

Quad channel high side driver for automotive applications

Features

Max transient supply voltage	V _{CC}	41V
Operating voltage range	V _{CC}	4.5 to 28V
Max on-state resistance (per ch.)	R _{ON}	160 mΩ
Current limitation (typ)	I _{LIMH}	10 A
Off-state supply current	I _S	2 μA ⁽¹⁾

1. Typical value with all loads connected.

■ General

- Inrush current active management by power limitation
- Very low standby current
- 3.0V CMOS compatible inputs
- Optimized electromagnetic emissions
- Very low electromagnetic susceptibility
- In compliance with the 2002/95/EC european directive

■ Diagnostic functions

- Open Drain status output
- On-state open load detection
- Off-state open load detection
- Output short to V_{CC} detection
- Overload and short to ground (power limitation) indication
- Thermal shutdown indication

■ Protections

- Undervoltage shut-down
- Overvoltage clamp
- Load current limitation
- Self limiting of fast thermal transients
- Protection against loss of ground and loss of V_{CC}
- Over temperature shutdown with auto restart (thermal shutdown)
- Reverse battery protected (see [Application schematic on page 22](#))
- Electrostatic discharge protection

Application

- All types of resistive, inductive and capacitive loads

Description

The VNZ5E160K-E is a quad channel high-side driver manufactured in the ST proprietary VIPower M0-5 technology and housed in the tiny PowerSSO-24 package.

The VNZ5E160K-E is designed to drive automotive grounded loads delivering protection, diagnostics and easy 3V and 5V CMOS-compatible interface with any microcontroller.

The device integrates advanced protective functions such as load current limitation, inrush and overload active management by power limitation, over temperature shut-off with auto restart and over-voltage active clamp.

A dedicated active low digital status pin is associated with every output channel in order to provide *Enhanced* diagnostic functions including fast detection of overload and short-circuit to ground, over temperature indication, short-circuit to V_{CC} diagnosis and ON & OFF-state open-load detection.

The diagnostic feedback of the whole device can be disabled by pulling the STAT_DIS pin up, thus allowing wired-ORing with other similar devices.

2.1 Absolute maximum ratings

Stressing the device above the rating listed in the “Absolute maximum ratings” table may cause permanent damage to the device. These are stress ratings only and operation of the device at these or any other conditions above those indicated in the operating sections of this specification is not implied. Exposure to the conditions in table below for extended periods may affect device reliability. Refer also to the STMicroelectronics SURE Program and other relevant quality document.

3 Application information

Figure 32. Application schematic

Note: *Channels 2, 3 and 4 have the same internal circuit as channel 1.*

3.1 GND protection network against reverse battery

3.1.1 Solution 1: resistor in the ground line (R_{GND} only)

This solution can be used with any type of load.

The following is an indication on how to dimension the R_{GND} resistor.

1. $R_{GND} \leq 600\text{mV} / (I_{S(on)\max})$.
2. $R_{GND} \geq (-V_{CC}) / (-I_{GND})$

where $-I_{GND}$ is the DC reverse ground pin current and can be found in the absolute maximum rating section of the device datasheet.

Power dissipation in R_{GND} (when $V_{CC} < 0$: during reverse battery situations) is:

$$P_D = (-V_{CC})^2 / R_{GND}$$

This resistor can be shared amongst several different HSDs. Please note that the value of this resistor should be calculated with formula (1) where $I_{S(on)\max}$ becomes the sum of the maximum On-state currents of the different devices.

Please note that if the microprocessor ground is not shared by the device ground then the R_{GND} will produce a shift ($I_{S(on)\max} * R_{GND}$) in the input thresholds and the status output values. This shift will vary depending on how many devices are ON in the case of several high side drivers sharing the same R_{GND} .

If the calculated power dissipation leads to a large resistor or several devices have to share the same resistor then ST suggests that Solution 2 is used (see below).

3.1.2 Solution 2: diode (D_{GND}) in the ground line

A resistor ($R_{GND}=1k\Omega$) should be inserted in parallel with D_{GND} if the device drives an inductive load.

This small signal diode can be safely shared amongst several different HSDs. Also in this case, the presence of the ground network will produce a shift (~600mV) in the input threshold and in the status output values if the microprocessor ground is not common with the device ground. This shift will not vary if more than one HSD shares the same diode/resistor network.

3.2 Load dump protection

D_{ld} is necessary (Voltage Transient Suppressor) if the load dump peak voltage exceeds to V_{CC} max DC rating. The same applies if the device is subject to transients on the V_{CC} line that are greater than the ones shown in the ISO T/R 7637/2 table.

3.3 MCU I/Os protection

If a ground protection network is used and negative transients are present on the V_{CC} line, the control pins will be pulled negative. ST suggests the insertion of resistors (R_{prot}) in the lines to prevent the μC I/Os pins from latching up.

