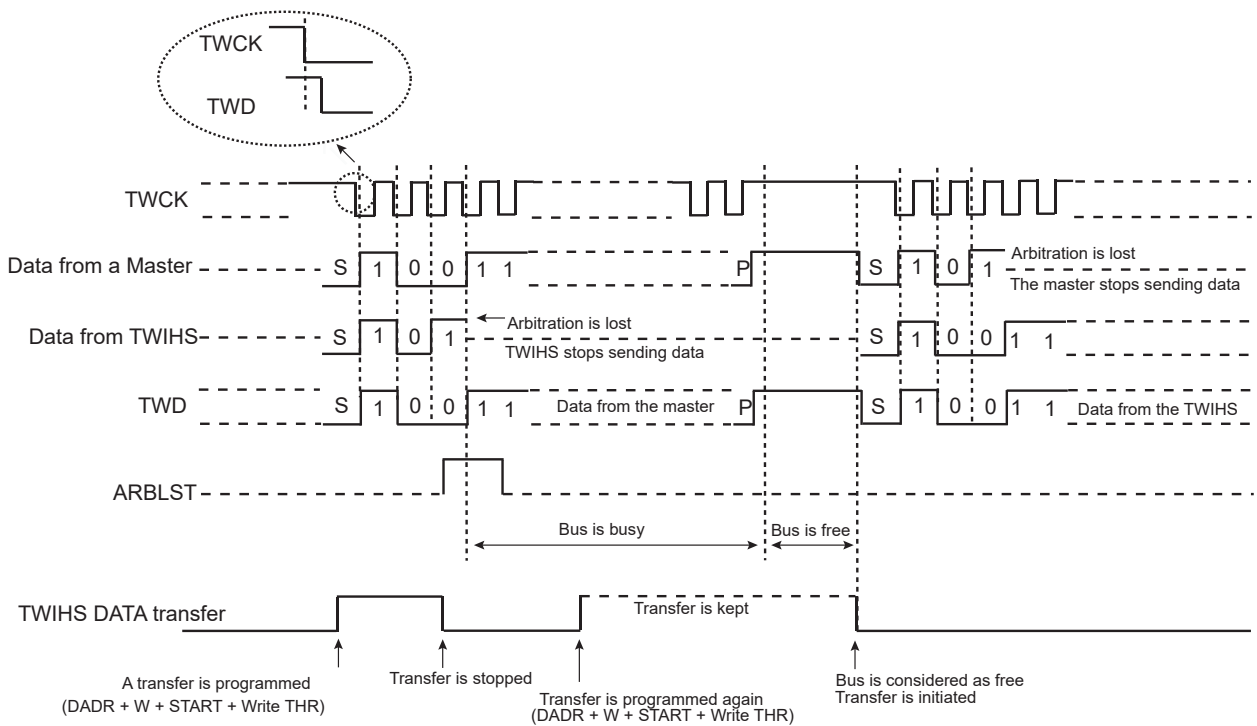

1. Program the TWIHS in Slave mode (SADR + MSDIS + SVEN) and perform a slave access (if TWIHS is addressed).
2. If the TWIHS has to be set in Master mode, wait until TXCOMP flag is at 1.
3. Program the Master mode (DADR + SVDIS + MSEN) and start the transfer (ex: START + Write in THR).
4. As soon as the Master mode is enabled, the TWIHS scans the bus in order to detect if it is busy or free. When the bus is considered free, the TWIHS initiates the transfer.
5. As soon as the transfer is initiated and until a STOP condition is sent, the arbitration becomes relevant and the user must monitor the ARBLST flag.
6. If the arbitration is lost (ARBLST is set to 1), the user must program the TWIHS in Slave mode in case the master that won the arbitration needs to access the TWIHS.
7. If the TWIHS has to be set in Slave mode, wait until the TXCOMP flag is at 1 and then program the Slave mode.

**Note:** If the arbitration is lost and the TWIHS is addressed, the TWIHS does not acknowledge, even if it is programmed in Slave mode as soon as ARBLST is set to 1. Then the master must repeat SADR.

**Figure 45-28. User Sends Data While the Bus is Busy**

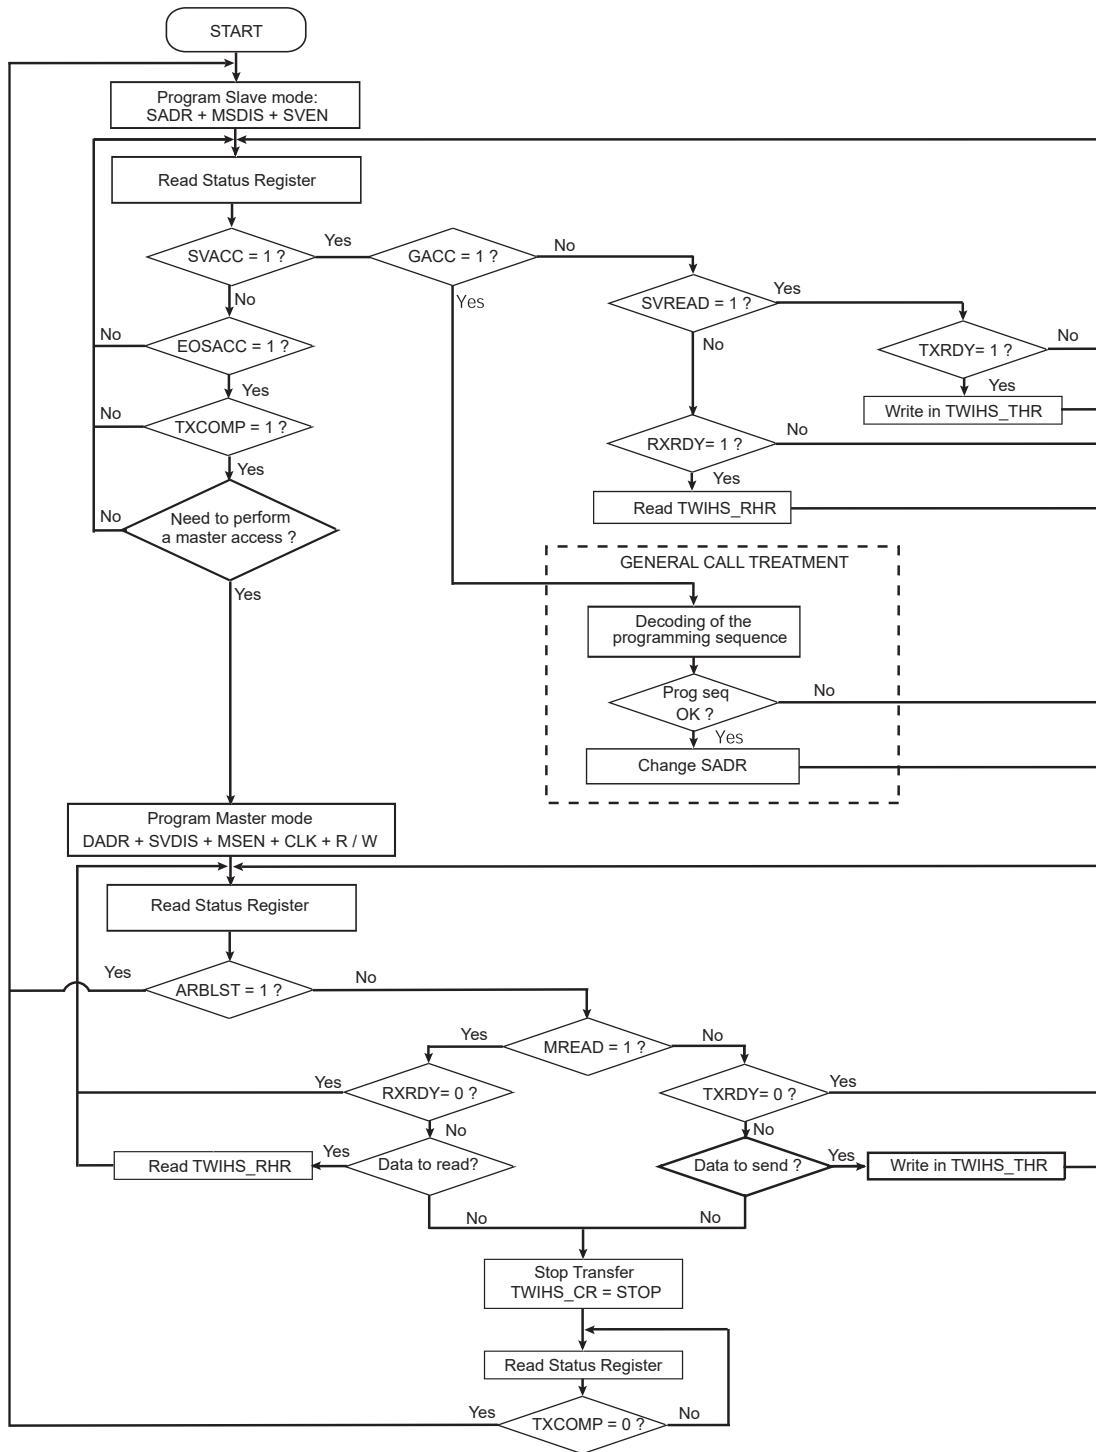

**Figure 45-29. Arbitration Cases**

The flowchart below gives an example of read and write operations in Multimaster mode.

**Figure 45-30. Multimaster Flowchart**

### 45.6.5 Slave Mode

#### 45.6.5.1 Definition

Slave mode is defined as a mode where the device receives the clock and the address from another device called the master.

In this mode, the device never initiates and never completes the transmission (START, REPEATED\_START and STOP conditions are always provided by the master).

### 45.6.5.2 Programming Slave Mode

The following fields must be programmed before entering Slave mode:

1. TWIHS\_SMR.SADR: The slave device address is used in order to be accessed by master devices in Read or Write mode.
2. (Optional) TWIHS\_SMR.MASK can be set to mask some SADR address bits and thus allow multiple address matching.
3. TWIHS\_CR.MSDIS: Disables the Master mode.
4. TWIHS\_CR.SVEN: Enables the Slave mode.

As the device receives the clock, values written in TWIHS\_CWGR are ignored.

### 45.6.5.3 Receiving Data

After a START or REPEATED START condition is detected, and if the address sent by the master matches the slave address programmed in the SADR (Slave Address) field, the SVACC (Slave Access) flag is set and SVREAD (Slave Read) indicates the direction of the transfer.

SVACC remains high until a STOP condition or a REPEATED START is detected. When such a condition is detected, the EOSACC (End Of Slave Access) flag is set.

#### 45.6.5.3.1 Read Sequence

In the case of a read sequence (SVREAD is high), the TWIHS transfers data written in the TWIHS\_THR until a STOP condition or a REPEATED\_START + an address different from SADR is detected. Note that at the end of the read sequence TXCOMP (Transmission Complete) flag is set and SVACC reset.

As soon as data is written in the TWIHS\_THR, TXRDY (Transmit Holding Register Ready) flag is reset, and it is set when the internal shifter is empty and the sent data acknowledged or not. If the data is not acknowledged, the NACK flag is set.

Note that a STOP or a REPEATED START always follows a NACK.

To clear the TXRDY flag, first set TWIHS\_CR.SVDIS, then set TWIHS\_CR.SVEN.

See [Read Access Ordered by a Master](#).

#### 45.6.5.3.2 Write Sequence

In the case of a write sequence (SVREAD is low), the RXRDY (Receive Holding Register Ready) flag is set as soon as a character has been received in TWIHS\_RHR. RXRDY is reset when reading TWIHS\_RHR.

The TWIHS continues receiving data until a STOP condition or a REPEATED\_START + an address different from SADR is detected. Note that at the end of the write sequence, the TXCOMP flag is set and SVACC is reset.

See [Write Access Ordered by a Master](#).

#### 45.6.5.3.3 Clock Stretching Sequence

If TWIHS\_THR or TWIHS\_RHR is not written/read in time, the TWIHS performs a clock stretching.

Clock stretching information is given by the SCLWS (Clock Wait State) bit.

See [Clock Stretching in Read Mode](#) and [Clock Stretching in Write Mode](#).

**Note:** Clock stretching can be disabled by configuring the SCLWSDIS bit in TWIHS\_SMR. In that case, the UNRE and OVRE flags indicate an underrun (when TWIHS\_THR is not filled on time) or an overrun (when TWIHS\_RHR is not read on time).

### 45.6.5.3.4 General Call

In the case where a GENERAL CALL is performed, the GACC (General Call Access) flag is set.

After GACC is set, the user must interpret the meaning of the GENERAL CALL and decode the new address programming sequence.

See [Master Performs a General Call](#).

### 45.6.5.4 Data Transfer

#### 45.6.5.4.1 Read Operation

The Read mode is defined as a data requirement from the master.

After a START or a REPEATED START condition is detected, the decoding of the address starts. If the slave address (SADR) is decoded, SVACC is set and SVREAD indicates the direction of the transfer.

Until a STOP or REPEATED START condition is detected, the TWIHS continues sending data loaded in TWIHS\_THR.

If a STOP condition or a REPEATED START + an address different from SADR is detected, SVACC is reset.

The figure below describes the read operation.

**Figure 45-31. Read Access Ordered by a Master**

**Note:**

1. When SVACC is low, the state of SVREAD becomes irrelevant.
2. TXRDY is reset when data has been transmitted from TWIHS\_THR to the internal shifter and set when this data has been acknowledged or non acknowledged.

#### 45.6.5.4.2 Write Operation

The Write mode is defined as a data transmission from the master.

After a START or a REPEATED START, the decoding of the address starts. If the slave address is decoded, SVACC is set and SVREAD indicates the direction of the transfer (SVREAD is low in this case).

Until a STOP or REPEATED START condition is detected, the TWIHS stores the received data in TWIHS\_RHR.

If a STOP condition or a REPEATED START + an address different from SADR is detected, SVACC is reset.

The figure below describes the write operation.

**Figure 45-32. Write Access Ordered by a Master**

**Note:**

1. When SVACC is low, the state of SVREAD becomes irrelevant.
2. RXRDY is set when data has been transmitted from the internal shifter to TWIHS\_RHR and reset when this data is read.

**45.6.5.4.3 General Call**

The general call is performed in order to change the address of the slave.

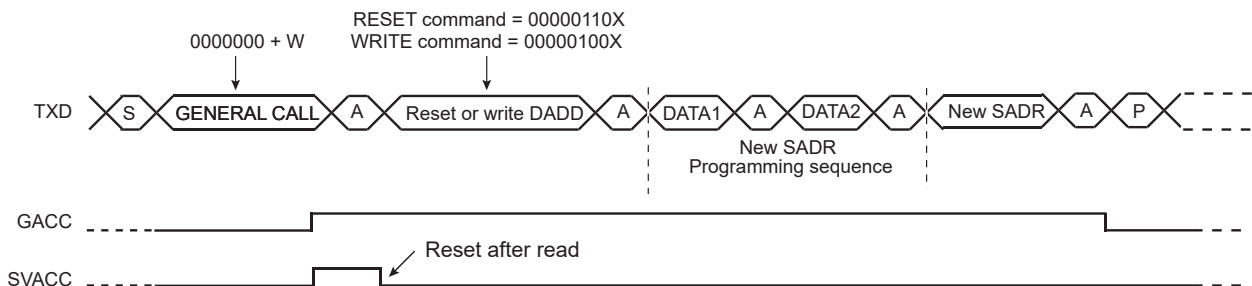

If a GENERAL CALL is detected, GACC is set.

After the detection of general call, decode the commands that follow.

In case of a WRITE command, decode the programming sequence and program a new SADR if the programming sequence matches.

The figure below describes the general call access.

**Figure 45-33. Master Performs a General Call**

**Note:** This method enables the user to create a personal programming sequence by choosing the programming bytes and their number. The programming sequence has to be provided to the master.

**45.6.5.4.4 Clock Stretching**

In both Read and Write modes, it may occur that TWIHS\_THR/TWIHS\_RHR buffer is not filled/emptied before the transmission/reception of a new character. In this case, to avoid sending/receiving undesired data, a clock stretching mechanism is implemented.

**Note:** Clock stretching can be disabled by setting TWIHS\_SMR.SCLWSDIS. In that case the UNRE and OVRE flags indicate an underrun (when TWIHS\_THR is not filled on time) or an overrun (when TWIHS\_RHR is not read on time).

**Clock Stretching in Read Mode**

The clock is tied low if the internal shifter is empty and if a STOP or REPEATED START condition was not detected. It is tied low until the internal shifter is loaded.

The figure below describes the clock stretching in Read mode.

**Figure 45-34. Clock Stretching in Read Mode**

**Note:**

1. TXRDY is reset when data has been written in TWIHS\_THR to the internal shifter and set when this data has been acknowledged or non acknowledged.
2. At the end of the read sequence, TXCOMP is set after a STOP or after a REPEATED\_START + an address different from SADR.
3. SCLWS is automatically set when the clock stretching mechanism is started.

**Clock Stretching in Write Mode**

The clock is tied low if the internal shifter and TWIHS\_RHR is full. If a STOP or REPEATED\_START condition was not detected, it is tied low until TWIHS\_RHR is read.

The figure below describes the clock stretching in Write mode.

**Figure 45-35. Clock Stretching in Write Mode**

**Note:**

1. At the end of the read sequence, TXCOMP is set after a STOP or after a REPEATED\_START + an address different from SADR.
2. SCLWS is automatically set when the clock stretching mechanism is started and automatically reset when the mechanism is finished.

### 45.6.5.4.5 Reversal after a Repeated Start

#### **Reversal of Read to Write**

The master initiates the communication by a read command and finishes it by a write command.

The figure below describes the REPEATED START and the reversal from Read mode to Write mode.

**Figure 45-36. Repeated Start and Reversal from Read Mode to Write Mode**

**Note:** TXCOMP is only set at the end of the transmission. This is because after the REPEATED START, SADR is detected again.

#### **Reversal of Write to Read**

The master initiates the communication by a write command and finishes it by a read command. The figure below describes the REPEATED START and the reversal from Write mode to Read mode.

**Figure 45-37. Repeated Start and Reversal from Write Mode to Read Mode**

**Note:**

1. In this case, if TWIHS\_THR has not been written at the end of the read command, the clock is automatically stretched before the ACK.
2. TXCOMP is only set at the end of the transmission. This is because after the REPEATED START, SADR is detected again.

### 45.6.5.5 Using the DMA Controller (DMAC) in Slave Mode

The use of the DMAC significantly reduces the CPU load.

#### 45.6.5.5.1 Data Transmit with the DMA in Slave Mode

The following procedure shows an example to transmit data with DMA.

1. Initialize the transmit DMA (memory pointers, transfer size, etc).

2. Configure the Slave mode.
3. Enable the DMA.
4. Wait for the DMA status flag indicating that the buffer transfer is complete.
5. Disable the DMA.
6. (Only if peripheral clock must be disabled) Wait for the TXCOMP flag to be raised in TWIHS\_SR.

#### 45.6.5.5.2 Data Receive with the DMA in Slave Mode

The following procedure shows an example to transmit data with DMA where the number of characters to receive is known.

1. Initialize the DMA (channels, memory pointers, size, etc.).
2. Configure the Slave mode.
3. Enable the DMA.
4. Wait for the DMA status flag indicating that the buffer transfer is complete.
5. Disable the DMA.
6. (Only if peripheral clock must be disabled) Wait for the TXCOMP flag to be raised in TWIHS\_SR.

#### 45.6.5.6 SMBus Mode

SMBus mode is enabled when a one is written to TWIHS\_CR.SMBEN. SMBus mode operation is similar to I<sup>2</sup>C operation with the following exceptions:

- Only 7-bit addressing can be used.
- The SMBus standard describes a set of timeout values to ensure progress and throughput on the bus. These timeout values must be programmed into the TWIHS\_SMBTR.
- Transmissions can optionally include a CRC byte, called Packet Error Check (PEC).
- A set of addresses have been reserved for protocol handling, such as alert response address (ARA) and host header (HH) address. Address matching on these addresses can be enabled by configuring the TWIHS\_CR.

##### 45.6.5.6.1 Packet Error Checking

Each SMBus transfer can optionally end with a CRC byte, called the PEC byte. Writing a one to TWIHS\_CR.PECEN will send/check the PEC field in the current transfer. The PEC generator is always updated on every bit transmitted or received, so that PEC handling on the following linked transfers is correct.

In Slave Receiver mode, the master calculates a PEC value and transmits it to the slave after all data bytes have been transmitted. Upon reception of this PEC byte, the slave compares it to the PEC value it has computed itself. If the values match, the data was received correctly, and the slave returns an ACK to the master. If the PEC values differ, data was corrupted, and the slave returns a NACK value.

TWIHS\_SR.PECERR is set automatically if a PEC error occurred.

In Slave Transmitter mode, the slave calculates a PEC value and transmits it to the master after all data bytes have been transmitted. Upon reception of this PEC byte, the master compares it to the PEC value it has computed itself. If the values match, the data was received correctly. If the PEC values differ, data was corrupted, and the master must take appropriate action.

See [Slave Read Write Flowcharts](#) for detailed flowcharts.

##### 45.6.5.6.2 Timeouts

The TWIHS SMBus Timing Register (TWIHS\_SMBTR) configures the SMBus timeout values. If a timeout occurs, the slave leaves the bus. The TOUT bit is also set in TWIHS\_SR.

### 45.6.5.7 High-Speed Slave Mode

High-speed mode is enabled when a one is written to TWIHS\_CR.HSEN. Furthermore, the analog pad filter must be enabled, a one must be written to TWIHS\_FILTR.PADFEN and the FILT bit must be cleared. TWIHS High-speed mode operation is similar to TWIHS operation with the following exceptions:

1. A master code is received first at normal speed before entering High-speed mode period.
2. When TWIHS High-speed mode is active, clock stretching is only allowed after acknowledge (ACK), not-acknowledge (NACK), START (S) or REPEATED START (Sr) (as consequence OVF may happen).

TWIHS High-speed mode allows transfers of up to 3.4 Mbit/s.

The TWIHS slave in High-speed mode requires that the peripheral clock runs at a minimum of 14 MHz if slave clock stretching is enabled (SCLWSDIS bit at '0'). If slave clock stretching is disabled (SCLWSDIS bit at '1'), the peripheral clock must run at a minimum of 11 MHz (assuming the system has no latency).

**Note:** When slave clock stretching is disabled, the TWIHS\_RHR must always be read before receiving the next data (MASTER write frame). It is strongly recommended to use either the polling method on the RXRDY flag in TWIHS\_SR, or the DMA. If the receive is managed by an interrupt, the TWIHS interrupt priority must be set to the right level and its latency minimized to avoid receive overrun.

**Note:** When slave clock stretching is disabled, the TWIHS\_THR must be filled with the first data to send before the beginning of the frame (MASTER read frame). It is strongly recommended to use either the polling method on the TXRDY flag in TWIHS\_SR, or the DMA. If the transmit is managed by an interrupt, the TWIHS interrupt priority must be set to the right level and its latency minimized to avoid transmit underrun.

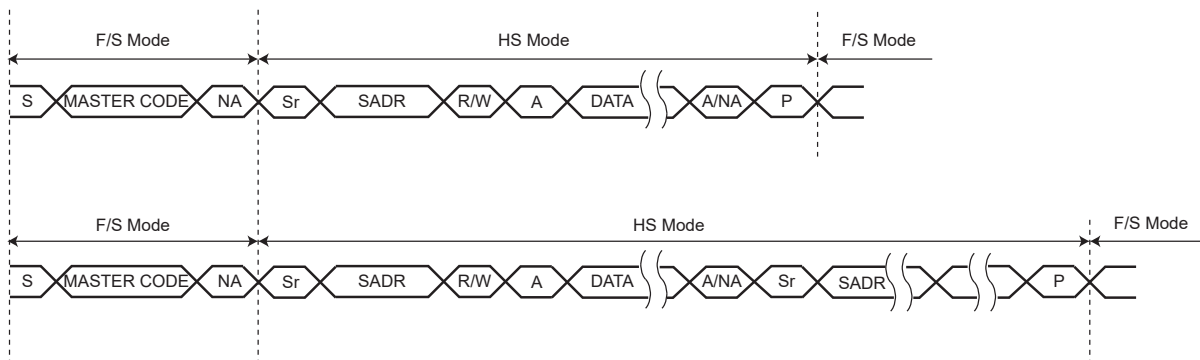

#### 45.6.5.7.1 Read/Write Operation

A TWIHS high-speed frame always begins with the following sequence:

1. START condition (S)
2. Master Code (0000 1XXX)
3. Not-acknowledge (NACK)

When the TWIHS is programmed in Slave mode and TWIHS High-speed mode is activated, master code matching is activated and internal timings are set to match the TWIHS High-speed mode requirements.

**Figure 45-38. High-Speed Mode Read/Write**

#### 45.6.5.7.2 Usage

TWIHS High-speed mode usage is the same as the standard TWIHS (See [Read/Write Flowcharts](#)).

#### 45.6.5.8 Alternative Command

In Slave mode, Alternative Command mode is useful when SMBus mode is enabled to send or check the PEC byte.

Alternative Command mode is enabled by setting the ACMEN bit of the [TWIHS Control Register](#) and the transfer is configured in TWIHS\_ACR.

For a combined transfer with PEC, only TWIHS\_ACR.NPEC must be set as the PEC byte is sent once at the end of the frame.

See [Slave Read Write Flowcharts](#) for detailed flowcharts.

#### 45.6.5.9 Asynchronous Partial Wakeup (SleepWalking)

The TWIHS includes an asynchronous start condition detector. It is capable of waking the device up from a Sleep mode upon an address match (and optionally an additional data match), including Sleep modes where the TWIHS peripheral clock is stopped.

After detecting the START condition on the bus, the TWIHS stretches TWCK until the TWIHS peripheral clock has started. The time required for starting the TWIHS depends on which Sleep mode the device is in. After the TWIHS peripheral clock has started, the TWIHS releases its TWCK stretching and receives one byte of data (slave address) on the bus. At this time, only a limited part of the device, including the TWIHS module, receives a clock, thus saving power. If the address phase causes a TWIHS address match (and, optionally, if the first data byte causes data match as well), the entire device is woken up and normal TWIHS address matching actions are performed. Normal TWIHS transfer then follows. If the TWIHS is not addressed (or if the optional data match fails), the TWIHS peripheral clock is automatically stopped and the device returns to its original Sleep mode.

The TWIHS has the capability to match on more than one address. The SADR1EN, SADR2EN and SADR3EN bits in TWIHS\_SMR enable address matching on additional addresses which can be configured through SADR1, SADR2 and SADR3 fields in the TWIHS\_SWMR. The SleepWalking matching process can be extended to the first received data byte if TWIHS\_SMR.DATAMEN is set and, in this case, a complete matching includes address matching and first received data matching. TWIHS\_SWMR.DATAM configures the data to match on the first received byte.

When the system is in Active mode and the TWIHS enters Asynchronous Partial Wakeup mode, the flag SVACC must be programmed as the unique source of the TWIHS interrupt and the data match comparison must be disabled.

When the system exits Wait mode as the result of a matching condition, the SVACC flag is used to determine if the TWIHS is the source of exit.

**Figure 45-39. Address Match Only (Data Matching Disabled)**

**Figure 45-40. No Address Match (Data Matching Disabled)**

**Figure 45-41. Address Match and Data Match (Data Matching Enabled)**

**Figure 45-42. Address Match and No Data Match (Data Matching Enabled)**

### 45.6.5.10 Slave Read Write Flowcharts

The flowchart below illustrates an example of read and write operations in Slave mode. A polling or interrupt method can be used to check the status bits. The interrupt method requires that TWIHS\_IER be configured first.

**Figure 45-43. Read Write Flowchart in Slave Mode**

**Figure 45-44. Read Write Flowchart in Slave Mode with SMBus PEC**

**Figure 45-45. Read Write Flowchart in Slave Mode with SMBus PEC and Alternative Command Mode**

### 45.6.6 FIFOs

#### 45.6.6.1 Overview

The TWI includes two FIFOs which can be enabled/disabled using TWIHS\_CR.FIFOEN/FIFODIS. Both Master and Slave modes must be disabled before enabling or disabling the FIFOs (TWIHS\_CR.MSDIS/SVDIS).

Writing TWIHS\_CR.FIFOEN to '1' enables a 16-data Transmit FIFO and a 16-data Receive FIFO.

It is possible to write or to read single or multiple data in the same access to TWIHS\_THR/RHR, depending on TWIHS\_FMR.TXRDYM/RXRDYM settings.

**Figure 45-46. FIFOs Block Diagram**

#### 45.6.6.2 Sending Data with FIFO Enabled

When the Transmit FIFO is enabled, write access to TWIHS\_THR loads the Transmit FIFO.

The Transmit FIFO level is provided in TWIHS\_FLR.TXFL. If the FIFO can accept the number of data to be transmitted, there is no need to monitor TWIHS\_SR.TXRDY and the data can be successively written in TWIHS\_THR.

If the FIFO cannot accept the data due to insufficient space, wait for the TXRDY flag to be set before writing the data in TWIHS\_THR.

When the space in the FIFO allows only a portion of the data to be written, the TXRDY flag must be monitored before writing the remaining data.

See the figure below and the figure [Sending/Receiving Data with FIFO Enabled in Slave Mode](#).

**Figure 45-47. Sending Data with FIFO Enabled in Master Mode**

### 45.6.6.3 Receiving Data with FIFO Enabled

When the Receive FIFO is enabled, TWIHS\_RHR access reads the FIFO.

When data are present in the Receive FIFO (RXRDY flag set to '1'), the exact number of data can be checked with TWIHS\_FLR.RXFL. All the data can be read successively in TWIHS\_RHR without checking the TWIHS\_SR.RXRDY flag between each access.

See the figure below and the figure [Sending/Receiving Data with FIFO Enabled in Slave Mode](#).

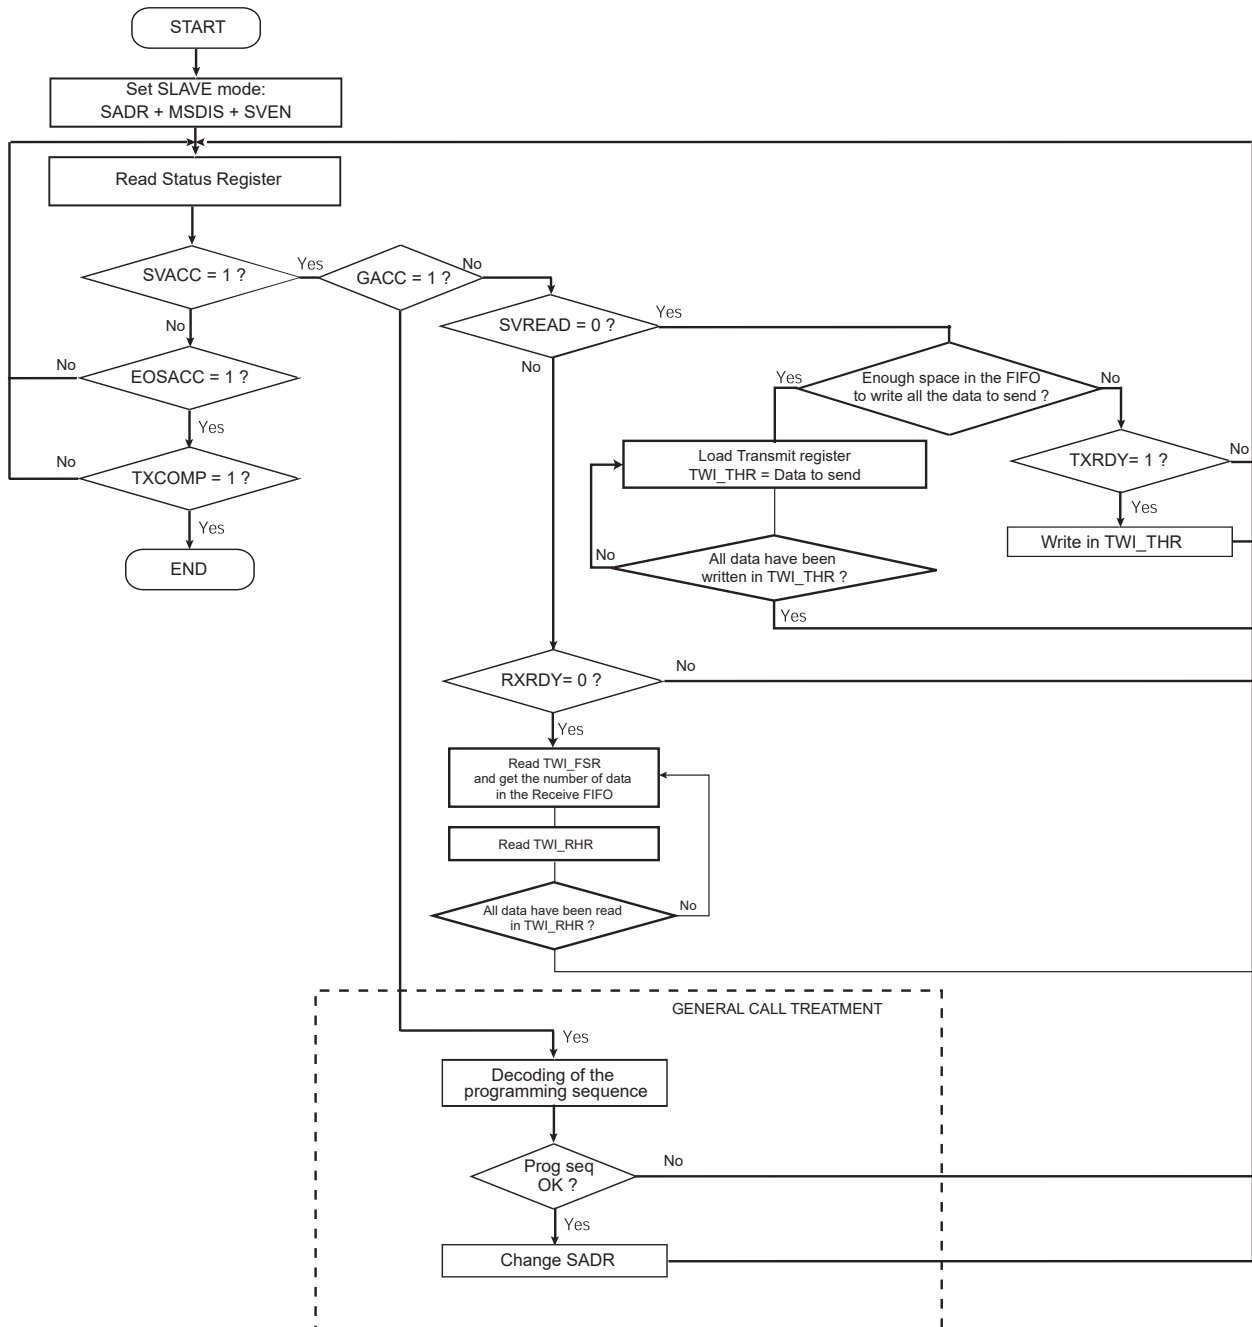

**Figure 45-48. Receiving Data with FIFO Enabled in Master Mode**

#### 45.6.6.4 Sending/Receiving with FIFO Enabled in Slave Mode

See sections [45.6.6.2 Sending Data with FIFO Enabled](#) and [45.6.6.3 Receiving Data with FIFO Enabled](#) for details.

**Figure 45-49. Sending/Receiving Data with FIFO Enabled in Slave Mode**

### 45.6.6.5 Clearing/Flushing FIFOs

Each FIFO can be cleared/flushed using TWIHS\_CR.TXFCLR/RXFCLR.

### 45.6.6.6 TXRDY and RXRDY Behavior

TWIHS\_SR.TXRDY/RXRDY flags display a specific behavior when FIFOs are enabled.

TXRDY indicates if a data can be written in the Transmit FIFO. Thus the TXRDY flag is set as long as the Transmit FIFO can accept new data. See figure [Figure 45-50](#).

RXRDY indicates if an unread data is present in the Receive FIFO. Thus the RXRDY flag is set as soon as one unread data is in the Receive FIFO. Refer to figure [Figure 45-51](#).

TXRDY and RXRDY behavior can be modified using the TXRDYM and RXRDYM fields in the TWI FIFO Mode Register (TWIHS\_FMR) to reduce the number of accesses to TWIHS\_THR/RHR.

As an example, in Master mode, the Transmit FIFO can be loaded with multiple data in the same access by configuring TXRDYM>0.

See TWI FIFO Mode Register for the FIFO configuration.

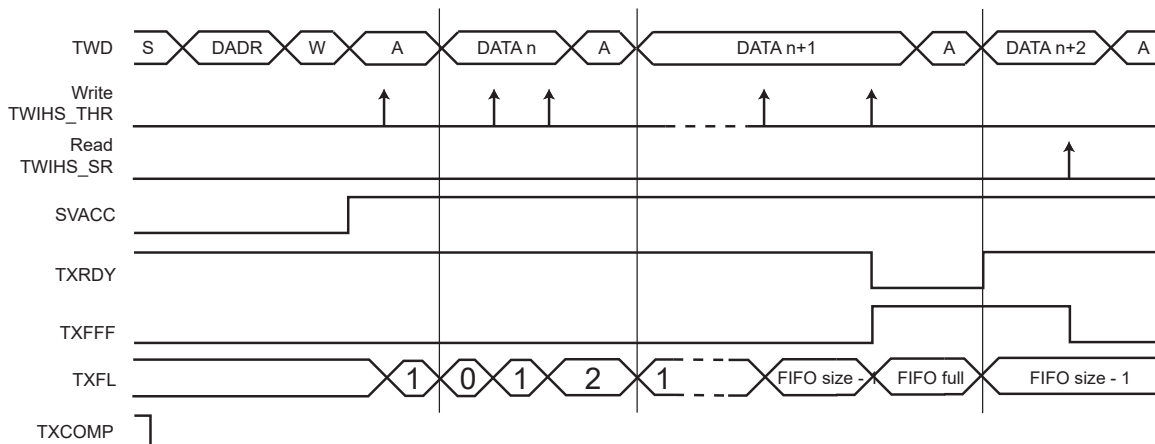

**Figure 45-50. TXRDY Behavior when TXRDYM = 0 in Master Mode**

**Figure 45-51. RXRDY Behavior when RXRDYM = 0 in Master and Slave Modes**

**Figure 45-52. TXRDY Behavior when TXRDYM = 0 in Slave Mode**

#### 45.6.6.7 Single Data Mode

In Single Data mode, only one data is written every time TWIHS\_THR is accessed, and only one data is read every time TWIHS\_RHR is accessed.

When TWIHS\_FMR.TXRDYM = 0, the Transmit FIFO operates in Single Data mode.

When TWIHS\_FMR.RXRDYM = 0, the Receive FIFO operates in Single Data mode.

See sections [45.7.18 TWIHS\\_THR](#) and [45.7.15 TWIHS\\_RHR](#).

#### 45.6.6.8 Multiple Data Mode

Multiple Data mode minimizes the number of accesses by concatenating the data to send/read in one access.

When TWIHS\_FMR.TXRDYM > 0, the Transmit FIFO operates in Multiple Data mode.

When TWIHS\_FMR.RXRDYM > 0, the Receive FIFO operates in Multiple Data mode.

In Multiple Data mode, it is possible to write/read up to four data in one TWIHS\_THR/TWIHS\_RHR register access.

The number of data to write/read is defined by the size of the register access. If the access is a byte-size register access, only one data is written/read. If the access is a halfword size register access, then up to two data are read and only one data is written. Lastly, if the access is a wordsize register access, then up to four data are read and up to two data are written.

Written/Read data are always right-aligned, as described in sections [45.7.16 TWIHS\\_RHR \(FIFO\\_ENABLED\)](#) and [45.7.19 TWIHS\\_THR \(FIFO\\_ENABLED\)](#).

As an example, if the Transmit FIFO is empty and there are six data to send, either of the following write accesses may be performed:

- six TWIHS\_THR-byte write accesses
- three TWIHS\_THR-halfword write accesses
- one TWIHS\_THR-word write access and one TWIHS\_THR halfword write access

With a Receive FIFO containing six data, any of the following read accesses may be performed:

- six TWIHS\_RHR-byte read accesses
- three TWIHS\_RHR-halfword read accesses
- one TWIHS\_RHR-word read access and one TWIHS\_RHR-halfword read access

##### 45.6.6.8.1 TXRDY and RXRDY Configuration

In Multiple Data mode, it is possible to write one or more data in the same TWIHS\_THR/TWIHS\_RHR access. The TXRDY flag indicates if one or more data can be written in the FIFO depending on the configuration of TWIHS\_FMR.TXRDYM/RXRDYM.

As an example, if two data are written each time in TWIHS\_THR, it is useful to configure the TXRDYM field to the value '1' so that the TXRDY flag is at '1' only when at least two data can be written in the Transmit FIFO.

In the same way, if four data are read each time in TWIHS\_RHR, it is useful to configure the RXRDYM field to the value '2' so that the RXRDY flag is at '1' only when at least four unread data are in the Receive FIFO.

##### 45.6.6.8.2 DMAC

When FIFOs operate in Multiple Data mode, the DMAC transfer type must be configured in byte, halfword or word depending on the TWIHS\_FMR.TXRDYM/RXRDYM settings.

#### 45.6.6.9 Transmit FIFO Lock

If a frame is terminated early due to a not-acknowledge error (NACK flag), SMBus timeout error (TOUT flag) or master code acknowledge error (MACK flag), a lock is set on the Transmit FIFO preventing any new frame from being sent until it is cleared. This allows clearing the FIFO if needed, resetting DMAC channels, etc., without any risk.

TWIHS\_SR.LOCK is used to check the state of the Transmit FIFO lock.

The Transmit FIFO lock can be cleared by setting TWIHS\_CR.TXFLCLR to '1'.

#### 45.6.6.10 FIFO Pointer Error

A FIFO overflow is reported in TWIHS\_FSR.

If the Transmit FIFO is full and a write access is performed on TWIHS\_THR, it generates a Transmit FIFO pointer error and sets TWIHS\_FSR.TXFPTEF.

In Multiple Data mode, if the number of data written in TWIHS\_THR (according to the register access size) is greater than the free space in the Transmit FIFO, a Transmit FIFO pointer error is generated and TWIHS\_FSR.TXFPTEF is set.

A FIFO underflow is reported in TWIHS\_FSR.

In Multiple Data mode, if the number of data read in TWIHS\_RHR (according to the register access size) is greater than the number of unread data in the Receive FIFO, a Receive FIFO pointer error is generated and TWIHS\_FSR.RXFPTEF is set.

No pointer error occurs if the FIFO state/level is checked before writing/reading in TWIHS\_THR/TWIHS\_RHR. The FIFO state/level can be checked either with TXRDY, RXRDY, TXFL or RXFL. When a pointer error occurs, other FIFO flags may not behave as expected; their states should be ignored.

If a Transmit or Receive pointer error occurs, a software reset must be performed using TWIHS\_CR.SWRST. Note that issuing a software while transmitting might leave a slave in an unknown state holding the TWD line. In such case, a Bus Clear Command will allow to make the slave release the TWD line (the first frame sent after might not be received properly by the slave).

#### 45.6.6.11 FIFO Thresholds

Each Transmit and Receive FIFO includes a threshold feature used to set a flag and an interrupt when a FIFO threshold is crossed. Thresholds are defined as a number of data in the FIFO, and the FIFO state (TXFL or RXFL) represents the number of data currently in the FIFO.

The Transmit FIFO threshold can be set using the field TWIHS\_FMR.TXFTHRES. Each time the Transmit FIFO level goes from 'above threshold' to 'equal to or below threshold', the flag TWIHS\_FESR.TXFTHF is set. The application is warned that the Transmit FIFO has reached the defined threshold and that it can be reloaded.

The Receive FIFO threshold can be set using the field TWIHS\_FMR.RXFTHRES. Each time the Receive FIFO level goes from 'below threshold' to 'equal to or above threshold', the flag TWIHS\_FESR.RXFTHF is set. The application is warned that the Receive FIFO has reached the defined threshold and that it can be read to prevent an underflow.

The TXFTHF and RXFTHF flags can be configured to generate an interrupt using TWIHS\_FIER and TWIHS\_FIDR.

#### 45.6.6.12 FIFO Flags

FIFOs come with a set of flags which can be configured to generate interrupts through TWIHS\_FIER and TWIHS\_FIDR.

FIFO flags state can be read in TWIHS\_FSR. They are cleared when TWIHS\_FSR is read.

### 45.6.7 TWIHS Comparison Function on Received Character

The comparison function differs if asynchronous partial wakeup (SleepWalking) is enabled or not.

If asynchronous partial wakeup is disabled (see the section “Power Management Controller (PMC)”), the TWIHS can extend the address matching on up to three slave addresses. The SADR1EN, SADR2EN and SADR3EN bits in TWIHS\_SMR enable address matching on additional addresses which can be configured through SADR1, SADR2 and SADR3 fields in the TWIHS\_SWMR. The DATAMEN bit in the TWIHS\_SMR has no effect.

The SVACC bit is set when there is a comparison match with the received slave address.

### 45.6.8 Register Write Protection

To prevent any single software error from corrupting TWIHS behavior, certain registers in the address space can be write-protected by setting the WPEN bit in the [TWIHS Write Protection Mode Register](#) (TWIHS\_WPMR).

If a write access to a write-protected register is detected, the WPVS bit in the [TWIHS Write Protection Status Register](#) (TWIHS\_WPSR) is set and the field WPVSR indicates the register in which the write access has been attempted.

The WPVS bit is automatically cleared after reading TWIHS\_WPSR.

The following registers can be write-protected:

- [TWIHS Slave Mode Register](#)
- [TWIHS Clock Waveform Generator Register](#)
- [TWIHS SMBus Timing Register](#)
- [TWIHS SleepWalking Matching Register](#)

### 45.7 Register Summary

| Offset              | Name                       | Bit Pos. |         |          |         |         |        |         |             |            |             |
|---------------------|----------------------------|----------|---------|----------|---------|---------|--------|---------|-------------|------------|-------------|

#### Bit 29 – FIFODIS FIFO Disable

| Value | Description                              |
|-------|--|
| 0     | No effect.                               |
| 1     | Disables the Transmit and Receive FIFOs. |

#### Bit 28 – FIFOEN FIFO Enable

| Value | Description                             |
|-------|---|
| 0     | No effect.                              |
| 1     | Enables the Transmit and Receive FIFOs. |

#### Bit 26 – LOCKCLR Lock Clear

| Value | Description                |
|-------|----------------------------|
| 0     | No effect.                 |
| 1     | Clears the TWIHS FSM lock. |

#### Bit 24 – THRCLR Transmit Holding Register Clear

| Value | Description  |
|-------|--|
| 0     | No effect.   |
| 1     | Clears the Transmit Holding Register and sets TXRDY, TXCOMP flags. |

**Bit 17 – ACMDIS** Alternative Command Mode Disable

| Value | Description                        |
|-------|------------------------------------|
| 0     | No effect.                         |
| 1     | Alternative Command mode disabled. |

**Bit 16 – ACMEN** Alternative Command Mode Enable

| Value | Description                       |
|-------|-----------------------------------|
| 0     | No effect.                        |
| 1     | Alternative Command mode enabled. |

**Bit 15 – CLEAR** Bus CLEAR Command

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | If Master mode is enabled, sends a bus clear command. |

**Bit 14 – PECRQ** PEC Request

| Value | Description                               |
|-------|---|
| 0     | No effect.                                |
| 1     | A PEC check or transmission is requested. |

**Bit 13 – PECDIS** Packet Error Checking Disable

| Value | Description                                    |
|-------|--|
| 0     | No effect.                                     |
| 1     | SMBus PEC (CRC) generation and check disabled. |

**Bit 12 – PECEN** Packet Error Checking Enable

| Value | Description                                   |
|-------|---|
| 0     | No effect.                                    |
| 1     | SMBus PEC (CRC) generation and check enabled. |

**Bit 11 – SMBDIS** SMBus Mode Disabled

| Value | Description          |
|-------|----------------------|
| 0     | No effect.           |
| 1     | SMBus mode disabled. |

**Bit 10 – SMBEN** SMBus Mode Enabled

| Value | Description                        |
|-------|------------------------------------|
| 0     | No effect.                         |
| 1     | If SMBDIS = 0, SMBus mode enabled. |

**Bit 9 – HSDIS** TWIHS High-Speed Mode Disabled

| Value | Description               |
|-------|---------------------------|
| 0     | No effect.                |
| 1     | High-speed mode disabled. |

**Bit 8 – HSEN** TWIHS High-Speed Mode Enabled

| Value | Description              |
|-------|--------------------------|
| 0     | No effect.               |
| 1     | High-speed mode enabled. |

**Bit 7 – SWRST** Software Reset

| Value | Description                   |
|-------|-------------------------------|
| 0     | No effect.                    |
| 1     | Equivalent to a system reset. |

**Bit 6 – QUICK** SMBus Quick Command

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | If Master mode is enabled, a SMBus Quick Command is sent. |

**Bit 5 – SVDIS** TWIHS Slave Mode Disabled

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | The Slave mode is disabled. The shifter and holding characters (if it contains data) are transmitted in case of read operation. In write operation, the character being transferred must be completely received before disabling. |

**Bit 4 – SVEN** TWIHS Slave Mode Enabled

Switching from Master to Slave mode is only permitted when TXCOMP = 1.

| Value | Description  |
|-------|--|
| 0     | No effect.   |
| 1     | Enables the Slave mode (SVDIS must be written to 0). |

**Bit 3 – MSDIS** TWIHS Master Mode Disabled

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | The Master mode is disabled, all pending data is transmitted. The shifter and holding characters (if it contains data) are transmitted in case of write operation. In read operation, the character being transferred must be completely received before disabling. |

**Bit 2 – MSEN** TWIHS Master Mode Enabled

Switching from Slave to Master mode is only permitted when TXCOMP = 1.

