MAXIM

8-Channel, ±V_{REF} Multirange Inputs, Serial 16-Bit ADC

MAX1302

General Description

The MAX1302 multirange, low-power, 16-bit, successive-approximation, analog-to-digital converter (ADC) operates from a single +5V supply and achieves throughput rates up to 115ksps. A separate digital supply allows digital interfacing with a 2.7V to 5.25V system using the SPI-/QSPI™-/MICROWIRE®-compatible serial interface. Partial power-down mode reduces the supply current to 1.3mA (typ). Full power-down mode reduces the power-supply current to 1µA (typ).

The MAX1302 provides eight (single-ended) or four (true differential) analog input channels. Each analog input channel is independently software programmable for seven single-ended input ranges (0V to +V_{REF}/2, -V_{REF}/2 to 0V, 0V to +V_{REF}, -V_{REF} to 0V, ±V_{REF}/4, ±V_{REF}/2, and ±V_{REF}), and three differential input ranges (±V_{REF}/2, ±V_{REF}, ±2 x V_{REF}).

An on-chip +4.096V reference offers a small convenient ADC solution. The MAX1302 also accepts an external reference voltage between 3.800V and 4.136V.

The MAX1302 is available in a 24-pin TSSOP package and is specified for operation from -40°C to +85°C.

Features

- **Software-Programmable Input Range for Each Channel**
- **Single-Ended Input Ranges**
  0V to +V_{REF}/2, -V_{REF}/2 to 0V, 0V to +V_{REF}, -V_{REF} to 0V, ±V_{REF}/4, ±V_{REF}/2, and ±V_{REF}
- **Differential Input Ranges**
  ±V_{REF}/2, ±V_{REF}, and ±2 x V_{REF}
- **Eight Single-Ended or Four Differential Analog Inputs (MAX1302)**
- **±6V Overvoltage Tolerant Inputs**
- **Internal or External Reference**
- **115ksps Maximum Sample Rate**
- **Single +5V Power Supply**
- **24-Pin TSSOP Package**

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Note 1: Parameter tested at V_{AVDD1} = V_{AVDD2} = V_{DVDD} = V_{DVDDO} = 5V.
Note 2: See definitions in the *Parameter Definitions* section at the end of the data sheet.
Note 3: Guaranteed by correlation with single-ended measurements.
Note 4: Not production tested. Guaranteed by design.
Note 5: To ensure external reference operation, V_{REFCAP} must exceed (V_{AVDD1} - 0.1V). To ensure internal reference operation, V_{REFCAP} must be below (V_{AVDD1} - 0.4V). Bypassing REFCAP with a 0.1µF or larger capacitor to AGND1 sets V_{REFCAP} ≈ 4.096V. The transition point between internal reference mode and external reference mode lies between the REFCAP buffer disable threshold minimum and maximum values (Figures 17 and 18).
Note 6: The SCLK duty cycle can vary between 40% and 60%, as long as the t_{CL} and t_{CH} timing requirements are met.