The values of these resistors are a compromise between the leakage current of μC and the current required by the HSD I/Os (Input levels compatibility) with the latch-up limit of the μC I/Os.

$$-V_{CCpeak}/I_{latchup} \leq R_{prot} \leq (V_{OH\mu C} - V_{IH} - V_{GND}) / I_{IHmax}$$

Calculation example:

For $V_{CCpeak} = -100V$ and $I_{latchup} \geq 20mA$; $V_{OH\mu C} \geq 4.5V$

$$5k\Omega \leq R_{prot} \leq 180k\Omega$$

Recommended R_{prot} value is $10k\Omega$.

3.4 Open-load detection in off-state

Off-state open load detection requires an external pull-up resistor (R_{PU}) connected between the OUTPUT pin and a positive supply voltage (V_{PU}) like the +5V line used to supply the microprocessor.

The external resistor has to be selected according to the following requirements:

1. no false open load indication when load is connected: in this case we have to avoid V_{OUT} to be higher than V_{OLmin} ; this results in the following condition:

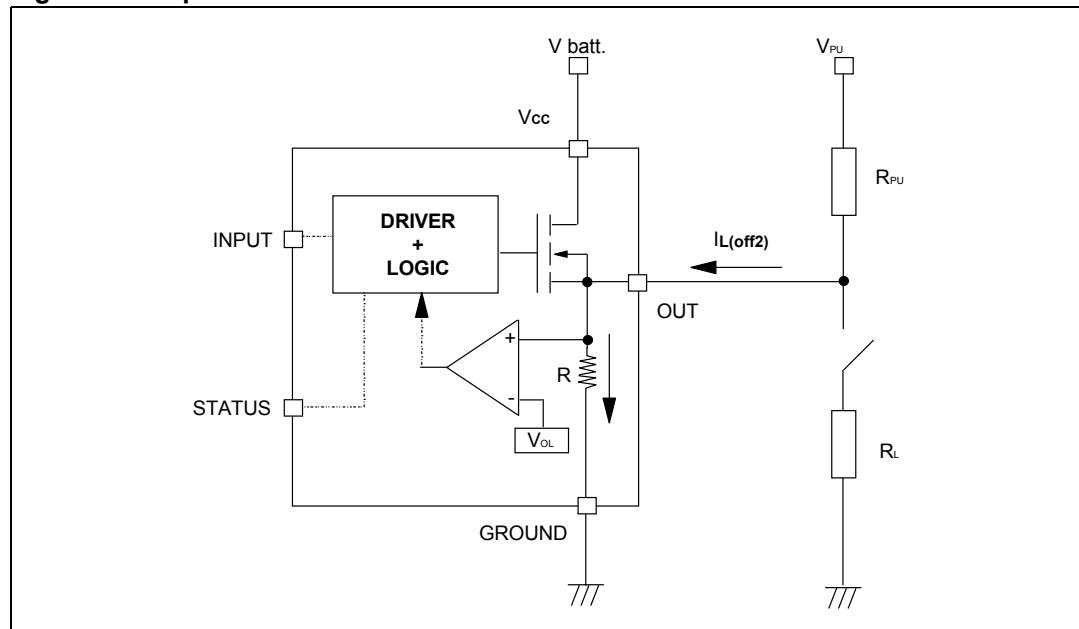

$$V_{OUT} = (V_{PU}/(R_L + R_{PU}))R_L < V_{OLmin}$$
.
2. no misdetection when the load is disconnected: in this case the V_{OUT} has to be higher than V_{OLmax} ; this results in the following condition:

$$R_{PU} < (V_{PU} - V_{OLmax}) / I_{L(off2)}$$
.

Because $I_{s(OFF)}$ may significantly increase if V_{out} is pulled high (up to several mA), the pull-up resistor R_{PU} should be connected to a supply that is switched OFF when the module is in standby.