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | Enables the Master mode (MSDIS must be written to 0). |

**Bit 1 – STOP** Send a STOP Condition

| Value | Description |
|-------|-------------|
| 0     | No effect.  |

| Value | Description   |
|-------|---|
| 1     | <p>STOP condition is sent just after completing the current byte transmission in Master Read mode.</p> <ul style="list-style-type: none"> <li>• In single data byte master read, both START and STOP must be set.</li> <li>• In multiple data bytes master read, the STOP must be set after the last data received but one.</li> <li>• In Master Read mode, if a NACK bit is received, the STOP is automatically performed.</li> <li>• In master data write operation, a STOP condition will be sent after the transmission of the current data is finished.</li> </ul> |

**Bit 0 – START** Send a START Condition

This action is necessary when the TWIHS peripheral needs to read data from a slave. When configured in Master mode with a write operation, a frame is sent as soon as the user writes a character in the Transmit Holding Register (TWIHS\_THR).

| Value | Description  |
|-------|--|
| 0     | No effect.   |
| 1     | A frame beginning with a START bit is transmitted according to the features defined in the TWIHS Master Mode Register (TWIHS_MMR). |

### 45.7.2 TWIHS Control Register (FIFO\_ENABLED)

**Name:** TWIHS\_CR (FIFO\_ENABLED)  
**Offset:** 0x00  
**Reset:** –  
**Property:** Write-only

This configuration is relevant only if TWIHS.CR.FIFOEN = '1'.

|        |     |       |       |         |        |        |         |        |        |

#### Bit 29 – FIFODIS FIFO Disable

| Value | Description                              |
|-------|--|
| 0     | No effect.                               |
| 1     | Disables the Transmit and Receive FIFOs. |

#### Bit 28 – FIFOEN FIFO Enable

| Value | Description                             |
|-------|---|
| 0     | No effect.                              |
| 1     | Enables the Transmit and Receive FIFOs. |

#### Bit 26 – TXFLCLR Transmit FIFO Lock CLEAR

| Value | Description                    |
|-------|--------------------------------|
| 0     | No effect.                     |
| 1     | Clears the Transmit FIFO Lock. |

#### Bit 25 – RXFCLR Receive FIFO Clear

| Value | Description |
|-------|-------------|
| 0     | No effect.  |

| Value | Description  |
|-------|--|
| 1     | Clears the Receive FIFO, Receive FIFO will become empty. |

**Bit 24 – TXFCLR** Transmit FIFO Clear

| Value | Description  |
|-------|--|
| 0     | No effect.   |
| 1     | Clears the Transmit FIFO, Transmit FIFO will become empty. |

**Bit 17 – ACMDIS** Alternative Command Mode Disable

| Value | Description                        |
|-------|------------------------------------|
| 0     | No effect.                         |
| 1     | Alternative Command mode disabled. |

**Bit 16 – ACMEN** Alternative Command Mode Enable

| Value | Description                       |
|-------|-----------------------------------|
| 0     | No effect.                        |
| 1     | Alternative Command mode enabled. |

**Bit 15 – CLEAR** Bus CLEAR Command

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | If Master mode is enabled, sends a bus clear command. |

**Bit 14 – PECRQ** PEC Request

| Value | Description                               |
|-------|---|
| 0     | No effect.                                |
| 1     | A PEC check or transmission is requested. |

**Bit 13 – PECDIS** Packet Error Checking Disable

| Value | Description                                    |
|-------|--|
| 0     | No effect.                                     |
| 1     | SMBus PEC (CRC) generation and check disabled. |

**Bit 12 – PECEN** Packet Error Checking Enable

| Value | Description                                   |
|-------|---|
| 0     | No effect.                                    |
| 1     | SMBus PEC (CRC) generation and check enabled. |

**Bit 11 – SMBDIS** SMBus Mode Disabled

| Value | Description          |
|-------|----------------------|
| 0     | No effect.           |
| 1     | SMBus mode disabled. |

**Bit 10 – SMBEN** SMBus Mode Enabled

| Value | Description                        |
|-------|------------------------------------|
| 0     | No effect.                         |
| 1     | If SMBDIS = 0, SMBus mode enabled. |

**Bit 9 – HSDIS** TWIHS High-Speed Mode Disabled

| Value | Description               |
|-------|---------------------------|
| 0     | No effect.                |
| 1     | High-speed mode disabled. |

**Bit 8 – HSEN** TWIHS High-Speed Mode Enabled

| Value | Description              |
|-------|--------------------------|
| 0     | No effect.               |
| 1     | High-speed mode enabled. |

**Bit 7 – SWRST** Software Reset

| Value | Description                   |
|-------|-------------------------------|
| 0     | No effect.                    |
| 1     | Equivalent to a system reset. |

**Bit 6 – QUICK** SMBus Quick Command

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | If Master mode is enabled, a SMBus Quick Command is sent. |

**Bit 5 – SVDIS** TWIHS Slave Mode Disabled

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | The Slave mode is disabled. The shifter and holding characters (if it contains data) are transmitted in case of read operation. In write operation, the character being transferred must be completely received before disabling. |

**Bit 4 – SVEN** TWIHS Slave Mode Enabled

Switching from Master to Slave mode is only permitted when TXCOMP = 1.

| Value | Description  |
|-------|--|
| 0     | No effect.   |
| 1     | Enables the Slave mode (SVDIS must be written to 0). |

**Bit 3 – MSDIS** TWIHS Master Mode Disabled

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | The Master mode is disabled, all pending data is transmitted. The shifter and holding characters (if it contains data) are transmitted in case of write operation. In read operation, the character being transferred must be completely received before disabling. |

**Bit 2 – MSEN** TWIHS Master Mode Enabled

Switching from Slave to Master mode is only permitted when TXCOMP = 1.

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | Enables the Master mode (MSDIS must be written to 0). |

**Bit 1 – STOP** Send a STOP Condition

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | STOP condition is sent just after completing the current byte transmission in Master Read mode. <ul style="list-style-type: none"><li>• In single data byte master read, both START and STOP must be set.</li><li>• In multiple data bytes master read, the STOP must be set after the last data received but one.</li><li>• In Master Read mode, if a NACK bit is received, the STOP is automatically performed.</li><li>• In master data write operation, a STOP condition will be sent after the transmission of the current data is finished.</li></ul> |

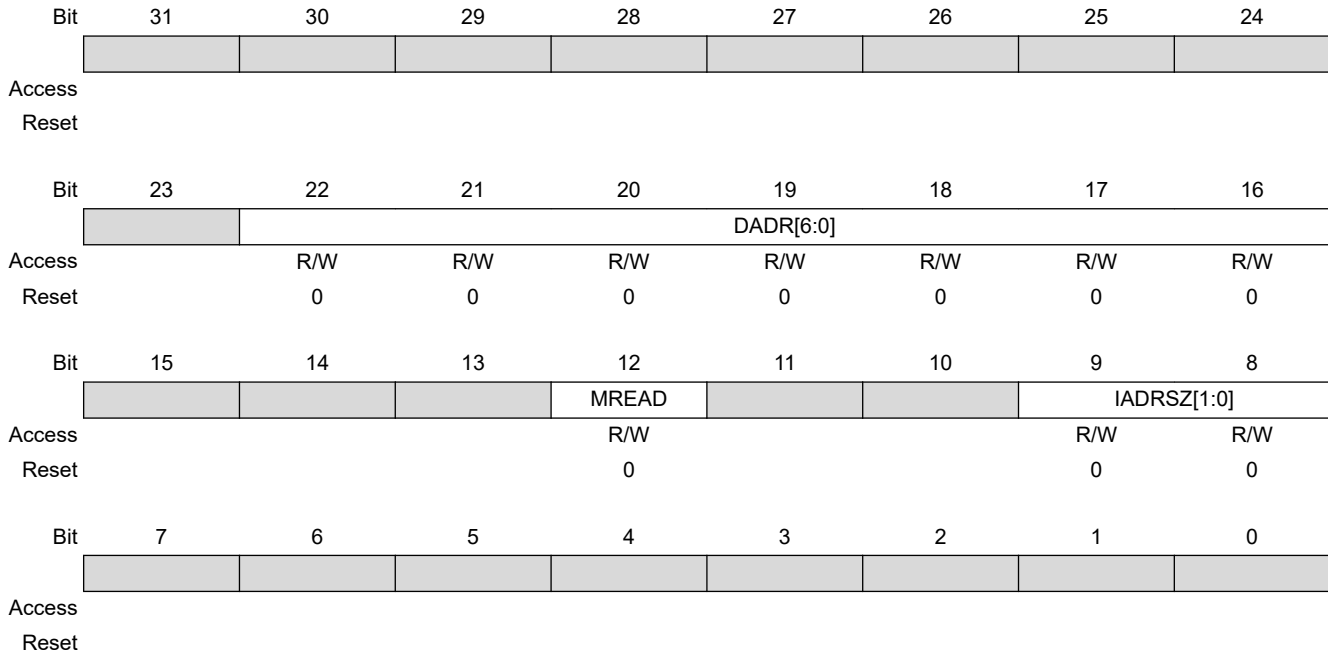

**Bit 0 – START** Send a START Condition

This action is necessary when the TWIHS peripheral needs to read data from a slave. When configured in Master mode with a write operation, a frame is sent as soon as the user writes a character in the Transmit Holding Register (TWIHS\_THR).

| Value | Description  |
|-------|--|
| 0     | No effect.   |
| 1     | A frame beginning with a START bit is transmitted according to the features defined in the TWIHS Master Mode Register (TWIHS_MMR). |

### 45.7.3 TWIHS Master Mode Register

**Name:** TWIHS\_MMR  
**Offset:** 0x04  
**Reset:** 0x00000000  
**Property:** Read/Write

**Bits 22:16 – DADR[6:0]** Device Address

The device address is used to access slave devices in Read or Write mode. These bits are only used in Master mode.

**Bit 12 – MREAD** Master Read Direction

| Value | Description             |
|-------|-------------------------|
| 0     | Master write direction. |
| 1     | Master read direction.  |

**Bits 9:8 – IADRSZ[1:0]** Internal Device Address Size

| Value | Name   | Description                        |
|-------|--------|------------------------------------|
| 0     | NONE   | No internal device address         |
| 1     | 1_BYTE | One-byte internal device address   |
| 2     | 2_BYTE | Two-byte internal device address   |
| 3     | 3_BYTE | Three-byte internal device address |

### 45.7.4 TWIHS Slave Mode Register

**Name:** TWIHS\_SMR  
**Offset:** 0x08  
**Reset:** 0x00000000  
**Property:** Read/Write

This register can only be written if the WPEN bit is cleared in the [TWIHS Write Protection Mode Register](#).

|        |           |          |         |         |      |      |     |        |
|--------|-----------|----------|---------|---------|------|------|-----|--------|
| Bit    | 31        | 30       | 29      | 28      | 27   | 26   | 25  | 24     |
|        | DATAMEN   | SADR3EN  | SADR2EN | SADR1EN |      |      |     |        |
| Access | R/W       | R/W      | R/W     | R/W     |      |      |     |        |
| Reset  | 0         | 0        | 0       | 0       |      |      |     |        |
|        |           |          |         |         |      |      |     |        |
| Bit    | 23        | 22       | 21      | 20      | 19   | 18   | 17  | 16     |
|        | SADR[6:0] |          |         |         |      |      |     |        |
| Access |           | R/W      | R/W     | R/W     | R/W  | R/W  | R/W | R/W    |
| Reset  |           | 0        | 0       | 0       | 0    | 0    | 0   | 0      |
|        |           |          |         |         |      |      |     |        |

|        |           | SCLWSDIS |         |         | SMHH | SMDA |     | NACKEN |
| Access |           | R/W      |         |         | R/W  | R/W  |     | R/W    |
| Reset  |           | 0        |         |         | 0    | 0    |     | 0      |

#### Bit 31 – DATAMEN Data Matching Enable

| Value | Description                                       |
|-------|---|
| 0     | Data matching on first received data is disabled. |
| 1     | Data matching on first received data is enabled.  |

#### Bit 30 – SADR3EN Slave Address 3 Enable

| Value | Description                           |
|-------|---------------------------------------|
| 0     | Slave address 3 matching is disabled. |
| 1     | Slave address 3 matching is enabled.  |

#### Bit 29 – SADR2EN Slave Address 2 Enable

| Value | Description                           |
|-------|---------------------------------------|
| 0     | Slave address 2 matching is disabled. |
| 1     | Slave address 2 matching is enabled.  |

#### Bit 28 – SADR1EN Slave Address 1 Enable

| Value | Description                           |
|-------|---------------------------------------|
| 0     | Slave address 1 matching is disabled. |

| Value | Description                          |
|-------|--------------------------------------|
| 1     | Slave address 1 matching is enabled. |

**Bits 22:16 – SADR[6:0]** Slave Address

The slave device address is used in Slave mode in order to be accessed by master devices in Read or Write mode.

SADR must be programmed before enabling the Slave mode or after a general call. Writes at other times have no effect.

**Bits 14:8 – MASK[6:0]** Slave Address Mask

A mask can be applied on the slave device address in Slave mode in order to allow multiple address answer. For each bit of the MASK field set to 1, the corresponding SADR bit is masked.

If the MASK field value is 0, no mask is applied to the SADR field.

**Bit 6 – SCLWSDIS** Clock Wait State Disable

| Value | Description  |
|-------|--|
| 0     | No effect.   |
| 1     | Clock stretching disabled in Slave mode, OVRE and UNRE indicate an overrun/underrun. |

**Bit 3 – SMHH** SMBus Host Header

| Value | Description                                    |
|-------|--|
| 0     | Acknowledge of the SMBus host header disabled. |
| 1     | Acknowledge of the SMBus host header enabled.  |

**Bit 2 – SMDA** SMBus Default Address

| Value | Description  |
|-------|--|
| 0     | Acknowledge of the SMBus default address disabled. |
| 1     | Acknowledge of the SMBus default address enabled.  |

**Bit 0 – NACKEN** Slave Receiver Data Phase NACK enable

| Value | Description  |
|-------|--|
| 0     | Normal value to be returned in the ACK cycle of the data phase in Slave Receiver mode. |
| 1     | NACK value to be returned in the ACK cycle of the data phase in Slave Receiver mode.   |

### 45.7.5 TWIHS Internal Address Register

**Name:** TWIHS\_IADR  
**Offset:** 0x0C  
**Reset:** 0x00000000  
**Property:** Read/Write

|        |             |     |     |     |     |     |     |     |
|--------|-------------|-----|-----|-----|-----|-----|-----|-----|
| Bit    | 31          | 30  | 29  | 28  | 27  | 26  | 25  | 24  |
|        |             |     |     |     |     |     |     |     |
| Access |             |     |     |     |     |     |     |     |
| Reset  |             |     |     |     |     |     |     |     |
| Bit    | 23          | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
|        | IADR[23:16] |     |     |     |     |     |     |     |
| Access | R/W         | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0           | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 15          | 14  | 13  | 12  | 11  | 10  | 9   | 8   |
|        | IADR[15:8]  |     |     |     |     |     |     |     |
| Access | R/W         | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0           | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 7           | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|        | IADR[7:0]   |     |     |     |     |     |     |     |
| Access | R/W         | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0           | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

**Bits 23:0 – IADR[23:0]** Internal Address  
 0, 1, 2 or 3 bytes depending on IADRSZ.

### 45.7.6 TWIHS Clock Waveform Generator Register

**Name:** TWIHS\_CWGR  
**Offset:** 0x10  
**Reset:** 0x00000000  
**Property:** Read/Write

This register can only be written if the WPEN bit is cleared in the [TWIHS Write Protection Mode Register](#). TWIHS\_CWGR is used in Master mode only.

|        |            |     |     |           |            |     |     |     |
|--------|------------|-----|-----|-----------|------------|-----|-----|-----|
| Bit    | 31         | 30  | 29  | 28        | 27         | 26  | 25  | 24  |
|        |            |     |     | HOLD[4:0] |            |     |     |     |
| Access |            |     |     | R/W       | R/W        | R/W | R/W | R/W |
| Reset  |            |     |     | 0         | 0          | 0   | 0   | 0   |
|        |            |     |     |           |            |     |     |     |
| Bit    | 23         | 22  | 21  | 20        | 19         | 18  | 17  | 16  |
|        |            |     |     | CKSRC     | CKDIV[2:0] |     |     |     |
| Access |            |     |     | R/W       |            | R/W | R/W | R/W |
| Reset  |            |     |     | 0         |            | 0   | 0   | 0   |
|        |            |     |     |           |            |     |     |     |
| Bit    | 15         | 14  | 13  | 12        | 11         | 10  | 9   | 8   |
|        | CHDIV[7:0] |     |     |           |            |     |     |     |
| Access | R/W        | R/W | R/W | R/W       | R/W        | R/W | R/W | R/W |
| Reset  | 0          | 0   | 0   | 0         | 0          | 0   | 0   | 0   |
|        |            |     |     |           |            |     |     |     |
| Bit    | 7          | 6   | 5   | 4         | 3          | 2   | 1   | 0   |
|        | CLDIV[7:0] |     |     |           |            |     |     |     |
| Access | R/W        | R/W | R/W | R/W       | R/W        | R/W | R/W | R/W |
| Reset  | 0          | 0   | 0   | 0         | 0          | 0   | 0   | 0   |

**Bits 28:24 – HOLD[4:0]** TWD Hold Time Versus TWCK Falling

If High-speed mode is selected TWD is internally modified on the TWCK falling edge to meet the I2C specified maximum hold time, else if High-speed mode is not configured TWD is kept unchanged after TWCK falling edge for a period of  $(HOLD + 3) \times t_{\text{peripheral clock}}$ .

**Bit 20 – CKSRC** Transfer Rate Clock Source

| Value | Name      | Description   |
|-------|-----------|---|
| 0     | PERIPH_CK | Peripheral clock is used to generate the TWIHS baud rate. |
| 1     | GCLK      | GCLK is used to generate the TWIHS baud rate.             |

**Bits 18:16 – CKDIV[2:0]** Clock Divider

The CKDIV is used to increase both SCL high and low periods.

**Bits 15:8 – CHDIV[7:0]** Clock High Divider

The SCL high period is defined as follows:

If CKSRC = 0

$$t_{\text{high}} = ((CHDIV \times 2^{CKDIV}) + 3) \times t_{\text{peripheral clock}}$$

If CKSRC = 1

$$t_{\text{high}} = (\text{CHDIV} \times 2^{\text{CKDIV}}) \times t_{\text{external clock}}$$

**Bits 7:0 – CLDIV[7:0]** Clock Low Divider

The SCL low period is defined as follows:

If CKSRC = 0

$$t_{\text{low}} = ((\text{CLDIV} \times 2^{\text{CKDIV}}) + 3) \times t_{\text{peripheral clock}}$$

If CKSRC = 1

$$t_{\text{low}} = (\text{CLDIV} \times 2^{\text{CKDIV}}) \times t_{\text{external clock}}$$

### 45.7.7 TWIHS Status Register

**Name:** TWIHS\_SR  
**Offset:** 0x20  
**Reset:** 0x03000009  
**Property:** Read-only

|        |      |      |      |        |        |        |        |        |  |
|--------|------|------|------|--------|--------|--------|--------|--------|--|
| Bit    | 31   | 30   | 29   | 28     | 27     | 26     | 25     | 24     |  |
|        |      |      |      |        |        |        | SDA    | SCL    |  |
| Access |      |      |      |        |        |        | R      | R      |  |
| Reset  |      |      |      |        |        |        | 1      | 1      |  |
| Bit    | 23   | 22   | 21   | 20     | 19     | 18     | 17     | 16     |  |
|        | LOCK |      |      | SMBHMH | SMBDAM | PECERR | TOUT   |        |  |
| Access | R    |      |      | R      | R      | R      | R      | R      |  |
| Reset  | 0    |      |      | 0      | 0      | 0      | 0      | 0      |  |
| Bit    | 15   | 14   | 13   | 12     | 11     | 10     | 9      | 8      |  |
|        |      |      |      |        | EOSACC | SCLWS  | ARBLST | NACK   |  |
| Access |      |      |      |        | R      | R      | R      | R      |  |
| Reset  |      |      |      |        | 0      | 0      | 0      | 0      |  |
| Bit    | 7    | 6    | 5    | 4      | 3      | 2      | 1      | 0      |  |
|        | UNRE | OVRE | GACC | SVACC  | SVREAD | TXRDY  | RXRDY  | TXCOMP |  |
| Access | R    | R    | R    | R      | R      | R      | R      | R      |  |
| Reset  | 0    | 0    | 0    | 0      | 1      | 0      | 0      | 1      |  |

#### Bit 25 – SDA SDA Line Value

| Value | Description                    |
|-------|--------------------------------|
| 0     | SDA line sampled value is '0'. |
| 1     | SDA line sampled value is '1'. |

#### Bit 24 – SCL SCL Line Value

| Value | Description                    |
|-------|--------------------------------|
| 0     | SCL line sampled value is '0'. |
| 1     | SCL line sampled value is '1'. |

**Bit 23 – LOCK** TWIHS Lock due to Frame Errors (cleared by writing a one to bit LOCKCLR in TWIHS\_CR)

| Value | Description  |
|-------|--|
| 0     | The TWIHS is not locked or LOCKCLR command issued in TWIHS_CR.   |
| 1     | The TWIHS is locked due to frame errors (see <a href="#">Handling Errors in Alternative Command</a> ). |

**Bit 21 – SMBHMH** SMBus Host Header Address Match (cleared on read)

| Value | Description  |
|-------|--|
| 0     | No SMBus Host Header Address received since the last read of TWIHS_SR. |

| Value | Description  |
|-------|--|
| 1     | An SMBus Host Header Address was received since the last read of TWIHS_SR. |

**Bit 20 – SMBDAM** SMBus Default Address Match (cleared on read)

| Value | Description  |
|-------|--|
| 0     | No SMBus Default Address received since the last read of TWIHS_SR.     |
| 1     | An SMBus Default Address was received since the last read of TWIHS_SR. |

**Bit 19 – PECERR** PEC Error (cleared on read)

| Value | Description  |
|-------|--|
| 0     | No SMBus PEC error occurred since the last read of TWIHS_SR. |
| 1     | An SMBus PEC error occurred since the last read of TWIHS_SR. |

**Bit 18 – TOUT** Timeout Error (cleared on read)

| Value | Description  |
|-------|--|
| 0     | No SMBus timeout occurred since the last read of TWIHS_SR. |
| 1     | An SMBus timeout occurred since the last read of TWIHS_SR. |

**Bit 16 – MACK** Master Code Acknowledge (cleared on read)

MACK used in Slave mode:

| Value | Description   |
|-------|---|
| 0     | No Master Code has been received since the last read of TWIHS_SR. |
| 1     | A Master Code has been received since the last read of TWIHS_SR.  |

**Bit 11 – EOSACC** End Of Slave Access (cleared on read)

This bit is used in Slave mode only.

EOSACC behavior can be seen in [Repeated Start and Reversal from Read Mode to Write Mode](#) and [Repeated Start and Reversal from Write Mode to Read Mode](#).

| Value | Description   |
|-------|---|
| 0     | A slave access is being performing.   |
| 1     | The Slave Access is finished. End Of Slave Access is automatically set as soon as SVACC is reset. |

**Bit 10 – SCLWS** Clock Wait State

This bit is used in Slave mode only.

SCLWS behavior can be seen in the figures, [Clock Stretching in Read Mode](#) and [Clock Stretching in Write Mode](#).

| Value | Description  |
|-------|--|
| 0     | The clock is not stretched.  |
| 1     | The clock is stretched. TWIHS_THR / TWIHS_RHR buffer is not filled / emptied before the transmission / reception of a new character. |

**Bit 9 – ARBLST** Arbitration Lost (cleared on read)

This bit is used in Master mode only.

| Value | Description  |
|-------|--|
| 0     | Arbitration won.   |
| 1     | Arbitration lost. Another master of the TWIHS bus has won the multimaster arbitration. TXCOMP is set at the same time. |

**Bit 8 – NACK** Not Acknowledged (cleared on read)

- NACK used in Master mode:

0: Each data byte has been correctly received by the far-end side TWIHS slave component.

1: A data or address byte has not been acknowledged by the slave component. Set at the same time as TXCOMP.

- NACK used in Slave Read mode:

0: Each data byte has been correctly received by the master.

1: In Read mode, a data byte has not been acknowledged by the master. When NACK is set, the user must not fill TWIHS\_THR even if TXRDY is set, because it means that the master stops the data transfer or re-initiate it.

**Note:** In Slave Write mode, all data are acknowledged by the TWIHS.

**Bit 7 – UNRE** Underrun Error (cleared on read)

This bit is used only if clock stretching is disabled.

| Value | Description                            |
|-------|--|
| 0     | TWIHS_THR has been filled on time.     |
| 1     | TWIHS_THR has not been filled on time. |

**Bit 6 – OVRE** Overrun Error (cleared on read)

This bit is used only if clock stretching is disabled.

| Value | Description  |
|-------|--|
| 0     | TWIHS_RHR has not been loaded while RXRDY was set.   |
| 1     | TWIHS_RHR has been loaded while RXRDY was set. Reset by read in TWIHS_SR when TXCOMP is set. |

**Bit 5 – GACC** General Call Access (cleared on read)

This bit is used in Slave mode only.

GACC behavior can be seen in [Master Performs a General Call](#).

| Value | Description   |
|-------|---|
| 0     | No general call has been detected.  |
| 1     | A general call has been detected. After the detection of general call, if need be, the user may acknowledge this access and decode the following bytes and respond according to the value of the bytes. |

**Bit 4 – SVACC** Slave Access

This bit is used in Slave mode only.

SVACC behavior can be seen in [Read Access Ordered by a Master](#), [Clock Stretching in Read Mode](#), [Repeated Start and Reversal from Read Mode to Write Mode](#) and [Repeated Start and Reversal from Write Mode to Read Mode](#).

| Value | Description   |
|-------|---|
| 0     | TWIHS is not addressed. SVACC is automatically cleared after a NACK or a STOP condition is detected.  |
| 1     | Indicates that the address decoding sequence has matched (A master has sent SADR). SVACC remains high until a NACK or a STOP condition is detected. |

### Bit 3 – SVREAD Slave Read

This bit is used in Slave mode only. When SVACC is low (no slave access has been detected) SVREAD is irrelevant.

SVREAD behavior can be seen in [Read Access Ordered by a Master](#), [Clock Stretching in Read Mode](#), [Repeated Start and Reversal from Read Mode to Write Mode](#) and [Repeated Start and Reversal from Write Mode to Read Mode](#).

| Value | Description   |
|-------|---|
| 0     | Indicates that a write access is performed by a master. |
| 1     | Indicates that a read access is performed by a master.  |

### Bit 2 – TXRDY Transmit Holding Register Ready (cleared by writing TWIHS\_THR)

- TXRDY used in Master mode:

0: The transmit holding register has not been transferred into the internal shifter. Set to 0 when writing into TWIHS\_THR.

1: As soon as a data byte is transferred from TWIHS\_THR to internal shifter or if a NACK error is detected, TXRDY is set at the same time as TXCOMP and NACK. TXRDY is also set when MSEN is set (enables TWIHS).

TXRDY behavior in Master mode can be seen in [Master Write with One Data Byte](#), [Master Write with Multiple Data Bytes](#) and [Master Write with One-Byte Internal Address and Multiple Data Bytes](#).

- TXRDY used in Slave mode:

0: As soon as data is written in the TWIHS\_THR, until this data has been transmitted and acknowledged (ACK or NACK).

1: Indicates that the TWIHS\_THR is empty and that data has been transmitted and acknowledged.

If TXRDY is high and if a NACK has been detected, the transmission is stopped. Thus when TRDY = NACK = 1, the user must not fill TWIHS\_THR to avoid losing it.

TXRDY behavior in Slave mode can be seen in [Read Access Ordered by a Master](#), [Clock Stretching in Read Mode](#), [Repeated Start and Reversal from Read Mode to Write Mode](#) and [Repeated Start and Reversal from Write Mode to Read Mode](#).

### Bit 1 – RXRDY Receive Holding Register Ready (cleared by reading TWIHS\_RHR)

RXRDY behavior in Master mode can be seen in [Master Read with One Data Byte](#), [Master Read with Multiple Data Bytes](#) and [Master Read Clock Stretching with Multiple Data Bytes](#).

RXRDY behavior in Slave mode can be seen in [Write Access Ordered by a Master](#), [Clock Stretching in Write Mode](#), [Repeated Start and Reversal from Read Mode to Write Mode](#) and [Repeated Start and Reversal from Write Mode to Read Mode](#).

| Value | Description   |
|-------|---|
| 0     | No character has been received since the last TWIHS_RHR read operation. |

| Value | Description  |
|-------|--|
| 1     | A byte has been received in the TWIHS_RHR since the last read. |

**Bit 0 – TXCOMP** Transmission Completed (cleared by writing TWIHS\_THR)

- TXCOMP used in Master mode:

0: During the length of the current frame.

1: When both holding register and internal shifter are empty and STOP condition has been sent.

TXCOMP behavior in Master mode can be seen in [Master Write with One-Byte Internal Address and Multiple Data Bytes](#) and in [Master Read with Multiple Data Bytes](#).

- TXCOMP used in Slave mode:

0: As soon as a START is detected.

1: After a STOP or a REPEATED START + an address different from SADR is detected.

TXCOMP behavior in Slave mode can be seen in [Clock Stretching in Read Mode](#), [Clock Stretching in Write Mode](#), [Repeated Start and Reversal from Read Mode to Write Mode](#) and [Repeated Start and Reversal from Write Mode to Read Mode](#).

### 45.7.8 TWIHS Status Register (FIFO\_ENABLED)

**Name:** TWIHS\_SR (FIFO\_ENABLED)  
**Offset:** 0x20  
**Reset:** 0x03000009  
**Property:** Read-only

This configuration is relevant only if TWIHS\_CR.FIFOEN = '1'.

|        |         |      |      |        |        |        |        |        |  |
|--------|---------|------|------|--------|--------|--------|--------|--------|--|
| Bit    | 31      | 30   | 29   | 28     | 27     | 26     | 25     | 24     |  |
|        |         |      |      |        |        |        | SDA    | SCL    |  |
| Access |         |      |      |        |        |        | R      | R      |  |
| Reset  |         |      |      |        |        |        | 1      | 1      |  |
|        |         |      |      |        |        |        |        |        |  |
| Bit    | 23      | 22   | 21   | 20     | 19     | 18     | 17     | 16     |  |

|        |         |      |      |        |        |        |        |        |  |
| Bit    | 7       | 6    | 5    | 4      | 3      | 2      | 1      | 0      |  |
|        | UNRE    | OVRE | GACC | SVACC  | SVREAD | TXRDY  | RXRDY  | TXCOMP |  |
| Access | R       | R    | R    | R      | R      | R      | R      | R      |  |
| Reset  | 0       | 0    | 0    | 0      | 1      | 0      | 0      | 1      |  |

#### Bit 25 – SDA SDA Line Value

| Value | Description                    |
|-------|--------------------------------|
| 0     | SDA line sampled value is '0'. |
| 1     | SDA line sampled value is '1'. |

#### Bit 24 – SCL SCL Line Value

| Value | Description                    |
|-------|--------------------------------|
| 0     | SCL line sampled value is '0'. |
| 1     | SCL line sampled value is '1'. |

#### Bit 23 – TXFLOCK Transmit FIFO Lock

| Value | Description                      |
|-------|----------------------------------|
| 0     | The Transmit FIFO is not locked. |
| 1     | The Transmit FIFO is locked.     |

#### Bit 21 – SMBHMH SMBus Host Header Address Match (cleared on read)

| Value | Description  |
|-------|--|
| 0     | No SMBus Host Header Address received since the last read of TWIHS_SR. |

| Value | Description  |
|-------|--|
| 1     | An SMBus Host Header Address was received since the last read of TWIHS_SR. |

**Bit 20 – SMBDAM** SMBus Default Address Match (cleared on read)

| Value | Description  |
|-------|--|
| 0     | No SMBus Default Address received since the last read of TWIHS_SR.     |
| 1     | An SMBus Default Address was received since the last read of TWIHS_SR. |

**Bit 19 – PECERR** PEC Error (cleared on read)

| Value | Description  |
|-------|--|
| 0     | No SMBus PEC error occurred since the last read of TWIHS_SR. |
| 1     | An SMBus PEC error occurred since the last read of TWIHS_SR. |

**Bit 18 – TOUT** Timeout Error (cleared on read)

| Value | Description  |
|-------|--|
| 0     | No SMBus timeout occurred since the last read of TWIHS_SR. |
| 1     | An SMBus timeout occurred since the last read of TWIHS_SR. |

**Bit 16 – MCACK** Master Code Acknowledge (cleared on read)

- MACK used in Slave mode:

| Value | Description   |
|-------|---|
| 0     | No Master Code has been received since the last read of TWIHS_SR. |
| 1     | A Master Code has been received since the last read of TWIHS_SR.  |

**Bit 11 – EOSACC** End Of Slave Access (cleared on read)

This bit is used in Slave mode only.

EOSACC behavior can be seen in [Repeated Start and Reversal from Read Mode to Write Mode](#) and [Repeated Start and Reversal from Write Mode to Read Mode](#).

| Value | Description   |
|-------|---|
| 0     | A slave access is being performing.   |
| 1     | The Slave Access is finished. End Of Slave Access is automatically set as soon as SVACC is reset. |

**Bit 10 – SCLWS** Clock Wait State

This bit is used in Slave mode only.

SCLWS behavior can be seen in [Clock Stretching in Read Mode](#) and [Clock Stretching in Write Mode](#).

| Value | Description  |
|-------|--|
| 0     | The clock is not stretched.  |
| 1     | The clock is stretched. TWIHS_THR / TWIHS_RHR buffer is not filled / emptied before the transmission / reception of a new character. |

**Bit 9 – ARBLST** Arbitration Lost (cleared on read)

This bit is used in Master mode only.

| Value | Description  |
|-------|--|
| 0     | Arbitration won.   |
| 1     | Arbitration lost. Another master of the TWIHS bus has won the multimaster arbitration. TXCOMP is set at the same time. |

**Bit 8 – NACK** Not Acknowledged (cleared on read)

**Note:** In Slave Write mode, all data are acknowledged by the TWIHS.

- NACK used in Master mode:

0: Each data byte has been correctly received by the far-end side TWIHS slave component.

1: A data or address byte has not been acknowledged by the slave component. Set at the same time as TXCOMP.

- NACK used in Slave Read mode:

0: Each data byte has been correctly received by the master.

1: In Read mode, a data byte has not been acknowledged by the master. When NACK is set, the user must not fill TWIHS\_THR even if TXRDY is set, because it means that the master stops the data transfer or re-initiate it.

**Bit 7 – UNRE** Underrun Error (cleared on read)

This bit is used only if clock stretching is disabled.

| Value | Description                            |
|-------|--|
| 0     | TWIHS_THR has been filled on time.     |
| 1     | TWIHS_THR has not been filled on time. |

**Bit 6 – OVRE** Overrun Error (cleared on read)

This bit is used only if clock stretching is disabled.

| Value | Description  |
|-------|--|
| 0     | TWIHS_RHR has not been loaded while RXRDY was set.   |
| 1     | TWIHS_RHR has been loaded while RXRDY was set. Reset by read in TWIHS_SR when TXCOMP is set. |

**Bit 5 – GACC** General Call Access (cleared on read)

This bit is used in Slave mode only.

GACC behavior can be seen in [Master Performs a General Call](#).

| Value | Description   |
|-------|---|
| 0     | No general call has been detected.  |
| 1     | A general call has been detected. After the detection of general call, if need be, the user may acknowledge this access and decode the following bytes and respond according to the value of the bytes. |

**Bit 4 – SVACC** Slave Access

This bit is used in Slave mode only.

SVACC behavior can be seen in [Read Access Ordered by a Master](#), [Write Access Ordered by a Master](#), [Repeated Start and Reversal from Read Mode to Write Mode](#) and [Repeated Start and Reversal from Write Mode to Read Mode](#).

| Value | Description   |
|-------|---|
| 0     | TWIHS is not addressed. SVACC is automatically cleared after a NACK or a STOP condition is detected.  |
| 1     | Indicates that the address decoding sequence has matched (A master has sent SADR). SVACC remains high until a NACK or a STOP condition is detected. |

### Bit 3 – SVREAD Slave Read

This bit is used in Slave mode only. When SVACC is low (no slave access has been detected) SVREAD is irrelevant.

SVREAD behavior can be seen in [Read Access Ordered by a Master](#), [Write Access Ordered by a Master](#), [Repeated Start and Reversal from Read Mode to Write Mode](#) and [Repeated Start and Reversal from Write Mode to Read Mode](#).

| Value | Description   |
|-------|---|
| 0     | Indicates that a write access is performed by a master. |
| 1     | Indicates that a read access is performed by a master.  |

### Bit 2 – TXRDY Transmit Holding Register Ready (cleared by writing TWIHS\_THR)

- TXRDY used in Master mode:

TXRDY behavior in Master mode can be seen in [Master Write with One Data Byte](#), [Master Write with Multiple Data Bytes](#) and [Master Write with One-Byte Internal Address and Multiple Data Bytes](#).

- TXRDY used in Slave mode:

If TXRDY is high and if a NACK has been detected, the transmission is stopped. Thus when TRDY = NACK = 1, the user must not fill TWIHS\_THR to avoid losing it.

TXRDY behavior in Slave mode can be seen in [Read Access Ordered by a Master](#), [Clock Stretching in Read Mode](#), [Repeated Start and Reversal from Read Mode to Write Mode](#) and [Repeated Start and Reversal from Write Mode to Read Mode](#).

| Value | Description  |
|-------|--|
| 0     | The transmit holding register has not been transferred into the internal shifter. Set to 0 when writing into TWIHS_THR.  |
| 1     | As soon as a data byte is transferred from TWIHS_THR to internal shifter or if a NACK error is detected, TXRDY is set at the same time as TXCOMP and NACK. TXRDY is also set when MSEN is set (enables TWIHS). |
| 0     | As soon as data is written in the TWIHS_THR, until this data has been transmitted and acknowledged (ACK or NACK).  |
| 1     | Indicates that the TWIHS_THR is empty and that data has been transmitted and acknowledged.   |

### Bit 1 – RXRDY Receive Holding Register Ready (cleared by reading TWIHS\_RHR)

RXRDY behavior in Master mode can be seen in [Master Read with One Data Byte](#), [Master Read with Multiple Data Bytes](#) and [Master Read Clock Stretching with Multiple Data Bytes](#).

RXRDY behavior in Slave mode can be seen in [Write Access Ordered by a Master](#), [Clock Stretching in Write Mode](#), [Repeated Start and Reversal from Read Mode to Write Mode](#) and [Repeated Start and Reversal from Write Mode to Read Mode](#).

| Value | Description   |
|-------|---|
| 0     | No character has been received since the last TWIHS_RHR read operation. |

| Value | Description  |
|-------|--|
| 1     | A byte has been received in the TWIHS_RHR since the last read. |

**Bit 0 – TXCOMP** Transmission Completed (cleared by writing TWIHS\_THR)

- TXCOMP used in Master mode:

0: During the length of the current frame.

1: When both holding register and internal shifter are empty and STOP condition has been sent.

TXCOMP behavior in Master mode can be seen in [Master Write with One-Byte Internal Address and Multiple Data Bytes](#) and in [Master Read with Multiple Data Bytes](#).

- TXCOMP used in Slave mode:

0: As soon as a START is detected.

1: After a STOP or a REPEATED START + an address different from SADR is detected.

TXCOMP behavior in Slave mode can be seen in [Clock Stretching in Read Mode](#), [Clock Stretching in Write Mode](#), [Repeated Start and Reversal from Read Mode to Write Mode](#) and [Repeated Start and Reversal from Write Mode to Read Mode](#).

### 45.7.9 TWIHS SMBus Timing Register

**Name:** TWIHS\_SMBTR  
**Offset:** 0x38  
**Reset:** 0x00000000  
**Property:** Read/Write

This register can only be written if the WPEN bit is cleared in the [TWIHS Write Protection Mode Register](#).

|        |            |     |     |     |     |     |     |     |
|--------|------------|-----|-----|-----|-----|-----|-----|-----|
| Bit    | 31         | 30  | 29  | 28  | 27  | 26  | 25  | 24  |
|        | THMAX[7:0] |     |     |     |     |     |     |     |
| Access | R/W        | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0          | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 23         | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
|        | TLOWM[7:0] |     |     |     |     |     |     |     |
| Access | R/W        | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0          | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 15         | 14  | 13  | 12  | 11  | 10  | 9   | 8   |
|        | TLOWS[7:0] |     |     |     |     |     |     |     |
| Access | R/W        | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0          | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| Bit    | 7          | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|        | PRESC[3:0] |     |     |     |     |     |     |     |
| Access |            |     |     |     | R/W | R/W | R/W | R/W |
| Reset  |            |     |     |     | 0   | 0   | 0   | 0   |

**Bits 31:24 – THMAX[7:0]** Clock High Maximum Cycles

Clock cycles in clock high maximum count. Prescaled by PRESC. Used for bus free detection. Used to time THIGH:MAX.

**Bits 23:16 – TLOWM[7:0]** Master Clock Stretch Maximum Cycles

| Value | Description   |
|-------|---|
| 0     | TLOW:MEXT timeout check disabled.   |
| 1-255 | Clock cycles in master maximum clock stretch count. Prescaled by PRESC. Used to time TLOW:MEXT. |

**Bits 15:8 – TLOWS[7:0]** Slave Clock Stretch Maximum Cycles

| Value | Description  |
|-------|--|
| 0     | TLOW:SEXT timeout check disabled.  |
| 1-255 | Clock cycles in slave maximum clock stretch count. Prescaled by PRESC. Used to time TLOW:SEXT. |

**Bits 3:0 – PRESC[3:0]** SMBus Clock Prescaler

Used to specify how to prescale the TLOWS, TLOWM and THMAX counters in SMBTR. Counters are prescaled according to the following formula:

$$f_{\text{Prescaled}} = \frac{f_{\text{peripheral clock}}}{2^{(\text{PRESC} + 1)}}$$

### 45.7.10 TWIHS Alternative Command Register

**Name:** TWIHS\_ACR  
**Offset:** 0x40  
**Reset:** 0x00000000  
**Property:** Read/Write

|        |             |     |     |     |     |     |      |      |
|--------|-------------|-----|-----|-----|-----|-----|------|------|
| Bit    | 31          | 30  | 29  | 28  | 27  | 26  | 25   | 24   |
|        |             |     |     |     |     |     | NPEC | NDIR |
| Access |             |     |     |     |     |     | R/W  | R/W  |
| Reset  |             |     |     |     |     |     | 0    | 0    |
|        |             |     |     |     |     |     |      |      |
| Bit    | 23          | 22  | 21  | 20  | 19  | 18  | 17   | 16   |
|        | NDATAL[7:0] |     |     |     |     |     |      |      |
| Access | R/W         | R/W | R/W | R/W | R/W | R/W | R/W  | R/W  |
| Reset  | 0           | 0   | 0   | 0   | 0   | 0   | 0    | 0    |
|        |             |     |     |     |     |     |      |      |
| Bit    | 15          | 14  | 13  | 12  | 11  | 10  | 9    | 8    |
|        |             |     |     |     |     |     | PEC  | DIR  |
| Access |             |     |     |     |     |     | R/W  | R/W  |
| Reset  |             |     |     |     |     |     | 0    | 0    |
|        |             |     |     |     |     |     |      |      |
| Bit    | 7           | 6   | 5   | 4   | 3   | 2   | 1    | 0    |
|        | DATAL[7:0]  |     |     |     |     |     |      |      |
| Access | R/W         | R/W | R/W | R/W | R/W | R/W | R/W  | R/W  |
| Reset  | 0           | 0   | 0   | 0   | 0   | 0   | 0    | 0    |

#### Bit 25 – NPEC Next PEC Request (SMBus Mode only)

| Value | Description                                |
|-------|--|
| 0     | The next transfer does not use a PEC byte. |
| 1     | The next transfer uses a PEC byte.         |

#### Bit 24 – NDIR Next Transfer Direction

| Value | Description      |
|-------|------------------|
| 0     | Write direction. |
| 1     | Read direction.  |

#### Bits 23:16 – NDATAL[7:0] Next Data Length

| Value | Description   |
|-------|---|
| 0     | No data to send (see <a href="#">Alternative Command</a> ). |
| 1–255 | Number of bytes to send for the next transfer.              |

#### Bit 9 – PEC PEC Request (SMBus Mode only)

| Value | Description                           |
|-------|---------------------------------------|
| 0     | The transfer does not use a PEC byte. |
| 1     | The transfer uses a PEC byte.         |

**Bit 8 – DIR** Transfer Direction

| Value | Description      |
|-------|------------------|
| 0     | Write direction. |
| 1     | Read direction.  |

**Bits 7:0 – DATAL[7:0]** Data Length

| Value | Description   |
|-------|---|
| 0     | No data to send (see <a href="#">Alternative Command</a> ). |
| 1–255 | Number of bytes to send during the transfer.                |

### 45.7.11 TWIHS Filter Register

**Name:** TWIHS\_FILTR  
**Offset:** 0x44  
**Reset:** 0x00000000  
**Property:** Read/Write

TWIHS digital input filtering follows a majority decision based on three samples from SDA/SCL lines at peripheral clock frequency.

|        |    |    |    |    |    |         |            |      |     |

| Access |    |    |    |    |    | R/W     | R/W        | R/W  |     |
| Reset  |    |    |    |    |    | 0       | 0          | 0    |     |

#### Bits 10:8 – THRES[2:0] Digital Filter Threshold

| Value | Description   |
|-------|---|
| 0     | No filtering applied on TWIHS inputs.   |
| 1–7   | Maximum pulse width of spikes to be suppressed by the input filter, defined in peripheral clock cycles. |

#### Bit 2 – PADFCFG PAD Filter Config

See the electrical characteristics section for filter configuration details.