Pin Description

PIN	NAME	FUNCTION
1	AVDD1	Analog Supply Voltage 1. Connect AVDD1 to a +4.75V to +5.25V power-supply voltage. Bypass AVDD1 to AGND1 with a 0.1µF capacitor.
2	CH0	Analog Input Channel 0
3	CH1	Analog Input Channel 1
4	CH2	Analog Input Channel 2
5	CH3	Analog Input Channel 3
6	CH4	Analog Input Channel 4
7	CH5	Analog Input Channel 5
8	CH6	Analog Input Channel 6
9	CH7	Analog Input Channel 7
10	$\overline{CS}$	Active-Low Chip-Select Input. When $\overline{CS}$ is low, data is clocked into the device from DIN on the rising edge of SCLK. With $\overline{CS}$ low, data is clocked out of DOUT on the falling edge of SCLK. When $\overline{CS}$ is high, activity on SCLK and DIN is ignored and DOUT is high impedance.
11	DIN	Serial Data Input. When $\overline{CS}$ is low, data is clocked in on the rising edge of SCLK. When $\overline{CS}$ is high, transitions on DIN are ignored.
12	SSTRB	Serial-Strobe Output. When using the internal clock, SSTRB rising edge transitions indicate that data is ready to be read from the device. When operating in external clock mode, SSTRB is always low. SSTRB does not tri-state, regardless of the state of $\overline{CS}$, and therefore requires a dedicated I/O line.
13	SCLK	Serial Clock Input. When $\overline{CS}$ is low, transitions on SCLK clock data into DIN and out of DOUT. When $\overline{CS}$ is high, transitions on SCLK are ignored.
14	DOUT	Serial Data Output. When $\overline{CS}$ is low, data is clocked out of DOUT with each falling SCLK transition. When $\overline{CS}$ is high, DOUT is high impedance.
15	DGNDO	Digital I/O Ground. DGND, DGNDO, AGND3, AGND2, and AGND1 must be connected together.
16	DGND	Digital Ground. DGND, DGNDO, AGND3, AGND2, and AGND1 must be connected together.
17	DVDDO	Digital I/O Supply Voltage Input. Connect DVDDO to a +2.7V to +5.25V power-supply voltage. Bypass DVDDO to DGNDO with a 0.1µF capacitor.
18	DVDD	Digital-Supply Voltage Input. Connect DVDD to a +4.75V to +5.25V power-supply voltage. Bypass DVDD to DGND with a 0.1µF capacitor.
19	REFCAP	Bandgap-Voltage Bypass Node. For external reference operation, connect REFCAP to AVDD. For internal reference operation, bypass REFCAP with a 0.01µF capacitor to AGND1 ($V_{REFCAP} \approx 4.096V$).
20	REF	Reference-Buffer Output/ADC Reference Input. For external reference operation, apply an external reference voltage from 3.800V to 4.136V to REF. For internal reference operation, bypassing REF with a 1µF capacitor to AGND1 sets V_{REF} = 4.096V ±1%.

Pin Description (continued)

PIN	NAME	FUNCTION
21	AGND3	Analog Signal Ground 3. AGND3 is the ADC negative reference potential. Connect AGND3 to AGND1. DGND, DGNDO, AGND3, AGND2, and AGND1 must be connected together.
22	AVDD2	Analog Supply Voltage 2. Connect AVDD2 to a +4.75V to +5.25V power-supply voltage. Bypass AVDD2 to AGND2 with a 0.1µF capacitor.
23	AGND2	Analog Ground 2. This ground carries approximately five times more current than AGND1. DGND, DGNDO, AGND3, AGND2, and AGND1 must be connected together.
24	AGND1	Analog Ground 1. DGND, DGNDO, AGND3, AGND2, and AGND1 must be connected together.

Detailed Description

The MAX1302 multirange, low-power, 16-bit successive-approximation ADC operates from a single +5V supply and has a separate digital supply allowing digital interface with 2.7V to 5.25V systems. This 16-bit ADC has internal track-and-hold (T/H) circuitry that supports single-ended and fully differential inputs. For single-ended conversions, the valid analog input voltage range spans from -V_{REF} below ground to +V_{REF} above ground. The maximum allowable differential input voltage spans from -2 x V_{REF} to +2 x V_{REF}. Data can be converted in a variety of software-programmable channel and data-acquisition configurations. Microprocessor (µP) control is made easy through an SPI-/QSPI-/MICROWIRE-compatible serial interface.

The MAX1302 has eight single-ended analog input channels or four differential channels (see the *Block Diagram*). Each analog input channel is independently software programmable for seven single-ended input ranges (0V to +V_{REF}/2, -V_{REF}/2 to 0V, 0V to +V_{REF}, -V_{REF} to 0V, ±V_{REF}/4, ±V_{REF}/2, and ±V_{REF}) and three differential input ranges (±V_{REF}/2, ±V_{REF}, and ±2 x V_{REF}). Additionally, all analog input channels are fault tolerant to ±6V. A fault condition on an idle channel does not affect the conversion result of other channels.

