

STP16DPS05

Low voltage 16-bit constant current LED sink driver with outputs error detection

Features

- Low voltage power supply down to 3 V
- 16 constant current output channels
- Adjustable output current through external resistor
- Short and open output error detection
- Serial data IN/Parallel data OUT
- 3.3 V micro driver-able
- Output current: 20-85 mA
- 30 MHz clock frequency
- Available in high thermal efficiency TSSOP exposed pad
- ESD protection 2.0 kV HBM, 200 V MM

Description

The STP16DPS05 is a monolithic, low voltage, low current power 16-bit shift register designed for LED panel displays. The device contains a 16-bit serial-in, parallel-out shift register that feeds a 16-bit D-type storage register. In the output stage, sixteen regulated current sources were designed to provide 5-100 mA constant current to drive the LEDs.

The STP16DP05 features open and short LED detections on the outputs. The STP16DP05 is backward compatible with STP16C/L596. The detection circuit checks 3 different conditions that can occur on the output line: short to GND, short to V_O or open line.

Table 1. Device summary

Order codes	Package	Packaging
STP16DPS05MTR	SO-24 (tape and reel)	1000 parts per reel
STP16DPS05TTR	TSSOP24 (tape and reel)	2500 parts per reel
STP16DPS05XTTR	TSSOP24 exposed pad (tape and reel)	2500 parts per reel
STP16DP05PTR	QSOP-24	2500 parts per reel

The data detection results are loaded in the shift register and shifted out via the serial line output.

The detection functionality is implemented without increasing the pin count number, through a secondary function of the LATCH and output enable pin (DM1 and DM2 respectively), a dedicated logic sequence allows the device to enter or leave from detection mode. Through an external resistor, users can adjust the STP16DPS05 output current, controlling in this way the light intensity of LEDs, in addition, user can adjust LED's brightness intensity from 0% to 100% via $\overline{OE}/DM2$ pin.

The STP16DPS05 guarantees a 20 V output driving capability, allowing users to connect more LEDs in series. The high clock frequency, 30 MHz, makes the device suitable for high data rate transmission. The 3.3 V voltage supply is well useful for applications that interface any 3.3V micro. Compared with a standard TSSOP package, the TSSOP exposed pad increases heat dissipation capability by a 2.5 factor.

2 Electrical ratings

2.1 Absolute maximum ratings

Stressing the device above the rating listed in the [Table 4](#) may cause permanent damage to the device. These are stress ratings only and operation of the device at these or any other conditions above those indicated in the operating sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

7 Detection mode functionality

7.1 Phase one: “entering in detection mode”

From the “normal mode” condition the device can switch to the “error mode” by a logic sequence on the $\overline{OE/DM2}$ and LE/DM1 pins as showed in the following table and diagram:

Table 12. Entering in detection truth table

CLK	1°	2°	3°	4°	5°
$\overline{OE/DM2}$	H	L	H	H	H
LE/DM1	L	L	L	H	L

Figure 14. Entering in detection timing diagram

After these five CLK cycles the device goes into the “error detection mode” and at the 6th rise front of CLK the SDI data are ready for the sampling.

7.2 Phase two: “error detection”

The 16 data bits must be set “1” in order to set ON all the outputs during the detection. The data are latched by LE/DM1 and after that the outputs are ready for the detection process. When the microcontroller switches the $\overline{OE/DM2}$ to LOW, the device drives the LEDs in order to analyze if an OPEN or SHORT condition has occurred.

Figure 15. Detection diagram

The LEDs status will be detected at least in 1 microsecond and after this time the microcontroller sets $\overline{OE/DM2}$ in HIGH state and the output data detection result will go to the microprocessor via SDO.

Detection mode and normal mode use both the same format data. As soon as all the detection data bits are available on the serial line, the device may go back to normal mode of operation. To re-detect the status the device must go back in normal mode and re-entering in error detection mode.

Figure 16. Timing example for open and/or short detection

7.3 Phase three: “resuming to normal mode”

The sequence for re-entering in normal mode is showed in the following table and diagram:

Figure 17. Resuming to normal mode timing diagram

CLK	1°	2°	3°	4°	5°
$\overline{\text{OE/DM2}}$	H	L	H	H	H
LE/DM1	L	L	L	L	L

Note: For proper device operation the “Entering in detection” sequence must be follow by a “resume mode” sequence, it is not possible to insert consecutive equal sequence.

7.4 Error detection conditions

$V_{DD} = 3.3$ to 5 V temperature range -40 to 125 °C

Table 13. Detection conditions

SW-1 or SW-3b	Open line or output short to GND detected	$\Rightarrow I_{ODEC} \leq 0.5 \times I_O$	No error detected	$\Rightarrow I_{ODEC} \geq 0.5 \times I_O$
SW-2 or SW-3a	Short on LED or short to V-LED detected	$\Rightarrow V_O \geq 2.4 \text{ V}$	No error detected	$\Rightarrow V_O \leq 2.2 \text{ V}$

Note: Where: I_O = the output current programmed by the R_{EXT} , I_{ODEC} = the detected output current in detection mode

Using the follow formula is possible measure the Iodec

$I_{ODEC} = (V_{led}-V_{load}) / R_{load}$

The tables below shows the I_{ODEC} average value at 3.3 V and 5.0 V of power supply voltage.

The I_{ODEC} is the current value recognized by the devices output open error detection