#### Bit 1 – PADFEN PAD Filter Enable

| Value | Description  |
|-------|--|
| 0     | PAD analog filter is disabled.   |
| 1     | PAD analog filter is enabled. (The analog filter must be enabled if High-speed mode is enabled.) |

#### Bit 0 – FILT RX Digital Filter

# SAMA5D2 Series

## Two-wire Interface (TWIHS)

| Value | Description   |
|-------|---|
| 0     | No filtering applied on TWIHS inputs.                             |
| 1     | TWIHS input filtering is active (only in Standard and Fast modes) |

### 45.7.12 TWIHS Interrupt Enable Register

**Name:** TWIHS\_IER  
**Offset:** 0x24  
**Reset:** –  
**Property:** Write-only

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Enables the corresponding interrupt.

|        |      |      |        |        |        |        |        |        |
|--------|------|------|--------|--------|--------|--------|--------|--------|
| Bit    | 31   | 30   | 29     | 28     | 27     | 26     | 25     | 24     |
|        |      |      |        |        |        |        |        |        |
| Access |      |      |        |        |        |        |        |        |
| Reset  |      |      |        |        |        |        |        |        |
|        |      |      |        |        |        |        |        |        |

**Bit 21 – SMBHHM** SMBus Host Header Address Match Interrupt Enable

**Bit 20 – SMBDAM** SMBus Default Address Match Interrupt Enable

**Bit 19 – PECERR** PEC Error Interrupt Enable

**Bit 18 – TOUT** Timeout Error Interrupt Enable

**Bit 16 – MACK** Master Code Acknowledge Interrupt Enable

**Bit 11 – EOSACC** End Of Slave Access Interrupt Enable

**Bit 10 – SCL\_WS** Clock Wait State Interrupt Enable

**Bit 9 – ARBLST** Arbitration Lost Interrupt Enable

**Bit 8 – NACK** Not Acknowledge Interrupt Enable

**Bit 7 – UNRE** Underrun Error Interrupt Enable

**Bit 6 – OVRE** Overrun Error Interrupt Enable

**Bit 5 – GACC** General Call Access Interrupt Enable

**Bit 4 – SVACC** Slave Access Interrupt Enable

**Bit 2 – TXRDY** Transmit Holding Register Ready Interrupt Enable

**Bit 1 – RXRDY** Receive Holding Register Ready Interrupt Enable

**Bit 0 – TXCOMP** Transmission Completed Interrupt Enable

### 45.7.13 TWIHS Interrupt Disable Register

**Name:** TWIHS\_IDR  
**Offset:** 0x28  
**Reset:** –  
**Property:** Write-only

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Disables the corresponding interrupt.

|        |      |      |        |        |        |        |        |        |
|--------|------|------|--------|--------|--------|--------|--------|--------|
| Bit    | 31   | 30   | 29     | 28     | 27     | 26     | 25     | 24     |
|        |      |      |        |        |        |        |        |        |
| Access |      |      |        |        |        |        |        |        |
| Reset  |      |      |        |        |        |        |        |        |
|        |      |      |        |        |        |        |        |        |
| Bit    | 23   | 22   | 21     | 20     | 19     | 18     | 17     | 16     |

**Bit 21 – SMBHHM** SMBus Host Header Address Match Interrupt Disable

**Bit 20 – SMBDAM** SMBus Default Address Match Interrupt Disable

**Bit 19 – PECERR** PEC Error Interrupt Disable

**Bit 18 – TOUT** Timeout Error Interrupt Disable

**Bit 16 – MACK** Master Code Acknowledge Interrupt Disable

**Bit 11 – EOSACC** End Of Slave Access Interrupt Disable

**Bit 10 – SCL\_WS** Clock Wait State Interrupt Disable

**Bit 9 – ARBLST** Arbitration Lost Interrupt Disable

**Bit 8 – NACK** Not Acknowledge Interrupt Disable

**Bit 7 – UNRE** Underrun Error Interrupt Disable

**Bit 6 – OVRE** Overrun Error Interrupt Disable

**Bit 5 – GACC** General Call Access Interrupt Disable

**Bit 4 – SVACC** Slave Access Interrupt Disable

**Bit 2 – TXRDY** Transmit Holding Register Ready Interrupt Disable

**Bit 1 – RXRDY** Receive Holding Register Ready Interrupt Disable

**Bit 0 – TXCOMP** Transmission Completed Interrupt Disable

### 45.7.14 TWIHS Interrupt Mask Register

**Name:** TWIHS\_IMR  
**Offset:** 0x2C  
**Reset:** 0x00000000  
**Property:** Read-only

The following configuration values are valid for all listed bit names of this register:

0: The corresponding interrupt is disabled.

1: The corresponding interrupt is enabled.

|        |      |      |        |        |        |        |        |        |
|--------|------|------|--------|--------|--------|--------|--------|--------|
| Bit    | 31   | 30   | 29     | 28     | 27     | 26     | 25     | 24     |
|        |      |      |        |        |        |        |        |        |
| Access |      |      |        |        |        |        |        |        |
| Reset  |      |      |        |        |        |        |        |        |
| Bit    | 23   | 22   | 21     | 20     | 19     | 18     | 17     | 16     |
|        |      |      | SMBHHM | SMBDAM | PECERR | TOUT   |        | MACK   |
| Access |      |      | R      | R      | R      | R      |        |        |
| Reset  |      |      | 0      | 0      | 0      | 0      |        |        |
| Bit    | 15   | 14   | 13     | 12     | 11     | 10     | 9      | 8      |
|        |      |      |        |        | EOSACC | SCL_WS | ARBLST | NACK   |
| Access |      |      |        |        | R      | R      | R      | R      |
| Reset  |      |      |        |        | 0      | 0      | 0      | 0      |
| Bit    | 7    | 6    | 5      | 4      | 3      | 2      | 1      | 0      |
|        | UNRE | OVRE | GACC   | SVACC  |        | TXRDY  | RXRDY  | TXCOMP |
| Access | R    | R    | R      | R      |        |        | R      | R      |
| Reset  | 0    | 0    | 0      | 0      |        |        | 0      | 0      |

**Bit 21 – SMBHHM** SMBus Host Header Address Match Interrupt Mask

**Bit 20 – SMBDAM** SMBus Default Address Match Interrupt Mask

**Bit 19 – PECERR** PEC Error Interrupt Mask

**Bit 18 – TOUT** Timeout Error Interrupt Mask

**Bit 16 – MACK** Master Code Acknowledge Interrupt Mask

**Bit 11 – EOSACC** End Of Slave Access Interrupt Mask

**Bit 10 – SCL\_WS** Clock Wait State Interrupt Mask

**Bit 9 – ARBLST** Arbitration Lost Interrupt Mask

**Bit 8 – NACK** Not Acknowledge Interrupt Mask

**Bit 7 – UNRE** Underrun Error Interrupt Mask

**Bit 6 – OVRE** Overrun Error Interrupt Mask

**Bit 5 – GACC** General Call Access Interrupt Mask

**Bit 4 – SVACC** Slave Access Interrupt Mask

**Bit 2 – TXRDY** Transmit Holding Register Ready Interrupt Mask

**Bit 1 – RXRDY** Receive Holding Register Ready Interrupt Mask

**Bit 0 – TXCOMP** Transmission Completed Interrupt Mask

### 45.7.15 TWIHS Receive Holding Register

**Name:** TWIHS\_RHR  
**Offset:** 0x30  
**Reset:** 0x00000000  
**Property:** Read-only

**Bits 7:0 – RXDATA[7:0]** Master or Slave Receive Holding Data

### 45.7.16 TWIHS Receive Holding Register (FIFO Enabled)

**Name:** TWIHS\_RHR (FIFO\_ENABLED)  
**Offset:** 0x30  
**Reset:** 0x00000000  
**Property:** Read-only

If FIFO is enabled (FIFOEN bit in TWIHS\_CR), refer to [45.6.6.8 Multiple Data Mode](#) for details.

**Bits 15:8 – RXDATA1[7:0]** Master or Slave Receive Holding Data 1

**Bits 7:0 – RXDATA0[7:0]** Master or Slave Receive Holding Data 0

### 45.7.17 TWIHS SleepWalking Matching Register

**Name:** TWIHS\_SWMR  
**Offset:** 0x4C  
**Reset:** 0x00000000  
**Property:** Read/Write

This register can only be written if the WPEN bit is cleared in the [TWIHS Write Protection Mode Register](#).

|        |            |     |     |     |     |     |     |     |

**Bits 31:24 – DATAM[7:0] Data Match**

The TWIHS module extends the SleepWalking matching process to the first received data, comparing it with DATAM if DATAMEN bit is enabled.

**Bits 22:16 – SADR3[6:0] Slave Address 3**

Slave address 3. The TWIHS module matches on this additional address if SADR3EN bit is enabled.

**Bits 14:8 – SADR2[6:0] Slave Address 2**

Slave address 2. The TWIHS module matches on this additional address if SADR2EN bit is enabled.

**Bits 6:0 – SADR1[6:0] Slave Address 1**

Slave address 1. The TWIHS module matches on this additional address if SADR1EN bit is enabled.

**45.7.18 TWIHS Transmit Holding Register**

**Name:** TWIHS\_THR  
**Offset:** 0x34  
**Reset:** 0x00000000  
**Property:** Write-only

**Bits 7:0 – TXDATA[7:0]** Master or Slave Transmit Holding Data

### 45.7.19 TWIHS Transmit Holding Register (FIFO Enabled)

**Name:** TWIHS\_THR (FIFO\_ENABLED)  
**Offset:** 0x34  
**Reset:** 0x00000000  
**Property:** Write-only

If FIFO is enabled (FIFOEN bit in TWIHS\_CR), refer to [45.6.6.8 Multiple Data Mode](#) for details.

|        |    |    |               |     |     |     |     |             |  |
| Access |    |    |               |     |     |     |     |             |  |
| Reset  |    |    |               |     |     |     |     |             |  |
|        |    |    |               |     |     |     |     |             |  |
| Bit    | 7  | 6  | 5             | 4   | 3   | 2   | 1   | 0           |  |
|        |    |    | RXRDYM[1:0]   |     |     |     |     | TXRDYM[1:0] |  |
| Access |    |    | R/W           | R/W |     |     | R/W | R/W         |  |
| Reset  |    |    | 0             | 0   |     |     | 0   | 0           |  |

#### Bits 29:24 – RXFTHRES[5:0] Receive FIFO Threshold

| Value | Description   |
|-------|---|
| 0–16  | Defines the Receive FIFO threshold value (number of data). RXFTH flag in TWIHS_FSR will be set when Receive FIFO goes from “below” threshold state to “equal or above” threshold state. |

#### Bits 21:16 – TXFTHRES[5:0] Transmit FIFO Threshold

| Value | Description   |
|-------|---|
| 0–16  | Defines the Transmit FIFO threshold value (number of data). TXFTH flag in TWIHS_FSR will be set when Transmit FIFO goes from “above” threshold state to “equal or below” threshold state. |

#### Bits 5:4 – RXRDYM[1:0] Receiver Ready Mode

If FIFOs are enabled, the RXRDY flag (in TWIHS\_SR) behaves as follows.

| Value | Name     | Description  |
|-------|----------|--|
| 0     | ONE_DATA | RXRDY will be at level ‘1’ when at least one unread data is in the Receive FIFO  |
| 1     | TWO_DATA | RXRDY will be at level ‘1’ when at least two unread data are in the Receive FIFO |

# SAMA5D2 Series

## Two-wire Interface (TWIHS)

| Value | Name      | Description   |
|-------|-----------|---|
| 2     | FOUR_DATA | RXRDY will be at level '1' when at least four unread data are in the Receive FIFO |

### Bits 1:0 – TXRDYM[1:0] Transmitter Ready Mode

If FIFOs are enabled, the TXRDY flag (in TWIHS\_SR) behaves as follows.

| Value | Name      | Description  |
|-------|-----------|--|
| 0     | ONE_DATA  | TXRDY will be at level '1' when at least one data can be written in the Transmit FIFO  |
| 1     | TWO_DATA  | TXRDY will be at level '1' when at least two data can be written in the Transmit FIFO  |
| 2     | FOUR_DATA | TXRDY will be at level '1' when at least four data can be written in the Transmit FIFO |

### 45.7.21 TWIHS FIFO Level Register

**Name:** TWIHS\_FLR  
**Offset:** 0x54  
**Reset:** 0x00000000  
**Property:** Read-only

|        |                   |    |           |    |    |    |    |    |                  |
|--------|-------------------|----|-----------|----|----|----|----|----|------------------|
| Bit    | 31                | 30 | 29        | 28 | 27 | 26 | 25 | 24 |                  |
|        | [Greyed out bits] |    |           |    |    |    |    |    |                  |
| Access |                   |    |           |    |    |    |    |    |                  |
| Reset  |                   |    |           |    |    |    |    |    |                  |
| Bit    | 23                | 22 | 21        | 20 | 19 | 18 | 17 | 16 |                  |
|        | [Greyed out bits] |    | RXFL[5:0] |    |    |    |    |    | [Greyed out bit] |
| Access |                   |    | R         | R  | R  | R  | R  | R  |                  |
| Reset  |                   |    | 0         | 0  | 0  | 0  | 0  | 0  |                  |
| Bit    | 15                | 14 | 13        | 12 | 11 | 10 | 9  | 8  |                  |
|        | [Greyed out bits] |    |           |    |    |    |    |    |                  |
| Access |                   |    |           |    |    |    |    |    |                  |
| Reset  |                   |    |           |    |    |    |    |    |                  |
| Bit    | 7                 | 6  | 5         | 4  | 3  | 2  | 1  | 0  |                  |
|        | [Greyed out bits] |    | TXFL[5:0] |    |    |    |    |    | [Greyed out bit] |
| Access |                   |    | R         | R  | R  | R  | R  | R  |                  |
| Reset  |                   |    | 0         | 0  | 0  | 0  | 0  | 0  |                  |

#### Bits 21:16 – RXFL[5:0] Receive FIFO Level

| Value | Description   |
|-------|---|
| 0     | There is no unread data in the Receive FIFO             |
| 1-16  | Indicates the number of unread DATA in the Receive FIFO |

#### Bits 5:0 – TXFL[5:0] Transmit FIFO Level

| Value | Description                                       |
|-------|---|
| 0     | There is no data in the Transmit FIFO             |
| 1-16  | Indicates the number of DATA in the Transmit FIFO |

### 45.7.22 TWIHS FIFO Status Register

**Name:** TWIHS\_FSR  
**Offset:** 0x60  
**Reset:** 0x00000000  
**Property:** Read-only

|        |         |         |        |       |       |        |       |       |
|--------|---------|---------|--------|-------|-------|--------|-------|-------|
| Bit    | 31      | 30      | 29     | 28    | 27    | 26     | 25    | 24    |
|        |         |         |        |       |       |        |       |       |
| Access |         |         |        |       |       |        |       |       |
| Reset  |         |         |        |       |       |        |       |       |
|        |         |         |        |       |       |        |       |       |
| Bit    | 23      | 22      | 21     | 20    | 19    | 18     | 17    | 16    |

| Reset  |         |         |        |       |       |        |       |       |
|        |         |         |        |       |       |        |       |       |
| Bit    | 15      | 14      | 13     | 12    | 11    | 10     | 9     | 8     |
|        |         |         |        |       |       |        |       |       |
| Access |         |         |        |       |       |        |       |       |
| Reset  |         |         |        |       |       |        |       |       |
|        |         |         |        |       |       |        |       |       |
| Bit    | 7       | 6       | 5      | 4     | 3     | 2      | 1     | 0     |
|        | RXFPTEF | TXFPTEF | RXFTHF | RXFFF | RXFEF | TXFTHF | TXFFF | TXFEF |
| Access | R       | R       | R      | R     | R     | R      | R     | R     |
| Reset  | 0       | 0       | 0      | 0     | 0     | 0      | 0     | 0     |

**Bit 7 – RXFPTEF** Receive FIFO Pointer Error Flag  
 See [45.6.6.10 FIFO Pointer Error](#) for details.

| Value | Description   |
|-------|---|
| 0     | No Receive FIFO pointer occurred                            |
| 1     | Receive FIFO pointer error occurred. Receiver must be reset |

**Bit 6 – TXFPTEF** Transmit FIFO Pointer Error Flag  
 See [45.6.6.10 FIFO Pointer Error](#) for details.

| Value | Description   |
|-------|---|
| 0     | No Transmit FIFO pointer occurred                               |
| 1     | Transmit FIFO pointer error occurred. Transceiver must be reset |

**Bit 5 – RXFTHF** Receive FIFO Threshold Flag

| Value | Description  |
|-------|--|
| 0     | Number of unread DATA in Receive FIFO is below RXFTHRES threshold.                                     |
| 1     | Number of unread DATA in Receive FIFO has reached RXFTHRES threshold since the last read of TWIHS_FSR. |

**Bit 4 – RXFFF** Receive FIFO Full Flag

| Value | Description  |
|-------|--|
| 0     | Receive FIFO is not empty.                                     |
| 1     | Receive FIFO has been filled since the last read of TWIHS_FSR. |

**Bit 3 – RXFEF** Receive FIFO Empty Flag

| Value | Description   |
|-------|---|
| 0     | Receive FIFO is not empty.                                      |
| 1     | Receive FIFO has been emptied since the last read of TWIHS_FSR. |

**Bit 2 – TXFTHF** Transmit FIFO Threshold Flag (cleared on read)

| Value | Description  |
|-------|--|
| 0     | Number of DATA in Transmit FIFO is above TXFTHRES threshold.                                     |
| 1     | Number of DATA in Transmit FIFO has reached TXFTHRES threshold since the last read of TWIHS_FSR. |

**Bit 1 – TXFFF** Transmit FIFO Full Flag (cleared on read)

| Value | Description   |
|-------|---|
| 0     | Transmit FIFO is not full.                                      |
| 1     | Transmit FIFO has been filled since the last read of TWIHS_FSR. |

**Bit 0 – TXFEF** Transmit FIFO Empty Flag (cleared on read)

| Value | Description  |
|-------|--|
| 0     | Transmit FIFO is not empty.                                      |
| 1     | Transmit FIFO has been emptied since the last read of TWIHS_FSR. |

### 45.7.23 TWIHS FIFO Interrupt Enable Register

**Name:** TWIHS\_FIER  
**Offset:** 0x64  
**Reset:** –  
**Property:** Write-only

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Enables the corresponding interrupt.

|        |         |         |        |       |       |        |       |       |
|--------|---------|---------|--------|-------|-------|--------|-------|-------|

| Access |              |    |    |    |    |    |    | R    |
| Reset  |              |    |    |    |    |    |    | 0    |

**Bits 31:8 – WPVSR[23:0]** Write Protection Violation Source

When WPVS = 1, WPVSR indicates the register address offset at which a write access has been attempted.

**Bit 0 – WPVS** Write Protection Violation Status

| Value | Description   |
|-------|---|
| 0     | No write protection violation has occurred since the last read of the TWIHS_WPSR.   |
| 1     | A write protection violation has occurred since the last read of the TWIHS_WPSR. If this violation is an unauthorized attempt to write a protected register, the associated violation is reported into field WPVSR. |

## 46. Flexible Serial Communication Controller (FLEXCOM)

### 46.1 Description

The Flexible Serial Communication Controller (FLEXCOM) offers several serial communication protocols that are managed by the three submodules USART, SPI, and TWI.

The Universal Synchronous Asynchronous Receiver Transceiver (USART) provides one full-duplex universal synchronous asynchronous serial link. Data frame format is widely programmable (data length, parity, number of stop bits) to support a maximum of standards. The receiver implements parity error, framing error and overrun error detection. The receiver timeout enables handling variable-length frames and the transmitter timeguard facilitates communications with slow remote devices. Multidrop communications are also supported through address bit handling in reception and transmission.

The USART features three test modes: Remote Loopback, Local Loopback and Automatic Echo.

The USART supports specific operating modes providing interfaces on RS485, LIN, and SPI, with ISO7816 T = 0 or T = 1 smart card slots, and infrared transceivers. The hardware handshaking feature enables an out-of-band flow control by automatic management of the pins RTS and CTS.

The USART supports the connection to the DMA Controller, which enables data transfers to the transmitter and from the receiver. The DMAC provides chained buffer management without any intervention of the processor.

The Serial Peripheral Interface (SPI) circuit is a synchronous serial data link that provides communication with external devices in Master or Slave mode. It also enables communication between processors if an external processor is connected to the system.

The Serial Peripheral Interface is essentially a shift register that serially transmits data bits to other SPIs. During a data transfer, one SPI system acts as the “master” which controls the data flow, while the other devices act as “slaves” which have data shifted into and out by the master. Different CPUs can take turn being masters (multiple master protocol, contrary to single master protocol where one CPU is always the master while all of the others are always slaves). One master can simultaneously shift data into multiple slaves. However, only one slave can drive its output to write data back to the master at any given time.

A slave device is selected when the master asserts its NSS signal. If multiple slave devices exist, the master generates a separate slave select signal for each slave (NPCS).

The SPI system consists of two data lines and two control lines:

- Master Out Slave In (MOSI)—This data line supplies the output data from the master shifted into the input(s) of the slave(s).
- Master In Slave Out (MISO)—This data line supplies the output data from a slave to the input of the master. There may be no more than one slave transmitting data during any particular transfer.
- Serial Clock (SPCK)—This control line is driven by the master and regulates the flow of the data bits. The master can transmit data at a variety of baud rates; there is one SPCK pulse for each bit that is transmitted.
- Slave Select (NSS)—This control line allows slaves to be turned on and off by hardware.

The Two-wire Interface (TWI) interconnects components on a unique two-wire bus, made up of one clock line and one data line with speeds of up to 400 kbits per second in Fast mode and up to 3.4 Mbits per second in High-speed Slave mode only, based on a byte-oriented transfer format. It can be used with any Two-wire Interface bus Serial EEPROM and I<sup>2</sup>C-compatible devices, such as a Real-Time Clock (RTC),

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

Dot Matrix/Graphic LCD Controller and temperature sensor. The TWI is programmable as a master or a slave with sequential or single-byte access. Multiple master capability is supported.

Arbitration of the bus is performed internally and puts the TWI in Slave mode automatically if the bus arbitration is lost.

A configurable baud rate generator permits the output data rate to be adapted to a wide range of core clock frequencies.

The following table lists the compatibility level of any Two-wire Interface in Master mode and a full I<sup>2</sup>C compatible device.

**Table 46-1. TWI Compatibility with I<sup>2</sup>C Standard**

| I <sup>2</sup> C Standard                    | TWI           |
|--|---------------|
| Standard Mode Speed (100 kHz)                | Supported     |
| Fast Mode Speed (400 kHz)                    | Supported     |
| High-speed Mode (Slave only, 3.4 MHz)        | Supported     |
| 7- or 10-bit <sup>(1)</sup> Slave Addressing | Supported     |
| Repeated Start (Sr) Condition                | Supported     |
| ACK and NACK Management                      | Supported     |
| Input Filtering                              | Supported     |
| Slope Control                                | Not Supported |
| Clock Stretching                             | Supported     |
| Multi Master Capability                      | Supported     |

Notes: 1. 10-bit support in Master mode only

## 46.2 Embedded Characteristics

### 46.2.1 USART/UART Characteristics

- 32-byte Transmit and Receive FIFOs
- Programmable Baud Rate Generator
- Baud Rate can be Independent of the Processor/Peripheral Clock
- Comparison Function on Received Character
- 5-bit to 9-bit Full-duplex Synchronous or Asynchronous Serial Communications
  - 1, 1.5 or 2 Stop Bits in Asynchronous Mode or 1 or 2 Stop Bits in Synchronous Mode
  - Parity Generation and Error Detection
  - Framing Error Detection, Overrun Error Detection
  - Digital Filter on Receive Line
  - MSB- or LSB-first
  - Optional Break Generation and Detection
  - By 8 or by 16 Oversampling Receiver Frequency
  - Optional Hardware Handshaking RTS-CTS

- Receiver Timeout and Transmitter Timeguard
  - Optional Multidrop Mode with Address Generation and Detection
- RS485 with Driver Control Signal
- ISO7816, T = 0 or T = 1 Protocols for Interfacing with Smart Cards
  - NACK Handling, Error Counter with Repetition and Iteration Limit
- IrDA Modulation and Demodulation
  - Communication at up to 115.2 kbit/s
- SPI Mode
  - MASTER or Slave
  - Serial Clock Programmable Phase and Polarity
  - SPI Serial Clock (SCK) Frequency up to  $f_{\text{peripheral clock}}/6$
- LIN Mode
  - Compliant with LIN 1.3 and LIN 2.0 specifications
  - Master or Slave
  - Processing of Frames with Up to 256 Data Bytes
  - Response Data Length can be Configurable or Defined Automatically by the Identifier
  - Self-synchronization in Slave Node Configuration
  - Automatic Processing and Verification of the “Synch Break” and the “Synch Field”
  - “Synch Break” Detection Even When Partially Superimposed with a Data Byte
  - Automatic Identifier Parity Calculation/Sending and Verification
  - Parity Sending and Verification Can be Disabled
  - Automatic Checksum Calculation/sending and Verification
  - Checksum Sending and Verification Can be Disabled
  - Support Both “Classic” and “Enhanced” Checksum Types
  - Full LIN Error Checking and Reporting
  - Frame Slot Mode: Master Allocates Slots to the Scheduled Frames Automatically
  - Generation of the Wakeup Signal
- Test Modes
  - Remote Loopback, Local Loopback, Automatic Echo
- Supports Connection of:
  - Two DMA Controller (DMAC) Channels
  - Offers Buffer Transfer without Processor Intervention
- Register Write Protection

#### 46.2.2 SPI Characteristics

- 32-byte Transmit and Receive FIFOs
- Master or Slave Serial Peripheral Bus Interface
  - 8-bit to 16-bit programmable data length per chip select
  - Programmable phase and polarity per chip select
  - Programmable transfer delay between consecutive transfers and delay before SPI clock per chip select
  - Programmable delay between chip selects
- Selectable Mode Fault Detection

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

---

- Master Mode Can Drive SPCK up to Peripheral Clock
- Master Mode Bit Rate Can Be Independent of the Processor/Peripheral Clock
- Slave Mode Operates on SPCK, Asynchronously with Core and Bus Clock
- Two Chip Selects with External Decoder Support Allow Communication with up to 3 Peripherals
- Communication with Serial External Devices Supported
  - Serial memories, such as DataFlash and 3-wire EEPROMs
  - Serial peripherals, such as ADCs, DACs, LCD controllers, CAN controllers and sensors
  - External coprocessors
- Connection to DMA Channel Capabilities, Optimizing Data Transfers
  - One channel for the receiver
  - One channel for the transmitter
- Register Write Protection

### 46.2.3 TWI/SMBus Characteristics

- 16-byte Transmit and Receive FIFOs
- Bit Rate: Up to 400 kbit/s in Fast Mode and 3.4 Mbit/s in High-Speed Mode (Slave Only)
- Bit Rate can be Independent of the Processor/Peripheral Clock
- SMBus Support
- Compatible with Two-wire Interface Serial Memory and I<sup>2</sup>C Compatible Devices<sup>(1)</sup>
- Master and Multi-Master Operation (Standard and Fast Mode Only)
- Slave Mode Operation (Standard, Fast and High-Speed Mode)
- One, Two or Three Bytes for Slave Address
- Sequential Read/Write Operations
- General Call Supported in Slave Mode
- Connection to DMA Controller Channels Optimizes Data Transfers
  - One Channel for the Receiver
  - One Channel for the Transmitter
- Register Write Protection

Note: 1. See table [TWI Compatibility with I<sup>2</sup>C Standard](#) for further details.

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

### 46.3 Block Diagram

Figure 46-1. FLEXCOM Block Diagram

### 46.4 I/O Lines Description

Table 46-2. I/O Lines Description

| Name        | Description |           |      | Type |
|-------------|-------------|-----------|------|------|
|             | USART/UART  | SPI       | TWI  |      |
| FLEXCOM_IO0 | TXD         | MOSI      | TWD  | I/O  |
| FLEXCOM_IO1 | RXD         | MISO      | TWCK | I/O  |
| FLEXCOM_IO2 | SCK         | SPCK      | –    | I/O  |
| FLEXCOM_IO3 | CTS         | NPCS0/NSS | –    | I/O  |
| FLEXCOM_IO4 | RTS         | NPCS1     | –    | O    |

### 46.5 Product Dependencies

#### 46.5.1 I/O Lines

The pins used for interfacing the FLEXCOM are multiplexed with the PIO lines. The programmer must first program the PIO controller to assign the desired FLEXCOM pins to their peripheral function. If I/O lines of the FLEXCOM are not used by the application, they can be used for other purposes by the PIO Controller.

### 46.5.2 Power Management

The peripheral clock is not continuously provided to the FLEXCOM. The programmer must first enable the FLEXCOM Clock in the Power Management Controller (PMC) before using the USART or SPI or TWI.

In SleepWalking mode (asynchronous partial wakeup), the PMC must be configured to enable SleepWalking for the FLEXCOM in the Sleepwalking Enable Register (PMC\_SLPWK\_ER). The peripheral clock can be automatically provided to the FLEXCOM, depending on the instructions (requests) provided by the FLEXCOM to the PMC.

### 46.5.3 Interrupt Sources

The FLEXCOM interrupt line is connected on one of the internal sources of the Interrupt Controller. Using the FLEXCOM interrupt requires the Interrupt Controller to be programmed first.

## 46.6 Register Accesses

Register accesses support 8-bit, 16-bit and 32-bit accesses, which means that only an 8-bit part of a 32-bit register can be written in one access, for instance. For this the access must be done with the right size at the right address.

8-bit, 16-bit and 32-bit accesses are supported for register accesses. However, a field in a register cannot be partially written (e.g., if a field is bigger than 8 bits, the whole field must be written).

This feature helps avoiding a read-modify-write process if only a small part of the register is to be modified.

## 46.7 USART Functional Description

### 46.7.1 Baud Rate Generator

The baud rate generator provides the bit period clock named “baud rate clock” to both the receiver and the transmitter.

Configuring the USCLKS field in FLEX\_US\_MR selects the baud rate generator clock from one of the following sources:

- the peripheral clock
- a division of the peripheral clock, the divider being product dependent, but generally set to 8
- a fully programmable generic clock (GCLK) provided by PMC and independent of processor/peripheral clock
- the external clock, available on the SCK pin

The baud rate generator is based upon a 16-bit divider, which is programmed with the CD field of the Baud Rate Generator Register (FLEX\_US\_BRGR). If a zero is written to CD, the baud rate generator does not generate any clock. If a one is written to CD, the divider is bypassed and becomes inactive.

If the external SCK clock is selected, the duration of the low and high levels of the signal provided on the SCK pin must be longer than a peripheral clock period. The frequency of the signal provided on SCK must be at least three times lower than peripheral clock in USART mode (field USART\_MODE differs from 0xE or 0xF) or six times lower in SPI mode (field USART\_MODE equals 0xE or 0xF).

If GCLK is selected, the baud rate is independent of the processor/peripheral clock and thus processor/peripheral clock frequency can be changed without affecting the USART transfer. The GCLK frequency must be at least three times lower than peripheral clock frequency.

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

If GCLK is selected (USCLKS = 2) and the SCK pin is driven (CLKO = 1), the CD field must be greater than 1.

**Figure 46-2. Baud Rate Generator**

### 46.7.1.1 Baud Rate in Asynchronous Mode

If the USART is programmed to operate in Asynchronous mode, the selected clock is first divided by CD, which is field-programmed in FLEX\_US\_BRGR. The resulting clock is provided to the receiver as a sampling clock and then divided by 16 or 8, depending on the programming of FLEX\_US\_MR.OVER.

If OVER is set, the receiver sampling is eight times higher than the baud rate clock. If OVER is cleared, the sampling is performed at 16 times the baud rate clock.

The baud rate is calculated as per the following formula:

$$\text{Baud rate} = \frac{\text{Selected Clock}}{(8(2 - \text{OVER})\text{CD})}$$

This gives a maximum baud rate of peripheral clock divided by 8, assuming that peripheral clock is the highest possible clock and that the OVER bit is set.

#### 46.7.1.1.1 Baud Rate Calculation Example

The following table shows calculations of CD to obtain a baud rate at 38,400 bit/s for different source clock frequencies. It also shows the actual resulting baud rate and the error.

**Table 46-3. Baud Rate Example (OVER = 0)**

| Source Clock (MHz) | Expected Baud Rate (bit/s) | Calculation Result | CD | Actual Baud Rate (bit/s) | Error |
|--------------------|----------------------------|--------------------|----|--------------------------|-------|
| 3,686,400          | 38,400                     | 6.00               | 6  | 38,400.00                | 0.00% |
| 4,915,200          | 38,400                     | 8.00               | 8  | 38,400.00                | 0.00% |

The baud rate is calculated with the following formula:

$$\text{Baud rate} = \text{MCK} / \text{CD} \times 16$$

The baud rate error is calculated with the following formula. It is not recommended to work with an error higher than 5%.

$$\text{Error} = 1 - \left( \frac{\text{Expected Baud Rate}}{\text{Actual Baud Rate}} \right)$$

### 46.7.1.2 Fractional Baud Rate in Asynchronous Mode

The baud rate generator previously defined is subject to the following limitation: the output frequency changes by only integer multiples of the reference frequency. An approach to this problem is to integrate a fractional N clock generator that has a high resolution. The generator architecture is modified to obtain baud rate changes by a fraction of the reference source clock. This fractional part is programmed with the FP field in FLEX\_US\_BRGR. If FP is not 0, the fractional part is activated. The resolution is one eighth of the clock divider. The fractional baud rate is calculated using the following formula:

$$\text{Baud rate} = \frac{\text{Selected Clock}}{\left( 8(2 - \text{OVER}) \left( \text{CD} + \frac{\text{FP}}{8} \right) \right)}$$

The modified architecture is presented in the following figure.

**Figure 46-3. Fractional Baud Rate Generator**

When the value of field FP is greater than 0, the SCK (oversampling clock) generates nonconstant duty cycles. The SCK high duration is increased by “selected clock” period from time to time. The duty cycle depends on the value of the CD field.

### 46.7.1.3 Baud Rate in Synchronous Mode or SPI Mode

If the USART is programmed to operate in Synchronous mode, the selected clock is simply divided by the CD field in FLEX\_US\_BRGR:

$$\text{Baud rate} = \frac{\text{Selected Clock}}{\text{CD}}$$

In Synchronous mode, if the external clock is selected (USCLKS = 3) and CLKO = 0 (Slave mode), the clock is provided directly by the signal on the USART SCK pin. No division is active. The value written in FLEX\_US\_BRGR has no effect. The external clock frequency must be at least three times lower than the system clock. In Synchronous mode master (USCLKS = 0 or 1, CLKO = 1), the receive part limits the SCK maximum frequency to  $f_{\text{peripheral clock}}/3$  in USART mode, or  $f_{\text{peripheral clock}}/6$  in SPI mode.

When either the external clock SCK or the internal clock divided (peripheral clock/DIV or GCLK) is selected, the value programmed in CD must be even if the user has to ensure a 50:50 mark/space ratio on the SCK pin. If the peripheral clock is selected, the baud rate generator ensures a 50:50 duty cycle on the SCK pin, even if the value programmed in CD is odd.

### 46.7.1.4 Baud Rate in ISO 7816 Mode

The ISO7816 specification defines the bit rate with the following formula:

$$B = \frac{D_i}{F_i} \times f$$

where:

- B is the bit rate
- $D_i$  is the bit rate adjustment factor
- $F_i$  is the clock frequency division factor

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

- $f$  is the ISO7816 clock frequency (Hz)

$D_i$  is a binary value encoded on a 4-bit field, named  $D_i$ , as represented in the following table.

**Table 46-4. Binary and Decimal Values for  $D_i$**

|                 |      |      |      |      |      |      |      |      |
|-----------------|------|------|------|------|------|------|------|------|
| $D_i$ field     | 0001 | 0010 | 0011 | 0100 | 0101 | 0110 | 1000 | 1001 |
| $D_i$ (decimal) | 1    | 2    | 4    | 8    | 16   | 32   | 12   | 20   |

$F_i$  is a binary value encoded on a 4-bit field, named  $F_i$ , as represented in the following table.

**Table 46-5. Binary and Decimal Values for  $F_i$**

|                 |      |      |      |      |      |      |      |      |      |      |      |      |
|-----------------|------|------|------|------|------|------|------|------|------|------|------|------|
| $F_i$ field     | 0000 | 0001 | 0010 | 0011 | 0100 | 0101 | 0110 | 1001 | 1010 | 1011 | 1100 | 1101 |
| $F_i$ (decimal) | 372  | 372  | 558  | 744  | 1116 | 1488 | 1860 | 512  | 768  | 1024 | 1536 | 2048 |

The following table shows the resulting  $F_i/D_i$  Ratio, which is the ratio between the ISO7816 clock and the baud rate clock.

**Table 46-6. Possible Values for the  $F_i/D_i$  Ratio**

|           |       |       |       |       |      |       |       |      |       |      |       |
|-----------|-------|-------|-------|-------|------|-------|-------|------|-------|------|-------|
| $F_i/D_i$ | 372   | 558   | 744   | 1116  | 1488 | 1806  | 512   | 768  | 1024  | 1536 | 2048  |
| 1         | 372   | 558   | 744   | 1116  | 1488 | 1860  | 512   | 768  | 1024  | 1536 | 2048  |
| 2         | 186   | 279   | 372   | 558   | 744  | 930   | 256   | 384  | 512   | 768  | 1024  |
| 4         | 93    | 139.5 | 186   | 279   | 372  | 465   | 128   | 192  | 256   | 384  | 512   |
| 8         | 46.5  | 69.75 | 93    | 139.5 | 186  | 232.5 | 64    | 96   | 128   | 192  | 256   |
| 16        | 23.25 | 34.87 | 46.5  | 69.75 | 93   | 116.2 | 32    | 48   | 64    | 96   | 128   |
| 32        | 11.62 | 17.43 | 23.25 | 34.87 | 46.5 | 58.13 | 16    | 24   | 32    | 48   | 64    |
| 12        | 31    | 46.5  | 62    | 93    | 124  | 155   | 42.66 | 64   | 85.33 | 128  | 170.6 |
| 20        | 18.6  | 27.9  | 37.2  | 55.8  | 74.4 | 93    | 25.6  | 38.4 | 51.2  | 76.8 | 102.4 |

If the USART is configured in ISO7816 mode, the clock selected by the USCLKS field in FLEX\_US\_MR is first divided by the value programmed in field CD field in FLEX\_US\_BRGR. The resulting clock can be provided to the SCK pin to feed the smart card clock inputs. This means that FLEX\_US\_MR.CLKO can be set.

This clock is then divided by the value programmed in the  $F_i/D_i$ \_RATIO field in the  $F_i/D_i$  Ratio Register (FLEX\_US\_FIDI). This is performed by the Sampling Divider, which performs a division by up to 65535 in ISO7816 mode. The noninteger values of the  $F_i/D_i$  Ratio are not supported and the user must program the  $F_i/D_i$ \_RATIO field to a value as close as possible to the expected value.

The  $F_i/D_i$ \_RATIO field resets to the value 0x174 (372 in decimal) and is the most common divider between the ISO7816 clock and the bit rate ( $F_i = 372$ ,  $D_i = 1$ ).

The following figure shows the relation between the Elementary Time Unit, corresponding to a bit time, and the ISO 7816 clock.

**Figure 46-4. Elementary Time Unit (ETU)**

### 46.7.2 Receiver and Transmitter Control

After reset, the receiver is disabled. The user must enable the receiver by setting the RXEN bit in the USART Control Register (FLEX\_US\_CR). However, the receiver registers can be programmed before the receiver clock is enabled.

After reset, the transmitter is disabled. The user must enable it by setting the TXEN bit in FLEX\_US\_CR. However, the transmitter registers can be programmed before being enabled.

The receiver and the transmitter can be enabled together or independently.

At any time, the software can perform a reset on the receiver or the transmitter of the USART by setting the corresponding bit, RSTRX and RSTTX respectively, in FLEX\_US\_CR. The software resets clear the status flag and reset internal state machines but the user interface configuration registers hold the value configured prior to software reset. Regardless of what the receiver or the transmitter is performing, the communication is immediately stopped.

The user can also independently disable the receiver or the transmitter by setting RXDIS and TXDIS respectively in FLEX\_US\_CR. If the receiver is disabled during a character reception, the USART waits until the end of reception of the current character, then the reception is stopped. If the transmitter is disabled while it is operating, the USART waits the end of transmission of both the current character and character being stored in the USART Transmit Holding Register (FLEX\_US\_THR). If a timeguard is programmed, it is handled normally.

### 46.7.3 Synchronous and Asynchronous Modes

#### 46.7.3.1 Transmitter Operations

The transmitter performs the same in both Synchronous and Asynchronous operating modes (SYNC = 0 or SYNC = 1). One start bit, up to 9 data bits, 1 optional parity bit and up to 2 stop bits are successively shifted out on the TXD pin at each falling edge of the programmed serial clock.

The number of data bits is selected by the CHRL field and the MODE9 bit in FLEX\_US\_MR. Nine bits are selected by setting the MODE9 bit regardless of the CHRL field. The parity bit is set according to the PAR field in FLEX\_US\_MR. The even, odd, space, marked or none parity bit can be configured. The MSBF bit in FLEX\_US\_MR configures which data bit is sent first. If written to 1, the most significant bit is sent first. If written to 0, the less significant bit is sent first. The number of stop bits is selected by the NBSTOP field in FLEX\_US\_MR. The 1.5 stop bit is supported in Asynchronous mode only.

**Figure 46-5. Character Transmit**

Example: 8-bit, Parity Enabled One Stop

The characters are sent by writing in FLEX\_US\_THR. The transmitter reports two status bits in the USART Channel Status Register (FLEX\_US\_CSR): TXRDY (Transmitter Ready), which indicates that FLEX\_US\_THR is empty and TXEMPTY, which indicates that all the characters written in FLEX\_US\_THR have been processed. When the current character processing is completed, the last character written in FLEX\_US\_THR is transferred into the shift register of the transmitter and FLEX\_US\_THR is emptied, thus TXRDY rises.

Both TXRDY and TXEMPTY bits are low when the transmitter is disabled. Writing a character in FLEX\_US\_THR while TXRDY is low has no effect and the written character is lost.

**Figure 46-6. Transmitter Status**

### 46.7.3.2 Manchester Encoder

When the Manchester encoder is in use, characters transmitted through the USART are encoded based on biphase Manchester II format. To enable this mode, set the FLEX\_US\_MR.MAN bit to 1. Depending on polarity configuration, a logic level (zero or one), is transmitted as a coded signal one-to-zero or zero-to-one. Thus, a transition always occurs at the midpoint of each bit time. It consumes more bandwidth than the original NRZ signal (2x) but the receiver has more error control since the expected input must show a change at the center of a bit cell. An example of Manchester encoded sequence is: the byte 0xB1 or 10110001 encodes to 10 01 10 10 01 01 01 10, assuming the default polarity of the encoder. The following figure illustrates this coding scheme.

**Figure 46-7. NRZ to Manchester Encoding**

The Manchester encoded character can also be encapsulated by adding both a configurable preamble and a start frame delimiter pattern. Depending on the configuration, the preamble is a training sequence, composed of a predefined pattern with a programmable length from 1 to 15 bit times. If the preamble length is set to 0, the preamble waveform is not generated prior to any character. The preamble pattern is

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

chosen among the following sequences: ALL\_ONE, ALL\_ZERO, ONE\_ZERO or ZERO\_ONE, writing the FLEX\_US\_MAN.TX\_PP field. The TX\_PL field is used to configure the preamble length. The following figure illustrates and defines the valid patterns. To improve flexibility, the encoding scheme can be configured using the FLEX\_US\_MAN.TX\_MPOL bit. If the TX\_MPOL bit is set to zero (default), a logic zero is encoded with a zero-to-one transition and a logic one is encoded with a one-to-zero transition. If the TX\_MPOL bit is set to one, a logic one is encoded with a one-to-zero transition and a logic zero is encoded with a zero-to-one transition.

**Figure 46-8. Preamble Patterns, Default Polarity Assumed**

A start frame delimiter is to be configured using the FLEX\_US\_MR.ONEBIT bit. It consists of a user-defined pattern that indicates the beginning of a valid data. The following figure illustrates these patterns. If the start frame delimiter, also known as the start bit, is one bit, (ONEBIT = 1), a logic zero is Manchester encoded and indicates that a new character is being sent serially on the line. If the start frame delimiter is a synchronization pattern also referred to as sync (ONEBIT = 0), a sequence of three bit times is sent serially on the line to indicate the start of a new character. The sync waveform is in itself an invalid Manchester waveform as the transition occurs at the middle of the second bit time. Two distinct sync patterns are used: the command sync and the data sync. The command sync has a logic one level for one and a half bit times, then a transition to logic zero for the second one and a half bit times. If the FLEX\_US\_MR.MODSYNC bit is set to 1, the next character is a command. If it is set to 0, the next character is a data. When direct memory access is used, the MODSYNC bit can be immediately updated with a modified character located in memory. To enable this mode, the FLEX\_US\_MR.VAR\_SYNC bit must be set. In this case, the FLEX\_US\_MR.MODSYNC bit is bypassed and the sync configuration is held in the FLEX\_US\_THR.TXSYNH bit. The USART character format is modified and includes sync information.

**Figure 46-9. Start Frame Delimiter**

### 46.7.3.2.1 Drift Compensation

Drift compensation is available only in 16X Oversampling mode. An hardware recovery system allows a larger clock drift. To enable the hardware system, the bit in the FLEX\_US\_MAN register must be set. If the RXD edge is one 16X clock cycle from the expected edge, this is considered as normal jitter and no corrective actions is taken. If the RXD event is between 4 and 2 clock cycles before the expected edge, then the current period is shortened by one clock cycle. If the RXD event is between 2 and 3 clock cycles after the expected edge, then the current period is lengthened by one clock cycle. These intervals are considered to be drift and so corrective actions are automatically taken.

**Figure 46-10. Bit Resynchronization**

### 46.7.3.3 Asynchronous Receiver

If the USART is programmed in Asynchronous operating mode (SYNC = 0), the receiver oversamples the RXD input line. The oversampling is either 16 or 8 times the baud rate clock, depending on the FLEX\_US\_MR.OVER bit.

The receiver samples the RXD line. If the line is sampled during one half of a bit time to 0, a start bit is detected and data, parity and stop bits are successively sampled on the bit rate clock.

If the oversampling is 16 (OVER = 0), a start is detected at the eighth sample to 0. Data bits, parity bit and stop bit are assumed to have a duration corresponding to 16 oversampling clock cycles. If the oversampling is 8 (OVER = 1), a start is detected at the fourth sample to 0. Data bits, parity bit and stop bit are assumed to have a duration corresponding to 8 oversampling clock cycles.

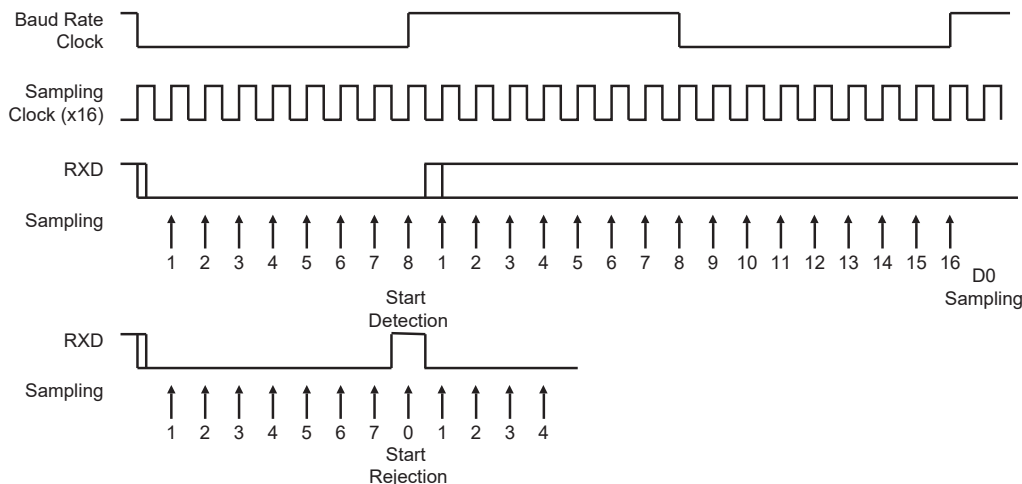

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

The number of data bits, first bit sent and Parity mode are selected by the same fields and bits as the transmitter, i.e., respectively CHRL, MODE9, MSBF and PAR. For the synchronization mechanism only, the number of stop bits has no effect on the receiver as it considers only one stop bit, regardless of the NBSTOP field, so that resynchronization between the receiver and the transmitter can occur. Moreover, as soon as the stop bit is sampled, the receiver starts looking for a new start bit so that resynchronization can also be accomplished when the transmitter is operating with one stop bit.

The following figures illustrate start detection and character reception when USART operates in Asynchronous mode.

**Figure 46-11. Asynchronous Start Detection**

**Figure 46-12. Asynchronous Character Reception**

Example: 8-bit, Parity Enabled

### 46.7.3.4 Manchester Decoder

When the FLEX\_US\_MR.MAN bit is set, the Manchester decoder is enabled. The decoder performs both preamble and start frame delimiter detection. One input line is dedicated to Manchester encoded input data.