8-Channel, ±V_{REF} Multirange Inputs, Serial 16-Bit ADC

Power Supplies

To maintain a low-noise environment, the MAX1302 provides separate power supplies for each section of circuitry. Table 1 shows the four separate power supplies. Achieve optimal performance using separate AVDD1, AVDD2, DVDD, and DVDDO supplies. Alternatively, connect AVDD1, AVDD2, and DVDD together as close to the device as possible for a convenient power connection. Connect AGND1, AGND2, AGND3, DGND, and DGNDO together as close as possible to the device. Bypass each supply to the corresponding ground using a 0.1µF capacitor (Table 1). If significant low-frequency noise is present, add a 10µF capacitor in parallel with the 0.1µF bypass capacitor.

Converter Operation

The MAX1302 ADC features a fully differential, successive-approximation register (SAR) conversion technique and an on-chip T/H block to convert voltage signals into a 16-bit digital result. Both single-ended and differential configurations are supported with programmable unipolar and bipolar signal ranges.

Track-and-Hold Circuitry

The MAX1302 features a switched-capacitor T/H architecture that allows the analog input signal to be stored as charge on sampling capacitors. See Figures 2, 3, and 4 for T/H timing and the sampling instants for each operating mode. The MAX1302 analog input circuitry buffers the input signal from the sampling capacitors, resulting in a constant analog input impedance with varying input voltage (Figure 5).

Analog Input Circuitry

Select differential or single-ended conversions using the associated analog input configuration byte (Table 2). The analog input signal source must be capable of driving the ADC's 6kΩ input resistance (Figure 6).

Figure 6 shows the simplified analog input circuit. The analog inputs are ±6V fault tolerant and are protected by back-to-back diodes. The summing junction voltage, V_{SJ}, is a function of the channel's input common-mode voltage:

$$V_{SJ} = \left(\frac{R1}{R1 + R2}\right) \times 2.375V + \left(1 + \left(\frac{R1}{R1 + R2}\right)\right) \times V_{CM}$$

In differential mode, the input voltages are measured between two input channels, as shown in Table 5. Be aware that changing DIF/$\overline{SGL}$ adjusts the FSR, as shown in Table 6.

