## VOLTAGE DETECTOR

AZ70XX

### General Description

The AZ70XX series ICs are under voltage detectors with a built in voltage threshold and low power consumption. The AZ70XX are specifically designed to accurately monitor power supplies.

The AZ70XX use a precision on-chip voltage reference and a comparator to measure the input operating voltage. These ICs can accurately reset the system after detecting voltage at the time of switching power on and instantaneous power off in various CPU systems and other logic systems. The detect voltage thresholds are 2.3V/2.5V/2.7V/2.9V/3.1V/3.3V/4.2V/4.5V for AZ7023/25/27/29/31/33/42/45 respectively. Built in hysteresis helps to prevent erratic operation in the presence of noise.

The AZ70XX series are available in 2 standard packages: TO-92 (bulk or ammo packing) and SOT-89-3.

## Operating Diagram (Continued)

Figure 12 is a typical timing waveform for AZ70XX. In normal steady-state operation when  $V_{CC} > V_{DET}$ , the output will be in a logic high state and  $V_{OUT}$  is dependent upon the voltage that the pull-up resistor connected to.

Here is some explanations for AZ70XX's operation.

1. When the input voltage  $V_{CC}$  falls below  $V_{DET}$ , the output will pull down to logic low after a delay time of  $t_{pH}$ . In general, at rated output current and  $V_{CC}$ ,  $V_{OUT}$  can be pulled down to a voltage as low as within 0.4V from GND. (See the Electrical Characteristics section). The voltage level  $V_{DET}$  means the detect voltage.
2. The output,  $V_{OUT}$ , will stay valid until  $V_{CC}$  falls below the minimum operating voltage,  $V_{OPR}$  (0.8V

typical). Below minimum operating voltage, the output is undefined.

3. During power-up,  $V_{OUT}$  will remain undefined until  $V_{CC}$  rises above  $V_{OPR}$ , at which time the output will become valid.  $V_{OUT}$  will be in its active low state while  $V_{OPR} < V_{CC} < V_{DET+}$  ( $V_{DET+} = V_{DET} + V_{HYS}$ ).  $V_{DET+}$  is the release voltage.  $V_{HYS}$  means the hysteresis voltage and is the difference voltage between the  $V_{DET+}$  and  $V_{DET}$ .

4. When  $V_{CC}$  rises above  $V_{DET+}$ , the output will be in its inactive state. After a delay time of  $t_{pLH}$ ,  $V_{OUT}$  will be in its logic high state .