An optional preamble sequence can be defined. Its length is user-defined and totally independent of the transmitter side. Use the FLEX\_US\_MAN.RX\_PL field to configure the length of the preamble sequence. If the length is set to 0, no preamble is detected and the function is disabled. In addition, the polarity of the input stream is programmable with the FLEX\_US\_MAN.RX\_MPOL bit. Depending on the desired application, the preamble pattern matching is to be defined via the FLEX\_US\_MAN.RX\_PP field. See figure [Preamble Patterns, Default Polarity Assumed](#) for available preamble patterns.

Unlike preamble, the start frame delimiter is shared between Manchester Encoder and Decoder. So, if ONEBIT bit = 1, only a zero encoded Manchester can be detected as a valid start frame delimiter. If ONEBIT = 0, only a sync pattern is detected as a valid start frame delimiter. Decoder operates by

detecting transition on incoming stream. If RXD is sampled during one quarter of a bit time to zero, a start bit is detected. See the following figure. The sample pulse rejection mechanism applies.

The FLEX\_US\_MAN.RXIDLEV bit informs the USART of the receiver line idle state value (receiver line inactive). The user must define RXIDLEV to ensure reliable synchronization. By default, RXIDLEV is set to one (receiver line is at level 1 when there is no activity).

**Figure 46-13. Asynchronous Start Bit Detection**

The receiver is activated and starts preamble and frame delimiter detection, sampling the data at one quarter and then three quarters. If a valid preamble pattern or start frame delimiter is detected, the receiver continues decoding with the same synchronization. If the stream does not match a valid pattern or a valid start frame delimiter, the receiver resynchronizes on the next valid edge. The minimum time threshold to estimate the bit value is three quarters of a bit time.

If a valid preamble (if used) followed with a valid start frame delimiter is detected, the incoming stream is decoded into NRZ data and passed to USART for processing. The following figure illustrates Manchester pattern mismatch. When incoming data stream is passed to the USART, the receiver is also able to detect Manchester code violation. A code violation is a lack of transition in the middle of a bit cell. In this case, the MANE flag in FLEX\_US\_CSR is raised. It is cleared by writing a one to FLEX\_US\_CR.RSTSTA. See figure "Manchester Error Flag" below for an example of Manchester error detection during the data phase.

**Figure 46-14. Preamble Pattern Mismatch**

**Figure 46-15. Manchester Error Flag**

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

When the start frame delimiter is a sync pattern (ONEBIT = 0), both command and data delimiter are supported. If a valid sync is detected, the received character is written as RXCHR field in the Receive Holding Register (FLEX\_US\_RHR) and the RXSYNH is updated. RXCHR is set to 1 when the received character is a command, and it is set to 0 if the received character is a data. This mechanism alleviates and simplifies the direct memory access as the character contains its own sync field in the same register.

As the decoder is setup to be used in Unipolar mode, the first bit of the frame has to be a zero-to-one transition.

### 46.7.3.5 Radio Interface: Manchester Encoded USART Application

This section describes low data rate RF transmission systems and their integration with a Manchester encoded USART. These systems are based on transmitter and receiver ICs that support ASK and FSK modulation schemes.

The goal is to perform full-duplex radio transmission of characters using two different frequency carriers. See configuration in the following figure.

**Figure 46-16. Manchester Encoded Characters RF Transmission**

The USART peripheral is configured as a Manchester encoder/decoder. Looking at the downstream communication channel, Manchester encoded characters are serially sent to the RF transmitter. This may also include a user defined preamble and a start frame delimiter. Mostly, preamble is used in the RF receiver to distinguish between a valid data from a transmitter and signals due to noise. The Manchester stream is then modulated. See the following figure for an example of ASK modulation scheme. When a logic one is sent to the ASK modulator, the power amplifier, referred to as PA, is enabled and transmits an RF signal at downstream frequency. When a logic zero is transmitted, the RF signal is turned off. If the FSK modulator is activated, two different frequencies are used to transmit data. When a logic 1 is sent, the modulator outputs an RF signal at frequency F0 and switches to F1 if the data sent is a 0. See figure "FSK Modulator Output" below.

From the receiver side, another carrier frequency is used. The RF receiver performs a bit check operation examining demodulated data stream. If a valid pattern is detected, the receiver switches to Receiving mode. The demodulated stream is sent to the Manchester decoder. Because of bit checking inside RF IC, the data transferred to the microcontroller is reduced by a user-defined number of bits. The Manchester preamble length is to be defined in accordance with the RF IC configuration.

**Figure 46-17. ASK Modulator Output**

**Figure 46-18. FSK Modulator Output**

#### 46.7.3.6 Synchronous Receiver

In Synchronous mode (SYNC = 1), the receiver samples the RXD signal on each rising edge of the baud rate clock. If a low level is detected, it is considered as a start. All data bits, the parity bit and the stop bits are sampled and the receiver waits for the next start bit. Synchronous mode operations provide a high-speed transfer capability.

Configuration fields and bits are the same as in Asynchronous mode.

The following figure illustrates a character reception in Synchronous mode.

**Figure 46-19. Synchronous Mode Character Reception**

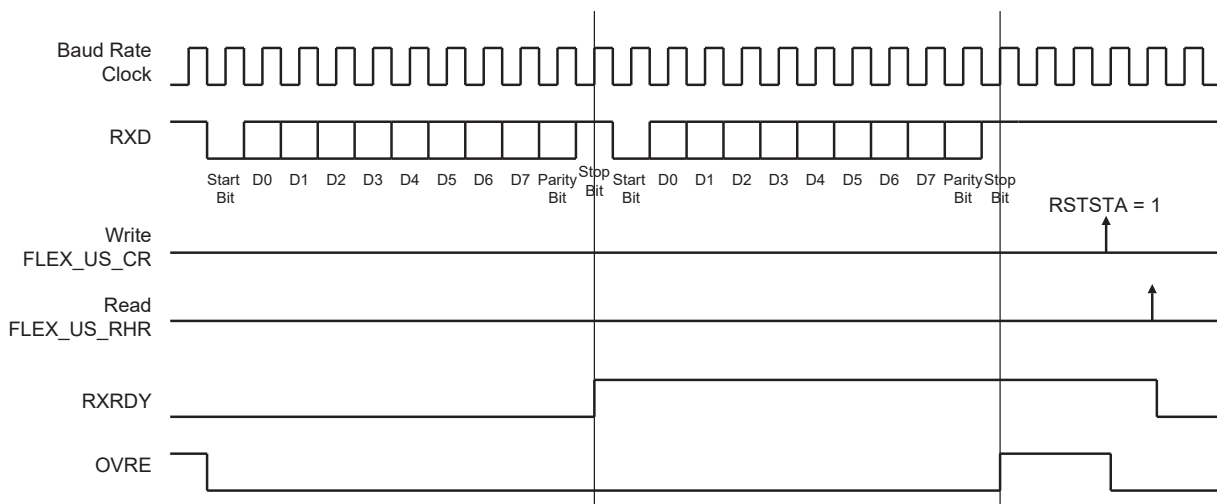

Example: 8-bit, Parity Enabled 1 Stop

#### 46.7.3.7 Receiver Operations

When a character reception is completed, it is transferred to the Receive Holding Register (FLEX\_US\_RHR) and the FLEX\_US\_CSR.RXRDY bit is raised. If a character is completed while the RXRDY is set, the Overrun Error (OVRE) bit is set. The last character is transferred into FLEX\_US\_RHR and overwrites the previous one. The OVRE bit is cleared by writing a one to Reset Status bit FLEX\_US\_CR.RSTSTA.

**Figure 46-20. Receiver Status**

### 46.7.3.8 Parity

The USART supports five parity modes that are selected by writing to the FLEX\_US\_MR.PAR field. The PAR field also enables the Multidrop mode (see section [Multidrop Mode](#)). Even and odd parity bit generation and error detection are supported.

If even parity is selected, the parity generator of the transmitter drives the parity bit to 0 if a number of 1s in the character data bit is even, and to 1 if the number of 1s is odd. Accordingly, the receiver parity checker counts the number of received 1s and reports a parity error if the sampled parity bit does not correspond. If odd parity is selected, the parity generator of the transmitter drives the parity bit to 1 if a number of 1s in the character data bit is even, and to 0 if the number of 1s is odd. Accordingly, the receiver parity checker counts the number of received 1s and reports a parity error if the sampled parity bit does not correspond. If the mark parity is used, the parity generator of the transmitter drives the parity bit to 1 for all characters. The receiver parity checker reports an error if the parity bit is sampled to 0. If the space parity is used, the parity generator of the transmitter drives the parity bit to 0 for all characters. The receiver parity checker reports an error if the parity bit is sampled to 1. If parity is disabled, the transmitter does not generate any parity bit and the receiver does not report any parity error.

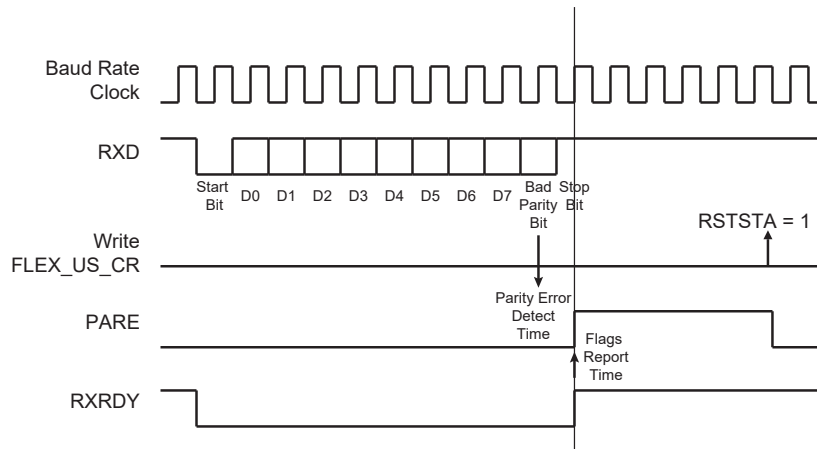

The following table shows an example of the parity bit for the character 0x41 (character ASCII “A”) depending on the configuration of the USART. Because there are two bits set to 1 in the character value, the parity bit is set to 1 when the parity is odd, or configured to 0 when the parity is even.

**Table 46-7. Parity Bit Examples**

| Character | Hexadecimal | Binary    | Parity Bit | Parity Mode |
|-----------|-------------|-----------|------------|-------------|
| A         | 0x41        | 0100 0001 | 1          | Odd         |
| A         | 0x41        | 0100 0001 | 0          | Even        |
| A         | 0x41        | 0100 0001 | 1          | Mark        |
| A         | 0x41        | 0100 0001 | 0          | Space       |
| A         | 0x41        | 0100 0001 | None       | None        |

When the receiver detects a parity error, it sets the Parity Error bit FLEX\_US\_CSR.PARE. The PARE bit can be cleared by writing a one to the FLEX\_US\_CR.RSTSTA bit. The following figure illustrates the parity bit status setting and clearing.

**Figure 46-21. Parity Error**

#### 46.7.3.9 Multidrop Mode

If the value 0x6 or 0x07 is written to the FLEX\_US\_MR.PAR field, the USART runs in Multidrop mode. This mode differentiates the data characters and the address characters. Data are transmitted with the parity bit to 0 and addresses are transmitted with the parity bit to 1.

If the USART is configured in Multidrop mode, the receiver sets the PARE parity error bit when the parity bit is high and the transmitter is able to send a character with the parity bit high when a one is written to the FLEX\_US\_CR.SENDA bit.

To handle parity error, the PARE bit is cleared by writing a one to the FLEX\_US\_CR.RSTSTA bit.

The transmitter sends an address byte (parity bit set) when the FLEX\_US\_CR.SENDA bit is written to 1. In this case, the next byte written to FLEX\_US\_THR is transmitted as an address. Any character written in FLEX\_US\_THR when the SENDA command is not written is transmitted normally with parity to 0.

#### 46.7.3.10 Transmitter Timeguard

The timeguard feature enables the USART interface with slow remote devices.

The timeguard function enables the transmitter to insert an idle state on the TXD line between two characters. This idle state actually acts as a long stop bit.

The duration of the idle state is programmed in the TG field of the Transmitter Timeguard Register (FLEX\_US\_TTGR). When this field is written to zero, no timeguard is generated. Otherwise, the transmitter holds a high level on TXD after each transmitted byte during the number of bit periods programmed in TG in addition to the number of stop bits.

As illustrated in the following figure, the behavior of the TXRDY and TXEMPTY status bits is modified by the programming of a timeguard. TXRDY rises only when the start bit of the next character is sent, and thus remains to 0 during the timeguard transmission if a character has been written in FLEX\_US\_THR. TXEMPTY remains low until the timeguard transmission is completed as the timeguard is part of the current character being transmitted.

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

**Figure 46-22. Timeguard Operations**

The following table indicates the maximum length of a timeguard period that the transmitter can handle in relation to the function of the baud rate.

**Table 46-8. Maximum Timeguard Length Depending on Baud Rate**

| Baud Rate (bit/s) | Bit Time ( $\mu$ s) | Timeguard (ms) |
|-------------------|---------------------|----------------|
| 1,200             | 833                 | 212.50         |
| 9,600             | 104                 | 26.56          |
| 14,400            | 69.4                | 17.71          |
| 19,200            | 52.1                | 13.28          |
| 28,800            | 34.7                | 8.85           |
| 38,400            | 26                  | 6.63           |
| 56,000            | 17.9                | 4.55           |
| 57,600            | 17.4                | 4.43           |
| 115,200           | 8.7                 | 2.21           |

### 46.7.3.11 Receiver Timeout

The Receiver Timeout provides support in handling variable-length frames. This feature detects an idle condition on the RXD line. When a timeout is detected, the FLEX\_US\_CSR.TIMEOUT bit rises and can generate an interrupt, thus indicating to the driver an end of frame.

The timeout delay period (during which the receiver waits for a new character) is programmed in the TO field of the Receiver Timeout Register (FLEX\_US\_RTOR). If the TO field is written to 0, the Receiver Timeout is disabled and no timeout is detected. The FLEX\_US\_CSR.TIMEOUT bit remains at 0. Otherwise, the receiver loads a 16-bit counter with the value programmed in TO. This counter is decremented at each bit period and reloaded each time a new character is received. If the counter reaches 0, the FLEX\_US\_CSR.TIMEOUT bit rises. Then, the user can either:

- Stop the counter clock until a new character is received. This is performed by writing a '1' to FLEX\_US\_CR.STTTO. In this case, the idle state on RXD before a new character is received does not provide a timeout. This prevents having to handle an interrupt before a character is received and enables waiting for the next idle state on RXD after a frame is received.
- Obtain an interrupt while no character is received. This is performed by writing a '1' to FLEX\_US\_CR.RETTO. In this case, the counter starts counting down immediately from the value

TO. This generates a periodic interrupt so that a user timeout can be handled, for example when no key is pressed on a keyboard.

The following figure shows the block diagram of the Receiver Timeout feature.

**Figure 46-23. Receiver Timeout Block Diagram**

The following table gives the maximum timeout period for some standard baud rates.

**Table 46-9. Maximum Timeout Period**

| Baud Rate (bit/s) | Bit Time ( $\mu\text{s}$ ) | Timeout (ms) |
|-------------------|----------------------------|--------------|
| 600               | 1,667                      | 109,225      |
| 1,200             | 833                        | 54,613       |
| 2,400             | 417                        | 27,306       |
| 4,800             | 208                        | 13,653       |
| 9,600             | 104                        | 6,827        |
| 14,400            | 69                         | 4,551        |
| 19,200            | 52                         | 3,413        |
| 28,800            | 35                         | 2,276        |
| 38,400            | 26                         | 1,704        |
| 56,000            | 18                         | 1,170        |
| 57,600            | 17                         | 1,138        |
| 200,000           | 5                          | 328          |

### 46.7.3.12 Framing Error

The receiver is capable of detecting framing errors. A framing error happens when the stop bit of a received character is detected at level 0. This can occur if the receiver and the transmitter are fully desynchronized.

A framing error is reported on the FLEX\_US\_CSR.FRAME bit. The FRAME bit is asserted in the middle of the stop bit as soon as the framing error is detected. It is cleared by writing a one to the FLEX\_US\_CR.RSTSTA bit.

**Figure 46-24. Framing Error Status**

### 46.7.3.13 Transmit Break

The user can request the transmitter to generate a break condition on the TXD line. A break condition drives the TXD line low during at least one complete character. It appears the same as a 0x00 character sent with the parity and the stop bits to 0. However, the transmitter holds the TXD line at least during one character until the user requests the break condition to be removed.

A break is transmitted by setting the FLEX\_US\_CR.STTBK bit. This can be done at any time, either while the transmitter is empty (no character in either the shift register or in FLEX\_US\_THR) or when a character is being transmitted. If a break is requested while a character is being shifted out, the character is first completed before the TXD line is held low.

Once the Start Break command is requested, further Start Break commands are ignored until the end of the break is completed.

The break condition is removed by setting the FLEX\_US\_CR.STPBRK bit. If the Stop Break command is requested before the end of the minimum break duration (one character, including start, data, parity and stop bits), the transmitter ensures that the break condition completes.

The transmitter considers the break as though it is a character, i.e., the Start Break and Stop Break commands are processed only if the FLEX\_US\_CSR.TXRDY bit = 1 and the start of the break condition clears the TXRDY and TXEMPTY bits as if a character was processed.

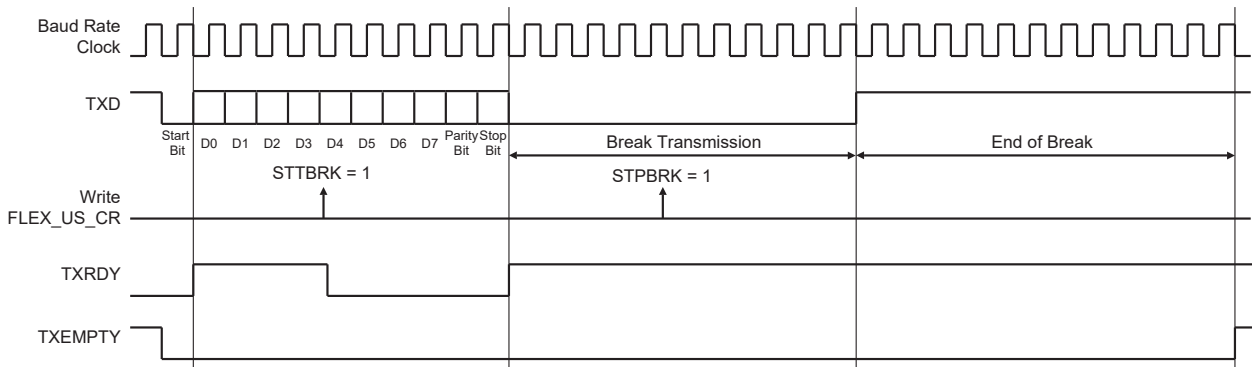

Setting both the FLEX\_US\_CR.STTBK and FLEX\_US\_CR.STPBRK bits can lead to an unpredictable result. All Stop Break commands requested without a previous Start Break command are ignored. A byte written into the Transmit Holding register while a break is pending, but not started, is ignored.

After the break condition, the transmitter returns the TXD line to 1 for a minimum of 12 bit times. Thus, the transmitter ensures that the remote receiver detects correctly the end of break and the start of the next character. If the timeguard is programmed with a value higher than 12, the TXD line is held high for the timeguard period.

After holding the TXD line for this period, the transmitter resumes normal operations.

The following figure illustrates the effect of both the Start Break (STTBK) and Stop Break (STPBRK) commands on the TXD line.

**Figure 46-25. Break Transmission**

### 46.7.3.14 Receive Break

The receiver detects a break condition when all data, parity and stop bits are low. This corresponds to detecting a framing error with data to 0x00, but FRAME remains low.

When the low stop bit is detected, the receiver asserts the FLEX\_US\_CSR.RXBRK bit. FLEX\_US\_CSR.RXBRK may be cleared by setting the FLEX\_US\_CR.RSTSTA bit.

An end of receive break is detected by a high level for at least 2/16ths of a bit period in Asynchronous operating mode or one sample at high level in Synchronous operating mode. The end of break detection also asserts the RXBRK bit.

### 46.7.3.15 Hardware Handshaking

The USART features a hardware handshaking out-of-band flow control. The RTS and CTS pins are used to connect with the remote device, as shown in the following figure.

**Figure 46-26. Connection with a Remote Device for Hardware Handshaking**

Setting the USART to operate with hardware handshaking is performed by writing the FLEX\_US\_MR.USART\_MODE field to the value 0x2.

The USART behavior when hardware handshaking is enabled is the same as the behavior in standard Synchronous or Asynchronous mode, except that the receiver drives the RTS pin as described below and the level on the CTS pin modifies the behavior of the transmitter as described below. Using this mode requires using the DMAC channel for reception. The transmitter can handle hardware handshaking in any case.

**Figure 46-27. RTS Line Software Control when FLEX\_US\_MR.USART\_MODE = 2**

The following figure shows how the transmitter operates if hardware handshaking is enabled. The CTS pin disables the transmitter. If a character is being processed, the transmitter is disabled only after the completion of the current character and transmission of the next character happens as soon as the pin CTS falls.

**Figure 46-28. Transmitter Behavior when Operating with Hardware Handshaking**

If USART FIFOs are enabled (bit `FLEX_US_CR.FIFOEN`), the RTS pin can be controlled by the USART Receive FIFO thresholds. The RTS pin control through Receive FIFO thresholds can be activated with the `FLEX_US_FMR.FRTSC` bit. Once activated, the RTS pin will be controlled by Receive FIFO thresholds, set to level 1 each time `RXFTHRES` is reached and set to level '0' each time `RXFTHRES2` is reached (and `RXFTHRES` is not reached).

**Figure 46-29. Receiver Behavior When FIFO Enabled and FRTSC Set to '1'**

**Note:** In this mode, `RXFTHRES` must be  $> \text{RXFTHRES2}$ .

### 46.7.4 ISO7816 Mode

The USART features an ISO7816-compatible operating mode. This mode permits interfacing with smart cards and Security Access Modules (SAM) communicating through an ISO7816 link. Both T = 0 and T = 1 protocols defined by the ISO7816 specification are supported.

Setting the USART in ISO7816 mode is performed by writing the `FLEX_US_MR.USART_MODE` field to the value 0x4 for protocol T = 0 and to the value 0x6 for protocol T = 1.

#### 46.7.4.1 ISO7816 Mode Overview

The ISO7816 is a half-duplex communication on only one bidirectional line. The baud rate is determined by a division of the clock provided to the remote device (see figure in section [Baud Rate Generator](#)).

The USART connects to a smart card as shown in the following figure. The TXD line becomes bidirectional and the baud rate generator feeds the ISO7816 clock on the SCK pin. As the TXD pin becomes bidirectional, its output remains driven by the output of the transmitter but only when the transmitter is active while its input is directed to the input of the receiver. The USART is considered as the master of the communication as it generates the clock.

**Figure 46-30. Connection of a Smart Card to the USART**

When operating in ISO7816, either in T = 0 or T = 1 modes, the character format is partially predefined. The configuration is forced to 8 data bits, and 1 or 2 stop bits, regardless of the values programmed in the CHRL, MODE9 and CHMODE fields. MSBF can be used to transmit LSB or MSB first. The bit INVDATA can be used to transmit in Normal or Inverse mode.

The USART cannot operate concurrently in both Receiver and Transmitter modes as the communication is unidirectional at a time. It has to be configured according to the required mode by enabling or disabling either the receiver or the transmitter as desired. Enabling both the receiver and the transmitter at the same time in ISO7816 mode may lead to unpredictable results.

The ISO7816 specification defines an inverse transmission format. Data bits of the character must be transmitted on the I/O line at their negative value.

**46.7.4.2 Protocol T = 0**

In T = 0 protocol, a character is made up of 1 start bit, 8 data bits, 1 parity bit and 1 guard time, which lasts two bit times. The transmitter shifts out the bits and does not drive the I/O line during the guard time.

If no parity error is detected, the I/O line remains at 1 during the guard time and the transmitter can continue with the transmission of the next character, as shown in the following figure.

If a parity error is detected by the receiver, it drives the I/O line to 0 during the guard time, as shown in figure "T = 0 Protocol with Parity Error" below. This error bit is also named NACK, for Non Acknowledge. In this case, the character lasts 1 bit time more, as the guard time length is the same and is added to the error bit time which lasts 1 bit time.

When the USART is the receiver and it detects an error, it does not load the erroneous character in the Receive Holding Register (FLEX\_US\_RHR). It appropriately sets the PARE bit in the Status Register (FLEX\_US\_CSR) so that the software can handle the error.

**Figure 46-31. T = 0 Protocol without Parity Error**

**Figure 46-32. T = 0 Protocol with Parity Error**

#### **46.7.4.2.1 Receive Error Counter**

The USART receiver also records the total number of errors. This can be read in the Number of Error (FLEX\_US\_NER) register. The NB\_ERRORS field can record up to 255 errors. Reading FLEX\_US\_NER automatically clears the NB\_ERRORS field.

#### **46.7.4.2.2 Receive NACK Inhibit**

The USART can be configured to inhibit an error. This is done by writing a '1' to FLEX\_US\_MR.INACK. In this case, no error signal is driven on the I/O line even if a parity bit is detected.

Moreover, if INACK = 1, the erroneous received character is stored in the Receive Holding register as if no error occurred, and the RXRDY bit rises.

#### **46.7.4.2.3 Transmit Character Repetition**

When the USART is transmitting a character and gets a NACK, it can automatically repeat the character before moving on to the next one. Repetition is enabled by writing the FLEX\_US\_MR.MAX\_ITERATION field at a value higher than 0. Each character can be transmitted up to eight times: the first transmission plus seven repetitions.

If MAX\_ITERATION does not equal zero, the USART repeats the character as many times as the value loaded in MAX\_ITERATION.

When the USART repetition number reaches MAX\_ITERATION, and the last repeated character is not acknowledged, the FLEX\_US\_CSR.ITER bit is set. If the repetition of the character is acknowledged by the receiver, the repetitions are stopped and the iteration counter is cleared.

The FLEX\_US\_CSR.ITER bit can be cleared by writing the FLEX\_US\_CR.RSTIT bit to 1.

#### **46.7.4.2.4 Disable Successive Receive NACK**

The receiver can limit the number of successive NACKs sent back to the remote transmitter. This is programmed by setting the FLEX\_US\_MR.DSNACK bit. The maximum number of NACKs transmitted is programmed in the MAX\_ITERATION field. As soon as MAX\_ITERATION is reached, no error signal is driven on the I/O line and the FLEX\_US\_CSR.ITER bit is set.

#### **46.7.4.3 Protocol T = 1**

When operating in ISO7816 protocol T = 1, the transmission is similar to an asynchronous format with only one stop bit. The parity is generated when transmitting and checked when receiving. Parity error detection sets the FLEX\_US\_CSR.PARE bit.

#### **46.7.5 IrDA Mode**

The USART features an IrDA mode supplying half-duplex point-to-point wireless communication. It embeds the modulator and demodulator which allows a glueless connection to the infrared transceivers, as shown in the following figure. The modulator and demodulator are compliant with the IrDA specification version 1.1 and support data transfer speeds ranging from 2.4 kbit/s to 115.2 kbit/s.

The USART IrDA mode is enabled by setting the FLEX\_US\_MR.USART\_MODE field to the value 0x8. The IrDA Filter Register (FLEX\_US\_IF) allows configuring the demodulator filter. The USART transmitter and receiver operate in a normal Asynchronous mode and all parameters are accessible. Note that the modulator and the demodulator are activated.

**Figure 46-33. Connection to IrDA Transceivers**

The receiver and the transmitter must be enabled or disabled according to the direction of the transmission to be managed.

To receive IrDA signals, the following needs to be done:

- Disable TX and Enable RX
- Configure the TXD pin as PIO and set it as an output to 0 (to avoid LED transmission). Disable the internal pullup (better for power consumption).
- Receive data

### 46.7.5.1 IrDA Modulation

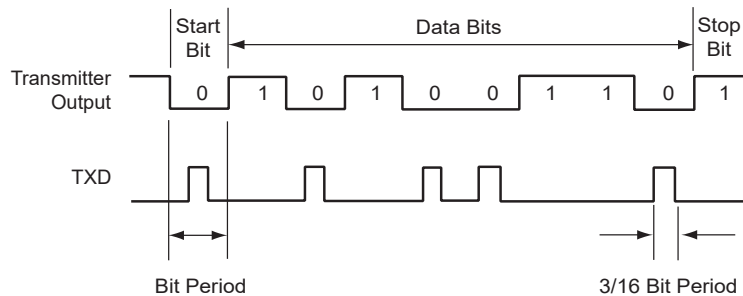

For baud rates up to and including 115.2 kbit/s, the RZI modulation scheme is used. “0” is represented by a light pulse of 3/16th of a bit time. Some examples of signal pulse duration are shown in the following table.

**Table 46-10. IrDA Pulse Duration**

| Baud Rate    | Pulse Duration (3/16) |
|--------------|-----------------------|
| 2.4 kbit/s   | 78.13 $\mu$ s         |
| 9.6 kbit/s   | 19.53 $\mu$ s         |
| 19.2 kbit/s  | 9.77 $\mu$ s          |
| 38.4 kbit/s  | 4.88 $\mu$ s          |
| 57.6 kbit/s  | 3.26 $\mu$ s          |
| 115.2 kbit/s | 1.63 $\mu$ s          |

The following figure shows an example of character transmission.

**Figure 46-34. IrDA Modulation**

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

### 46.7.5.2 IrDA Baud Rate

The following table gives some examples of CD values, baud rate error and pulse duration. Note that the requirement on the maximum acceptable error of  $\pm 1.87\%$  must be met.

**Table 46-11. IrDA Baud Rate Error**

| Peripheral Clock | Baud Rate (bit/s) | CD  | Baud Rate Error | Pulse Time ( $\mu$ s) |
|------------------|-------------------|-----|-----------------|-----------------------|
| 3,686,400        | 115,200           | 2   | 0.00%           | 1.63                  |
| 20,000,000       | 115,200           | 11  | 1.38%           | 1.63                  |
| 32,768,000       | 115,200           | 18  | 1.25%           | 1.63                  |

### 46.7.5.3 IrDA Demodulator

The demodulator is based on the IrDA Receive filter comprised of an 8-bit down counter which is loaded with the value programmed in FLEX\_US\_IF. When a falling edge is detected on the RXD pin, the Filter Counter starts counting down at the peripheral clock speed. If a rising edge is detected on the RXD pin, the counter stops and is reloaded with FLEX\_US\_IF. If no rising edge is detected when the counter reaches 0, the input of the receiver is driven low during one bit time.

The following figure illustrates the operations of the IrDA demodulator.

**Figure 46-35. IrDA Demodulator Operations**

The programmed value in the FLEX\_US\_IF register must always meet the following criteria:

$$t_{\text{peripheral clock}} \times (\text{IRDA\_FILTER} + 3) < 1.41 \mu\text{s}$$

As the IrDA mode uses the same logic as the ISO7816, note that the FLEX\_US\_FIDI.FI\_DI\_RATIO field must be set to a value higher than 0 to make sure IrDA communications operate correctly.

### 46.7.6 RS485 Mode

The USART features the RS485 mode to enable line driver control. While operating in RS485 mode, the USART behaves as though in Asynchronous or Synchronous mode and configuration of all the parameters is possible. The difference is that the RTS pin is driven high when the transmitter is operating. The behavior of the RTS pin is controlled by the TXEMPTY bit. A typical connection of the USART to an RS485 bus is shown in the following figure.

**Figure 46-36. Typical Connection to an RS485 Bus**

The USART is set in RS485 mode by writing the value 0x1 to the FLEX\_US\_MR.USART\_MODE field.

The RTS pin is at a level inverse to the TXEMPTY bit. Significantly, the RTS pin remains high when a timeguard is programmed, so that the line can remain driven after the last character completion. The following figure gives an example of the RTS waveform during a character transmission when the timeguard is enabled.

**Figure 46-37. Example of RTS Drive with Timeguard**

#### 46.7.7 USART Comparison Function on Received Character

The CMP flag in FLEX\_US\_CSR is set when the received character matches the conditions programmed in FLEX\_US\_CMPR. The CMP flag is set as soon as FLEX\_US\_RHR is loaded with the new received character. The CMP flag is cleared by writing a one to FLEX\_US\_CR.RSTSTA.

FLEX\_US\_CMPR can be programmed to provide different comparison methods:

- If VAL1 equals VAL2, then the comparison is performed on a single value and the flag is set to 1 if the received character equals VAL1.
- If VAL1 is strictly lower than VAL2, then any value between VAL1 and VAL2 sets the CMP flag.
- If VAL1 is strictly higher than VAL2, then the flag CMP is set to 1 if any received character equals VAL1 or VAL2.

When the FLEX\_US\_CMPR.CMPMODE bit is set to FLAG\_ONLY (value 0), all received data are loaded in FLEX\_US\_RHR and the CMP flag provides the status of the comparison result.

By programming the START\_CONDITION.CMPMODE bit (value 1), the comparison function result triggers the start of the loading of FLEX\_US\_RHR (see the following figure). The trigger condition exists as soon as the received character value matches the condition defined by the programming of VAL1, VAL2 and CMPPAR in FLEX\_US\_CMPR. The comparison trigger event is restarted by writing a 1 to the FLEX\_US\_CR.REQCLR bit.

The value programmed in the VAL1 and VAL2 fields must not exceed the maximum value of the received character (see CHRL field in register [46.10.6 FLEX\\_US\\_MR](#)).

**Figure 46-38. Receive Holding Register Management**

CMPMODE = 1, VAL1 = VAL2 = 0x06

### 46.7.8 SPI Mode

The Serial Peripheral Interface (SPI) mode is a synchronous serial data link that provides communication with external devices in Master or Slave mode. It also enables communication between processors if an external processor is connected to the system.

The Serial Peripheral Interface is essentially a shift register that serially transmits data bits to other SPIs. During a data transfer, one SPI system acts as the “master” which controls the data flow, while the other devices act as “slaves” which have data shifted into and out by the master. Different CPUs can take turns being masters and one master may simultaneously shift data into multiple slaves. (Multiple master protocol is the opposite of single master protocol, where one CPU is always the master while all of the others are always slaves.) However, only one slave may drive its output to write data back to the master at any given time.

A slave device is selected when its NSS signal is asserted by the master. The USART in SPI Master mode can address only one SPI slave because it can generate only one NSS signal.

The SPI system consists of two data lines and two control lines:

- Master Out Slave In (MOSI): This data line supplies the output data from the master shifted into the input of the slave.
- Master In Slave Out (MISO): This data line supplies the output data from a slave to the input of the master.
- Serial Clock (SCK): This control line is driven by the master and regulates the flow of the data bits. The master may transmit data at a variety of bit rates. The SCK line cycles once for each bit that is transmitted.
- Slave Select (NSS): This control line allows the master to select or deselect the slave.

#### 46.7.8.1 Modes of Operation

The USART can operate in SPI Master mode or in SPI Slave mode.

Operation in SPI Master mode is programmed by writing 0xE to the FLEX\_US\_MR.USART\_MODE field. In this case, the SPI lines must be connected as described below:

- The MOSI line is driven by the output pin TXD

- The MISO line drives the input pin RXD
- The SCK line is driven by the output pin SCK
- The NSS line is driven by the output pin RTS

Operation in SPI Slave mode is programmed by writing to 0xF the FLEX\_US\_MR.USART\_MODE field. In this case, the SPI lines must be connected as described below:

- The MOSI line drives the input pin RXD
- The MISO line is driven by the output pin TXD
- The SCK line drives the input pin SCK
- The NSS line drives the input pin CTS

In order to avoid an unpredictable behavior, any change of the SPI mode must be followed by a software reset of the transmitter and of the receiver (except the initial configuration after a hardware reset). (See section [Receiver and Transmitter Control](#).)

### 46.7.8.2 Bit Rate

In SPI mode, the bit rate generator operates in the same way as in USART Synchronous mode. See section [46.7.1.3 Baud Rate in Synchronous Mode or SPI Mode](#). However, some restrictions apply:

In SPI Master mode:

- The external clock SCK must not be selected (USCLKS  $\neq$  0x3), and the FLEX\_US\_MR.CLKO bit must be set in order to generate correctly the serial clock on the SCK pin.
- To ensure a correct behavior of the receiver and the transmitter, the value programmed in CD must be  $\geq$  6.
- If the divided peripheral clock is selected, the value programmed in CD must be even to ensure a 50:50 mark/space ratio on the SCK pin; this value can be odd if the peripheral clock is selected.

In SPI Slave mode:

- The external clock (SCK) selection is forced regardless of the value of the FLEX\_US\_MR.USCLKS field. Likewise, the value written in FLEX\_US\_BRGR has no effect, because the clock is provided directly by the signal on the USART SCK pin.
- To ensure a correct behavior of the receiver and the transmitter, the external clock (SCK) frequency must be at least six times lower than the system clock.

### 46.7.8.3 Data Transfer

Up to nine data bits are successively shifted out on the TXD pin at each rising or falling edge (depending of CPOL and CPHA) of the programmed serial clock. There is no Start bit, no Parity bit and no Stop bit.

The number of data bits is selected by the CHRL field and the MODE9 bit in FLEX\_US\_MR. The nine bits are selected by setting the MODE9 bit regardless of the CHRL field. The MSB data bit is always sent first in SPI mode (Master or Slave).

Four combinations of polarity and phase are available for data transfers. The clock polarity is programmed with the FLEX\_US\_MR.CPOL bit. The clock phase is programmed with the CPHA bit. These two parameters determine the edges of the clock signal upon which data are driven and sampled. Each of the two parameters has two possible states, resulting in four possible combinations that are incompatible with one another. Thus, a master/slave pair must use the same parameter pair values to communicate. If multiple slaves are used and fixed in different configurations, the master must reconfigure itself each time it needs to communicate with a different slave.

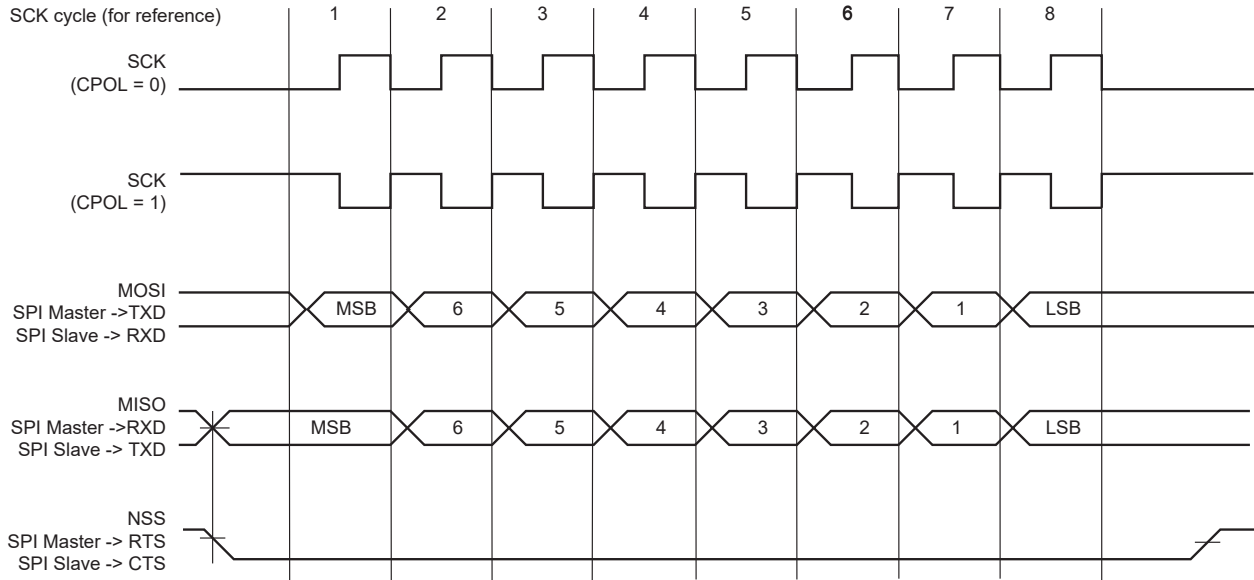

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

**Table 46-12. SPI Bus Protocol Mode**

| SPI Bus Protocol Mode | CPOL | CPHA |
|-----------------------|------|------|
| 0                     | 0    | 1    |
| 1                     | 0    | 0    |
| 2                     | 1    | 1    |
| 3                     | 1    | 0    |

**Figure 46-39. SPI Transfer Format (CPHA = 1, 8 bits per transfer)**

**Figure 46-40. SPI Transfer Format (CPHA = 0, 8 bits per transfer)**

### 46.7.8.4 Receiver and Transmitter Control

See section [Receiver and Transmitter Control](#).

#### 46.7.8.5 Character Transmission

The characters are sent by writing in the Transmit Holding Register (FLEX\_US\_THR). An additional condition for transmitting a character can be added when the USART is configured in SPI Master mode. In the “USART Mode Register (SPI\_MODE)” (FLEX\_US\_MR), the value configured on the WRDBT bit can prevent any character transmission (even if FLEX\_US\_THR has been written) while the receiver side is not ready (character not read). When WRDBT = 0, the character is transmitted whatever the receiver status. If WRDBT = 1, the transmitter waits for the Receive Holding Register (FLEX\_US\_RHR) to be read before transmitting the character (RXRDY flag cleared), thus preventing any overflow (character loss) on the receiver side.

The chip select line is deasserted for a period equivalent to 3 bits between the transmission of two data.

The transmitter reports two status bits in FLEX\_US\_CSR: TXRDY (Transmitter Ready), which indicates that FLEX\_US\_THR is empty and TXEMPTY, which indicates that all the characters written in FLEX\_US\_THR have been processed. When the current character processing is completed, the last character written in FLEX\_US\_THR is transferred into the shift register of the transmitter and FLEX\_US\_THR is emptied, and thus TXRDY rises.

Both the TXRDY and the TXEMPTY bits are low when the transmitter is disabled. Writing a character in FLEX\_US\_THR while TXRDY is low has no effect and the written character is lost.

If the USART is in SPI Slave mode and if a character must be sent while FLEX\_US\_THR is empty, the UNRE (Underrun Error) bit is set. The TXD transmission line stays at high level during all this time. The UNRE bit is cleared by writing a one to the FLEX\_US\_CR.RSTSTA bit.

In SPI Master mode, the slave select line (NSS) is asserted at low level one  $t_{bit}$  ( $t_{bit}$  being the nominal time required to transmit a bit) before the transmission of the MSB bit and released at high level one  $t_{bit}$  after the transmission of the LSB bit. So, the slave select line (NSS) is always released between each character transmission and a minimum delay of three  $t_{bit}$  always inserted. However, in order to address slave devices supporting the CSAAT mode (Chip Select Active After Transfer), the slave select line (NSS) can be forced at low level by writing a one to the FLEX\_US\_CR.RTSEN bit. The slave select line (NSS) can be released at high level only by writing a one to the FLEX\_US\_CR.RTSDIS bit (for example, when all data have been transferred to the slave device).

In SPI Slave mode, the transmitter does not require a falling edge of the slave select line (NSS) to initiate a character transmission but only a low level. However, this low level must be present on the slave select line (NSS) at least one  $t_{bit}$  before the first serial clock cycle corresponding to the MSB bit.

#### 46.7.8.6 Character Reception

When a character reception is completed, it is transferred to the Receive Holding Register (FLEX\_US\_RHR) and the RXRDY bit in the Status Register (FLEX\_US\_CSR) rises. If a character is completed while RXRDY is set, the OVRE (Overrun Error) bit is set. The last character is transferred into FLEX\_US\_RHR and overwrites the previous one. The OVRE bit is cleared by writing a one to the FLEX\_US\_CR.RSTSTA bit.

To ensure correct behavior of the receiver in SPI Slave mode, the master device sending the frame must ensure a minimum delay of one  $t_{bit}$  between each character transmission. The receiver does not require a falling edge of the slave select line (NSS) to initiate a character reception but only a low level. However, this low level must be present on the slave select line (NSS) at least one  $t_{bit}$  before the first serial clock cycle corresponding to the MSB bit.

#### 46.7.8.7 Receiver Timeout

Because the receiver bit rate clock is active only during data transfers in SPI mode, a receiver timeout is impossible in this mode, whatever the timeout value is in field FLEX\_US\_RTOR.TO.

### 46.7.9 LIN Mode

The LIN mode provides master node and slave node connectivity on a LIN bus.

The LIN (Local Interconnect Network) is a serial communication protocol which efficiently supports the control of mechatronic nodes in distributed automotive applications.

The main properties of the LIN bus are:

- Single master/multiple slaves concept
- Low-cost silicon implementation based on common UART/SCI interface hardware, an equivalent in software, or as a pure state machine.
- Self synchronization without quartz or ceramic resonator in the slave nodes
- Deterministic signal transmission
- Low cost single-wire implementation
- Speed up to 20 kbit/s

LIN provides cost efficient bus communication where the bandwidth and versatility of CAN are not required.

The LIN mode enables processing LIN frames with a minimum of action from the microprocessor.

#### 46.7.9.1 Modes of Operation

The USART can act either as a LIN master node or as a LIN slave node.

The node configuration is chosen by setting the USART\_MODE field in the USART Mode Register (FLEX\_US\_MR):

- LIN master node (USART\_MODE = 0xA)
- LIN slave node (USART\_MODE = 0xB)

In order to avoid unpredictable behavior, any change of the LIN node configuration must be followed by a software reset of the transmitter and of the receiver (except the initial node configuration after a hardware reset). (See section [46.7.2 Receiver and Transmitter Control](#).)

#### 46.7.9.2 Baud Rate Configuration

See section [Baud Rate in Asynchronous Mode](#).

- LIN master node: The baud rate is configured in FLEX\_US\_BRGR.
- LIN slave node: The initial baud rate is configured in FLEX\_US\_BRGR. This configuration is automatically copied in the LIN Baud Rate Register (FLEX\_US\_LINBRR) when writing FLEX\_US\_BRGR. After the synchronization procedure, the baud rate is updated in FLEX\_US\_LINBRR.

#### 46.7.9.3 Receiver and Transmitter Control

See section [46.7.2 Receiver and Transmitter Control](#).

#### 46.7.9.4 Character Transmission

See section [Transmitter Operations](#).

#### 46.7.9.5 Character Reception

See section [Receiver Operations](#).

#### 46.7.9.6 Header Transmission (Master Node Configuration)

All the LIN Frames start with a header which is sent by the master node and consists of a Synch Break Field, Synch Field and Identifier Field.

So in master node configuration, the frame handling starts with the sending of the header.

The header is transmitted as soon as the identifier is written in the LIN Identifier Register (FLEX\_US\_LINIR). At this moment the flag TXRDY falls.

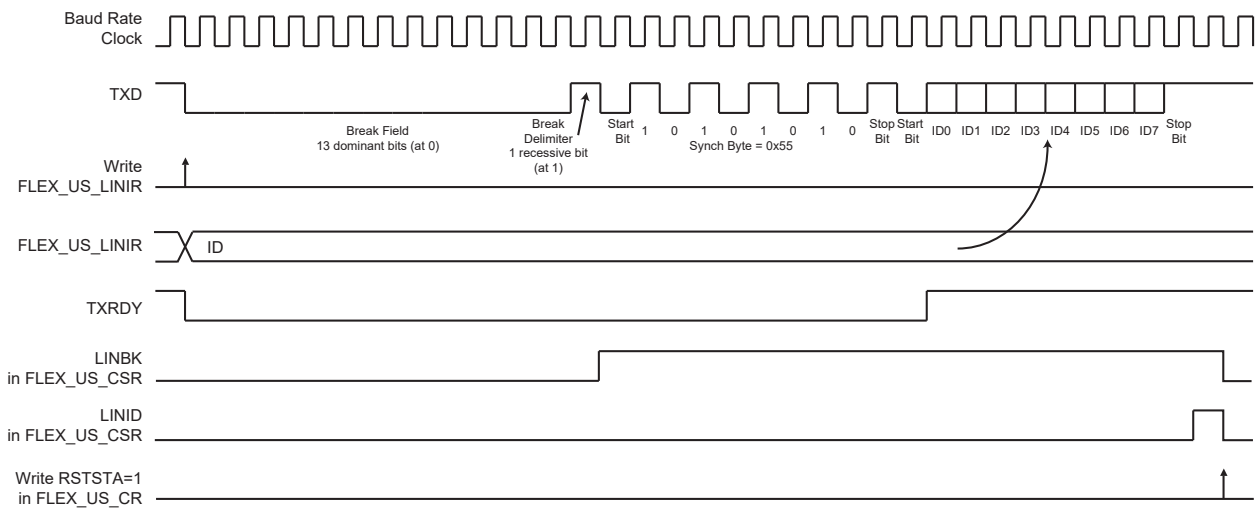

The Break Field, the Synch Field and the Identifier Field are sent automatically one after the other.