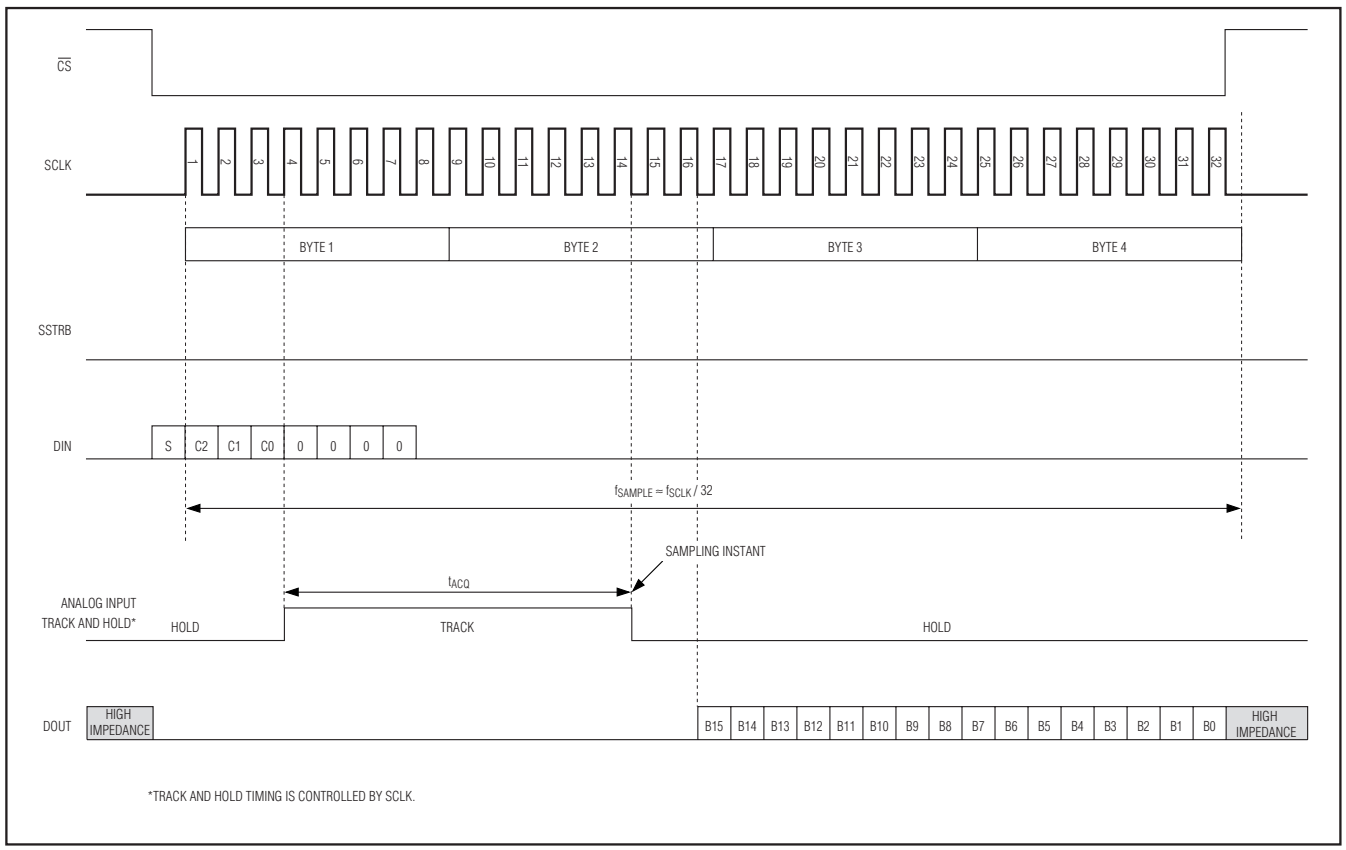

Figure 2. External Clock-Mode Conversion (Mode 0)

As a result, the analog input impedance is relatively constant over the input voltage as shown in Figure 5.

Single-ended conversions are internally referenced to AGND1 (Tables 3 and 4). In differential mode, IN+ and IN- are selected according to Tables 3 and 5. When configuring differential channels, the differential pair follows the analog configuration byte for the positive channel. For example, to configure CH2 and CH3 for a ±V_{REF} differential conversion, set the CH2 analog configuration byte for a differential conversion with the ±V_{REF} range (1010 1100). To initiate a conversion for the CH2 and CH3 differential pair, issue the command 1010 0000.

Analog Input Bandwidth

The MAX1302 input-tracking circuitry has a 1.5MHz small-signal bandwidth. The 1.5MHz input bandwidth makes it possible to digitize high-speed transient events. Harmonic distortion increases when digitizing signal frequencies above 15kHz as shown in the -SFDR, THD vs. Analog Input Frequency plot in the *Typical Operating Characteristics*.

Analog Input Range and Fault Tolerance

Figure 7 illustrates the software-selectable single-ended analog input voltage range that produces a valid digital output. Each analog input channel can be independently programmed to one of seven single-ended input ranges by setting the R[2:0] control bits with DIF/$\overline{SGL}$ = 0.