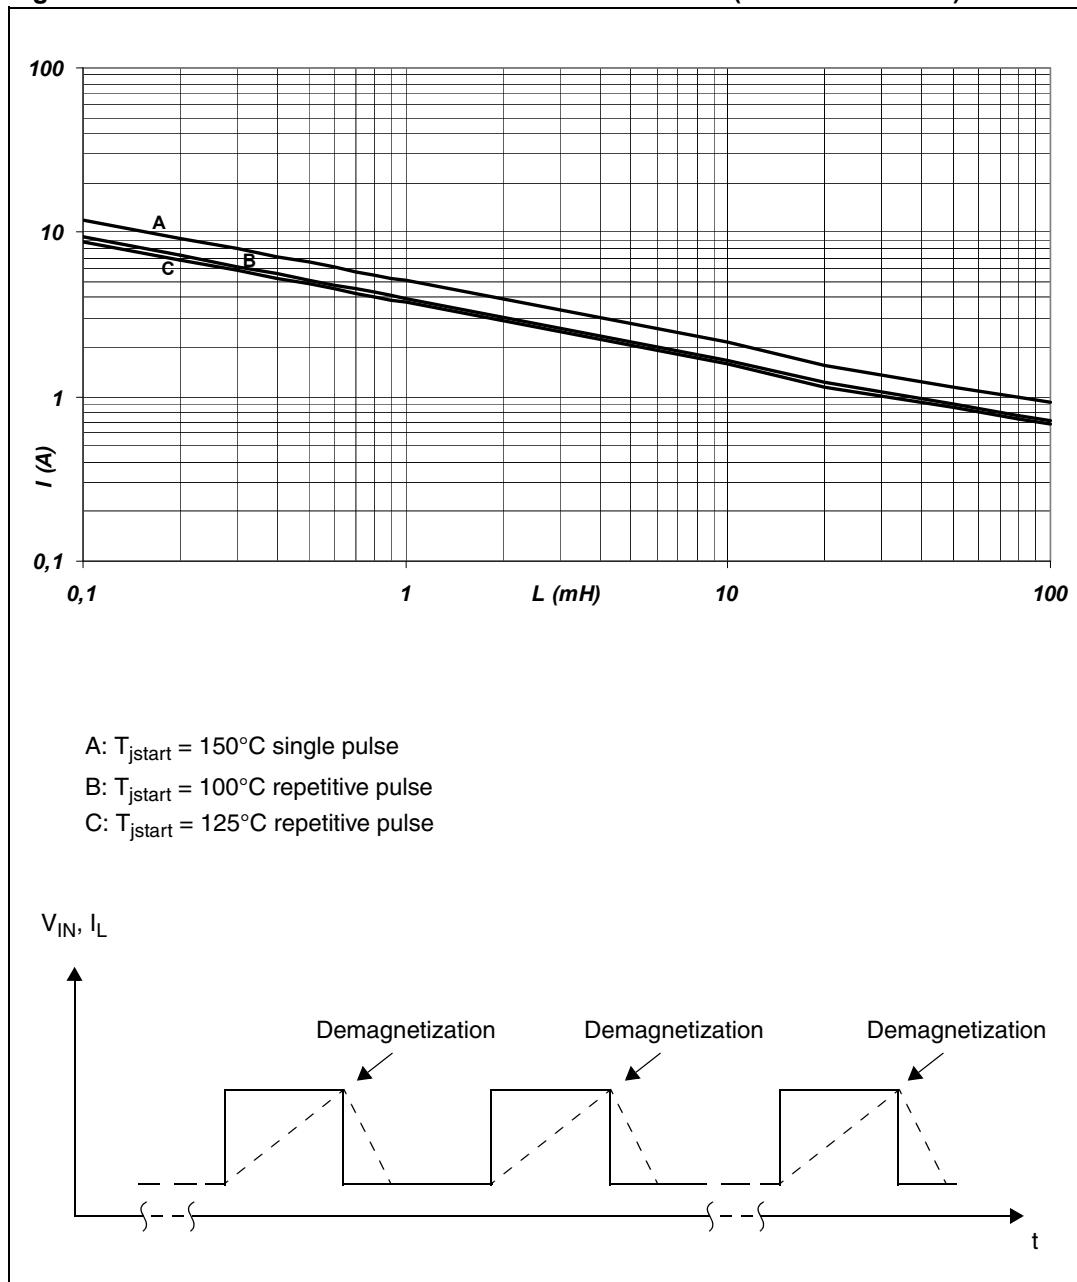

The values of V_{OLmin} , V_{OLmax} and $I_{L(off2)}$ are available in the Electrical characteristics section.

3.5 Maximum demagnetization energy ($V_{CC} = 13.5V$)

Figure 34. Maximum turn-off current versus inductance (for each channel)

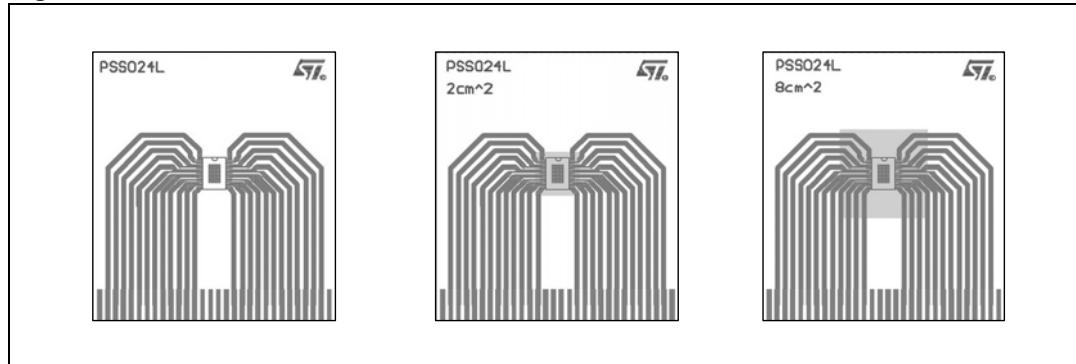

Note: Values are generated with $R_L = 0 \Omega$.

In case of repetitive pulses, T_{jstart} (at beginning of each demagnetization) of every pulse must not exceed the temperature specified above for curves A and B.