The Break Field consists of 13 dominant bits and 1 recessive bit, the Synch Field is the character 0x55 and the Identifier corresponds to the character written in the LIN Identifier Register (FLEX\_US\_LINIR). The Identifier parity bits can be automatically computed and sent (see section [Identifier Parity](#)).

The flag TXRDY rises when the identifier character is transferred into the shift register of the transmitter.

As soon as the Synch Break Field is transmitted, the FLEX\_US\_CSR.LINBK flag bit is set. Likewise, as soon as the Identifier Field is sent, the FLEX\_US\_CSR.LINID flag bit is set. These flags are reset by writing a one to the FLEX\_US\_CR.RSTSTA bit.

**Figure 46-41. Header Transmission**

### 46.7.9.7 Header Reception (Slave Node Configuration)

All the LIN frames start with a header which is sent by the master node and consists of a Synch Break Field, Synch Field and Identifier Field.

In slave node configuration, the frame handling starts with the reception of the header.

The USART uses a break detection threshold of 11 nominal bit times at the actual baud rate. At any time, if 11 consecutive recessive bits are detected on the bus, the USART detects a Break Field. As long as a Break Field has not been detected, the USART stays idle and the received data are not taken in account.

When a Break Field has been detected, the FLEX\_US\_CSR.LINBK flag is set and the USART expects the Synch Field character to be 0x55. This field is used to update the actual baud rate in order to remain synchronized (see section [Slave Node Synchronization](#)). If the received Synch character is not 0x55, an Inconsistent Synch Field error is generated (see section [LIN Errors](#)).

After receiving the Synch Field, the USART expects to receive the Identifier Field.

When the Identifier Field has been received, the FLEX\_US\_CSR.LINID flag bit is set. At this moment, the IDCHR field in the LIN Identifier Register (FLEX\_US\_LINIR) is updated with the received character. The Identifier parity bits can be automatically computed and checked (see section [Identifier Parity](#)).

If the header is not entirely received within the time given by the maximum length of the header  $t_{Header\_Maximum}$ , the FLEX\_US\_CSR.LINHTE error flag bit is set.

The flag bits LINID, LINBK and LINHTE are reset by writing a one to the FLEX\_US\_CR.RSTSTA bit.

**Figure 46-42. Header Reception**

### 46.7.9.8 Slave Node Synchronization

The synchronization is done only in slave node configuration. The procedure is based on time measurement between the falling edges of the Synch Field. The falling edges are available in distances of 2, 4, 6 and 8 bit times.

**Figure 46-43. Synch Field**

The time measurement is made by a 19-bit counter driven by the sampling clock (see section [Baud Rate Generator](#)).

When the start bit of the Synch Field is detected, the counter is reset. Then during the next eight  $t_{bit}$  of the Synch Field, the counter is incremented. At the end of these eight  $t_{bit}$ , the counter is stopped. At this moment, the 16 most significant bits of the counter (value divided by 8) give the new clock divider (LINCD) and the 3 least significant bits of this value (the remainder) give the new fractional part (LINFp).

Once the Synch Field has been entirely received, the clock divider (LINCD) and the fractional part (LINFp) are updated in the LIN Baud Rate Register (FLEX\_US\_LINBRR) with the computed values, if the Synchronization is not disabled by the SYNCDIS bit in the LIN Mode Register (FLEX\_US\_LINMR).

After reception of the Synch Field:

- If it appears that the computed baud rate deviation compared to the initial baud rate is superior to the maximum tolerance  $FTol\_Unsynch$  ( $\pm 15\%$ ), then the clock divider (LINCD) and the fractional part (LINFp) are not updated, and the FLEX\_US\_CSR.LINSTE error flag bit is set.
- If it appears that the sampled Synch character is not equal to 0x55, then the clock divider (LINCD) and the fractional part (LINFp) are not updated, and the FLEX\_US\_CSR.LINISFE error flag bit is set.

Flags LINSTE and LINISFE are reset by writing a one to the FLEX\_US\_CR.RSTSTA bit.

**Figure 46-44. Slave Node Synchronization**

The synchronization accuracy depends on several parameters:

- The nominal clock frequency ( $f_{Nom}$ ) (the theoretical slave node clock frequency)
- The baud rate
- The oversampling ( $OVER = 0 \Rightarrow 16X$  or  $OVER = 1 \Rightarrow 8X$ )

The following formula is used to compute the deviation of the slave bit rate relative to the master bit rate after synchronization ( $f_{SLAVE}$  is the real slave node clock frequency).

$$\text{Baud rate deviation} = \left( 100 \times \frac{[\alpha \times 8 \times (2 - \text{Over}) + \beta] \times \text{Baud rate}}{8 \times f_{SLAVE}} \right) \%$$

$$\text{Baud rate deviation} = \left( 100 \times \frac{[\alpha \times 8 \times (2 - \text{Over}) + \beta] \times \text{Baud rate}}{8 \times \left( \frac{f_{TOL\_UNSYNCH}}{100} \right) \times f_{Nom}} \right) \%$$

$$-0.5 \leq \alpha \leq +0.5 \quad -1 < \beta < +1$$

$f_{TOL\_UNSYNCH}$  is the deviation of the real slave node clock from the nominal clock frequency. The LIN Standard imposes that it must not exceed  $\pm 15\%$ . The LIN Standard imposes also that for communication between two nodes, their bit rate must not differ by more than  $\pm 2\%$ . This means that the baud rate deviation must not exceed  $\pm 1\%$ .

Therefore, a minimum value for the nominal clock frequency can be computed as follows:

$$f_{Nom}(\text{min}) = \left( 100 \times \frac{[0.5 \times 8 \times (2 - \text{Over}) + 1] \times \text{Baud rate}}{8 \times \left( \frac{-15}{100} + 1 \right) \times 1\%} \right) \text{Hz}$$

Examples:

- Baud rate = 20 kbit/s,  $OVER = 0$  (Oversampling 16X)  $\Rightarrow f_{Nom}(\text{min}) = 2.64$  MHz
- Baud rate = 20 kbit/s,  $OVER = 1$  (Oversampling 8X)  $\Rightarrow f_{Nom}(\text{min}) = 1.47$  MHz
- Baud rate = 1 kbit/s,  $OVER = 0$  (Oversampling 16X)  $\Rightarrow f_{Nom}(\text{min}) = 132$  kHz
- Baud rate = 1 kbit/s,  $OVER = 1$  (Oversampling 8X)  $\Rightarrow f_{Nom}(\text{min}) = 74$  kHz

### 46.7.9.9 Identifier Parity

A protected identifier consists of two subfields: the identifier and the identifier parity. Bits 0 to 5 are assigned to the identifier, and bits 6 and 7 are assigned to the parity.

The USART interface can generate/check these parity bits, but this feature can also be disabled. The user can choose between two modes via the FLEX\_US\_LINMR.PARDIS bit:

- PARDIS = 0:
  - During header transmission, the parity bits are computed and sent with the six least significant bits of the IDCHR field of the LIN Identifier Register (FLEX\_US\_LINIR). Bits 6 and 7 of this register are discarded.
  - During header reception, the parity bits of the identifier are checked. If the parity bits are wrong, an Identifier Parity error occurs (see section [Parity](#)). Only the six least significant bits of the IDCHR field are updated with the received Identifier. Bits 6 and 7 are stuck to 0.
- PARDIS = 1:
  - During header transmission, all the bits of the IDCHR field of the LIN Identifier Register (FLEX\_US\_LINIR) are sent on the bus.
  - During header reception, all the bits of the IDCHR field are updated with the received Identifier.

### 46.7.9.10 Node Action

Depending on the identifier, the node is affected—or not—by the LIN response. Consequently, after sending or receiving the identifier, the USART must be configured. There are three possible configurations:

- PUBLISH: the node sends the response.
- SUBSCRIBE: the node receives the response.
- IGNORE: the node is not concerned by the response, it does not send and does not receive the response.

This configuration is made by the LIN Node Action (NACT) field in USART LIN Mode Register (FLEX\_US\_LINMR).

Example: a LIN cluster that contains a master and two slaves:

- Data transfer from the master to slave 1 and to slave 2:

NACT(master) = PUBLISH

NACT(slave 1) = SUBSCRIBE

NACT(slave 2) = SUBSCRIBE

- Data transfer from the master to slave 1 only:

NACT(master) = PUBLISH

NACT(slave 1) = SUBSCRIBE

NACT(slave 2) = IGNORE

- Data transfer from slave 1 to the master:

NACT(master) = SUBSCRIBE

NACT(slave 1) = PUBLISH

NACT(slave 2) = IGNORE

- Data transfer from slave 1 to slave 2:

NACT(master) = IGNORE

NACT(slave 1) = PUBLISH

NACT(slave 2) = SUBSCRIBE

- Data transfer from slave 2 to the master and to slave 1:

NACT(master) = SUBSCRIBE

NACT(slave 1) = SUBSCRIBE

NACT(slave 2) = PUBLISH

### 46.7.9.11 Response Data Length

The LIN response data length is the number of data fields (bytes) of the response excluding the checksum.

The response data length can either be configured by the user or be defined automatically by bits 4 and 5 of the Identifier (compatibility to LIN Specification 1.1). The user can choose between these two modes by the FLEX\_US\_LINMR.DLM bit:

- DLM = 0: The response data length is configured by the user via the FLEX\_US\_LINMR.DLC field. The response data length is equal to (DLC + 1) bytes. DLC can be programmed from 0 to 255, so the response can contain from 1 data byte up to 256 data bytes.
- DLM = 1: The response data length is defined by the Identifier (IDCHR in FLEX\_US\_LINIR) according to the table below. The FLEX\_US\_LINMR.DLC field is discarded. The response can contain 2 or 4 or 8 data bytes.

**Table 46-13. Response Data Length if DLM = 1**

| IDCHR[5] | IDCHR[4] | Response Data Length (bytes) |
|----------|----------|------------------------------|
| 0        | 0        | 2                            |
| 0        | 1        | 2                            |
| 1        | 0        | 4                            |
| 1        | 1        | 8                            |

**Figure 46-45. Response Data Length**

### 46.7.9.12 Checksum

The last field of a frame is the checksum. The checksum contains the inverted 8-bit sum with carry, over all data bytes or all data bytes and the protected identifier. Checksum calculation over the data bytes only is called classic checksum and it is used for communication with LIN 1.3 slaves. Checksum calculation over the data bytes and the protected identifier byte is called enhanced checksum and it is used for communication with LIN 2.0 slaves.

The USART can be configured to:

- Send/Check an Enhanced checksum automatically (CHKDIS = 0 & CHKTYP = 0)
- Send/Check a Classic checksum automatically (CHKDIS = 0 & CHKTYP = 1)
- Not send/check a checksum (CHKDIS = 1)

This configuration is made by the Checksum Type (CHKTYP) and Checksum Disable (CHKDIS) bits of FLEX\_US\_LINMR.

If the checksum feature is disabled, the user can send it manually all the same, by considering the checksum as a normal data byte and by adding 1 to the response data length (see section [Response Data Length](#)).

### 46.7.9.13 Frame Slot Mode

This mode is useful only for master nodes. It respects the following rule: each frame slot shall be longer than or equal to  $t_{\text{Frame\_Maximum}}$ .

If the Frame Slot mode is enabled (FSDIS = 0) and a frame transfer has been completed, the TXRDY flag is set again only after  $t_{\text{Frame\_Maximum}}$  delay, from the start of frame. So the master node cannot send a new header if the frame slot duration of the previous frame is inferior to  $t_{\text{Frame\_Maximum}}$ .

If the Frame Slot mode is disabled (FSDIS = 1) and a frame transfer has been completed, the TXRDY flag is set again immediately.

The  $t_{\text{Frame\_Maximum}}$  is calculated as follows:

If the Checksum is sent (CHKDIS = 0):

- $t_{\text{Header\_Nominal}} = 34 \times t_{\text{bit}}$
- $t_{\text{Response\_Nominal}} = 10 \times (\text{NData} + 1) \times t_{\text{bit}}$
- $t_{\text{Frame\_Maximum}} = 1.4 \times (t_{\text{Header\_Nominal}} + t_{\text{Response\_Nominal}} + 1)^{(1)}$
- $t_{\text{Frame\_Maximum}} = 1.4 \times (34 + 10 \times (\text{DLC} + 1 + 1) + 1) \times t_{\text{bit}}$
- $t_{\text{Frame\_Maximum}} = (77 + 14 \times \text{DLC}) \times t_{\text{bit}}$

If the Checksum is not sent (CHKDIS = 1):

- $t_{\text{Header\_Nominal}} = 34 \times t_{\text{bit}}$
- $t_{\text{Response\_Nominal}} = 10 \times \text{NData} \times t_{\text{bit}}$
- $t_{\text{Frame\_Maximum}} = 1.4 \times (t_{\text{Header\_Nominal}} + t_{\text{Response\_Nominal}} + 1)^{(1)}$
- $t_{\text{Frame\_Maximum}} = 1.4 \times (34 + 10 \times (\text{DLC} + 1) + 1) \times t_{\text{bit}}$
- $t_{\text{Frame\_Maximum}} = (63 + 14 \times \text{DLC}) \times t_{\text{bit}}$

Note: 1. The term "+1" leads to an integer result for  $t_{\text{Frame\_Maximum}}$  (LIN Specification 1.3).

**Figure 46-46. Frame Slot Mode**

### 46.7.9.14 LIN Errors

#### 46.7.9.14.1 Bit Error

This error is generated in master of slave node configuration, when the USART is transmitting and if the transmitted value on the Tx line is different from the value sampled on the Rx line. If a bit error is detected, the transmission is aborted at the next byte border.

This error is reported by the FLEX\_US\_CSR.LINBE flag.

#### 46.7.9.14.2 Inconsistent Synch Field Error

This error is generated in slave node configuration, if the Synch Field character received is other than 0x55.

This error is reported by the FLEX\_US\_CSR.LINISFE flag.

#### 46.7.9.14.3 Identifier Parity Error

This error is generated in slave node configuration, if the parity of the identifier is wrong. This error can be generated only if the parity feature is enabled (PARDIS = 0).

This error is reported by the FLEX\_US\_CSR.LINIPE flag.

#### 46.7.9.14.4 Checksum Error

This error is generated in master of slave node configuration, if the received checksum is wrong. This flag can be set to 1 only if the checksum feature is enabled (CHKDIS = 0).

This error is reported by the FLEX\_US\_CSR.LINCE flag.

#### 46.7.9.14.5 Slave Not Responding Error

This error is generated in master of slave node configuration, when the USART expects a response from another node (NACT = SUBSCRIBE) but no valid message appears on the bus within the time given by the maximum length of the message frame,  $t_{Frame\_Maximum}$  (see section [Frame Slot Mode](#)). This error is disabled if the USART does not expect any message (NACT = PUBLISH or NACT = IGNORE).

This error is reported by the FLEX\_US\_CSR.LINSNRE.

#### 46.7.9.14.6 Synch Tolerance Error

This error is generated in slave node configuration if, after the clock synchronization procedure, it appears that the computed baud rate deviation compared to the initial baud rate is superior to the maximum tolerance FTol\_Unsynch ( $\pm 15\%$ ).

This error is reported by the FLEX\_US\_CSR.LINSTE flag.

### 46.7.9.14.7 Header Timeout Error

This error is generated in slave node configuration, if the Header is not entirely received within the time given by the maximum length of the Header,  $t_{Header\_Maximum}$ .

This error is reported by the FLEX\_US\_CSR.LINHTE flag.

### 46.7.9.15 LIN Frame Handling

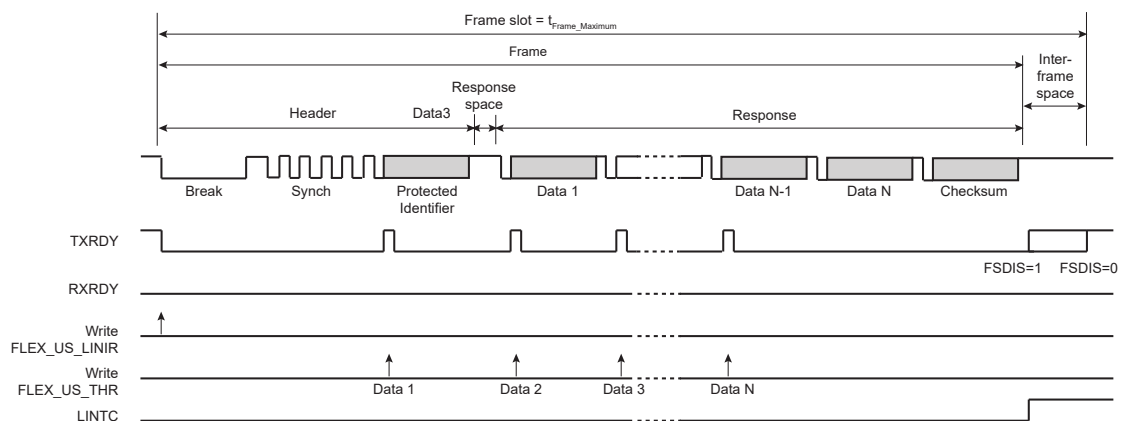

#### 46.7.9.15.1 Master Node Configuration

- Write FLEX\_US\_CR.TXEN and FLEX\_US\_CR.RXEN to enable both the transmitter and the receiver.
- Write FLEX\_US\_MR.USART\_MODE to select the LIN mode and the master node configuration.
- Write FLEX\_US\_BRGR.CD and FLEX\_US\_BRGR.FP to configure the baud rate.
- Write NACT, PARDIS, CHKDIS, CHKTYPE, DLCM, FSDIS and DLC in FLEX\_US\_LINMR to configure the frame transfer.
- Check that FLEX\_US\_CSR.TXRDY is set to 1.
- Write FLEX\_US\_LINIR.IDCHR to send the header.

What comes next depends on the NACT configuration:

- Case 1: NACT = PUBLISH, the USART sends the response.
  - Wait until FLEX\_US\_CSR.TXRDY rises.
  - Write FLEX\_US\_THR.TCHR to send a byte.
  - If all the data have not been written, repeat the two previous steps.
  - Wait until FLEX\_US\_CSR.LINTC rises.
  - Check the LIN errors.
- Case 2: NACT = SUBSCRIBE, the USART receives the response.
  - Wait until FLEX\_US\_CSR.RXRDY rises.
  - Read FLEX\_US\_RHR.RCHR.
  - If all the data have not been read, repeat the two previous steps.
  - Wait until FLEX\_US\_CSR.LINTC rises.
  - Check the LIN errors.
- Case 3: NACT = IGNORE, the USART is not concerned by the response.
  - Wait until FLEX\_US\_CSR.LINTC rises.
  - Check the LIN errors.

**Figure 46-47. Master Node Configuration, NACT = PUBLISH**

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

**Figure 46-48. Master Node Configuration, NACT = SUBSCRIBE**

**Figure 46-49. Master Node Configuration, NACT = IGNORE**

### 46.7.9.15.2 Slave Node Configuration

- Write FLEX\_US\_CR.TXEN and FLEX\_US\_CR.RXEN to enable both the transmitter and the receiver.
- Write FLEX\_US\_MR.USART\_MODE to select the LIN mode and the slave node configuration.
- Write FLEX\_US\_BRGR.CD and FLEX\_US\_BRGR.FP to configure the baud rate.
- Wait until FLEX\_US\_CSR.LINID rises.
- Check LINISFE and LINPE errors.
- Read FLEX\_US\_RHR.IDCHR.
- Write NACT, PARDIS, CHKDIS, CHKTYPE, DLCM and DLC in FLEX\_US\_LINMR to configure the frame transfer.

**IMPORTANT:** If the NACT configuration for this frame is PUBLISH, FLEX\_US\_LINMR must be written with NACT = PUBLISH even if this field is already correctly configured, in order to set the TXREADY flag and the corresponding write transfer request.

What comes next depends on the NACT configuration:

- Case 1: NACT = PUBLISH, the LIN controller sends the response.
  - Wait until FLEX\_US\_CSR.TXRDY rises.
  - Write FLEX\_US\_THR.TCHR to send a byte.
  - If all the data have not been written, repeat the two previous steps.
  - Wait until FLEX\_US\_CSR.LINTC rises.
  - Check the LIN errors.

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

- Case 2: NACT = SUBSCRIBE, the USART receives the response.
  - Wait until FLEX\_US\_CSR.RXRDY rises.
  - Read FLEX\_US\_RHR.RCHR.
  - If all the data have not been read, repeat the two previous steps.
  - Wait until FLEX\_US\_CSR.LINTC rises.
  - Check the LIN errors.
- Case 3: NACT = IGNORE, the USART is not concerned by the response.
  - Wait until FLEX\_US\_CSR.LINTC rises.
  - Check the LIN errors.

**Figure 46-50. Slave Node Configuration, NACT = PUBLISH**

**Figure 46-51. Slave Node Configuration, NACT = SUBSCRIBE**

**Figure 46-52. Slave Node Configuration, NACT = IGNORE**

### 46.7.9.16 LIN Frame Handling with the DMAC

The USART can be used in association with the DMAC in order to transfer data directly into/from the on- and off-chip memories without any processor intervention.

The DMAC uses the trigger flags, TXRDY and RXRDY, to write or read into the USART. The DMAC always writes in the Transmit Holding Register (FLEX\_US\_THR) and it always reads in the Receive

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

Holding Register (FLEX\_US\_RHR). The size of the data written or read by the DMAC in the USART is always a byte.

### 46.7.9.16.1 Master Node Configuration

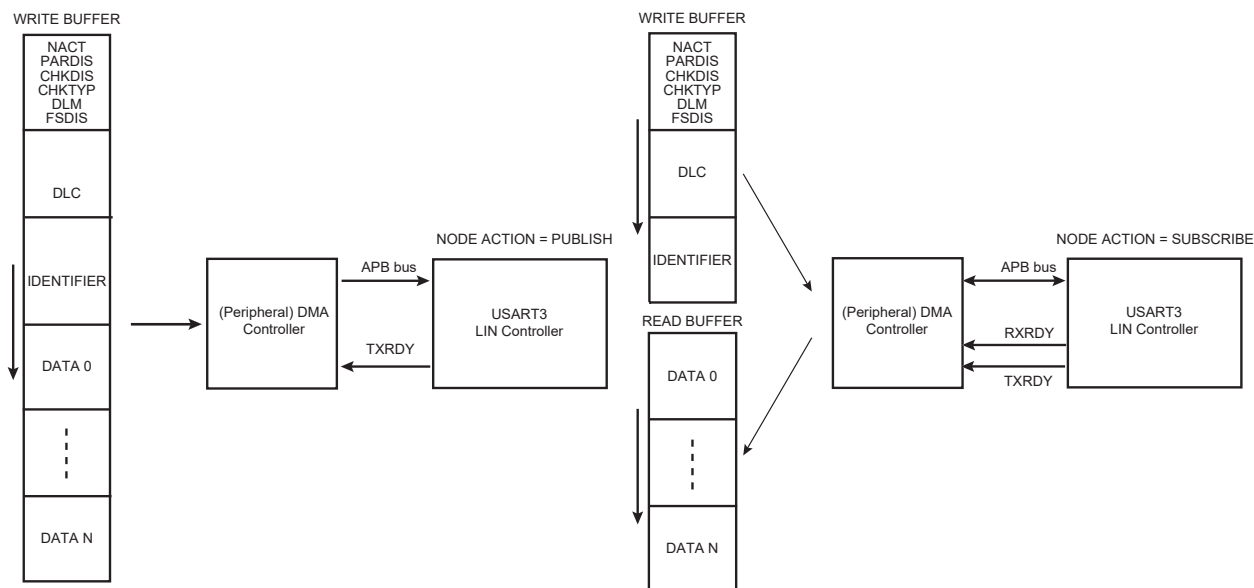

The user can choose between two DMAC modes by configuring the FLEX\_US\_LINMR.PDCM bit:

- PDCM = 1: The LIN configuration is stored in the WRITE buffer and it is written by the DMAC in the Transmit Holding register FLEX\_US\_THR (instead of the LIN Mode register FLEX\_US\_LINMR). Because the DMAC transfer size is limited to a byte, the transfer is split into two accesses. During the first access, the NACT, PARDIS, CHKDIS, CHKTYP, DLM and FSDIS bits are written. During the second access, the 8-bit DLC field is written.
- PDCM = 0: The LIN configuration is not stored in the WRITE buffer and it must be written by the user in FLEX\_US\_LINMR.

The WRITE buffer also contains the Identifier and the data, if the USART sends the response (NACT = PUBLISH).

The READ buffer contains the data if the USART receives the response (NACT = SUBSCRIBE).

**Figure 46-53. Master Node with DMAC (PDCM = 1)**

**Figure 46-54. Master Node with DMAC (PDCM = 0)**

### 46.7.9.16.2 Slave Node Configuration

In this configuration, the DMAC transfers only the data. The identifier must be read by the user in the LIN Identifier Register (FLEX\_US\_LINIR). The LIN mode must be written by the user in FLEX\_US\_LINMR.

The WRITE buffer contains the data if the USART sends the response (NACT = PUBLISH).

The READ buffer contains the data if the USART receives the response (NACT = SUBSCRIBE).

**Figure 46-55. Slave Node with DMAC**

### 46.7.9.17 Wakeup Request

Any node in a sleeping LIN cluster may request a wakeup.

In the LIN 2.0 specification, the wakeup request is issued by forcing the bus to the dominant state from 250  $\mu$ s to 5 ms. For this, it is necessary to send the character 0xF0 in order to impose five successive dominant bits. Whatever the baud rate is, this character respects the specified timings.

- Baud rate min = 1 kbit/s  $\rightarrow t_{bit} = 1$  ms  $\rightarrow 5 t_{bit} = 5$  ms
- Baud rate max = 20 kbit/s  $\rightarrow t_{bit} = 50$   $\mu$ s  $\rightarrow 5 t_{bit} = 250$   $\mu$ s

In the LIN 1.3 specification, the wakeup request should be generated with the character 0x80 in order to impose eight successive dominant bits.

Using the FLEX\_US\_LINMR.WKUPTYP bit, the user can choose to send either a LIN 2.0 wakeup request (WKUPTYP = 0) or a LIN 1.3 wakeup request (WKUPTYP = 1).

A wakeup request is transmitted by writing the FLEX\_US\_CR.LINWKUP bit to 1. Once the transfer is completed, the LINTC flag is asserted in the Status Register (FLEX\_US\_CSR). It is cleared by writing a one to the FLEX\_US\_CR.RSTSTA bit.

### 46.7.9.18 Bus Idle Timeout

If the LIN bus is inactive for a certain duration, the slave nodes shall automatically enter in Sleep mode. In the LIN 2.0 specification, this timeout is defined as 4 seconds. In the LIN 1.3 specification, it is defined as 25,000  $t_{bit}$ .

In slave Node configuration, the receiver timeout detects an idle condition on the RXD line. When a timeout is detected, the FLEX\_US\_CSR.TIMEOUT bit rises and can generate an interrupt, thus indicating to the driver to go into Sleep mode.

The timeout delay period (during which the receiver waits for a new character) is programmed in the FLEX\_US\_RTOR.TO field. If a zero is written to the TO field, the Receiver Timeout is disabled and no timeout is detected. The FLEX\_US\_CSR.TIMEOUT bit remains at 0. Otherwise, the receiver loads a 17-bit counter with the value programmed in TO. This counter is decremented at each bit period and reloaded each time a new character is received. If the counter reaches 0, the FLEX\_US\_CSR.TIMEOUT bit rises.

If STTTO is performed, the counter clock is stopped until a first character is received.

If RETTO is performed, the counter starts counting down immediately from the value TO.

**Table 46-14. Receiver Timeout Programming**

| LIN Specification | Baud Rate    | Timeout period   | TO     |
|-------------------|--------------|------------------|--------|
| 2.0               | 1,000 bit/s  | 4s               | 4,000  |
|                   | 2,400 bit/s  |                  | 9,600  |
|                   | 9,600 bit/s  |                  | 38,400 |
|                   | 19,200 bit/s |                  | 76,800 |
|                   | 20,000 bit/s |                  | 80,000 |
| 1.3               | –            | 25,000 $t_{bit}$ | 25,000 |

**46.7.10 Test Modes**

The USART can be programmed to operate in three different test modes. The internal loopback capability allows on-board diagnostics. In Loopback mode, the USART interface pins are disconnected or not and reconfigured for loopback internally or externally.

**46.7.10.1 Normal Mode**

Normal mode connects the RXD pin on the receiver input and the transmitter output on the TXD pin.

**Figure 46-56. Normal Mode Configuration**

**46.7.10.2 Automatic Echo Mode**

Automatic Echo mode allows bit-by-bit retransmission. When a bit is received on the RXD pin, it is sent to the TXD pin, as shown in the following figure. Programming the transmitter has no effect on the TXD pin. The RXD pin is still connected to the receiver input, thus the receiver remains active.

**Figure 46-57. Automatic Echo Mode Configuration**

**46.7.10.3 Local Loopback Mode**

Local Loopback mode connects the output of the transmitter directly to the input of the receiver, as shown in the following figure. The TXD and RXD pins are not used. The RXD pin has no effect on the receiver and the TXD pin is continuously driven high, as in idle state.

**Figure 46-58. Local Loopback Mode Configuration**

### 46.7.10.4 Remote Loopback Mode

Remote Loopback mode directly connects the RXD pin to the TXD pin, as shown in the following figure. The transmitter and the receiver are disabled and have no effect. This mode allows bit-by-bit retransmission.

**Figure 46-59. Remote Loopback Mode Configuration**

## 46.7.11 USART FIFOs

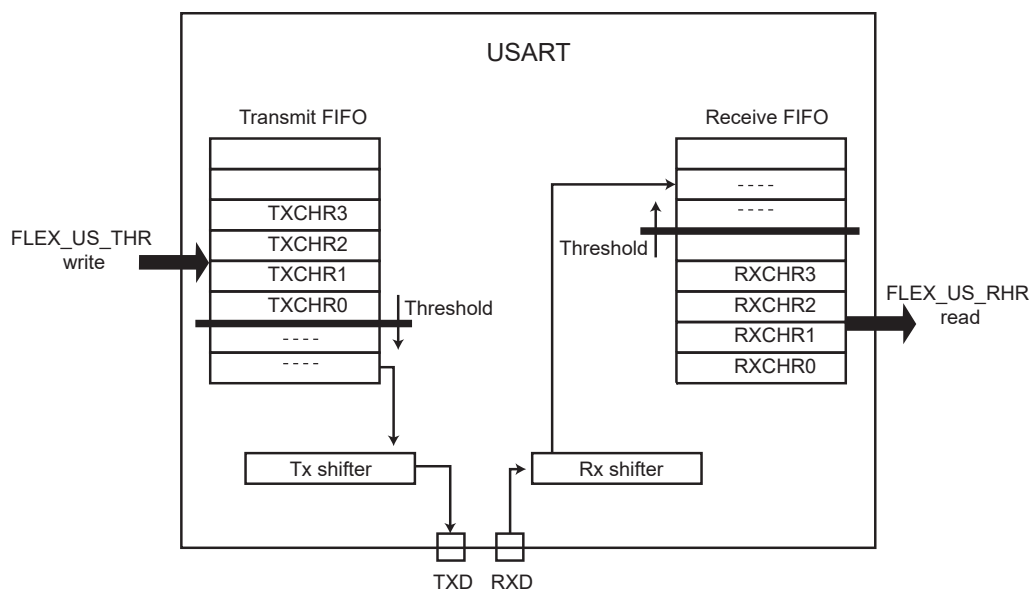

### 46.7.11.1 Overview

The USART includes two FIFOs which can be enabled/disabled using FLEX\_US\_CR.FIFOEN/FIFODIS. Both the transmitter and the receiver must be disabled before enabling or disabling the FIFOs, using the FLEX\_US\_CR.TXDIS/RXDIS bits.

Writing FLEX\_US\_CR.FIFOEN to '1' enables a 32-data Transmit FIFO and a 32-data Receive FIFO.

It is possible to write or to read single or multiple data in the same access to FLEX\_US\_THR/RHR. See sections [USART Single Data Mode](#) and [USART Multiple Data Mode](#).

**Figure 46-60. FIFOs Block Diagram**

### 46.7.11.2 Sending Data with FIFO Enabled

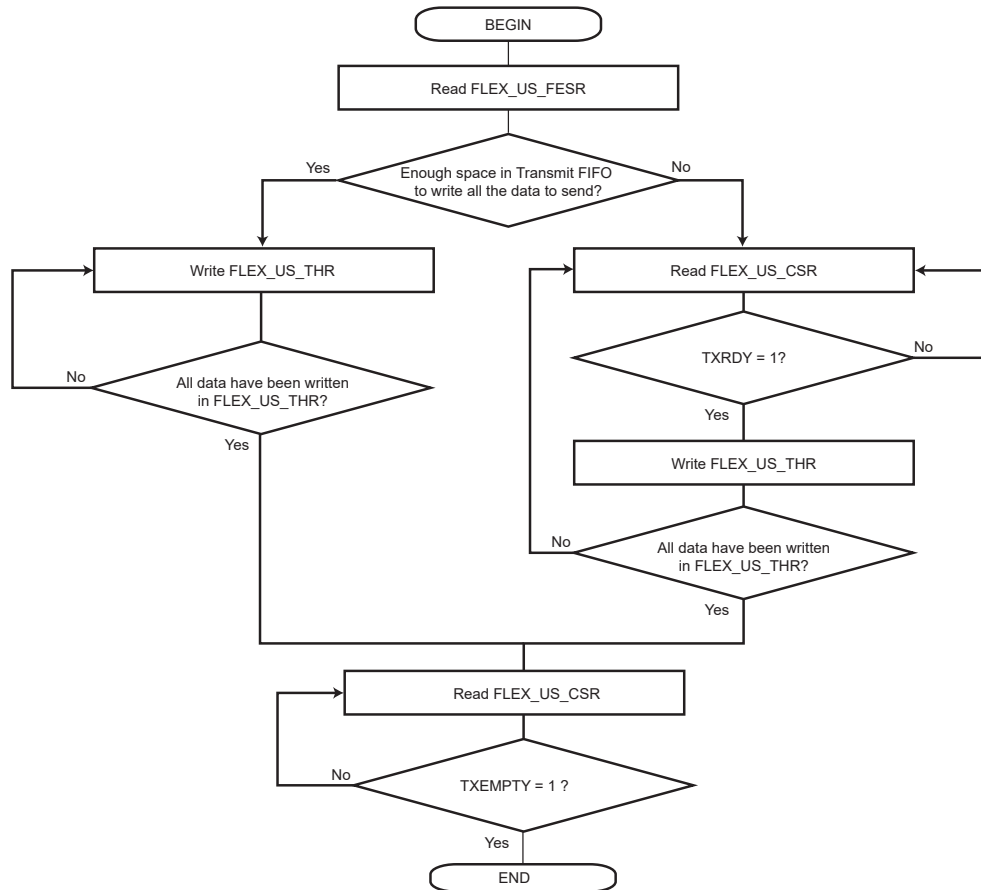

When the Transmit FIFO is enabled, write access to FLEX\_US\_THR loads the Transmit FIFO.

The FIFO level is provided in FLEX\_US\_FLR.TXFL. If the FIFO can accept the number of data to be transmitted, there is no need to monitor FLEX\_US\_CSR.TXRDY and the data can be successively written in FLEX\_US\_THR.

If the FIFO cannot accept the data due to insufficient space, wait for the TXRDY flag to be set before writing the data in FLEX\_US\_THR.

When the space in the FIFO allows only a portion of the data to be written, the TXRDY flag must be monitored before writing the remaining data.

**Figure 46-61. Sending Data with FIFO Enabled**

### 46.7.11.3 Receiving Data with FIFO Enabled

When the Receive FIFO is enabled, FLEX\_US\_RHR access reads the FIFO.

When data are present in the Receive FIFO (RXRDY flag set to '1'), the exact number of data can be checked with FLEX\_US\_FLR.RXFL. All the data can be read successively in FLEX\_US\_RHR without checking the RXRDY flag between each access.

**Figure 46-62. Receiving Data with FIFO Enabled**

#### 46.7.11.4 Clearing/Flushing FIFOs

Each FIFO can be cleared/flushed using FLEX\_US\_CR.TXFCLR/RXFCLR.

#### 46.7.11.5 TXEMPTY, TXRDY and RXRDY Behavior

FLEX\_US\_CSR.TXEMPTY, FLEX\_US\_CSR.TXRDY and FLEX\_US\_CSR.RXRDY flags display a specific behavior when FIFOs are enabled.

The TXEMPTY flag is cleared as long as there are characters in the Transmit FIFO or in the internal shift register. TXEMPTY is set when there are no characters in the Transmit FIFO and in the internal shift register.

TXRDY indicates if a data can be written in the Transmit FIFO. Thus the TXRDY flag is set as long as the Transmit FIFO can accept new data. See figure [TXRDY in Single Data Mode and TXRDYM = 0](#).

RXRDY indicates if an unread data is present in the Receive FIFO. Thus the RXRDY flag is set as soon as one unread data is in the Receive FIFO. See figure [RXRDY in Single Data Mode and RXRDYM = 0](#) below.

TXRDY and RXRDY behavior can be modified using the TXRDYM and RXRDYM fields in the USART FIFO Mode Register (FLEX\_US\_FMR) to reduce the number of accesses to FLEX\_US\_RHR/THR.

However, for some configurations, the following constraints apply:

- If FLEX\_US\_MR.MODE9 is set, FLEX\_US\_FMR.TXRDYM/RXRDYM must be cleared.
- If FLEX\_US\_MR.USART\_MODE is set to either LIN\_MASTER or LIN\_SLAVE, FLEX\_US\_FMR.TXRDYM/RXRDYM must be cleared.

See USART FIFO Mode Register for the FIFO configuration.

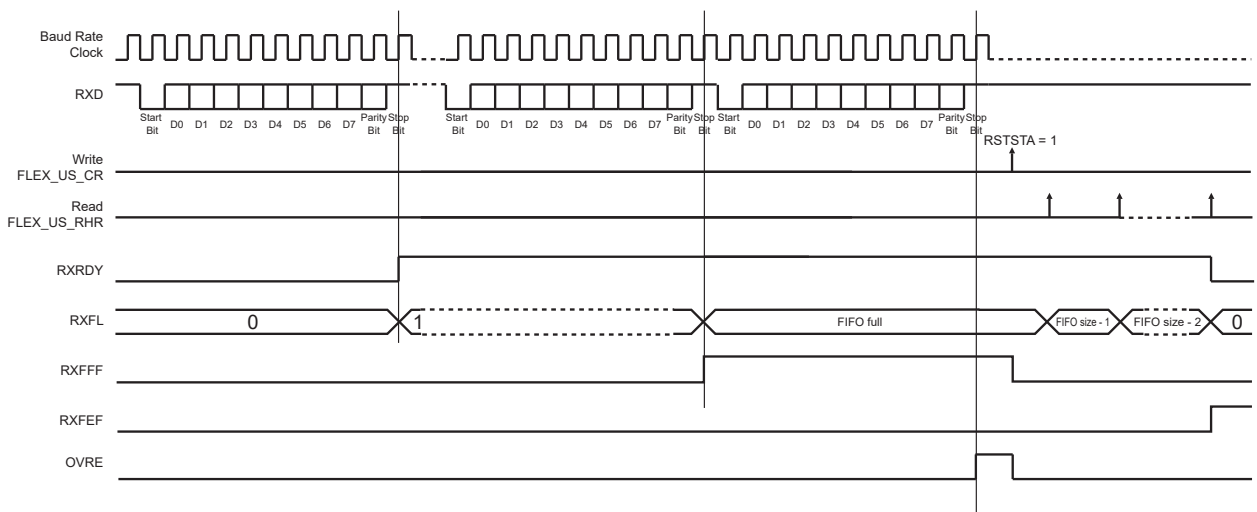

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

**Figure 46-63. TXRDY in Single Data Mode and TXRDYM = 0**

**Figure 46-64. RXRDY in Single Data Mode and RXRDYM = 0**

### 46.7.11.6 USART Single Data Mode

In Single Data mode, only one data is written every time FLEX\_US\_THR is accessed, and only one data is read every time FLEX\_US\_RHR is accessed.

When FLEX\_US\_FMR.TXRDYM = 0, the Transmit FIFO operates in Single Data mode.

When FLEX\_US\_FMR.RXRDYM = 0, the Receive FIFO operates in Single Data mode.

If FLEX\_US\_MR.MODE9 is set, or if FLEX\_US\_MR.USART\_MODE is set to either LIN\_MASTER or LIN\_SLAVE, the FIFOs must operate in Single Data mode.

See [USART Receive Holding Register \(FLEX\\_US\\_RHR\)](#) and [USART Transmit Holding Register \(FLEX\\_US\\_THR\)](#).

#### 46.7.11.6.1 DMAC

The DMAC transfer type must be configured in bytes or halfwords when FIFOs operate in Single Data mode (the same applies when FIFOs are disabled).

#### 46.7.11.7 USART Multiple Data Mode

Multiple Data mode minimizes the number of accesses by concatenating the data to send/read in one access.

When `FLEX_US_FMR.TXRDYM > 0`, the Transmit FIFO operates in Multiple Data mode.

When `FLEX_US_FMR.RXRDYM > 0`, the Receive FIFO operates in Multiple Data mode.

However, Multiple Data mode cannot be used for the following configurations:

- If `FLEX_US_MR.MODE9` is set
- If `FLEX_US_MR.USART_MODE` is set to either `LIN_MASTER` or `LIN_SLAVE`

In Multiple Data mode, it is possible to write/read up to four data in one `FLEX_US_THR/FLEX_US_RHR` access.

The number of data to write/read is defined by the size of the register access. If the access is a byte-size register access, only one data is written/read, if the access is a halfword size register access, then two data are written/read and, finally, if the access is a word-size register access, four data are written/read.

Written/read data are always right-aligned, as described in sections [USART Receive Holding Register \(FIFO Multi Data\)](#) and [USART Transmit Holding Register \(FIFO Multi Data\)](#).

As an example, if the Transmit FIFO is empty and there are six data to send, either of the following write accesses may be performed:

- six `FLEX_US_THR`-byte write accesses
- three `FLEX_US_THR`-halfword write accesses
- one `FLEX_US_THR` word write access and one `FLEX_US_THR` halfword write access

With a Receive FIFO containing six data, any of the following read accesses may be performed:

- six `FLEX_US_RHR`-byte read accesses
- three `FLEX_US_RHR`-halfword read accesses
- one `FLEX_US_RHR`-word read access and one `FLEX_US_RHR`-halfword read access

##### 46.7.11.7.1 TXRDY and RXRDY Configuration

In Multiple Data mode, it is possible to write one or more data in the same `FLEX_US_THR/FLEX_US_RHR` access. The `TXRDY` flag indicates if one or more data can be written in the FIFO depending on the configuration of `FLEX_US_FMR.TXRDYM/RXRDYM`.

As an example, if four data are written each time in `FLEX_US_THR`, it is useful to configure the `TXRDYM` field to the value '2' so that the `TXRDY` flag is at '1' only when at least four data can be written in the Transmit FIFO.

In the same way, if four data are read each time in `FLEX_US_RHR`, it is useful to configure the `RXRDYM` field to the value '2' so that the `RXRDY` flag is at '1' only when at least four unread data are in the Receive FIFO.

##### 46.7.11.7.2 DMAC

When FIFOs operate in Multiple Data mode, the DMAC transfer type must be configured in byte, halfword or word depending on the `FLEX_US_FMR.TXRDYM/RXRDYM` settings.

##### 46.7.11.8 Transmit FIFO Lock

- LIN Mode:

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

---

If a frame is aborted using the Abort LIN Transmission bit (FLEX\_US\_CR.LINABT), a lock is set on the Transmit FIFO, preventing any new frame from being sent until it is cleared. This allows clearing the FIFO if needed, resetting DMAC channels, etc., without any risk.

The TXFLOCK bit in the USART FIFO Event Status Register (FLEX\_US\_FESR) is used to check the state of the Transmit FIFO lock.

The Transmit FIFO lock can be cleared by setting FLEX\_US\_CR.TXFLCLR to '1'.

### 46.7.11.9 FIFO Pointer Error

A FIFO overflow is reported in FLEX\_US\_FESR.

If the Transmit FIFO is full and a write access is performed on FLEX\_US\_THR, it generates a Transmit FIFO pointer error and sets FLEX\_US\_FESR.TXFPTEF.

In Multiple Data mode, if the number of data written in FLEX\_US\_THR (according to the register access size) is greater than the free space in the Transmit FIFO, a Transmit FIFO pointer error is generated and FLEX\_US\_FESR.TXFPTEF is set.

A FIFO underflow is reported in FLEX\_US\_FESR.

In Multiple Data mode, if the number of data read in FLEX\_US\_RHR (according to the register access size) is greater than the number of unread data in the Receive FIFO, a Receive FIFO pointer error is generated and FLEX\_US\_FESR.RXFPTEF is set.

No pointer error occurs if the FIFO state/level is checked before writing/reading in FLEX\_US\_THR/ FLEX\_US\_RHR. The FIFO state/level can be checked either with TXRDY, RXRDY, TXFL or RXFL. When a pointer error occurs, other FIFO flags may not behave as expected; their states should be ignored.

If a Transmit pointer error occurs, a transmitter reset must be performed using FLEX\_US\_CR.RSTTX. If a Receive pointer error occurs, a receiver reset must be performed using FLEX\_US\_CR.RSTRX.

### 46.7.11.10 FIFO Thresholds

Each Transmit and Receive FIFO includes a threshold feature used to set a flag and an interrupt when a FIFO threshold is crossed. Thresholds are defined as a number of data in the FIFO, and the FIFO state (TXFL or RXFL) represents the number of data currently in the FIFO.

The Transmit FIFO threshold can be set using the field FLEX\_US\_FMR.TXFTHRES. Each time the Transmit FIFO level goes from 'above threshold' to 'equal to or below threshold', the flag FLEX\_US\_FESR.TXFTHF is set. The application is warned that the Transmit FIFO has reached the defined threshold and that it can be reloaded.

The Receive FIFO threshold can be set using the field FLEX\_US\_FMR.RXFTHRES. Each time the Receive FIFO level goes from 'below threshold' to 'equal to or above threshold', the flag FLEX\_US\_FESR.RXFTHF is set. The application is warned that the Receive FIFO has reached the defined threshold and that it can be read to prevent an underflow.

The Receive FIFO threshold 2 can be set using the field FLEX\_US\_FMR.RXFTHRES2. Each time the Receive FIFO level goes from 'above threshold 2' to 'equal to or below threshold 2', the flag FLEX\_US\_FESR.RXFTHF2 is set. The application is warned that the Receive FIFO has reached the defined threshold and that it can be read to prevent an underflow.

The TXFTHF, RXFTHF and RXTHF2 flags can be configured to generate an interrupt using FLEX\_US\_FIER and FLEX\_US\_FIDR.

### 46.7.11.11 FIFO Flags

FIFOs come with a set of flags which can be configured to generate interrupts through FLEX\_US\_FIER and FLEX\_US\_FIDR.

FIFO flags state can be read in FLEX\_US\_FESR. They are cleared by writing FLEX\_US\_CR.RSTSTA to '1'.

#### 46.7.12 USART Register Write Protection

The FLEXCOM operating mode (FLEX\_MR.OPMODE) must be set to FLEX\_MR\_OPMODE\_USART to enable access to the write protection registers.

To prevent any single software error from corrupting USART behavior, certain registers in the address space can be write-protected by setting the WPEN (Write Protection Enable) bit in the [USART Write Protection Mode Register \(FLEX\\_US\\_WPMR\)](#).

If a write access to a write-protected register is detected, the Write Protection Violation Status (WPVS) flag in the [USART Write Protection Status Register \(FLEX\\_US\\_WPSR\)](#) is set and the Write Protection Violation Source (WPVSR) field indicates the register in which the write access has been attempted.

The WPVS bit is automatically cleared after reading FLEX\_US\_WPSR.

The following registers can be write-protected when WPEN is set:

- USART Mode Register
- USART Baud Rate Generator Register
- USART Receiver Timeout Register
- USART Transmitter Timeguard Register
- USART FI DI RATIO Register
- USART IrDA FILTER Register
- USART Manchester Configuration Register
- USART Comparison Register

## 46.8 SPI Functional Description

### 46.8.1 Modes of Operation

The SPI operates in Master mode or in Slave mode.

- The SPI operates in Master mode by writing a 1 to the MSTR bit in the SPI Mode Register (FLEX\_SPI\_MR):
  - The pins NPCS0 to NPCS1 are all configured as outputs.
  - The SPCK pin is driven.
  - The MISO line is wired on the receiver input.
  - The MOSI line is driven as an output by the transmitter.
- The SPI operates in Slave mode if the MSTR bit in FLEX\_SPI\_MR is written to 0:
  - The MISO line is driven by the transmitter output.
  - The MOSI line is wired on the receiver input.
  - The SPCK pin is driven by the transmitter to synchronize the receiver.
  - The NPCS0 pin becomes an input, and is used as a slave select signal (NSS).
  - Pin NPCS1 is not driven and can be used for other purposes.

The data transfers are identically programmable for both modes of operation. The bit rate generator is activated only in Master mode.

### 46.8.2 Data Transfer

Four combinations of polarity and phase are available for data transfers. The clock polarity is programmed with the CPOL bit in the SPI Chip Select Register (FLEX\_SPI\_CSR). The clock phase is programmed with the NCPHA bit. These two parameters determine the edges of the clock signal on which data are driven and sampled. Each of the two parameters has two possible states, resulting in four possible combinations that are incompatible with one another. Consequently, a master/slave pair must use the same parameter pair values to communicate. If multiple slaves are connected and require different configurations, the master must reconfigure itself each time it needs to communicate with a different slave.

The following table shows the four modes and corresponding parameter settings.

**Table 46-15. SPI Bus Protocol Mode**

| SPI Mode | CPOL | NCPHA | Shift SPCK Edge | Capture SPCK Edge | SPCK Inactive Level |
|----------|------|-------|-----------------|-------------------|---------------------|
| 0        | 0    | 1     | Falling         | Rising            | Low                 |
| 1        | 0    | 0     | Rising          | Falling           | Low                 |
| 2        | 1    | 1     | Rising          | Falling           | High                |
| 3        | 1    | 0     | Falling         | Rising            | High                |

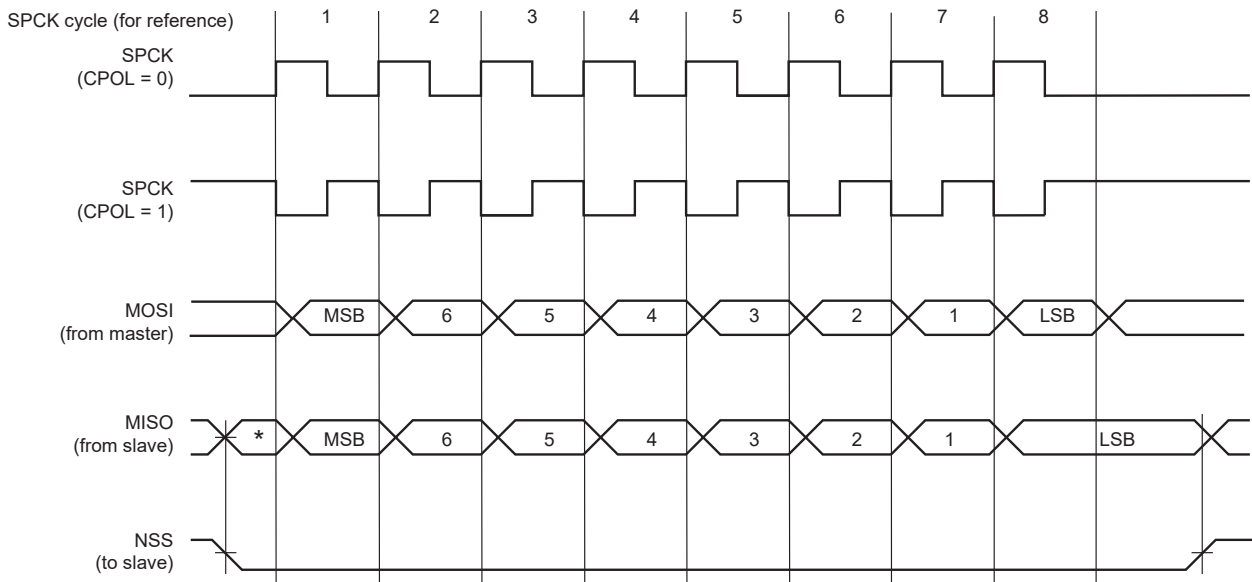

The following figures show examples of data transfers.

**Figure 46-65. SPI Transfer Format (NCPHA = 1, 8 bits per transfer)**

\* Not defined.

**Figure 46-66. SPI Transfer Format (NCPHA = 0, 8 bits per transfer)**

\* Not defined.

### 46.8.3 Master Mode Operations

When configured in Master mode, the SPI operates on the clock generated by the internal programmable bit rate generator. It fully controls the data transfers to and from the slave(s) connected to the SPI bus. The SPI drives the chip select line to the slave and the serial clock signal (SPCK).

The SPI features two holding registers, the Transmit Data Register (FLEX\_SPI\_TDR) and the Receive Data Register (FLEX\_SPI\_RDR), and a single shift register. The holding registers maintain the data flow at a constant rate.

After enabling the SPI, a data transfer starts when the processor writes to FLEX\_SPI\_TDR. The written data are immediately transferred in the shift register and the transfer on the SPI bus starts. While the data in the shift register is shifted on the MOSI line, the MISO line is sampled and shifted in the shift register. Data cannot be loaded in FLEX\_SPI\_RDR without transmitting data. If there is no data to transmit, a dummy data can be used (FLEX\_SPI\_TDR filled with ones). When the WDRBT bit is set, a new data cannot be transmitted if FLEX\_SPI\_RDR has not been read. If Receiving mode is not required, for example when communicating with a slave receiver only (such as an LCD), the receive status flags in the SPI Status Register (FLEX\_SPI\_SR) can be discarded.

Before writing the TDR, the FLEX\_SPI\_MR.PCS field must be set in order to select a slave.

If new data are written in FLEX\_SPI\_TDR during the transfer, it is kept in FLEX\_SPI\_TDR until the current transfer is completed. Then, the received data are transferred from the shift register to FLEX\_SPI\_RDR, the data in FLEX\_SPI\_TDR is loaded in the shift register and a new transfer starts.

As soon as the FLEX\_SPI\_TDR is written, the Transmit Data Register Empty (TDRE) flag in FLEX\_SPI\_SR is cleared. When the data written in FLEX\_SPI\_TDR is loaded into the shift register, the FLEX\_SPI\_SR.TDRE flag is set. The TDRE bit is used to trigger the Transmit DMA channel (see figure below).

The end of transfer is indicated by FLEX\_SPI\_SR.TXEMPTY. If a transfer delay (DLYBCT) is greater than 0 for the last transfer, TXEMPTY is set after the completion of this delay. The peripheral clock can be switched off at this time.

**Note:**

1. When the SPI is enabled, the TDRE and TXEMPTY flags are set.
2. The TXEMPTY flag alone cannot be used to detect the end of the buffer DMA transfer.

**Figure 46-67. TDRE and TXEMPTY Flag Behavior**

The transfer of received data from the shift register to FLEX\_SPI\_RDR is indicated by the Receive Data Register Full (RDRF) bit in FLEX\_SPI\_SR. When the received data are read, the RDRF bit is cleared.

If FLEX\_SPI\_RDR has not been read before new data are received, the Overrun Error bit (OVRES) in FLEX\_SPI\_SR is set. As long as this flag is set, data are loaded in FLEX\_SPI\_RDR. The user has to read the status register to clear the OVRES bit.

The following figures show, respectively, a block diagram of the SPI when operating in Master mode and a flow chart describing how transfers are handled.

### 46.8.3.1 Master Mode Block Diagram

Figure 46-68. Master Mode Block Diagram

### 46.8.3.2 Master Mode Flowchart

Figure 46-69. Master Mode

The following figure shows the behavior of Transmit Data Register Empty (TDRE), Receive Data Register (RDRF) and Transmission Register Empty (TXEMPTY) status flags within FLEX\_SPI\_SR during an 8-bit data transfer in Fixed mode without the DMAC involved.

**Figure 46-70. Status Register Flags Behavior**

### 46.8.3.3 Clock Generation

The SPI bit rate clock is generated by dividing a source clock which can be the peripheral clock or a programmable clock from the GCLK. The divider can be a value between 1 and 255.

If the SCBR field is programmed to 1 and the clock source is GCLK, the operating bit rate is peripheral clock (refer to the section “Electrical Characteristics” for the SPCK maximum frequency). Triggering a transfer while SCBR is at 0 can lead to unpredictable results.

At reset, SCBR is 0 and the user has to program it to a valid value before performing the first transfer.

The divisor can be defined independently for each chip select, as it has to be programmed in the FLEX\_SPI\_CSR.SCBR field. This allows the SPI to automatically adapt the bit rate for each interfaced peripheral without reprogramming.

If GCLK is selected as source clock (FLEX\_SPI\_MR.BRSRCCLK = 1), the bit rate is independent of the processor/bus clock. Thus, the processor clock can be changed while SPI is enabled. The processor clock frequency changes must be performed only by programming the PMC\_MCKR.PRES field (refer to the section “Power Management Controller” (PMC)). Any other method to modify the processor/bus clock frequency (PLL multiplier, etc.) is forbidden when SPI is enabled.

The peripheral clock frequency must be at least three times higher than GCLK.

### 46.8.3.4 Transfer Delays

The figure below shows a chip select transfer change and consecutive transfers on the same chip select. Three delays can be programmed to modify the transfer waveforms:

- The delay between the chip selects. It is programmable only once for all chip selects by writing the FLEX\_SPI\_MR.DLYBCS field. The SPI slave device deactivation delay is managed through DLYBCS. If there is only one SPI slave device connected to the master, the DLYBCS field does not need to be configured. If several slave devices are connected to a master, DLYBCS must be configured depending on the highest deactivation delay. Refer to the SPI slave device electrical characteristics.

- The delay before SPCK, independently programmable for each chip select by writing the DLYBS field. The SPI slave device activation delay is managed through DLYBS. Refer to the SPI slave device electrical characteristics to define DLYBS.
- The delay between consecutive transfers, independently programmable for each chip select by writing the DLYBCT field. The time required by the SPI slave device to process received data is managed through DLYBCT. This time depends on the SPI slave system activity.

These delays allow the SPI to be adapted to the interfaced peripherals and their speed and bus release time.

**Figure 46-71. Programmable Delays**

### 46.8.3.5 Peripheral Selection

The serial peripherals are selected through the assertion of the NPCS0 to NPCS1 signals. By default, all NPCS signals are high before and after each transfer.

- **Fixed Peripheral Select Mode:** SPI exchanges data with only one peripheral. Fixed Peripheral Select mode is enabled by writing the FLEX\_SPI\_MR.PS bit to zero. In this case, the current peripheral is defined by the FLEX\_SPI\_MR.PCS field, and the FLEX\_SPI\_TDR.PCS field has no effect.
- **Variable Peripheral Select Mode:** Data can be exchanged with more than one peripheral without having to reprogram FLEX\_SPI\_MR.PCS. Variable Peripheral Select Mode is enabled by setting the FLEX\_SPI\_MR.PS bit to one. The FLEX\_SPI\_TDR.PCS field is used to select the current peripheral. This means that the peripheral selection can be defined for each new data. The value must be written in a single access to FLEX\_SPI\_TDR in the following format:

[xxxxxxx(7-bit) + LASTXFER(1-bit)<sup>(1)</sup> + xxxx(4-bit) + PCS (4-bit) + TD (8 to 16-bit data)]  
 with LASTXFER at 0 or 1 depending on the CSAAT bit, and PCS equal to the chip select to assert, as defined in section [SPI Transmit Data Register \(FLEX\\_SPI\\_TDR\)](#).

Note: 1. Optional

The CSAAT, LASTXFER and CSNAAT bits are discussed in section [Peripheral Deselection with DMA](#).

If LASTXFER is used, the command must be issued after writing the last character. Instead of LASTXFER, the user can use the SPIDIS command. After the end of the DMA transfer, it is necessary to wait for the TXEMPTY flag and then write SPIDIS into the SPI Control Register (FLEX\_SPI\_CR). This does not change the configuration register values). The NPCS is disabled after the last character transfer. Then, another DMA transfer can be started if the FLEX\_SPI\_CR.SPIEN bit has previously been written.

#### **46.8.3.6 SPI Direct Access Memory Controller (DMAC)**

In both Fixed and Variable modes, the Direct Memory Access Controller (DMAC) can be used to reduce processor overhead.

The fixed peripheral selection allows buffer transfers with a single peripheral. Using the DMAC is an optimal means, as the size of the data transfer between the memory and the SPI is either 8 bits or 16 bits. However, if the peripheral selection is modified, FLEX\_SPI\_MR must be reprogrammed.

The variable peripheral selection allows buffer transfers with multiple peripherals without reprogramming FLEX\_SPI\_MR. Data written in FLEX\_SPI\_TDR is 32 bits wide and defines the real data to be transmitted and the destination peripheral. Using the DMAC in this mode requires 32-bit wide buffers, with the data in the LSBs and the PCS and LASTXFER fields in the MSBs. However, the SPI still controls the number of bits (8 to 16) to be transferred through MISO and MOSI lines with the chip select configuration registers. This is not the optimal means in terms of memory size for the buffers, but it provides a very effective means to exchange data with several peripherals without any intervention of the processor.

#### **46.8.3.7 Peripheral Chip Select Decoding**

The user can program the SPI to operate with up to 3 slave peripherals by decoding the two chip select lines, NPCS0 to NPCS1 with an external decoder/demultiplexer (see the following figure). This can be enabled by setting the FLEX\_SPI\_MR.PCSDEC bit.

When operating without decoding, the SPI makes sure that in any case only one chip select line is activated, i.e., one NPCS line driven low at a time. If two bits are defined low in a PCS field, only the lowest numbered chip select is driven low.

When operating with decoding, the SPI directly outputs the value defined by the PCS field on the NPCS lines of either FLEX\_SPI\_MR or FLEX\_SPI\_TDR (depending on PS).

As the SPI sets a default value of 0x3 on the chip select lines (i.e., all chip select lines at 1) when not processing any transfer, only 3 peripherals can be decoded.

The SPI has only two Chip Select registers. As a result, when external decoding is activated, each NPCS chip select defines the characteristics of up to two peripherals. As an example, FLEX\_SPI\_CR0 defines the characteristics of the externally decoded peripherals 0 to 1, corresponding to the PCS values 0x0 to 0x1. Consequently, the user has to make sure to connect compatible peripherals on the decoded chip select lines 0 to 1 and 2. The following figure shows this type of implementation.

If the CSAAT bit is used, with or without the DMAC, the mode fault detection for NPCS0 line must be disabled. This is not needed for all other chip select lines since mode fault detection is only on NPCS0.

**Figure 46-72. Chip Select Decoding Application Block Diagram: Single Master/Multiple Slave Implementation**

#### 46.8.3.8 Peripheral Deselection without DMA

During a transfer of more than one data on a Chip Select without the DMA, FLEX\_SPI\_TDR is loaded by the processor, the TDRE flag rises as soon as the content of FLEX\_SPI\_TDR is transferred into the internal shift register. When this flag is detected high, FLEX\_SPI\_TDR can be reloaded. If this reload by the processor occurs before the end of the current transfer, and if the next transfer is performed on the same chip select as the current transfer, the Chip Select is not deasserted between the two transfers. But depending on the application software handling the SPI status register flags (by interrupt or polling method) or servicing other interrupts or other tasks, the processor may not reload FLEX\_SPI\_TDR in time to keep the chip select active (low). A null DLYBCT value (delay between consecutive transfers) in FLEX\_SPI\_CSR, gives even less time for the processor to reload FLEX\_SPI\_TDR. With some SPI slave peripherals, if the chip select line must remain active (low) during a full set of transfers, communication errors can occur.

To facilitate interfacing with such devices, the Chip Select registers [CSR0...CSR1] can be programmed with the Chip Select Active After Transfer (CSAAT) bit to 1. This allows the chip select lines to remain in their current state (low = active) until a transfer to another chip select is required. Even if FLEX\_SPI\_TDR is not reloaded, the chip select remains active. To de-assert the chip select line at the end of the transfer, the Last Transfer (LASTXFER) bit in FLEX\_SPI\_CR must be set after writing the last data to transmit into FLEX\_SPI\_TDR.

#### 46.8.3.9 Peripheral Deselection with DMA

DMA provides faster reloads of FLEX\_SPI\_TDR compared to software. However, depending on the system activity, it is not guaranteed that FLEX\_SPI\_TDR is written with the next data before the end of the current transfer. Consequently, a data can be lost by the deassertion of the NPCS line for SPI slave peripherals requiring the chip select line to remain active between two transfers. The only way to guarantee a safe transfer in this case is the use of the CSAAT and LASTXFER bits.

When the CSAAT bit is cleared, the NPCS does not rise in all cases between two transfers on the same peripheral. During a transfer on a Chip Select, the TDRE flag rises as soon as the content of FLEX\_SPI\_TDR is transferred into the internal shift register. When this flag is detected, FLEX\_SPI\_TDR can be reloaded. If this reload occurs before the end of the current transfer and if the next transfer is performed on the same chip select as the current transfer, the Chip Select is not deasserted between the two transfers. This can lead to difficulties to interface with some serial peripherals requiring the chip select

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

to be deasserted after each transfer. To facilitate interfacing with such devices, FLEX\_SPI\_CSR can be programmed with the Chip Select Not Active After Transfer (CSNAAT) bit to 1. This allows the chip select lines to be deasserted systematically during a time “DLYBCS” (the value of the CSNAAT bit is processed only if the CSAAT bit is cleared for the same chip select).

The following figure shows different peripheral deselection cases and the effect of the CSAAT and CSNAAT bits.

**Figure 46-73. Peripheral Deselection**

### 46.8.3.10 Mode Fault Detection

The SPI has the capability to operate in multi-master environment. Consequently, the NPCS0/NSS line must be monitored. If one of the masters on the SPI bus is currently transmitting, the NPCS0/NSS line is low and the SPI must not transmit a data. A mode fault is detected when the SPI is programmed in Master mode and a low level is driven by an external master on the NPCS0/NSS signal. In multi-master environment, NPCS0, MOSI, MISO and SPCK pins must be configured in open drain (through the PIO controller). When a mode fault is detected, the FLEX\_SPI\_SR.MODF bit is set until FLEX\_SPI\_SR is

read and the SPI is automatically disabled until it is re-enabled by writing the FLEX\_SPI\_CR.SPIEN bit to 1.

By default, the mode fault detection is enabled. The user can disable it by setting the FLEX\_SPI\_MR.MODFDIS bit.

#### 46.8.4 SPI Slave Mode

When operating in Slave mode, the SPI processes data bits on the clock provided on the SPI clock pin (SPCK).

The SPI waits until NSS goes active before receiving the serial clock from an external master. When NSS falls, the clock is validated and the data are loaded in FLEX\_SPI\_RDR according to the configuration value of the FLEX\_SPI\_CSR0.BITS field. These bits are processed following a phase and a polarity defined respectively by the FLEX\_SPI\_CSR0.NCPHA and FLEX\_SPI\_CSR0.CPOL bits. Note that the BITS field, CPOL bit and NCPHA bit of the other Chip Select registers have no effect when the SPI is programmed in Slave mode.

The bits are shifted out on the MISO line and sampled on the MOSI line.

**Note:** For more information on the BITS field, see also the note below the FLEX\_SPI\_CSRx register bitmap in section [SPI Chip Select Register](#)

When all bits are processed, the received data are transferred in FLEX\_SPI\_RDR and the RDRF bit rises. If FLEX\_SPI\_RDR has not been read before new data are received, the Overrun Error bit (OVRES) in FLEX\_SPI\_SR is set. As long as this flag is set, data are loaded in FLEX\_SPI\_RDR. The user must read FLEX\_SPI\_SR to clear the OVRES bit.

When a transfer starts, the data shifted out is the data present in the shift register. If no data has been written in FLEX\_SPI\_TDR, the last data received is transferred. If no data has been received since the last reset, all bits are transmitted low, as the shift register resets to 0.

When a first data is written in FLEX\_SPI\_TDR, it is transferred immediately in the shift register and the TDRE flag rises. If new data is written, it remains in FLEX\_SPI\_TDR until a transfer occurs, i.e., NSS falls and there is a valid clock on the SPCK pin. When the transfer occurs, the last data written in FLEX\_SPI\_TDR is transferred in the shift register and the TDRE flag rises. This enables frequent updates of critical variables with single transfers.

Then, a new data is loaded in the shift register from FLEX\_SPI\_TDR. If no character is ready to be transmitted, i.e., no character has been written in FLEX\_SPI\_TDR since the last load from FLEX\_SPI\_TDR to the shift register, FLEX\_SPI\_TDR is retransmitted. In this case the Underrun Error Status Flag (UNDES) is set in FLEX\_SPI\_SR.

If NSS rises between two characters, it must be kept high for two MCK clock periods or more and the next SPCK capture edge must not occur less than four MCK periods after NSS rise.

The following figure shows a block diagram of the SPI when operating in Slave mode.

**Figure 46-74. Slave Mode Functional Block Diagram**

### 46.8.5 SPI Comparison Function on Received Character

The comparison is only relevant for SPI Slave mode (MSTR = 0 in FLEX\_US\_MR).

The effect of a comparison match changes if the system is in Wait or Active mode.

In Wait mode, if asynchronous partial wakeup is enabled, a system wakeup is performed (see section [46.8.6 SPI Asynchronous and Partial Wake-up \(SleepWalking\)](#)).

In Active mode, the CMP flag in FLEX\_SPI\_SR is raised. It is set when the received character matches the conditions programmed in the SPI Comparison Register (FLEX\_SPI\_CMPR). The CMP flag is set as soon as FLEX\_SPI\_RDR is loaded with the new received character. The CMP flag is cleared by reading FLEX\_SPI\_SR.

The SPI Comparison Register can be programmed to provide different comparison methods. These are listed below:

- If VAL1 equals VAL2, then the comparison is performed on a single value and the flag is set to 1 if the received character equals VAL1.
- If VAL1 is strictly lower than VAL2, then any value between VAL1 and VAL2 sets the CMP flag.
- If VAL1 is strictly higher than VAL2, then the flag CMP is set to 1 if any received character equals VAL1 or VAL2.

When FLEX\_SPI\_MR.CMPMODE is cleared, all received data is loaded in FLEX\_SPI\_RDR and the CMP flag provides the status of the comparison result.

By setting the CMPMODE bit, the comparison result triggers the start of FLEX\_SPI\_RDR loading (see the figure below). The trigger condition exists as soon as the received character value matches the conditions defined by VAL1 and VAL2 in FLEX\_SPI\_CMPR. The comparison trigger event is restarted by writing a 1 to the FLEX\_SPI\_CR.REQCLR bit.

The value programmed in VAL1 and VAL2 fields must not exceed the maximum value of the received character (see BITS field in SPI Chip Select Register (FLEX\_SPI\_CSR)).

**Figure 46-75. Receive Data Register Management**

CMPMODE = 1, VAL1 = VAL2 = 0x06

#### 46.8.6 SPI Asynchronous and Partial Wake-up (SleepWalking)

This operating mode is a means of data pre-processing that qualifies an incoming event, thus allowing the SPI to decide whether or not to wake up the system. Asynchronous and partial wake-up is mainly used when the system is in Wait mode (refer to the section “Power Management Controller” (PMC) for further details). It can also be enabled when the system is fully running.

Asynchronous and partial wake-up can be used only when SPI is configured in Slave mode (FLEX\_SPI\_MR.MSTR is cleared).

The maximum SPI clock (SPCK) frequency that can be provided by the SPI master is bounded by the peripheral clock frequency. The SPCK frequency must be lower than or equal to the peripheral clock. The NSS line must be deasserted by the SPI master between two characters. The NSS deassertion duration time must be greater than or equal to six peripheral clock periods. The time between the assertion of NSS line (falling edge) and the first edge of the SPI clock must be higher than 15  $\mu$ s.

The FLEX\_SPI\_RDR register must be read before enabling the asynchronous and partial wake-up.

When asynchronous and partial wake-up is enabled for the SPI (refer to the section “Power Management Controller” (PMC)), the PMC decodes a clock request from the SPI. The request is generated as soon as there is a falling edge on the NSS line as this may indicate the beginning of a frame. If the system is in Wait mode (processor and peripheral clocks switched off), the PMC restarts the fast RC oscillator and provides the clock only to the SPI.

The SPI processes the received frame and compares the received character with VAL1 and VAL2 in FLEX\_SPI\_CMPR (section [FLEX\\_SPI\\_CMPR](#)).

The SPI instructs the PMC to disable the peripheral clock if the received character value does not meet the conditions defined by VAL1 and VAL2 fields in FLEX\_SPI\_CMPR (see [Figure 46-76](#)).

If the received character value meets the conditions, the SPI instructs the PMC to exit the system from Wait mode (see [Figure 46-77](#)).

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

The VAL1 and VAL2 fields can be programmed to provide different comparison methods and thus matching conditions.

- If VAL1 equals VAL2, then the comparison is performed on a single value and the wake-up is triggered if the received character equals VAL1.
- If VAL1 is strictly lower than VAL2, then any value between VAL1 and VAL2 wakes up the system.
- If VAL1 is strictly higher than VAL2, the wake-up is triggered if any received character equals VAL1 or VAL2.
- If VAL1 = 0 and VAL2 = 65535, the wake-up is triggered as soon as a character is received.

If the processor and peripherals are running, the SPI can be configured in Asynchronous and Partial Wake-up mode by enabling the PMC\_SLPWK\_ER (refer to the section “Power Management Controller” (PMC)). When activity is detected on the receive line, the SPI requests the clock from the PMC and the comparison is performed. If there is a comparison match, the SPI continues to request the clock. If there is no match, the clock is switched off for the SPI only, until a new activity is detected.

The CMPMODE configuration has no effect when Asynchronous and Partial Wake-up mode is enabled for the SPI (refer to PMC\_SLPWK\_ER in the section “Power Management Controller” (PMC)).

When the system is in Active mode and the SPI enters Asynchronous and Partial Wake-up mode, the flag RDRF must be programmed as the unique source of the SPI interrupt.

When the system exits Wait mode as the result of a matching condition, the RDRF flag is used to determine if the SPI is the source for the exit from Wait mode.

### Figure 46-76. Asynchronous Wake-up Use Case Example

Case with VAL1 = VAL2 = 0x55

**Figure 46-77. Asynchronous Event Generating Only Partial Wake-up**

Case with VAL1 = VAL2 = 0x55

### 46.8.7 SPI FIFOs

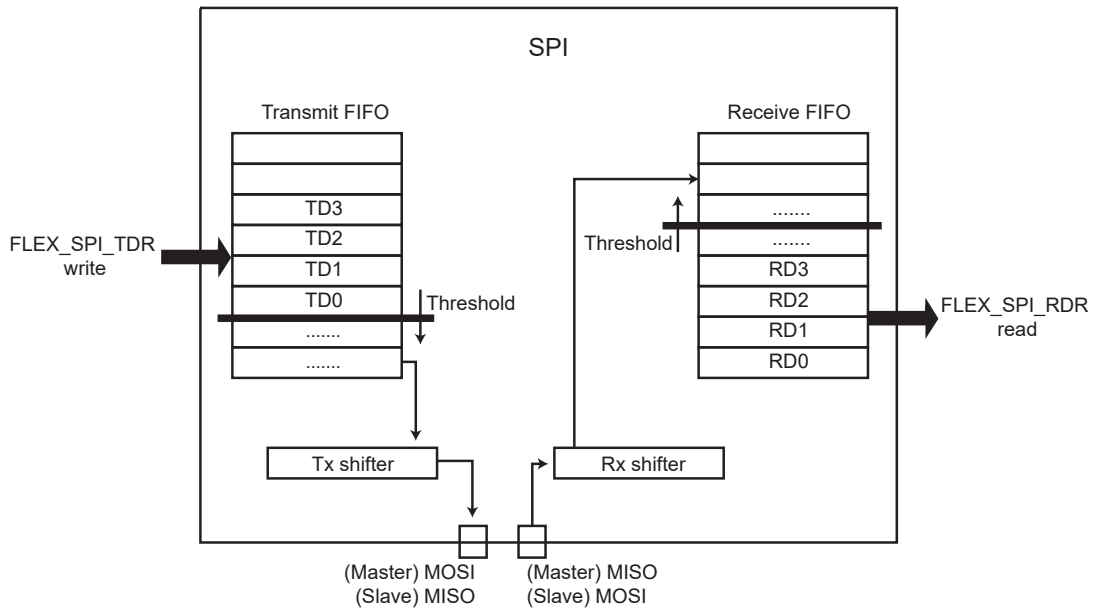

#### 46.8.7.1 Overview

The SPI includes two FIFOs which can be enabled/disabled using the FLEX\_SPI\_CR.FIFOEN/FIFODIS. The SPI module must be disabled before enabling or disabling the SPI FIFOs (FLEX\_SPI\_CR.SPIDIS).

Writing FLEX\_SPI\_CR.FIFOEN to '1' enables a FIFO\_DEPTH-data Transmit FIFO and a FIFO\_DEPTH-data Receive FIFO.

It is possible to write or to read single or multiple data in the same access to FLEX\_SPI\_TDR/RDR. See sections [SPI Single Data Mode](#) and [SPI Multiple Data Mode](#).

**Figure 46-78. FIFOs Block Diagram**

#### 46.8.7.2 Sending Data with FIFO Enabled

When the Transmit FIFO is enabled, write access to FLEX\_SPI\_TDR loads the Transmit FIFO.

The FIFO level is provided in FLEX\_SPI\_FLR.TXFL. If the FIFO can accept the number of data to be transmitted, there is no need to monitor FLEX\_SPI\_SR.TDRE and the data can be successively written in FLEX\_SPI\_TDR.

If the FIFO cannot accept the data due to insufficient space, wait for the TDRE flag to be set before writing the data in FLEX\_SPI\_TDR.

When the space in the FIFO allows only a portion of the data to be written, the TDRE flag must be monitored before writing the remaining data.

**Figure 46-79. Sending Data with FIFO Enabled**

### 46.8.7.3 Receiving Data with FIFO Enabled

When the Receive FIFO is enabled, FLEX\_SPI\_RDR access reads the FIFO.

When data are present in the Receive FIFO (RDRF flag set to '1'), the exact number of data can be checked with FLEX\_SPI\_FLR.RXFL. All the data can be read successively in FLEX\_SPI\_RDR without checking the RDRF flag between each access.

**Figure 46-80. Receiving Data with FIFO Enabled**

#### 46.8.7.4 Clearing/Flushing FIFOs

Each FIFO can be cleared/flushed using FLEX\_SPI\_CR.TXFCLR/RXFCLR.

#### 46.8.7.5 TXEMPTY, TDRE and RDRF Behavior

FLEX\_SPI\_SR.TXEMPTY, FLEX\_SPI\_SR.TDRE and FLEX\_SPI\_SR.RDRF flags display a specific behavior when FIFOs are enabled.

The TXEMPTY flag is cleared as long as there are characters in the Transmit FIFO or in the internal shift register. TXEMPTY is set when there are no characters in the Transmit FIFO and in the internal shift register.

TDRE indicates if a data can be written in the Transmit FIFO. Thus the TDRE flag is set as long as the Transmit FIFO can accept new data. See figure [TDRE in Single Data Mode and TXRDYM = 0](#).

RDRF indicates if an unread data is present in the Receive FIFO. Thus the RDRF flag is set as soon as one unread data is in the Receive FIFO. See figure [RDRF in Single Data Mode and RXRDYM = 0](#).

TDRE and RDRF behavior can be modified using the TXRDYM and RXRDYM fields in the SPI FIFO Mode Register (FLEX\_SPI\_FMR) to reduce the number of accesses to FLEX\_SPI\_TDR/RDR. However, for some configurations, the following constraints apply:

- When the Variable Peripheral Select mode is used (FLEX\_SPI\_MR.PS=1), TXRDYM/RXRDYM must be cleared.
- In Master mode (FLEX\_SPI\_MR.MSTR=1), RXRDYM must be cleared.

As an example, in Master mode, the Transmit FIFO can be loaded with multiple data in the same access by configuring TXRDYM>0.

See SPI FIFO Mode Register ([FLEX\\_SPI\\_FMR](#)) for the FIFO configuration.

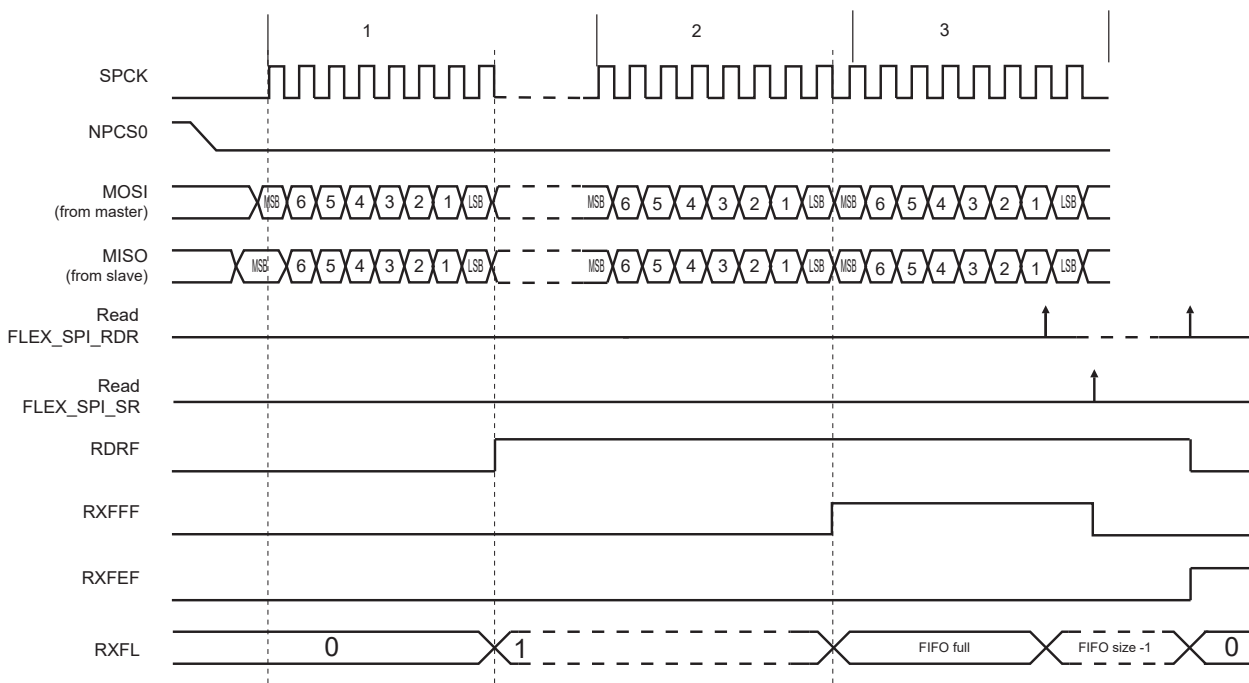

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

**Figure 46-81. TDRE in Single Data Mode and TXRDYM = 0**

**Figure 46-82. RDRF in Single Data Mode and RXRDYM = 0**

### 46.8.7.6 SPI Single Data Mode

In Single Data mode, only one data is written every time FLEX\_SPI\_TDR is accessed, and only one data is read every time FLEX\_SPI\_RDR is accessed.

When FLEX\_SPI\_FMR.TXRDYM = 0, the Transmit FIFO operates in Single Data mode.

When FLEX\_SPI\_FMR.RXRDYM = 0, the Receive FIFO operates in Single Data mode.

If Master mode is used (FLEX\_SPI\_MR.MSTR=1), the Receive FIFO must operate in Single Data mode.

If Variable Peripheral Select mode is used (FLEX\_SPI\_MR.PS=1), the Transmit FIFO must operate in Single Data mode.

See sections [SPI Transmit Data Register](#) and [SPI Receive Data Register](#).

### 46.8.7.6.1 DMAC

When FIFOs operate in Single Data mode, the DMAC transfer type must be configured either in bytes, halfwords or words depending on FLEX\_SPI\_MR.PS bit value and FLEX\_SPI\_CSRx.BITS field value.

The same applies when FIFOs are disabled.

### 46.8.7.7 SPI Multiple Data Mode

Multiple Data mode minimizes the number of accesses by concatenating the data to send/read in one access.

When FLEX\_SPI\_FMR.TXRDYM > 0, the Transmit FIFO operates in Multiple Data mode.

When FLEX\_SPI\_FMR.RXRDYM > 0, the Receive FIFO operates in Multiple Data mode.

Multiple data can be read from the Receive FIFO only in Slave mode (FLEX\_SPI\_MR.MSTR=0).

The Transmit FIFO can be loaded with multiple data in the same access by configuring TXRDYM>0 and when FLEX\_SPI\_MR.PS=0.

In Multiple Data mode, up to two data can be written in one FLEX\_SPI\_TDR write access. It is also possible to read up to four data in one FLEX\_SPI\_RDR access if FLEX\_SPI\_CSRx.BITS is configured to '0' (8-bit data size) and up to two data if FLEX\_SPI\_CSRx.BITS is configured to a value other than '0' (more than 8-bit data size).

The number of data to write/read is defined by the size of the register access. If the access is a byte-size register access, only one data is written/read. If the access is a halfword size register access, then up to two data are read and only one data is written. Lastly, if the access is a word-size register access, then up to four data are read and up to two data are written.

Written/read data are always right-aligned, as described in sections [SPI Receive Data Register \(FIFO Multiple Data, 8-bit\)](#), [SPI Receive Data Register \(FIFO Multiple Data, 16-bit\)](#) and [SPI Transmit Data Register \(FIFO Multiple Data, 8- to 16-bit\)](#).

As an example, if the Transmit FIFO is empty and there are six data to send, either of the following write accesses may be performed:

- six FLEX\_SPI\_TDR-byte write accesses
- three FLEX\_SPI\_TDR-halfword write accesses

With a Receive FIFO containing six data, any of the following read accesses may be performed:

- six FLEX\_SPI\_RDR-byte read accesses
- three FLEX\_SPI\_RDR-halfword read accesses
- one FLEX\_SPI\_RDR-word read access and one FLEX\_SPI\_RDR-halfword read access

### 46.8.7.7.1 TDRE and RDRF Configuration

In Multiple Data mode, it is possible to write one or more data in the same FLEX\_SPI\_TDR/RDR access. The TDRE flag indicates if one or more data can be written in the FIFO depending on the configuration of FLEX\_SPI\_FMR.TXRDYM/RXRDYM.

As an example, if two data are written each time in FLEX\_SPI\_TDR, it is useful to configure the TXRDYM field to the value '1' so that the TDRE flag is at '1' only when at least two data can be written in the Transmit FIFO.

Similarly, if four data are read each time in FLEX\_SPI\_RDR, it is useful to configure the RXRDYM field to the value '2' so that the RDRF flag is at '1' only when at least four unread data are in the Receive FIFO.

### 46.8.7.7.2 DMAC

It is mandatory to configure DMAC channel size (byte, halfword or word) according to FLEX\_SPI\_FMR.TXRDYM/RXRDYM configuration. See section [SPI Multiple Data Mode](#) for constraints.

### 46.8.7.8 FIFO Pointer Error

A FIFO overflow is reported in FLEX\_SPI\_SR.

If the Transmit FIFO is full and a write access is performed on FLEX\_SPI\_TDR, it generates a Transmit FIFO pointer error and sets FLEX\_SPI\_SR.TXFPTEF.

In Multiple Data mode, if the number of data written in FLEX\_SPI\_TDR (according to the register access size) is greater than the free space in the Transmit FIFO, a Transmit FIFO pointer error is generated and FLEX\_SPI\_SR.TXFPTEF is set.

A FIFO underflow is reported in FLEX\_SPI\_SR.

In Multiple Data mode, if the number of data read in FLEX\_SPI\_RDR (according to the register access size) is greater than the number of unread data in the Receive FIFO, a Receive FIFO pointer error is generated and FLEX\_SPI\_SR.RXFPTEF is set.

No pointer error occurs if the FIFO state/level is checked before writing/reading in FLEX\_SPI\_TDR/SPI\_RDR. The FIFO state/level can be checked either with TXRDY, RXRDY, TXFL or RXFL. When a pointer error occurs, other FIFO flags may not behave as expected; their states should be ignored.

If a pointer error occurs, a software reset must be performed using FLEX\_SPI\_CR.SWRST (configuration will be lost).

### 46.8.7.9 FIFO Thresholds

Each Transmit and Receive FIFO includes a threshold feature used to set a flag and an interrupt when a FIFO threshold is crossed. Thresholds are defined as a number of data in the FIFO, and the FIFO state (TXFL or RXFL) represents the number of data currently in the FIFO.

The Transmit FIFO threshold can be set using the field FLEX\_SPI\_FMR.TXFTHRES. Each time the Transmit FIFO level goes from 'above threshold' to 'equal to or below threshold', the flag FLEX\_SPI\_SR.TXFTHF is set. The application is warned that the Transmit FIFO has reached the defined threshold and that it can be reloaded.

The Receive FIFO threshold can be set using the field FLEX\_SPI\_FMR.RXFTHRES. Each time the Receive FIFO level goes from 'below threshold' to 'equal to or above threshold', the flag FLEX\_SPI\_SR.RXFTHF is set. The application is warned that the Receive FIFO has reached the defined threshold and that it can be read to prevent an underflow.

The TXFTHF and RXFTHF flags can be configured to generate an interrupt using FLEX\_SPI\_IER and FLEX\_SPI\_IDR.

### 46.8.7.10 FIFO Flags

FIFOs come with a set of flags which can be configured to generate interrupts through FLEX\_SPI\_IER and FLEX\_SPI\_IDR.

FIFO flags state can be read in FLEX\_SPI\_SR. They are cleared when FLEX\_SPI\_SR is read.

### 46.8.8 SPI Register Write Protection

The FLEXCOM operating mode (FLEX\_MR.OPMODE) must be set to FLEX\_MR\_OPMODE\_SPI to enable access to the write protection registers.

To prevent any single software error from corrupting SPI behavior, certain registers in the address space can be write-protected by setting the WPEN (Write Protection Enable), WPITEN (Write Protection Interrupt Enable), and/or WPCREN (Write Protection Control Enable) bits in the SPI Write Protection Mode Register (FLEX\_SPI\_WPMR).

If a write access to a write-protected register is detected, the Write Protection Violation Status (WPVS) flag in the SPI Write Protection Status Register (FLEX\_SPI\_WPSR) is set and the Write Protection Violation Source (WPVSR) field indicates the register in which the write access has been attempted.

The WPVS bit is automatically cleared after reading FLEX\_SPI\_WPSR.

The following registers can be write-protected when WPEN is set:

- SPI Mode Register
- SPI Chip Select Register
- SPI Comparison Register

The following registers can be write-protected when WPITEN is set:

- SPI Interrupt Enable Register
- SPI Interrupt Disable Register

The following register can be write-protected when WPCREN is set:

- SPI Control Register

## 46.9 TWI Functional Description

### 46.9.1 Transfer Format

The data put on the TWD line must be 8 bits long. Data are transferred MSB first; each byte must be followed by an acknowledgement. The number of bytes per transfer is unlimited (see figure below).

**Figure 46-83. Transfer Format**

Each transfer begins with a START condition and terminates with a STOP condition (see figure below).

- A high-to-low transition on the TWD line while TWCK is high defines the START condition.
- A low-to-high transition on the TWD line while TWCK is high defines a STOP condition.

**Figure 46-84. START and STOP Conditions**

## 46.9.2 Modes of Operation

The TWI has different modes of operation:

- Master Transmitter mode (Standard and Fast modes only)
- Master Receiver mode (Standard and Fast modes only)
- Multi-master Transmitter mode (Standard and Fast modes only)
- Multi-master Receiver mode (Standard and Fast modes only)
- Slave Transmitter mode (Standard, Fast and High-speed modes)
- Slave Receiver mode (Standard, Fast and High-speed modes)

These modes are described in the following sections.

## 46.9.3 Master Mode

### 46.9.3.1 Definition

The master is the device that starts a transfer, generates a clock and stops it. This operating mode is not available if High-speed mode is selected.

### 46.9.3.2 Programming Master Mode

The following fields must be programmed before entering Master mode:

1. DADR (+ IADRSZ + IADR if a 10-bit device is addressed): The device address is used to access slave devices in Read or Write mode.
2. CWGR + CKDIV + CHDIV + CLDIV: Clock waveform.
3. SVDIS: Disables Slave mode.
4. MSEN: Enables Master mode.

**Note:** If the TWI is already in Master mode, the device address (DADR) can be configured without disabling the Master mode.

### 46.9.3.3 Transfer Speed/Bit Rate

The TWI speed is defined in FLEX\_TWI\_CWGR. The TWI bit rate can be based either on the peripheral clock if the BRSRCCLK bit value is 0 or on a programmable clock source provided by the GCLK if the BRSRCCLK bit value is 1.

If BRSRCCLK = 1, the bit rate is independent of the processor/peripheral clock and thus processor/peripheral clock frequency can be changed without affecting the TWI transfer rate.

The GCLK frequency must be at least three times lower than the peripheral clock frequency.

### 46.9.3.4 Master Transmitter Mode

This operating mode is not available if High-speed mode is selected.

After the master initiates a START condition when writing into the Transmit Holding register FLEX\_TWI\_THR, it sends a 7-bit slave address, configured in the Master Mode Register (DADR in FLEX\_TWI\_MMR), to notify the slave device. The bit following the slave address indicates the transfer direction, 0 in this case (FLEX\_TWI\_MMR.MREAD = 0).

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

The TWI transfers require the slave to acknowledge each received byte. During the acknowledge clock pulse (ninth pulse), the master releases the data line (HIGH), enabling the slave to pull it down in order to generate the acknowledge. If the slave does not acknowledge the byte, then the Not Acknowledge flag (NACK) is set in the TWI Status Register (FLEX\_TWI\_SR) of the master and a STOP condition is sent. Alternatively, if the FLEX\_TWI\_MMR.NOAP bit is set, no stop condition will be sent and a START or STOP condition must be triggered manually through the FLEX\_TWI\_CR.START or FLEX\_TWI\_CR.STOP bit once the software is ready for the transmission of the condition. The NACK flag must be cleared by reading the TWI Status Register (FLEX\_TWI\_SR) before the next write into the TWI Transmit Holding Register (FLEX\_TWI\_THR). As with the other status bits, an interrupt can be generated if enabled in the interrupt enable Register (FLEX\_TWI\_IER). If the slave acknowledges the byte, the data written in FLEX\_TWI\_THR is then shifted in the internal shifter and transferred. When an acknowledge is detected, the TXRDY bit is set until a new write in FLEX\_TWI\_THR.

TXRDY is used as transmit ready for the DMA transmit channel.

**Note:** To clear the TXRDY flag in Master mode, write the FLEX\_TWI\_CR.MSDIS bit to 1, then write the FLEX\_TWI\_CR.MSEN bit to 1.

While no new data is written in FLEX\_TWI\_THR, the serial clock line is tied low. When new data is written in FLEX\_TWI\_THR, the SCL is released and the data is sent. To generate a STOP event, the STOP command must be performed by writing in the STOP field of the TWI Control Register (FLEX\_TWI\_CR).

After a master write transfer, the Serial Clock line is stretched (tied low) while no new data is written in FLEX\_TWI\_THR or until a STOP command is performed.

See the following figures.

**Figure 46-85. Master Write with One Data Byte**

**Figure 46-86. Master Write with Multiple Data Bytes**

**Figure 46-87. Master Write with One Byte Internal Address and Multiple Data Bytes**

### 46.9.3.5 Master Receiver Mode

Master Receiver mode is not available if High-speed mode is selected.

The read sequence begins by setting the START bit. After the start condition has been sent, the master sends a 7-bit slave address to notify the slave device. The bit following the slave address indicates the transfer direction, 1 in this case (`FLEX_TWI_MMR.MREAD = 1`). During the acknowledge clock pulse (9th pulse), the master releases the data line (HIGH), enabling the slave to pull it down in order to generate the acknowledge. The master polls the data line during this clock pulse and sets the `FLEX_TWI_SR.NACK` bit if the slave does not acknowledge the byte.

If an acknowledge is received, the master is then ready to receive data from the slave. After data has been received, the master sends an acknowledge condition to notify the slave that the data has been received except for the last data (see figure "Master Read with One Data Byte" below). When the `FLEX_TWI_SR.RXRDY` bit is set, a character has been received in the Receive Holding Register (`FLEX_TWI_RHR`). The `RXRDY` bit is reset when reading `FLEX_TWI_RHR`.

When a single data byte read is performed, with or without internal address (IADR), the START and STOP bits must be set at the same time. See figure "Master Read with One Data Byte" below. When a multiple data byte read is performed, with or without internal address (IADR), the STOP bit must be set after the next-to-last data received (same condition applies for START bit to generate a repeated start).

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

See figure "Master Read with Multiple Data Bytes" below. For internal address usage, see section [Internal Address](#).

If FLEX\_TWI\_RHR is full (RXRDY high) and the master is receiving data, the serial clock line will be tied low before receiving the last bit of the data and until FLEX\_TWI\_RHR is read. Once FLEX\_TWI\_RHR is read, the master will stop stretching the serial clock line and end the data reception. See figure "Master Read Clock Stretching with Multiple Data Bytes" below.

**WARNING** When receiving multiple bytes in Master Read mode, if the next-to-last access is not read (the RXRDY flag remains high), the last access will not be completed until FLEX\_TWI\_RHR is read. The last access stops on the next-to-last bit (clock stretching). When FLEX\_TWI\_RHR is read there is only half a bit period to send the STOP bit (or START bit) command, else another read access might occur (spurious access).

A possible workaround is to set the STOP bit (or START bit) before reading FLEX\_TWI\_RHR on the next-to-last access (within IT handler).

**Figure 46-88. Master Read with One Data Byte**

**Figure 46-89. Master Read with Multiple Data Bytes**

**Figure 46-90. Master Read Clock Stretching with Multiple Data Bytes**

RXRDY is used as receive ready trigger event for the DMA receive channel.

### 46.9.3.6 Internal Address

The TWI interface can perform transfers with 7-bit slave address devices and with 10-bit slave address devices.

#### 46.9.3.6.1 7-bit Slave Addressing

When addressing 7-bit slave devices, the internal address bytes are used to perform random address (read or write) accesses to reach one or more data bytes, e.g., within a memory page location in a serial memory. When performing read operations with an internal address, the TWI performs a write operation to set the internal address into the slave device, and then switch to Master Receiver mode. Note that the second start condition (after sending the IADR) is sometimes called “repeated start” (Sr) in I<sup>2</sup>C fully-compatible devices. See figure [Master Read with One, Two or Three Bytes Internal Address and One Data Byte](#).

See figures [Master Write with One, Two or Three Bytes Internal Address and One Data Byte](#) and [Internal Address Usage](#) for the master write operation with internal address.

The three internal address bytes are configurable through the Master Mode Register (FLEX\_TWI\_MMR).

If the slave device supports only a 7-bit address, i.e., no internal address, IADRSZ must be configured to 0.

The abbreviations listed below are used in the following figures:

|      |                 |
|------|-----------------|
| S    | Start           |
| Sr   | Repeated Start  |
| P    | Stop            |
| W    | Write           |
| R    | Read            |
| A    | Acknowledge     |
| N    | Not Acknowledge |
| DADR | Device Address  |

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

|      |                  |
|------|------------------|
| IADR | Internal Address |
|------|------------------|

**Figure 46-91. Master Write with One, Two or Three Bytes Internal Address and One Data Byte**

**Figure 46-92. Master Read with One, Two or Three Bytes Internal Address and One Data Byte**

### 46.9.3.6.2 10-bit Slave Addressing

For a slave address higher than seven bits, the user must configure the address size (IADRSZ) and set the other slave address bits in the Internal Address Register (FLEX\_TWI\_IADR). The two remaining internal address bytes, IADR[15:8] and IADR[23:16], can be used the same way as in 7-bit slave addressing.

Example: Address a 10-bit device (10-bit device address is b1 b2 b3 b4 b5 b6 b7 b8 b9 b10)

1. Program IADRSZ = 1
2. Program DADR with 1 1 1 1 0 b1 b2 (b1 is the MSB of the 10-bit address, b2, etc.)
3. Program FLEX\_TWI\_IADR with b3 b4 b5 b6 b7 b8 b9 b10 (b10 is the LSB of the 10-bit address)

The following figure shows a byte write to a TWI EEPROM. This demonstrates the use of internal addresses to access the device.

**Figure 46-93. Internal Address Usage**

### 46.9.3.7 Repeated Start

In addition to Internal Address mode, repeated start (Sr) can be generated manually by writing the START bit at the end of a transfer instead of the STOP bit. In such case the parameters of the next transfer (direction, SADR, etc.) will need to be set before writing the START bit at the end of the previous transfer.

See section [Read/Write Flowcharts](#).

### 46.9.3.8 Bus Clear Command

The TWI interface can perform a Bus Clear Command:

1. Configure the Master mode (DADR, CKDIV, etc).
2. Start the transfer by setting the FLEX\_TWI\_CR.CLEAR bit.

**Note:** If an alternative command is used (ACMEN bit = 1), the DATAL field must be cleared.

#### 46.9.3.9 SMBus Mode

SMBus mode is enabled when the FLEX\_TWI\_CR.SMBEN bit is written to one. SMBus mode operation is similar to I<sup>2</sup>C operation with the following exceptions:

1. Only 7-bit addressing can be used.
2. The SMBus standard describes a set of timeout values to ensure progress and throughput on the bus. These timeout values must be programmed into FLEX\_TWI\_SMBTR.
3. Transmissions can optionally include a CRC byte, called Packet Error Check (PEC).
4. A set of addresses has been reserved for protocol handling, such as alert response address (ARA) and host header (HH) address. Address matching on these addresses can be enabled by configuring FLEX\_TWI\_CR appropriately.

##### 46.9.3.9.1 Packet Error Checking

Each SMBus transfer can optionally end with a CRC byte, called the PEC byte. Writing the FLEX\_TWI\_CR.PECEN bit to one enables automatic PEC handling in the current transfer. Transfers with and without PEC can freely be intermixed in the same system, since some slaves may not support PEC. The PEC LFSR is always updated on every bit transmitted or received, so that PEC handling on combined transfers will be correct.

In Master Transmitter mode, the master calculates a PEC value and transmits it to the slave after all data bytes have been transmitted. Upon reception of this PEC byte, the slave will compare it to the PEC value it has computed itself. If the values match, the data was received correctly, and the slave will return an ACK to the master. If the PEC values differ, data was corrupted, and the slave will return a NACK value. Some slaves may not be able to check the received PEC in time to return a NACK if an error occurred. In this case, the slave should always return an ACK after the PEC byte, and some other mechanism must be implemented to verify that the transmission was received correctly.

In Master Receiver mode, the slave calculates a PEC value and transmits it to the master after all data bytes have been transmitted. Upon reception of this PEC byte, the master will compare it to the PEC value it has computed itself. If the values match, the data was received correctly. If the PEC values differ, data was corrupted, and the FLEX\_TWI\_SR.PECERR bit is set. In Master Receiver mode, the PEC byte is always followed by a NACK transmitted by the master, since it is the last byte in the transfer.

In combined transfers, the PECRQ bit should only be set in the last of the combined transfers. If Alternative Command mode is enabled, only the NPEC bit should be set.

Consider the following transfer:

S, ADR+W, COMMAND\_BYTE, ACK, SR, ADR+R, DATA\_BYTE, ACK, PEC\_BYTE, NACK, P

See section [Read/Write Flowcharts](#) for detailed flowcharts.

##### 46.9.3.9.2 Timeouts

The FLEX\_TWI\_SMBTR.TLOWS/TLOWM fields configure the SMBus timeout values. If a timeout occurs, the master transmits a STOP condition and leaves the bus. Furthermore, the FLEX\_TWI\_SR.TOUT bit is set.

##### 46.9.3.10 SMBus Quick Command (Master Mode Only)

The TWI interface can perform a quick command:

1. Configure the Master mode (DADR, CKDIV, etc).

2. Write the FLEX\_TWI\_MMR.MREAD bit at the value of the one-bit command to be sent.
3. Start the transfer by setting the FLEX\_TWI\_CR.QUICK bit.

**Note:** If an alternative command is used (ACMEN bit = 1), the DATAL field must be cleared.

**Figure 46-94. SMBus Quick Command**

### 46.9.3.11 Alternative Command

Another way to configure the transfer is to enable the Alternative Command mode with the ACMEN bit of the TWI Control Register.

In this mode, the transfer is configured through the TWI Alternative Command Register. It is possible to define a simple read or write transfer or a combined transfer with a repeated start.

In order to set a simple transfer, the DATAL field and the DIR field of the TWI Alternative Command Register must be filled accordingly and the NDATAL field must be cleared. To begin the transfer, either set the START bit in the TWI Control Register in case of a read transfer, or write the TWI Transmit Holding Register in case of a write transfer.

For a combined transfer linked by a repeated start, the NDATAL field must be filled with the length of the second transfer and NDIR with the corresponding direction.

The PEC and NPEC bits are used to set a PEC field. In the case of a single transfer with PEC, the PEC bit must be set. In the case of a combined transfer, the NPEC bit must be set.

**Note:** If the Alternative Command mode is used, the TWIHS\_MMR.IADRSZ field must be set to 0.

See [Read/Write Flowcharts](#) for detailed flowcharts.

### 46.9.3.12 Handling Errors in Alternative Command

In case of NACK generated by a slave device or SMBus timeout error, the TWI stops immediately the frame, but the DMA transfer may still be active. To prevent a new frame to be restarted with the remaining DMA data (transmit), the TWI prevents any start of frame until the FLEX\_TWI\_SR.LOCK flag is cleared.

The FLEX\_TWI\_SR.LOCK bit indicates the state of the TWI (locked or not locked).

When the TWI is locked, no transfer can begin until the LOCK is cleared using the FLEX\_TWI\_CR.LOCKCLR bit and until the error flags are cleared reading FLEX\_TWI\_SR.

In case of error, FLEX\_TWI\_THR may have been loaded with a new data. The FLEX\_TWI\_CR.THRCLR bit can be used to flush FLEX\_TWI\_THR. If the THRCLR bit is set, the TXRDY and TXCOMP flags are set.

### 46.9.3.13 Read/Write Flowcharts

The flowcharts shown in this section provide examples for read and write operations. A polling or interrupt method can be used to check the status bits. The interrupt method requires that the Interrupt Enable Register (FLEX\_TWI\_IER) be configured first.

### 46.9.4 Multi-Master Mode

#### 46.9.4.1 Definition

In Multi-Master mode, more than one master may handle the bus at the same time without data corruption by using arbitration.

Arbitration starts as soon as two or more masters place information on the bus at the same time, and stops (arbitration is lost) for the master that intends to send a logical one while the other master sends a logical zero.

As soon as arbitration is lost by a master, it stops sending data and listens to the bus in order to detect a STOP. When the STOP is detected, the master that has lost arbitration may put its data on the bus by respecting arbitration.

Arbitration is illustrated in figure "Arbitration Cases" below.

### 46.9.4.2 Different Multi-Master Modes

Two Multi-Master modes may be distinguished:

- TWI as Master Only—TWI is considered as a master only and will never be addressed.
- TWI as Master or Slave—TWI may be either a master or a slave and may be addressed.

**Note:** Arbitration is supported in both Multi-Master modes.

#### 46.9.4.2.1 TWI as Master Only

In this mode, the TWI is considered as a master only (MSEN is always at one) and must be driven like a master with the ARBLST (ARBitration Lost) flag in addition.

If arbitration is lost (ARBLST = 1), the user must reinitiate the data transfer.

If the user starts a transfer (ex.: DADR + START + W + Write in THR) and if the bus is busy, the TWI automatically waits for a STOP condition on the bus to initiate the transfer (see figure "User Sends Data While the Bus is Busy" below).

**Note:** The state of the bus (busy or free) is not indicated in the user interface.

#### 46.9.4.2.2 TWI as Master or Slave

The automatic reversal from master to slave is not supported in case of a lost arbitration.

Then, in the case where TWI may be either a master or a slave, the user must manage the pseudo Multi-Master mode described in the steps below:

1. Program the TWI in Slave mode (SADR + MSDIS + SVEN) and perform a slave access (if TWI is addressed).
2. If the TWI has to be set in Master mode, wait until TXCOMP flag is at 1.
3. Program the Master mode (DADR + SVDIS + MSEN) and start the transfer (ex: START + Write in THR).
4. As soon as the Master mode is enabled, the TWI scans the bus in order to detect if it is busy or free. When the bus is considered as free, the TWI initiates the transfer.
5. As soon as the transfer is initiated and until a STOP condition is sent, the arbitration becomes relevant and the user must monitor the ARBLST flag.
6. If the arbitration is lost (ARBLST is = 1), the user must program the TWI in Slave mode in case the master that won the arbitration needs to access the TWI.
7. If the TWI has to be set in Slave mode, wait until TXCOMP flag is at 1 and then program the Slave mode.

**Note:** In case the arbitration is lost and the TWI is addressed, the TWI will not acknowledge even if it is programmed in Slave mode as soon as ARBLST = 1. Then the master must repeat SADR.

**Figure 46-109. User Sends Data While the Bus is Busy**

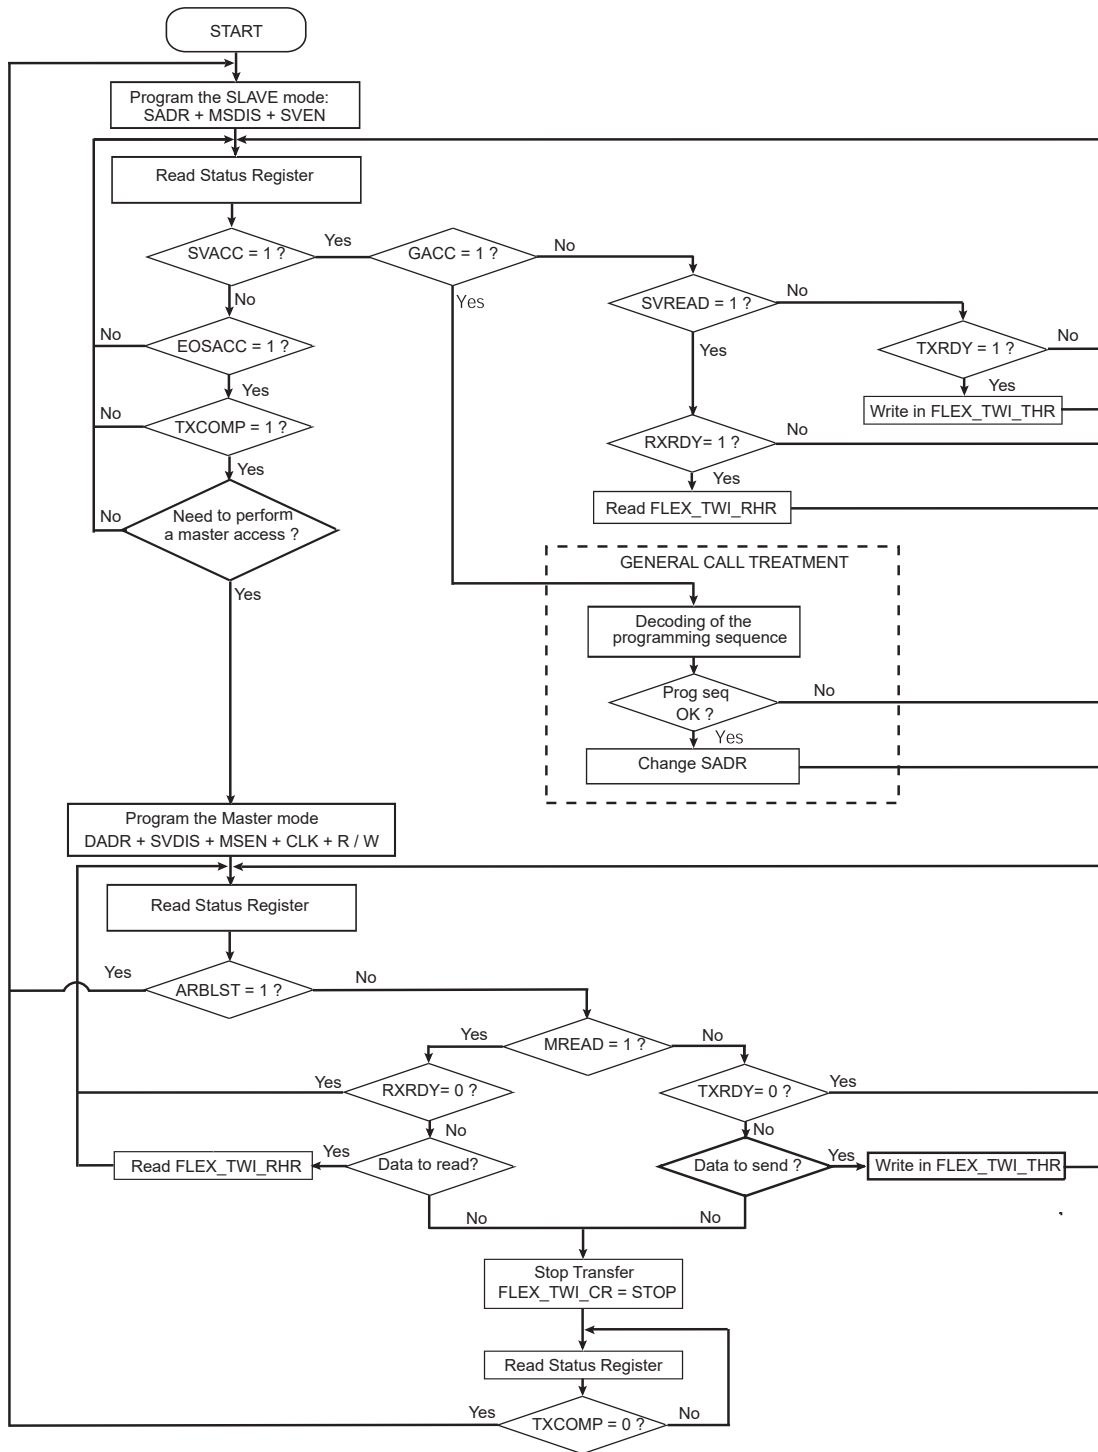

**Figure 46-110. Arbitration Cases**

The flowchart shown in the following figure gives an example of read and write operations in Multi-Master mode.

**Figure 46-111. Multi-Master Mode**

### 46.9.5 Slave Mode

#### 46.9.5.1 Definition

Slave mode is defined as a mode where the device receives the clock and the address from another device called the master.

In this mode, the device never initiates and never completes the transmission (START, REPEATED\_START and STOP conditions are always provided by the master).

#### 46.9.5.2 Programming Slave Mode

The following fields must be programmed before entering Slave mode:

1. FLEX\_TWI\_SMR.SADR: The slave device address is used in order to be accessed by master devices in Read or Write mode.
2. (Optional) FLEX\_TWI\_SMR.MASK can be set to mask some SADR address bits and thus allow multiple address matching.
3. FLEX\_TWI\_CR.MSDIS: Disables the Master mode.
4. FLEX\_TWI\_CR.SVEN: Enables the Slave mode.

As the device receives the clock, values written in FLEX\_TWI\_CWGR are not processed.

#### 46.9.5.3 Receiving Data

After a START or repeated START condition is detected, and if the address sent by the master matches the slave address programmed in the SADR (Slave Address) field, the SVACC (Slave Access) flag is set and SVREAD (Slave Read) indicates the direction of the transfer.

SVACC remains high until a STOP condition or a repeated START is detected. When such a condition is detected, EOSACC (End Of Slave Access) flag is set.

##### 46.9.5.3.1 Read Sequence

In the case of a read sequence (SVREAD is high), the TWI transfers data written in FLEX\_TWI\_THR (TWI Transmit Holding Register) until a STOP condition or a REPEATED\_START + an address different from SADR is detected. Note that at the end of the read sequence TXCOMP (Transmission Complete) flag is set and SVACC is reset.

As soon as data is written in FLEX\_TWI\_THR, the TXRDY (Transmit Holding Register Ready) flag is reset, and it is set when the internal shifter is empty and the sent data acknowledged or not. If the data is not acknowledged, the NACK flag is set.

Note that a STOP or a repeated START always follows a NACK.

See figure "Read Access Ordered by a Master" below.

**Note:** To clear the TXRDY flag in Slave mode, write the FLEX\_TWI\_CR.SVDIS bit to 1, then write the FLEX\_TWI\_CR.SVEN bit to 1.

##### 46.9.5.3.2 Write Sequence

In the case of a write sequence (SVREAD is low), the RXRDY (Receive Holding Register Ready) flag is set as soon as a character has been received in FLEX\_TWI\_RHR (TWI Receive Holding Register). RXRDY is reset when reading FLEX\_TWI\_RHR.

TWI continues receiving data until a STOP condition or a REPEATED\_START + an address different from SADR is detected. Note that at the end of the write sequence TXCOMP flag is set and SVACC reset.

See figure "Write Access Ordered by a Master" below.

##### 46.9.5.3.3 Clock Stretching Sequence

If FLEX\_TWI\_THR or FLEX\_TWI\_RHR is not written/read in time, the TWI performs a clock stretching.

Clock stretching information is given by the SCLWS (Clock Wait State) bit.

See figures "Clock Stretching in Read Mode" and "Clock Stretching in Write Mode" below.

**Note:** Clock stretching can be disabled by configuring the FLEX\_TWI\_SMR.SCLWSDIS bit. In that case, UNRE and OVRE flags will indicate underrun (when FLEX\_TWI\_THR is not filled on time) or overrun (when FLEX\_TWI\_RHR is not read on time).

### 46.9.5.3.4 General Call

In the case where a GENERAL CALL is performed, the GACC (General Call Access) flag is set.

After GACC is set, it is up to the user to interpret the meaning of the GENERAL CALL and to decode the new address programming sequence.

See figure "Master Performs a General Call" below.

### 46.9.5.4 Data Transfer

#### 46.9.5.4.1 Read Operation

The Read mode is defined as a data requirement from the master.

After a START or a REPEATED START condition is detected, the decoding of the address starts. If the slave address (SADR) is decoded, SVACC is set and SVREAD indicates the direction of the transfer.

Until a STOP or REPEATED START condition is detected, TWI continues sending data loaded in FLEX\_TWI\_THR.

If a STOP condition or a REPEATED START + an address different from SADR is detected, SVACC is reset.

The following figure describes the read operation.

**Figure 46-112. Read Access Ordered by a Master**

**Note:**

1. When SVACC is low, the state of SVREAD becomes irrelevant.
2. TXRDY is reset when data has been transmitted from FLEX\_TWI\_THR to the internal shifter and set when this data has been acknowledged or non acknowledged.

#### 46.9.5.4.2 Write Operation

The Write mode is defined as a data transmission from the master.

After a START or a REPEATED START, the decoding of the address starts. If the slave address is decoded, SVACC is set and SVREAD indicates the direction of the transfer (SVREAD is low in this case).

Until a STOP or REPEATED START condition is detected, TWI stores the received data in FLEX\_TWI\_RHR.

If a STOP condition or a REPEATED START + an address different from SADR is detected, SVACC is reset.

The following figure describes the write operation.

**Figure 46-113. Write Access Ordered by a Master**

**Note:**

1. When SVACC is low, the state of SVREAD becomes irrelevant.
2. RXRDY is set when data has been transmitted from the internal shifter to FLEX\_TWI\_RHR, and reset when this data is read.

#### 46.9.5.4.3 General Call

The general call is performed in order to change the address of the slave.

If a GENERAL CALL is detected, GACC is set.

After the detection of general call, it is up to the user to decode the commands which follow.

In case of a WRITE command, the user has to decode the programming sequence and program a new SADR if the programming sequence matches.

The following figure describes the general call access.

**Figure 46-114. Master Performs a General Call**

**Note:** This method enables to create a user-specific programming sequence by choosing the number of programming bytes. The programming sequence has to be provided to the master.

#### 46.9.5.4.4 Clock Stretching

In both Read and Write modes, it may happen that the FLEX\_TWI\_THR/FLEX\_TWI\_RHR buffer is not filled/emptied before the transmission/reception of a new character. In this case, to avoid sending/receiving undesired data, a clock stretching mechanism is implemented.

**Note:** Clock stretching can be disabled by setting the FLEX\_TWI\_SMR.SCLWSDIS bit. In that case, the UNRE and OVRE flags indicate an underrun (when FLEX\_TWI\_THR is not filled on time) or an overrun (when FLEX\_TWI\_RHR is not read on time).

##### — Clock Stretching in Read Mode

The clock is tied low if the internal shifter is empty and if a STOP or REPEATED START condition was not detected. It is tied low until the internal shifter is loaded.

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

The following figure describes clock stretching in Read mode.

**Figure 46-115. Clock Stretching in Read Mode**

**Note:**

1. TXRDY is reset when data has been written in FLEX\_TWI\_THR to the internal shifter, and set when this data has been acknowledged or non acknowledged.
2. At the end of the read sequence, TXCOMP is set after a STOP or after a REPEATED\_START + an address different from SADR.
3. SCLWS is automatically set when the clock stretching mechanism is started.

**— Clock Stretching in Write Mode**

The clock is tied low if the internal shifter and FLEX\_TWI\_RHR are full. If a STOP or REPEATED\_START condition was not detected, it is tied low until FLEX\_TWI\_RHR is read.

The following figure describes the clock stretching in Write mode.

**Figure 46-116. Clock Stretching in Write Mode**

**Note:**

1. At the end of the read sequence, TXCOMP is set after a STOP or after a REPEATED\_START + an address different from SADR.

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

2. SCLWS is automatically set when the clock stretching mechanism is started and automatically reset when the mechanism is finished.

### 46.9.5.4.5 Reversal after a Repeated Start

#### — Reversal of Read to Write

The master initiates the communication by a read command and finishes it by a write command.

The following figure describes the repeated start and the reversal from Read mode to Write mode.

**Figure 46-117. Repeated Start and Reversal from Read Mode to Write Mode**

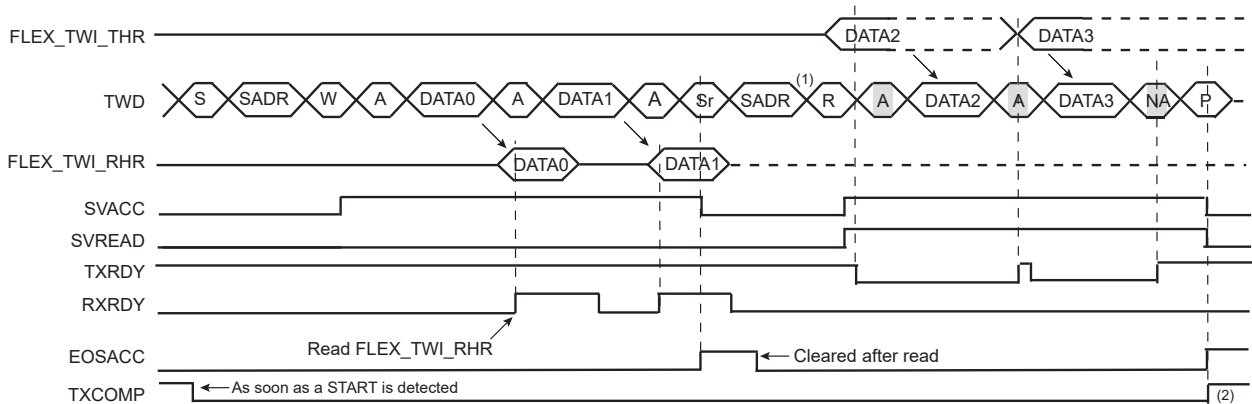

Note:  
1. TXCOMP is only set at the end of the transmission because after the repeated start, SADR is detected again.

#### — Reversal of Write to Read

The master initiates the communication by a write command and finishes it by a read command.

The following figure describes the repeated start and the reversal from Write mode to Read mode.

**Figure 46-118. Repeated Start and Reversal from Write Mode to Read Mode**

Notes:  
1. In this case, if FLEX\_TWI\_THR has not been written at the end of the read command, the clock is automatically stretched before the ACK.  
2. TXCOMP is only set at the end of the transmission because after the repeated start, SADR is detected again.

### 46.9.5.4.6 SMBus Mode

SMBus mode is enabled when the FLEX\_TWI\_CR.SMEN bit is written to one. SMBus mode operation is similar to I<sup>2</sup>C operation with the following exceptions:

1. Only 7-bit addressing can be used.
2. The SMBus standard describes a set of timeout values to ensure progress and throughput on the bus. These timeout values must be programmed into FLEX\_TWI\_SMBTR.
3. Transmissions can optionally include a CRC byte, called Packet Error Check (PEC).

4. A set of addresses have been reserved for protocol handling, such as alert response address (ARA) and host header (HH) address. Address matching on these addresses can be enabled by configuring FLEX\_TWI\_CR appropriately.

— **Packet Error Checking**

Each SMBus transfer can optionally end with a CRC byte, called the PEC byte. Writing the FLEX\_TWI\_CR.PECEN bit to one will send/check the FLEX\_TWI\_ACR.PEC field in the current transfer. The PEC generator is always updated on every bit transmitted or received, so that PEC handling on following linked transfers will be correct.

In Slave Receiver mode, the master calculates a PEC value and transmits it to the slave after all data bytes have been transmitted. Upon reception of this PEC byte, the slave will compare it to the PEC value it has computed itself. If the values match, the data was received correctly, and the slave will return an ACK to the master. If the PEC values differ, data was corrupted, and the slave will return a NACK value. The FLEX\_TWI\_SR.PECERR bit is set automatically if a PEC error occurred.

In Slave Transmitter mode, the slave calculates a PEC value and transmits it to the master after all data bytes have been transmitted. Upon reception of this PEC byte, the master will compare it to the PEC value it has computed itself. If the values match, the data was received correctly. If the PEC values differ, data was corrupted, and the master must take appropriate action.

See section [Slave Read/Write Flowcharts](#) for detailed flowcharts.

— **Timeouts**

The TWI SMBus Timing Register (FLEX\_TWI\_SMBTR) configures the SMBus timeout values. If a timeout occurs, the slave will leave the bus. Furthermore, the FLEX\_TWI\_SR.TOUT bit is set.

#### 46.9.5.5 High-Speed Slave Mode

High-speed mode is enabled when the FLEX\_TWI\_CR.HSEN bit is written to one. Furthermore, the analog pad filter must be enabled, the FLEX\_TWI\_FILTR.PADFEN bit must be written to one and the FLEX\_TWI\_FILTR.FILT bit must be cleared. TWI High-speed mode operation is similar to TWI operation with the following exceptions:

1. A master code is received first at normal speed before entering High-speed mode period.
2. When TWI High-speed mode is active, clock stretching is only allowed after acknowledge (ACK), not-acknowledge (NACK), START (S) or repeated START (Sr) (asa consequence, OVF may happen).

TWI High-speed mode allows transfers of up to 3.4 Mbit/s.

The TWI slave in High-speed mode requires that the peripheral clock runs at a minimum of 14 MHz if slave clock stretching is enabled (SCLWSDIS bit at '0'). If slave clock stretching is disabled (SCLWSDIS bit at '1'), the peripheral clock must run at a minimum of 11 MHz (assuming the system has no latency).

**Note:**

1. When slave clock stretching is disabled, FLEX\_TWI\_RHR must always be read before receiving the next data (MASTER write frame). It is strongly recommended to use either the polling method on the FLEX\_TWI\_SR.RXRDY flag, or the DMA. If the receive is managed by an interrupt, the TWI interrupt priority must be set to the right level and its latency minimized to avoid receive overrun.
2. When slave clock stretching is disabled, FLEX\_TWI\_THR must be filled with the first data to send before the beginning of the frame (MASTER read frame). It is strongly recommended to use either the polling method on the FLEX\_TWI\_SR.TXRDY flag, or the DMA. If the transmit is managed by an interrupt, the TWI interrupt priority must be set to the right level and its latency minimized to avoid transmit underrun.

### 46.9.5.5.1 Read/Write Operation

A TWI high-speed frame always begins with the following sequence:

1. START condition (S)
2. Master Code (0000 1XXX)
3. Not-acknowledge (NACK)

When the TWI is programmed in Slave mode and TWI High-speed mode is activated, master code matching is activated and internal timings are set to match the TWI High-speed mode requirements.

**Figure 46-119. High-Speed Mode Read/Write**

### 46.9.5.5.2 Usage

TWI High-speed mode usage is the same as the standard TWI (see section [Read/Write Flowcharts](#)).

### 46.9.5.6 Alternative Command

In Slave mode, the Alternative Command mode is used when the SMBus mode is enabled to send or check the PEC byte.

The Alternative Command mode is enabled by setting the ACMEN bit of the TWIHS Control Register, and the transfer is configured in TWIHS\_ACR.

For a combined transfer with PEC, only the NPEC bit in TWIHS\_ACR must be set as the PEC byte is sent once at the end of the frame.

See section [Slave Read/Write Flowcharts](#) for detailed flowcharts.

### 46.9.5.7 TWI Asynchronous and Partial Wakeup (SleepWalking)

The TWI module includes an asynchronous start condition detector, it is capable of waking the device up from a Sleep mode upon an address match (and optionally an additional data match), including Sleep modes where the TWI peripheral clock is stopped.

The FLEX\_TWI\_RHR register must be read prior to enable the asynchronous and partial wakeup.

After detecting the START condition on the bus, the TWI will stretch TWCK until the TWI peripheral clock has started. The time required for starting the TWI peripheral depends on which Sleep mode the device is in. After the TWI peripheral clock has started, the TWI releases its TWCK stretching and receives one byte of data (slave address) on the bus. At this time, only a limited part of the device, including the TWI module, receives a clock, thus saving power. If the address phase causes a TWIS address match (and optionally if the first data byte causes data match as well), the entire device is wakened and normal TWI address matching actions are performed. Normal TWI transfer then follows. If the TWI module is not addressed (or if the optional data match fails), the TWI peripheral clock is automatically stopped and the device returns to its original Sleep mode.

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

The TWI module has the capability to match on more than one address. The FLEX\_TWI\_SMR.SADR1EN/SADR2EN/SADR3EN bits enable address matching on additional addresses which can be configured through the FLEX\_TWI\_SWMR.SADR1/SADR2/SADR3 fields. The SleepWalking matching process can be extended to the first received data byte if the FLEX\_TWI\_SMR.DATAMEN bit is set. In that case, a complete matching includes address matching and first received data matching. The FLEX\_TWI\_SWMR.DATAM field can be used to configure the data to match on the first received byte.

When the system is in Active mode and the TWI enters asynchronous partial Wakeup mode, the flag SVACC must be programmed as the unique source of the TWI interrupt and the data match comparison must be disabled.

When the system exits Wait mode as the result of a matching condition, the SVACC flag is used to determine if the TWI is the source of the exit from Wait mode.

**Figure 46-120. Address Match and Data Matching Disabled**

**Figure 46-121. Address Does Not Match and Data Matching Disabled**

**Figure 46-122. Address and Data Match (Data Matching Enabled)**

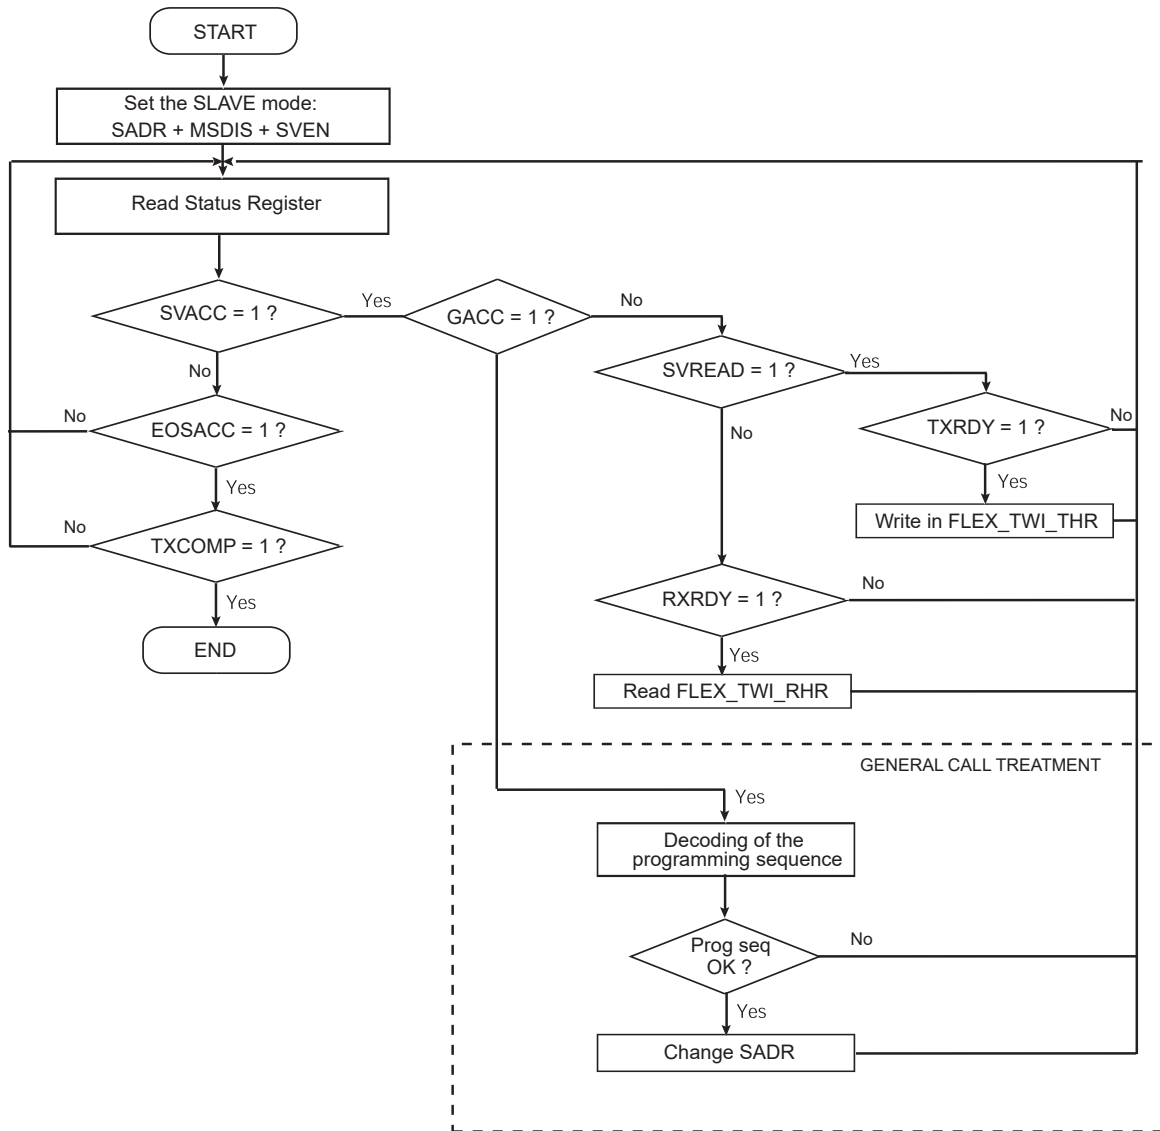

**Figure 46-123. Address Matches and Data Do Not Match (Data Matching Enabled)**

### 46.9.5.8 Slave Read/Write Flowcharts

The flowchart shown in the following figure gives an example of read and write operations in Slave mode. A polling or interrupt method can be used to check the status bits. The interrupt method requires that the Interrupt Enable Register (FLEX\_TWI\_IER) be configured first.

**Figure 46-124. Read/Write in Slave Mode**

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

**Figure 46-125. Read/Write in Slave Mode with SMBus PEC**

**Figure 46-126. Read/Write in Slave Mode with SMBus PEC and Alternative Command Mode**

### 46.9.6 TWI FIFOs

#### 46.9.6.1 Overview

The TWI includes two FIFOs which can be enabled/disabled using FLEX\_TWI\_CR.FIFOEN/FIFODIS. Both Master and Slave modes must be disabled before enabling or disabling the FIFOs (FLEX\_TWI\_CR.MSDIS/SVDIS).

Writing FLEX\_TWI\_CR.FIFOEN to '1' enables a 16-data Transmit FIFO and a 16-data Receive FIFO.

It is possible to write or to read single or multiple data in the same access to FLEX\_TWI\_THR/RHR, depending on FLEX\_TWI\_FMR.TXRDYM/RXRDYM settings.

**Figure 46-127. FIFOs Block Diagram**

#### 46.9.6.2 Sending Data with FIFO Enabled

When the Transmit FIFO is enabled, write access to FLEX\_TWI\_THR loads the Transmit FIFO.

The Transmit FIFO level is provided in FLEX\_TWI\_FLR.TXFL. If the FIFO can accept the number of data to be transmitted, there is no need to monitor FLEX\_TWI\_SR.TXRDY and the data can be successively written in FLEX\_TWI\_THR.

If the FIFO cannot accept the data due to insufficient space, wait for the TXRDY flag to be set before writing the data in FLEX\_TWI\_THR.

When the space in the FIFO allows only a portion of the data to be written, the TXRDY flag must be monitored before writing the remaining data.

See figures [Sending Data with FIFO Enabled in Master Mode](#) and [Sending/Receiving Data with FIFO Enabled in Slave Mode](#).

**Figure 46-128. Sending Data with FIFO Enabled in Master Mode**

### 46.9.6.3 Receiving Data with FIFO Enabled

When the Receive FIFO is enabled, FLEX\_TWI\_RHR access reads the FIFO.

When data are present in the Receive FIFO (RXRDY flag set to '1'), the exact number of data can be checked with FLEX\_TWI\_FLR.RXFL. All the data can be read successively in FLEX\_TWI\_RHR without checking the FLEX\_TWI\_SR.RXRDY flag between each access.

See figures [Receiving Data with FIFO Enabled in Master Mode](#) and [Sending/Receiving Data with FIFO Enabled in Slave Mode](#).

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

Figure 46-129. Receiving Data with FIFO Enabled in Master Mode

#### 46.9.6.4 Sending/Receiving with FIFO Enabled in Slave Mode

See sections [Sending Data with FIFO Enabled](#) and [Receiving Data with FIFO Enabled](#) for details.

**Figure 46-130. Sending/Receiving Data with FIFO Enabled in Slave Mode**

#### 46.9.6.5 Clearing/Flushing FIFOs

Each FIFO can be cleared/flushed using FLEX\_TWI\_CR.TXFCLR/RXFCLR.

#### 46.9.6.6 TXRDY and RXRDY Behavior

FLEX\_TWI\_SR.TXRDY/RXRDY flags display a specific behavior when FIFOs are enabled.

TXRDY indicates if a data can be written in the Transmit FIFO. Thus the TXRDY flag is set as long as the Transmit FIFO can accept new data. See figure [TXRDY Behavior when TXRDYM = 0 in Master mode](#).

RXRDY indicates if an unread data is present in the Receive FIFO. Thus the RXRDY flag is set as soon as one unread data is in the Receive FIFO. Refer to figure [RXRDY Behavior when RXRDYM = 0 in Master and Slave modes](#).

TXRDY and RXRDY behavior can be modified using the TXRDYM and RXRDYM fields in the TWI FIFO Mode Register (FLEX\_TWI\_FMR) to reduce the number of accesses to FLEX\_TWI\_THR/RHR.

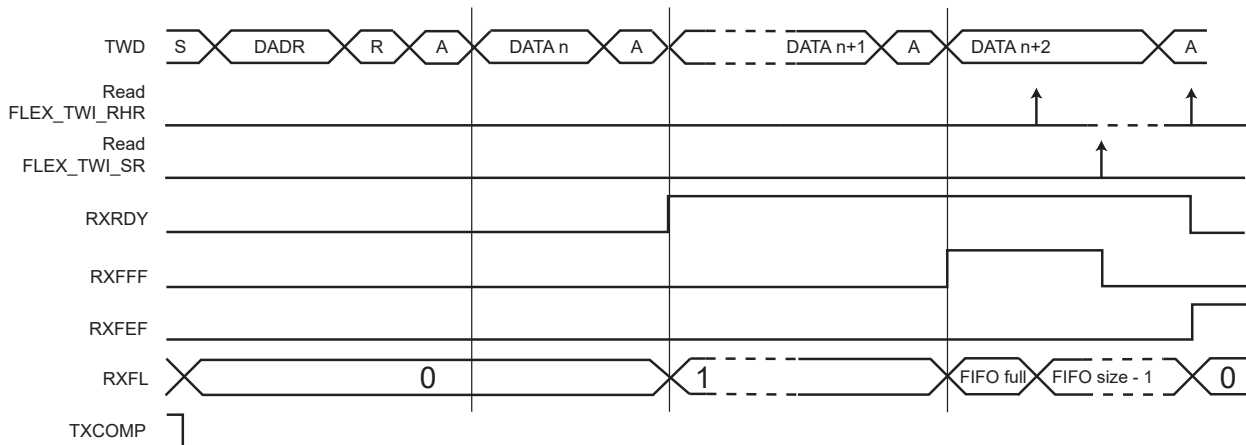

As an example, in Master mode, the Transmit FIFO can be loaded with multiple data in the same access by configuring TXRDYM>0.

See TWI FIFO Mode Register for the FIFO configuration.

**Figure 46-131. TXRDY Behavior when TXRDYM = 0 in Master Mode**

**Figure 46-132. RXRDY Behavior when RXRDYM = 0 in Master and Slave Modes**

**Figure 46-133. TXRDY Behavior when TXRDYM = 0 in Slave Mode**

### 46.9.6.7 TWI Single Data Mode

In Single Data mode, only one data is written every time FLEX\_TWI\_THR is accessed, and only one data is read every time FLEX\_TWI\_RHR is accessed.

When FLEX\_TWI\_FMR.TXRDYM = 0, the Transmit FIFO operates in Single Data mode.

When FLEX\_TWI\_FMR.RXRDYM = 0, the Receive FIFO operates in Single Data mode.

See sections [TWI Transmit Holding Register](#) and [TWI Receive Holding Register](#).

### 46.9.6.8 TWI Multiple Data Mode

Multiple Data mode minimizes the number of accesses by concatenating the data to send/read in one access.

When FLEX\_TWI\_FMR.TXRDYM > 0, the Transmit FIFO operates in Multiple Data mode.

When FLEX\_TWI\_FMR.RXRDYM > 0, the Receive FIFO operates in Multiple Data mode.

In Multiple Data mode, it is possible to write/read up to four data in one FLEX\_TWI\_THR/ FLEX\_TWI\_RHR register access.

The number of data to write/read is defined by the size of the register access. If the access is a byte-size register access, only one data is written/read. If the access is a halfword size register access, then up to two data are read and only one data is written. Lastly, if the access is a wordsize register access, then up to four data are read and up to two data are written.

Written/Read data are always right-aligned, as described in sections [TWI Receive Holding Register \(FIFO Enabled\)](#) and [TWI Transmit Holding Register \(FIFO Enabled\)](#).

As an example, if the Transmit FIFO is empty and there are six data to send, either of the following write accesses may be performed:

- six FLEX\_TWI\_THR-byte write accesses
- three FLEX\_TWI\_THR-halfword write accesses
- one FLEX\_TWI\_THR-word write access and one FLEX\_TWI\_THR halfword write access

With a Receive FIFO containing six data, any of the following read accesses may be performed:

- six FLEX\_TWI\_RHR-byte read accesses
- three FLEX\_TWI\_RHR-halfword read accesses
- one FLEX\_TWI\_RHR-word read access and one FLEX\_TWI\_RHR-halfword read access

#### **46.9.6.8.1 TXRDY and RXRDY Configuration**

In Multiple Data mode, it is possible to write one or more data in the same FLEX\_TWI\_THR/FLEX\_TWI\_RHR access. The TXRDY flag indicates if one or more data can be written in the FIFO depending on the configuration of FLEX\_TWI\_FMR.TXRDYM/RXRDYM.

As an example, if two data are written each time in FLEX\_TWI\_THR, it is useful to configure the TXRDYM field to the value '1' so that the TXRDY flag is at '1' only when at least two data can be written in the Transmit FIFO.

In the same way, if four data are read each time in FLEX\_TWI\_RHR, it is useful to configure the RXRDYM field to the value '2' so that the RXRDY flag is at '1' only when at least four unread data are in the Receive FIFO.

#### **46.9.6.8.2 DMAC**

When FIFOs operate in Multiple Data mode, the DMAC transfer type must be configured in byte, halfword or word depending on the FLEX\_TWI\_FMR.TXRDYM/RXRDYM settings.

#### **46.9.6.9 Transmit FIFO Lock**

If a frame is terminated early due to a not-acknowledge error (NACK flag), SMBus timeout error (TOUT flag) or master code acknowledge error (MACK flag), a lock is set on the Transmit FIFO preventing any new frame from being sent until it is cleared. This allows clearing the FIFO if needed, resetting DMAC channels, etc., without any risk.

FLEX\_TWI\_SR.LOCK is used to check the state of the Transmit FIFO lock.

The Transmit FIFO lock can be cleared by setting FLEX\_TWI\_CR.TXFLCLR to '1'.

#### **46.9.6.10 FIFO Pointer Error**

A FIFO overflow is reported in FLEX\_TWI\_FSR.

If the Transmit FIFO is full and a write access is performed on FLEX\_TWI\_THR, it generates a Transmit FIFO pointer error and sets FLEX\_TWI\_FSR.TXFPTEF.

In Multiple Data mode, if the number of data written in FLEX\_TWI\_THR (according to the register access size) is greater than the free space in the Transmit FIFO, a Transmit FIFO pointer error is generated and FLEX\_TWI\_FSR.TXFPTEF is set.

A FIFO underflow is reported in FLEX\_TWI\_FSR.

In Multiple Data mode, if the number of data read in FLEX\_TWI\_RHR (according to the register access size) is greater than the number of unread data in the Receive FIFO, a Receive FIFO pointer error is generated and FLEX\_TWI\_FSR.RXFPTEF is set.

No pointer error occurs if the FIFO state/level is checked before writing/reading in FLEX\_TWI\_THR/FLEX\_TWI\_RHR. The FIFO state/level can be checked either with TXRDY, RXRDY, TXFL or RXFL. When a pointer error occurs, other FIFO flags may not behave as expected; their states should be ignored.

If a Transmit or Receive pointer error occurs, a software reset must be performed using FLEX\_TWI\_CR.SWRST. Note that issuing a software while transmitting might leave a slave in an unknown state holding the TWD line. In such case, a Bus Clear Command will allow to make the slave release the TWD line (the first frame sent afterwards might not be received properly by the slave).

#### **46.9.6.11 FIFO Thresholds**

Each Transmit and Receive FIFO includes a threshold feature used to set a flag and an interrupt when a FIFO threshold is crossed. Thresholds are defined as a number of data in the FIFO, and the FIFO state (TXFL or RXFL) represents the number of data currently in the FIFO.

The Transmit FIFO threshold can be set using the field FLEX\_TWI\_FMR.TXFTHRES. Each time the Transmit FIFO level goes from 'above threshold' to 'equal to or below threshold', the flag FLEX\_TWI\_FESR.TXFTHF is set. The application is warned that the Transmit FIFO has reached the defined threshold and that it can be reloaded.

The Receive FIFO threshold can be set using the field FLEX\_TWI\_FMR.RXFTHRES. Each time the Receive FIFO level goes from 'below threshold' to 'equal to or above threshold', the flag FLEX\_TWI\_FESR.RXFTHF is set. The application is warned that the Receive FIFO has reached the defined threshold and that it can be read to prevent an underflow.

The TXFTHF and RXFTHF flags can be configured to generate an interrupt using FLEX\_TWI\_FIER and FLEX\_TWI\_FIDR.

### 46.9.6.12 FIFO Flags

FIFOs come with a set of flags which can be configured to generate interrupts through FLEX\_TWI\_FIER and FLEX\_TWI\_FIDR.

FIFO flags state can be read in FLEX\_TWI\_FSR. They are cleared when FLEX\_TWI\_FSR is read.

### 46.9.7 TWI Comparison Function on Received Character

The comparison function differs if the asynchronous partial wakeup (Sleepwalking) is enabled or not.

If asynchronous partial wakeup is disabled (refer to the section "Power Management Controller" (PMC)), the TWI has the capability to extend the address matching on up to three slave addresses. The FLEX\_TWI\_SMR.SADR1EN/SADR2EN/SADR3EN bits enable address matching on additional addresses which can be configured through the FLEX\_TWI\_SWMR.SADR1/SADR2/SADR3 fields. The DATAMEN bit has no effect.

The SVACC bit is set when there is a comparison match with the received slave address.

### 46.9.8 TWI Register Write Protection

The FLEXCOM operating mode (FLEX\_MR.OPMODE) must be set to FLEX\_MR\_OPMODE\_TWI to enable access to the write protection registers.

To prevent any single software error from corrupting TWI behavior, certain registers in the address space can be write-protected by setting the WPEN (Write Protection Enable), WPITEN (Write Protection Interrupt Enable), and/or WPCREN (Write Protection Control Enable) bits in the TWI Write Protection Mode Register (FLEX\_TWI\_WPMR).

If a write access to a write-protected register is detected, the Write Protection Violation Status (WPVS) flag in the TWI Write Protection Status Register (FLEX\_TWI\_WPSR) is set and the Write Protection Violation Source (WPVSR) field indicates the register in which the write access has been attempted.

The WPVS bit is automatically cleared after reading FLEX\_TWI\_WPSR.

The following register(s) can be write-protected when WPEN is set:

- TWI Slave Mode Register
- TWI Clock Waveform Generator Register
- TWI SMBus Timing Register
- TWI SleepWalking Matching Register
- TWI FIFO Mode Register

The following register(s) can be write-protected when WPITEN is set:

- TWI Interrupt Enable Register

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

---

---

- TWI Interrupt Disable Register

The following register(s) can be write-protected when WPCREN is set:

- TWI Control Register

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

### 46.10 Register Summary

| Offset                | Name                     | Bit Pos. |              |          |             |        |                 |                    |             |         |  |
|-----------------------|--------------------------|----------|--------------|----------|-------------|--------|-----------------|--------------------|-------------|---------|--|

## Flexible Serial Communication Controller (FLEXCOM)

### 46.10.1 FLEXCOM Mode Register

**Name:** FLEX\_MR  
**Offset:** 0x000  
**Reset:** 0x00000000  
**Property:** Read/Write

#### Bits 1:0 – OPMODE[1:0] FLEXCOM Operating Mode

| Value | Name   | Description  |
|-------|--------|--|
| 0     | NO_COM | No communication   |
| 1     | USART  | All UART-related protocols are selected (RS232, RS485, IrDA, ISO7816, LIN,)<br>SPI/TWI-related registers are not accessible and have no impact on IOs. |
| 2     | SPI    | SPI operating mode is selected.<br>USART/TWI related registers are not accessible and have no impact on IOs.   |
| 3     | TWI    | All TWI-related protocols are selected (TWI, SMBus).<br>USART/SPI-related registers are not accessible and have no impact on IOs.                      |

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

### 46.10.2 FLEXCOM Receive Holding Register

**Name:** FLEX\_RHR  
**Offset:** 0x010  
**Reset:** 0x00000000  
**Property:** Read-only

|        |              |    |    |    |    |    |    |    |
|--------|--------------|----|----|----|----|----|----|----|
| Bit    | 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 |
|        |              |    |    |    |    |    |    |    |
| Access |              |    |    |    |    |    |    |    |
| Reset  |              |    |    |    |    |    |    |    |
| Bit    | 23           | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|        |              |    |    |    |    |    |    |    |
| Access |              |    |    |    |    |    |    |    |
| Reset  |              |    |    |    |    |    |    |    |
| Bit    | 15           | 14 | 13 | 12 | 11 | 10 | 9  | 8  |
|        | RXDATA[15:8] |    |    |    |    |    |    |    |
| Access | R            | R  | R  | R  | R  | R  | R  | R  |
| Reset  | 0            | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| Bit    | 7            | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|        | RXDATA[7:0]  |    |    |    |    |    |    |    |
| Access | R            | R  | R  | R  | R  | R  | R  | R  |
| Reset  | 0            | 0  | 0  | 0  | 0  | 0  | 0  | 0  |

**Bits 15:0 – RXDATA[15:0] Receive Data**

This register is a mirror of:

- USART Receive Holding Register (FLEX\_US\_RHR) if FLEX\_MR.OPMODE field equals 1
- SPI Receive Data Register (FLEX\_SPI\_RDR) if FLEX\_MR.OPMODE field equals 2
- TWI Transmit Holding Register (FLEX\_TWI\_RHR) if FLEX\_MR.OPMODE field equals 3

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

### 46.10.3 FLEXCOM Transmit Holding Register

**Name:** FLEX\_THR  
**Offset:** 0x020  
**Reset:** 0x00000000  
**Property:** Read/Write

|        |              |     |     |     |     |     |     |     |
|--------|--------------|-----|-----|-----|-----|-----|-----|-----|
| Bit    | 31           | 30  | 29  | 28  | 27  | 26  | 25  | 24  |
|        |              |     |     |     |     |     |     |     |
| Access |              |     |     |     |     |     |     |     |
| Reset  |              |     |     |     |     |     |     |     |

| Reset  | –       | –       | –       | –      | –      | –       |        |        |

#### Bit 31 – FIFODIS FIFO Disable

| Value | Description                              |
|-------|--|
| 0     | No effect.                               |
| 1     | Disables the Transmit and Receive FIFOs. |

#### Bit 30 – FIFOEN FIFO Enable

| Value | Description                             |
|-------|---|
| 0     | No effect.                              |
| 1     | Enables the Transmit and Receive FIFOs. |

#### Bit 28 – REQCLR Request to Clear the Comparison Trigger

#### Bit 26 – TXFLCLR Transmit FIFO Lock CLEAR

| Value | Description                    |
|-------|--------------------------------|
| 0     | No effect.                     |
| 1     | Clears the Transmit FIFO Lock. |

#### Bit 25 – RXFCLR Receive FIFO Clear

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

| Value | Description               |
|-------|---------------------------|
| 0     | No effect.                |
| 1     | Empties the Receive FIFO. |

### Bit 24 – TXFCLR Transmit FIFO Clear

| Value | Description                |
|-------|----------------------------|
| 0     | No effect.                 |
| 1     | Empties the Transmit FIFO. |

### Bit 21 – LINWKUP Send LIN Wakeup Signal

| Value | Description                           |
|-------|---------------------------------------|
| 0     | No effect:                            |
| 1     | Sends a wakeup signal on the LIN bus. |

### Bit 20 – LINABT Abort LIN Transmission

| Value | Description                          |
|-------|--------------------------------------|
| 0     | No effect.                           |
| 1     | Aborts the current LIN transmission. |

### Bit 19 – RTSDIS Request to Send Disable

| Value | Description  |
|-------|--|
| 0     | No effect.   |
| 1     | Drives the RTS pin to 0 if FLEX_US_MR.USART_MODE field = 2, else drives the RTS pin to 1 if FLEX_US_MR.USART_MODE field = 0. |

### Bit 18 – RTSEN Request to Send Enable

| Value | Description  |
|-------|--|
| 0     | No effect.   |
| 1     | Drives the RTS pin to 1 if FLEX_US_MR.USART_MODE field = 2, else drives the RTS pin to 0 if FLEX_US_MR.USART_MODE field = 0. |

### Bit 15 – RETTO Start Timeout Immediately

| Value | Description                          |
|-------|--------------------------------------|
| 0     | No effect                            |
| 1     | Immediately restarts timeout period. |

### Bit 14 – RSTNACK Reset Non Acknowledge

| Value | Description              |
|-------|--------------------------|
| 0     | No effect                |
| 1     | Resets FLEX_US_CSR.NACK. |

### Bit 13 – RSTIT Reset Iterations

| Value | Description |
|-------|-------------|
| 0     | No effect.  |

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

| Value | Description   |
|-------|---|
| 1     | Resets FLEX_US_CSR.ITER. No effect if the ISO7816 is not enabled. |

### Bit 12 – SENDA Send Address

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | In Multidrop mode only, the next character written to FLEX_US_THR is sent with the address bit set. |

### Bit 11 – STTTO Clear TIMEOUT Flag and Start Timeout After Next Character Received

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | Starts waiting for a character before clocking the timeout counter. Immediately disables a timeout period in progress. Resets the FLEX_US_CSR.TIMEOUT status bit. |

### Bit 10 – STPBRK Stop Break

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | Stops transmission of the break after a minimum of one character length and transmits a high level during 12-bit periods. No effect if no break is being transmitted. |

### Bit 9 – STTBRK Start Break

| Value | Description  |
|-------|--|
| 0     | No effect.   |
| 1     | Starts transmission of a break after the characters present in FLEX_US_THR and the Transmit Shift Register have been transmitted. No effect if a break is already being transmitted. |

### Bit 8 – RSTSTA Reset Status Bits

| Value | Description  |
|-------|--|
| 0     | No effect.   |
| 1     | Resets the PARE, FRAME, OVRE, MANE, LINBE, LINISFE, LINIPE, LINC, LINSNRE, LINSTE, LINHTE, LINID, LINTC, LINBK, CMP and RXBRK in FLEX_US_CSR status bits, as well as the TXFEF, TXFFF, TXFTHF, RXFEF, RXFFF, RXFTHF, TXFPTEF, RXFPTEF in FLEX_US_FESR status bits. |

### Bit 7 – TXDIS Transmitter Disable

| Value | Description               |
|-------|---------------------------|
| 0     | No effect.                |
| 1     | Disables the transmitter. |

### Bit 6 – TXEN Transmitter Enable

| Value | Description                            |
|-------|--|
| 0     | No effect.                             |
| 1     | Enables the transmitter if TXDIS is 0. |

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

---

---

### Bit 5 – RXDIS Receiver Disable

| Value | Description            |
|-------|------------------------|
| 0     | No effect.             |
| 1     | Disables the receiver. |

### Bit 4 – RXEN Receiver Enable

| Value | Description                          |
|-------|--------------------------------------|
| 0     | No effect.                           |
| 1     | Enables the receiver, if RXDIS is 0. |

### Bit 3 – RSTTX Reset Transmitter

| Value | Description             |
|-------|-------------------------|
| 0     | No effect.              |
| 1     | Resets the transmitter. |

### Bit 2 – RSTRX Reset Receiver

| Value | Description          |
|-------|----------------------|
| 0     | No effect.           |
| 1     | Resets the receiver. |

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

### 46.10.5 USART Control Register (SPI\_MODE)

**Name:** FLEX\_US\_CR (SPI\_MODE)  
**Offset:** 0x200  
**Reset:** –  
**Property:** Write-only

This configuration is relevant only if USART\_MODE = 0xE or 0xF in the [USART Mode Register](#).

|        |       |      |       |      |       |       |    |        |
|--------|-------|------|-------|------|-------|-------|----|--------|
| Bit    | 31    | 30   | 29    | 28   | 27    | 26    | 25 | 24     |
|        |       |      |       |      |       |       |    |        |
| Access |       |      |       |      |       |       |    |        |
| Reset  |       |      |       |      |       |       |    |        |
|        |       |      |       |      |       |       |    |        |

| Reset  |       |      |       |      | –     | –     |    |        |
|        |       |      |       |      |       |       |    |        |
| Bit    | 15    | 14   | 13    | 12   | 11    | 10    | 9  | 8      |
|        |       |      |       |      |       |       |    | RSTSTA |
| Access |       |      |       |      |       |       |    | W      |
| Reset  |       |      |       |      |       |       |    | –      |
|        |       |      |       |      |       |       |    |        |
| Bit    | 7     | 6    | 5     | 4    | 3     | 2     | 1  | 0      |
|        | TXDIS | TXEN | RXDIS | RXEN | RSTTX | RSTRX |    |        |
| Access | W     | W    | W     | W    | W     | W     |    |        |
| Reset  | –     | –    | –     | –    | –     | –     |    |        |

#### Bit 19 – RCS Release SPI Chip Select

Applicable if USART operates in SPI Master mode (USART\_MODE = 0xE):

| Value | Description                                   |
|-------|---|
| 0     | No effect.                                    |
| 1     | Releases the Slave Select Line NSS (RTS pin). |

#### Bit 18 – FCS Force SPI Chip Select

Applicable if USART operates in SPI Master mode (USART\_MODE = 0xE):

| Value | Description  |
|-------|--|
| 0     | No effect.   |
| 1     | Forces the Slave Select Line NSS (RTS pin) to 0, even if USART is not transmitting, in order to address SPI slave devices supporting the CSAAT mode (Chip Select Active After Transfer). |

#### Bit 8 – RSTSTA Reset Status Bits

| Value | Description                                   |
|-------|---|
| 0     | No effect.                                    |
| 1     | Resets the FLEX_US_CSR.OVRE/UNRE status bits. |

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

### Bit 7 – TXDIS Transmitter Disable

| Value | Description               |
|-------|---------------------------|
| 0     | No effect.                |
| 1     | Disables the transmitter. |

### Bit 6 – TXEN Transmitter Enable

| Value | Description                            |
|-------|--|
| 0     | No effect.                             |
| 1     | Enables the transmitter if TXDIS is 0. |

### Bit 5 – RXDIS Receiver Disable

| Value | Description            |
|-------|------------------------|
| 0     | No effect.             |
| 1     | Disables the receiver. |

### Bit 4 – RXEN Receiver Enable

| Value | Description                          |
|-------|--------------------------------------|
| 0     | No effect.                           |
| 1     | Enables the receiver, if RXDIS is 0. |

### Bit 3 – RSTTX Reset Transmitter

| Value | Description             |
|-------|-------------------------|
| 0     | No effect.              |
| 1     | Resets the transmitter. |

### Bit 2 – RSTRX Reset Receiver

| Value | Description          |
|-------|----------------------|
| 0     | No effect.           |
| 1     | Resets the receiver. |

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

### 46.10.6 USART Mode Register

**Name:** FLEX\_US\_MR  
**Offset:** 0x204  
**Reset:** –  
**Property:** Read/Write

This register can only be written if the WPEN bit is cleared in the [USART Write Protection Mode Register](#).  
 For SPI configuration, see section [USART Mode Register \(SPI\\_MODE\)](#).

|        |     |             |          |             |        |      |                    |       |      |
|--------|-----|-------------|----------|-------------|--------|------|--------------------|-------|------|
|        | Bit | 31          | 30       | 29          | 28     | 27   | 26                 | 25    | 24   |

| Access |     | R/W         | R/W      | R/W         | R/W    | R/W  | R/W                | R/W   | R/W  |
| Reset  |     | –           | –        | –           | –      | –    | –                  | –     | –    |
|        |     |             |          |             |        |      |                    |       |      |
|        | Bit | 7           | 6        | 5           | 4      | 3    | 2                  | 1     | 0    |
|        |     | CHRL[1:0]   |          | USCLKS[1:0] |        |      | USART_MODE[3:0]    |       |      |
| Access |     | R/W         | R/W      | R/W         | R/W    | R/W  | R/W                | R/W   | R/W  |
| Reset  |     | –           | –        | –           | –      | –    | –                  | –     | –    |

#### Bit 31 – ONEBIT Start Frame Delimiter Selector

| Value | Description                                    |
|-------|--|
| 0     | Start frame delimiter is COMMAND or DATA SYNC. |
| 1     | Start frame delimiter is one bit.              |

#### Bit 30 – MODSYNC Manchester Synchronization Mode

| Value | Description                                      |
|-------|--|
| 0     | The Manchester start bit is a 0 to 1 transition  |
| 1     | The Manchester start bit is a 1 to 0 transition. |

#### Bit 29 – MAN Manchester Encoder/Decoder Enable

| Value | Description                              |
|-------|--|
| 0     | Manchester encoder/decoder are disabled. |
| 1     | Manchester encoder/decoder are enabled.  |

#### Bit 28 – FILTER Receive Line Filter

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

| Value | Description  |
|-------|--|
| 0     | The USART does not filter the receive line.  |
| 1     | The USART filters the receive line using a three-sample filter (1/16-bit clock) (2 over 3 majority). |

**Bits 26:24 – MAX\_ITERATION[2:0]** Maximum Number of Automatic Iterations

| Value | Description   |
|-------|---|
| 0–7   | Defines the maximum number of iterations in mode ISO7816, protocol T = 0. |

**Bit 23 – INVDATA** Inverted Data

| Value | Description  |
|-------|--|
| 0     | The data field transmitted on TXD line is the same as the one written in FLEX_US_THR or the content read in FLEX_US_RHR is the same as RXD line. Normal mode of operation.   |
| 1     | The data field transmitted on TXD line is inverted (voltage polarity only) compared to the value written in FLEX_US_THR or the content read in FLEX_US_RHR is inverted compared to what is received on RXD line (or ISO7816 IO line). Inverted mode of operation, useful for contactless card application. To be used with configuration bit MSBF. |

**Bit 22 – VAR\_SYNC** Variable Synchronization of Command/Data Sync Start Frame Delimiter

| Value | Description  |
|-------|--|
| 0     | User defined configuration of command or data sync field depending on MODSYNC value. |
| 1     | The sync field is updated when a character is written into FLEX_US_THR.              |

**Bit 21 – DSNACK** Disable Successive NACK

The MAX\_ITERATION field must be cleared if DSNACK is cleared.

| Value | Description  |
|-------|--|
| 0     | NACK is sent on the ISO line as soon as a parity error occurs in the received character (unless INACK is set).   |
| 1     | Successive parity errors are counted up to the value specified in the MAX_ITERATION field. These parity errors generate a NACK on the ISO line. As soon as this value is reached, no additional NACK is sent on the ISO line. The flag ITER is asserted. |

**Bit 20 – INACK** Inhibit Non Acknowledge

| Value | Description                |
|-------|----------------------------|
| 0     | The NACK is generated.     |
| 1     | The NACK is not generated. |

**Bit 19 – OVER** Oversampling Mode

| Value | Description       |
|-------|-------------------|
| 0     | 16x Oversampling. |
| 1     | 8x Oversampling.  |

**Bit 18 – CLKO** Clock Output Select

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

| Value | Description  |
|-------|--|
| 0     | The USART does not drive the SCK pin (Synchronous Slave mode or Asynchronous mode with external baud rate clock source). |
| 1     | The USART drives the SCK pin if USCLKS does not select the external clock SCK (USART Synchronous Master mode).           |

### Bit 17 – MODE9 9-bit Character Length

| Value | Description                    |
|-------|--------------------------------|
| 0     | CHRL defines character length. |
| 1     | 9-bit character length.        |

### Bit 16 – MSBF Bit Order

| Value | Description                                   |
|-------|---|
| 0     | Least significant bit is sent/received first. |
| 1     | Most significant bit is sent/received first.  |

### Bits 15:14 – CHMODE[1:0] Channel Mode

| Value | Name            | Description  |
|-------|-----------------|--|
| 0     | NORMAL          | Normal mode  |
| 1     | AUTOMATIC       | Automatic Echo. Receiver input is connected to the TXD pin.            |
| 2     | LOCAL_LOOPBACK  | Local Loopback. Transmitter output is connected to the Receiver Input. |
| 3     | REMOTE_LOOPBACK | Remote Loopback. RXD pin is internally connected to the TXD pin.       |

### Bits 13:12 – NBSTOP[1:0] Number of Stop Bits

| Value | Name    | Description                                    |
|-------|---------|--|
| 0     | 1_BIT   | 1 stop bit                                     |
| 1     | 1_5_BIT | 1.5 stop bit (SYNC = 0) or reserved (SYNC = 1) |
| 2     | 2_BIT   | 2 stop bits                                    |

### Bits 11:9 – PAR[2:0] Parity Type

| Value | Name      | Description                |
|-------|-----------|----------------------------|
| 0     | EVEN      | Even parity                |
| 1     | ODD       | Odd parity                 |
| 2     | SPACE     | Parity forced to 0 (Space) |
| 3     | MARK      | Parity forced to 1 (Mark)  |
| 4     | NO        | No parity                  |
| 6     | MULTIDROP | Multidrop mode             |

### Bit 8 – SYNC Synchronous Mode Select

| Value | Description                                 |
|-------|---|
| 0     | USART operates in Asynchronous mode (UART). |
| 1     | USART operates in Synchronous mode.         |

### Bits 7:6 – CHRL[1:0] Character Length

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

| Value | Name  | Description                |
|-------|-------|----------------------------|
| 0     | 5_BIT | Character length is 5 bits |
| 1     | 6_BIT | Character length is 6 bits |
| 2     | 7_BIT | Character length is 7 bits |
| 3     | 8_BIT | Character length is 8 bits |

### Bits 5:4 – USCLKS[1:0] Clock Selection

| Value | Name | Description  |
|-------|------|--|
| 0     | MCK  | Peripheral clock is selected   |
| 1     | DIV  | Peripheral clock divided (DIV = 8) is selected   |
| 2     | GCLK | PMC generic clock is selected. If the SCK pin is driven (CLKO = 1), the CD field must be greater than 1. |
| 3     | SCK  | External pin SCK is selected   |

### Bits 3:0 – USART\_MODE[3:0] USART Mode of Operation

| Value | Name             | Description  |
|-------|------------------|--|
| 0x0   | NORMAL           | Normal mode  |
| 0x1   | RS485            | RS485  |
| 0x2   | HW_HANDSHAKING   | Hardware handshaking   |
| 0x3   | MODEM            | Modem  |
| 0x4   | IS07816_T_0      | IS07816 Protocol: T = 0  |
| 0x6   | IS07816_T_1      | IS07816 Protocol: T = 1  |
| 0x8   | IRDA             | IrDA   |

## Flexible Serial Communication Controller (FLEXCOM)

### 46.10.7 USART Mode Register (SPI\_MODE)

**Name:** FLEX\_US\_MR (SPI\_MODE)  
**Offset:** 0x204  
**Reset:** –  
**Property:** Read/Write

This configuration is relevant only if USART\_MODE = 0xE or 0xF in the [USART Mode Register](#).

This register can only be written if the WPEN bit is cleared in the [USART Write Protection Mode Register](#).

|        |             |     |             |     |                 |     |      |      |

| Reset  | 0           | –   |             |     |                 |     | –    |      |
| Bit    | 7           | 6   | 5           | 4   | 3               | 2   | 1    | 0    |
|        | CHRL[1:0]   |     | USCLKS[1:0] |     | USART_MODE[3:0] |     |      |      |
| Access | R/W         | R/W | R/W         | R/W | R/W             | R/W | R/W  | R/W  |
| Reset  | 0           | –   | 0           | –   | 0               | 0   | 0    | –    |

#### Bit 20 – WRDBT Wait Read Data Before Transfer

| Value | Description   |
|-------|---|
| 0     | The character transmission starts as soon as a character is written into FLEX_US_THR (assuming TXRDY was set).                            |
| 1     | The character transmission starts when a character is written and only if RXRDY flag is cleared (Receive Holding Register has been read). |

#### Bit 16 – CPOL SPI Clock Polarity

CPOL is used to determine the inactive state value of the serial clock (SPCK). It is used with CPHA to produce the required clock/data relationship between master and slave devices.

Applicable if USART operates in SPI mode (slave or master, USART\_MODE = 0xE or 0xF):

| Value | Description   |
|-------|---|
| 0     | The inactive state value of SPCK is logic level zero. |
| 1     | The inactive state value of SPCK is logic level one.  |

#### Bits 15:14 – CHMODE[1:0] Channel Mode

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

| Value | Name   | Description |
|-------|--------|-------------|
| 0     | NORMAL | Normal mode |

### Bit 8 – CPHA SPI Clock Phase

CPHA determines which edge of SPCK causes data to change and which edge causes data to be captured. CPHA is used with CPOL to produce the required clock/data relationship between master and slave devices.

Applicable if USART operates in SPI mode (USART\_MODE = 0xE or 0xF):

| Value | Description  |
|-------|--|
| 0     | Data are changed on the leading edge of SPCK and captured on the following edge of SPCK. |
| 1     | Data are captured on the leading edge of SPCK and changed on the following edge of SPCK. |

### Bits 7:6 – CHRL[1:0] Character Length

| Value | Name  | Description                |
|-------|-------|----------------------------|
| 3     | 8_BIT | Character length is 8 bits |

### Bits 5:4 – USCLKS[1:0] Clock Selection

| Value | Name | Description                                   |
|-------|------|---|
| 0     | MCK  | Peripheral clock is selected                  |
| 1     | DIV  | Peripheral clock Divided (DIV= 8) is selected |
| 2     | GCLK | A PMC generic clock is selected               |
| 3     | SCK  | External pin SCK is selected                  |

### Bits 3:0 – USART\_MODE[3:0] USART Mode of Operation

| Value | Name       | Description |
|-------|------------|-------------|
| 0xE   | SPI_MASTER | SPI master  |
| 0xF   | SPI_SLAVE  | SPI slave   |

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

### 46.10.8 USART Interrupt Enable Register

**Name:** FLEX\_US\_IER  
**Offset:** 0x208  
**Reset:** –  
**Property:** Write-only

For SPI-specific configurations, see [USART Interrupt Enable Register \(SPI\\_MODE\)](#).

For LIN-specific configurations, see [USART Interrupt Enable Register \(LIN\\_MODE\)](#).

The following configuration values are valid for all listed bit names of this register:

0: No effect

1: Enables the corresponding interrupt.

|        |     |      |       |      |    |    |       |         |         |
|--------|-----|------|-------|------|----|----|-------|---------|---------|
|        | Bit | 31   | 30    | 29   | 28 | 27 | 26    | 25      | 24      |
|        |     |      |       |      |    |    |       |         | MANE    |
| Access |     |      |       |      |    |    |       |         | W       |
| Reset  |     |      |       |      |    |    |       |         | –       |
|        |     |      |       |      |    |    |       |         |         |
|        | Bit | 23   | 22    | 21   | 20 | 19 | 18    | 17      | 16      |
|        |     |      |       | CMP  |    |    | CTSIC |         |         |

### 46.10.12 USART Interrupt Disable Register (SPI\_MODE)

**Name:** FLEX\_US\_IDR (SPI\_MODE)  
**Offset:** 0x20C  
**Reset:** –  
**Property:** Write-only

This configuration is relevant only if USART\_MODE = 0xE or 0xF in the [USART Mode Register](#).

This register can only be written if the WPITEN bit is cleared in the [USART Write Protection Mode Register](#).

The following configuration values are valid for all listed bit names of this register:

0: No effect

1: Disables the corresponding interrupt.

|        |    |    |    |    |    |    |    |    |
|--------|----|----|----|----|----|----|----|----|
| Bit    | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 |
|        |    |    |    |    |    |    |    |    |
| Access |    |    |    |    |    |    |    |    |
| Reset  |    |    |    |    |    |    |    |    |

#### Bit 24 – MANE Manchester Error

| Value | Description   |
|-------|---|
| 0     | No Manchester error has been detected since the last RSTSTA command was issued.           |
| 1     | At least one Manchester error has been detected since the last RSTSTA command was issued. |

#### Bit 23 – CTS Image of CTS Input

| Value | Description               |
|-------|---------------------------|
| 0     | CTS input is driven low.  |
| 1     | CTS input is driven high. |

#### Bit 22 – CMP Comparison Status

| Value | Description   |
|-------|---|
| 0     | No received character matched the comparison criteria programmed in VAL1, VAL2 fields and CMPPAR bit in since the last RSTSTA command was issued. |
| 1     | A received character matched the comparison criteria since the last RSTSTA command was issued.  |

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

### Bit 19 – CTSIC Clear to Send Input Change Flag

| Value | Description  |
|-------|--|
| 0     | No input change has been detected on the CTS pin since the last read of FLEX_US_CSR.           |
| 1     | At least one input change has been detected on the CTS pin since the last read of FLEX_US_CSR. |

### Bit 13 – NACK Non Acknowledge Interrupt

| Value | Description  |
|-------|--|
| 0     | Non acknowledge has not been detected since the last RSTNACK.          |
| 1     | At least one non acknowledge has been detected since the last RSTNACK. |

### Bit 10 – ITER Max Number of Repetitions Reached

| Value | Description   |
|-------|---|
| 0     | Maximum number of repetitions has not been reached since the last RSTIT command was issued. |
| 1     | Maximum number of repetitions has been reached since the last RSTIT command was issued.     |

### Bit 9 – TXEMPTY Transmitter Empty (cleared by writing FLEX\_US\_THR)

| Value | Description  |
|-------|--|
| 0     | There are characters in either FLEX_US_THR or the Transmit Shift Register, or the transmitter is disabled. |
| 1     | There are no characters in FLEX_US_THR, nor in the Transmit Shift Register.                                |

### Bit 8 – TIMEOUT Receiver Timeout

| Value | Description  |
|-------|--|
| 0     | There has not been a timeout since the last Start Timeout command (FLEX_US_CR.STTTO) or the Timeout Register is 0. |
| 1     | There has been a timeout since the last Start Timeout command (FLEX_US_CR.STTTO).                                  |

### Bit 7 – PARE Parity Error

| Value | Description   |
|-------|---|
| 0     | No parity error has been detected since the last RSTSTA command was issued.           |
| 1     | At least one parity error has been detected since the last RSTSTA command was issued. |

### Bit 6 – FRAME Framing Error

| Value | Description   |
|-------|---|
| 0     | No stop bit has been detected low since the last RSTSTA command was issued.           |
| 1     | At least one stop bit has been detected low since the last RSTSTA command was issued. |

### Bit 5 – OVRE Overrun Error

| Value | Description   |
|-------|---|
| 0     | No overrun error has occurred since the last RSTSTA command was issued.           |
| 1     | At least one overrun error has occurred since the last RSTSTA command was issued. |

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

---

---

### Bit 2 – RXBRK Break Received/End of Break

| Value | Description  |
|-------|--|
| 0     | No break received or end of break detected since the last RSTSTA command was issued. |
| 1     | Break received or end of break detected since the last RSTSTA command was issued.    |

### Bit 1 – TXRDY Transmitter Ready (cleared by writing FLEX\_US\_THR)

When FIFOs are disabled:

0: A character in FLEX\_US\_THR is waiting to be transferred to the Transmit Shift Register, or an STTBRK command has been requested, or the transmitter is disabled. As soon as the transmitter is enabled, TXRDY becomes 1.

1: There is no character in FLEX\_US\_THR.

When FIFOs are enabled:

0: Transmit FIFO is full and cannot accept more data.

1: Transmit FIFO is not full; one or more data can be written according to TXRDYM field configuration.

TXRDY behavior with FIFO enabled is illustrated in [46.7.11.5 TXEMPTY, TXRDY and RXRDY Behavior](#).

### Bit 0 – RXRDY Receiver Ready (cleared by reading FLEX\_US\_RHR)

When FIFOs are disabled:

0: No complete character has been received since the last read of FLEX\_US\_RHR or the receiver is disabled. If characters were received when the receiver was disabled, RXRDY changes to 1 when the receiver is enabled.

1: At least one complete character has been received and FLEX\_US\_RHR has not yet been read.

When FIFOs are enabled:

0: Receive FIFO is empty; no data to read

1: At least one unread data is in the Receive FIFO

RXRDY behavior with FIFO enabled is illustrated in [46.7.11.5 TXEMPTY, TXRDY and RXRDY Behavior](#).

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

### 46.10.18 USART Channel Status Register (SPI\_MODE)

**Name:** FLEX\_US\_CSR (SPI\_MODE)  
**Offset:** 0x214  
**Reset:** –  
**Property:** Read-only

This configuration is relevant only if USART\_MODE = 0xE or 0xF in the [USART Mode Register](#).

|        |                         |     |      |                       |      |                       |         |                    |       |

| Access |                         |     | R    |                       |      |                       |         | R                  | R     |
| Reset  |                         |     | –    |                       |      |                       |         | –                  | –     |

#### Bit 23 – NSS Image of NSS Line

| Value | Description  |
|-------|--|
| 0     | NSS line is driven low (if NSSE = 1, falling edge occurred on NSS line). |
| 1     | NSS line is driven high (if NSSE = 1, rising edge occurred on NSS line). |

#### Bit 22 – CMP Comparison Match

| Value | Description   |
|-------|---|
| 0     | No received character matched the comparison criteria programmed in VAL1, VAL2 fields and CMPPAR bit in FLEX_US_CMPPR since the last RSTSTA command was issued. |
| 1     | A received character matched the comparison criteria since the last RSTSTA command was issued.  |

#### Bit 19 – NSSE NSS Line (Driving CTS Pin) Rising or Falling Edge Event (cleared on read)

| Value | Description  |
|-------|--|
| 0     | No NSS line event has been detected since the last read of FLEX_US_CSR.                        |
| 1     | A rising or falling edge has been detected on the NSS line since the last read of FLEX_US_CSR. |

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

### Bit 10 – UNRE Underrun Error

| Value | Description  |
|-------|--|
| 0     | No SPI underrun error has occurred since the last RSTSTA command was issued.           |
| 1     | At least one SPI underrun error has occurred since the last RSTSTA command was issued. |

### Bit 9 – TXEMPTY Transmitter Empty (cleared by writing FLEX\_US\_THR)

| Value | Description  |
|-------|--|
| 0     | There are characters in either FLEX_US_THR or the Transmit Shift Register, or the transmitter is disabled. |
| 1     | There are no characters in FLEX_US_THR, nor in the Transmit Shift Register.                                |

### Bit 5 – OVRE Overrun Error

| Value | Description   |
|-------|---|
| 0     | No overrun error has occurred since the last RSTSTA command was issued.           |
| 1     | At least one overrun error has occurred since the last RSTSTA command was issued. |

### Bit 1 – TXRDY Transmitter Ready (cleared by writing FLEX\_US\_THR)

| Value | Description   |
|-------|---|
| 0     | A character in FLEX_US_THR is waiting to be transferred to the Transmit Shift Register, or the transmitter is disabled. As soon as the transmitter is enabled, TXRDY becomes 1. |
| 1     | There is no character in FLEX_US_THR.   |

### Bit 0 – RXRDY Receiver Ready (cleared by reading FLEX\_US\_RHR)

| Value | Description  |
|-------|--|
| 0     | No complete character has been received since the last read of FLEX_US_RHR or the receiver is disabled. If characters were being received when the receiver was disabled, RXRDY changes to 1 when the receiver is enabled. |
| 1     | At least one complete character has been received and FLEX_US_RHR has not yet been read.   |

| Reset  | –      | –      | –       |       |        |         | –       | –       |

#### Bit 31 – LINHTE LIN Header Timeout Error

| Value | Description   |
|-------|---|
| 0     | No LIN header timeout error has been detected since the last RSTSTA command was issued. |
| 1     | A LIN header timeout error has been detected since the last RSTSTA command was issued.  |

#### Bit 30 – LINSTE LIN Synch Tolerance Error

| Value | Description  |
|-------|--|
| 0     | No LIN synch tolerance error has been detected since the last RSTSTA command was issued. |
| 1     | A LIN synch tolerance error has been detected since the last RSTSTA command was issued.  |

#### Bit 29 – LINSNRE LIN Slave Not Responding Error

| Value | Description   |
|-------|---|
| 0     | No LIN slave not responding error has been detected since the last RSTSTA command was issued. |

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

| Value | Description  |
|-------|--|
| 1     | A LIN slave not responding error has been detected since the last RSTSTA command was issued. |

### Bit 28 – LINCE LIN Checksum Error

| Value | Description   |
|-------|---|
| 0     | No LIN checksum error has been detected since the last RSTSTA command was issued. |
| 1     | A LIN checksum error has been detected since the last RSTSTA command was issued.  |

### Bit 27 – LINIPE LIN Identifier Parity Error

| Value | Description  |
|-------|--|
| 0     | No LIN identifier parity error has been detected since the last RSTSTA command was issued. |
| 1     | A LIN identifier parity error has been detected since the last RSTSTA command was issued.  |

### Bit 26 – LINISFE LIN Inconsistent Synch Field Error

| Value | Description  |
|-------|--|
| 0     | No LIN inconsistent synch field error has been detected since the last RSTSTA  |
| 1     | The USART is configured as a slave node and a LIN Inconsistent synch field error has been detected since the last RSTSTA command was issued. |

### Bit 25 – LINBE LIN Bit Error

| Value | Description  |
|-------|--|
| 0     | No bit error has been detected since the last RSTSTA command was issued. |
| 1     | A bit error has been detected since the last RSTSTA command was issued.  |

### Bit 23 – LINBLS LIN Bus Line Status

| Value | Description               |
|-------|---------------------------|
| 0     | LIN bus line is set to 0. |
| 1     | LIN bus line is set to 1. |

### Bit 15 – LINTC LIN Transfer Completed

| Value | Description   |
|-------|---|
| 0     | The USART is idle or a LIN transfer is ongoing.                             |
| 1     | A LIN transfer has been completed since the last RSTSTA command was issued. |

### Bit 14 – LINID LIN Identifier Sent or LIN Identifier Received

If USART operates in LIN Master mode (USART\_MODE = 0xA):

0: No LIN identifier has been sent since the last RSTSTA command was issued.

1: At least one LIN identifier has been sent since the last RSTSTA command was issued.

If USART operates in LIN Slave mode (USART\_MODE = 0xB):

0: No LIN identifier has been received since the last RSTSTA command was issued.

1: At least one LIN identifier has been received since the last RSTSTA.

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

### Bit 13 – LINBK LIN Break Sent or LIN Break Received

Applicable if USART operates in LIN Master mode (USART\_MODE = 0xA):

0: No LIN break has been sent since the last RSTSTA command was issued.

1: At least one LIN break has been sent since the last RSTSTA.

If USART operates in LIN Slave mode (USART\_MODE = 0xB):

0: No LIN break has received sent since the last RSTSTA command was issued.

1: At least one LIN break has been received since the last RSTSTA command was issued.

### Bit 9 – TXEMPTY Transmitter Empty (cleared by writing FLEX\_US\_THR)

| Value | Description  |
|-------|--|
| 0     | There are characters in either FLEX_US_THR or the Transmit Shift Register, or the transmitter is disabled. |
| 1     | There are no characters in FLEX_US_THR, nor in the Transmit Shift Register.                                |

### Bit 8 – TIMEOUT Receiver Timeout

| Value | Description  |
|-------|--|
| 0     | There has not been a timeout since the last start timeout command (FLEX_US_CR.STTTO) or the Timeout Register is 0. |
| 1     | There has been a timeout since the last start timeout command (FLEX_US_CR.STTTO).                                  |

### Bit 7 – PARE Parity Error

| Value | Description   |
|-------|---|
| 0     | No parity error has been detected since the last RSTSTA command was issued.           |
| 1     | At least one parity error has been detected since the last RSTSTA command was issued. |

### Bit 6 – FRAME Framing Error

| Value | Description   |
|-------|---|
| 0     | No stop bit has been detected low since the last RSTSTA command was issued.           |
| 1     | At least one stop bit has been detected low since the last RSTSTA command was issued. |

### Bit 5 – OVRE Overrun Error

| Value | Description   |
|-------|---|
| 0     | No overrun error has occurred since the last RSTSTA command was issued.           |
| 1     | At least one overrun error has occurred since the last RSTSTA command was issued. |

### Bit 1 – TXRDY Transmitter Ready (cleared by writing FLEX\_US\_THR)

| Value | Description   |
|-------|---|
| 0     | A character in FLEX_US_THR is waiting to be transferred to the Transmit Shift Register, or the transmitter is disabled. As soon as the transmitter is enabled, TXRDY becomes 1. |
| 1     | There is no character in FLEX_US_THR.   |

### Bit 0 – RXRDY Receiver Ready (cleared by reading FLEX\_US\_RHR)

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

| Value | Description  |
|-------|--|
| 0     | No complete character has been received since the last read of FLEX_US_RHR or the receiver is disabled. If characters were being received when the receiver was disabled, RXRDY changes to 1 when the receiver is enabled. |
| 1     | At least one complete character has been received and FLEX_US_RHR has not yet been read.   |

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

### 46.10.20 USART Receive Holding Register

**Name:** FLEX\_US\_RHR  
**Offset:** 0x218  
**Reset:** 0x00000000  
**Property:** Read-only

If FIFO is enabled (FLEX\_US\_CR.FIFOEN bit) and FLEX\_US\_FMR.RXRDYM = 0, see [46.7.11.6 USART Single Data Mode](#) for details.

#### Bit 15 – RXSYNH Received Sync

| Value | Description                           |
|-------|---------------------------------------|
| 0     | Last character received is a data.    |
| 1     | Last character received is a command. |

**Bits 8:0 – RXCHR[8:0]** Received Character  
 Last character received if RXRDY is set.

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

### 46.10.21 USART Receive Holding Register (FIFO Multi Data)

**Name:** FLEX\_US\_RHR (FIFO\_MULTI\_DATA)  
**Offset:** 0x218  
**Reset:** 0x00000000  
**Property:** Read-only

If FIFO is enabled (FLEX\_US\_CR.FIFOEN bit) and FLEX\_US\_FMR.RXRDYM > 0, see [46.7.11.7 USART Multiple Data Mode](#) for details.

| Bit    | 31          | 30 | 29 | 28 | 27 | 26 | 25 | 24 |
|--------|-------------|----|----|----|----|----|----|----|
|        | RXCHR3[7:0] |    |    |    |    |    |    |    |
| Access | R           | R  | R  | R  | R  | R  | R  | R  |
| Reset  | 0           | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| Bit    | 23          | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|        | RXCHR2[7:0] |    |    |    |    |    |    |    |
| Access | R           | R  | R  | R  | R  | R  | R  | R  |
| Reset  | 0           | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| Bit    | 15          | 14 | 13 | 12 | 11 | 10 | 9  | 8  |
|        | RXCHR1[7:0] |    |    |    |    |    |    |    |
| Access | R           | R  | R  | R  | R  | R  | R  | R  |
| Reset  | 0           | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| Bit    | 7           | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|        | RXCHR0[7:0] |    |    |    |    |    |    |    |
| Access | R           | R  | R  | R  | R  | R  | R  | R  |
| Reset  | 0           | 0  | 0  | 0  | 0  | 0  | 0  | 0  |

**Bits 0:7, 8:15, 16:23, 24:31 – RXCHR<sub>x</sub>** Received Character  
 First unread character in the Receive FIFO if RXRDY is set.

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

### 46.10.22 USART Transmit Holding Register

**Name:** FLEX\_US\_THR  
**Offset:** 0x21C  
**Reset:** –  
**Property:** Write-only

If FIFO is enabled (FLEX\_US\_CR.FIFOEN bit) and FLEX\_US\_FMR.TXRDY = 0, see [46.7.11.6 USART Single Data Mode](#) for details.

**Bit 15 – TXSYNH** Sync Field to be Transmitted

| Value | Description   |
|-------|---|
| 0     | The next character sent is encoded as a data. Start frame delimiter is DATA SYNC.       |
| 1     | The next character sent is encoded as a command. Start frame delimiter is COMMAND SYNC. |

**Bits 8:0 – TXCHR[8:0]** Character to be Transmitted

The next character to be transmitted after the current character if TXRDY is not set.

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

### 46.10.23 USART Transmit Holding Register (FIFO Multi Data)

**Name:** FLEX\_US\_THR (FIFO\_MULTI\_DATA)  
**Offset:** 0x21C  
**Reset:** –  
**Property:** Write-only

If FIFO is enabled (FLEX\_US\_CR.FIFOEN bit) and FLEX\_US\_FMR.TXRDY > 0, see [46.7.11.7 USART Multiple Data Mode](#) for details.

|        |             |    |    |    |    |    |    |    |

| Access | W           | W  | W  | W  | W  | W  | W  | W  |
| Reset  | –           | –  | –  | –  | –  | –  | –  | –  |

**Bits 0:7, 8:15, 16:23, 24:31 – TXCHR<sub>x</sub>** Character to be Transmitted  
 Next character to be transmitted.

# SAMA5D2 Series

## Flexible Serial Communication Controller (FLEXCOM)

### 46.10.24 USART Baud Rate Generator Register

**Name:** FLEX\_US\_BRGR  
**Offset:** 0x220  
**Reset:** 0x00000000  
**Property:** Read/Write

This register can only be written if the WPEN bit is cleared in the [USART Write Protection Mode Register](#).

|        |          |     |     |     |     |         |     |     |

| Reset  | 0        | 0   | 0   | 0   | 0   | 0       | 0   | 0   |

#### Bits 18:16 – FP[2:0] Fractional Part

When the value of field FP is greater than 0, the SCK (oversampling clock) generates nonconstant duty cycles. The SCK high duration is increased by “selected clock” period from time to time. The duty cycle depends on the value of the CD field.

| Value | Description  |
|-------|--|
| 0     | Fractional divider is disabled.                    |
| 1–7   | Baud rate resolution, defined by $FP \times 1/8$ . |

#### Bits 15:0 – CD[15:0] Clock Divider

| CD | USART_MODE ≠ ISO7816 |          | USART_MODE = ISO7816 |   |
|----|----------------------|----------|----------------------|---|
|    | SYNC = 0             |          |                      | SYNC = 1                                    |