8-Channel, ±V_{REF} Multirange Inputs, Serial 16-Bit ADC

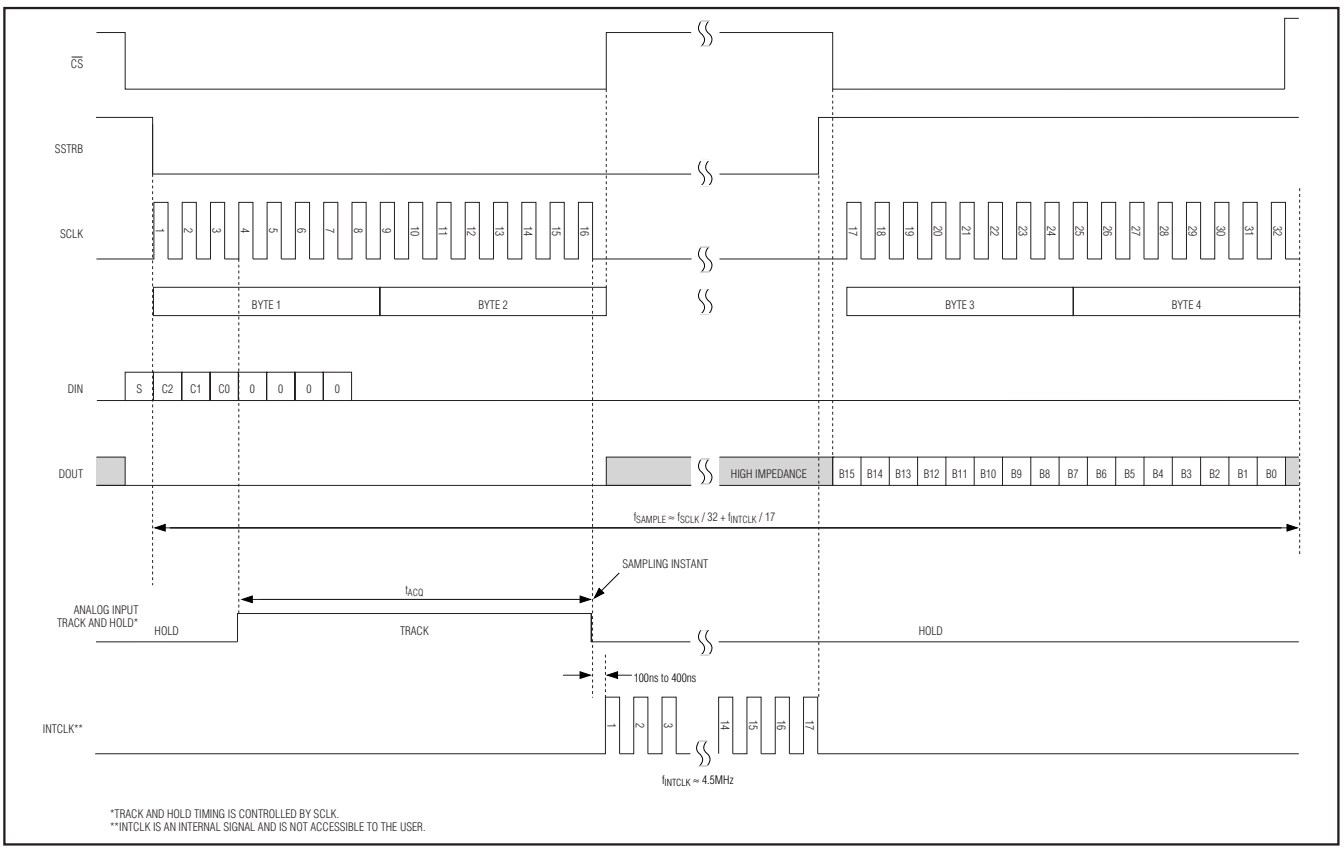

Figure 3. External Acquisition-Mode Conversion (Mode 1)

Figure 8 illustrates the software-selectable differential analog input voltage range that produces a valid digital output. Each analog input differential pair can be independently programmed to one of three differential input ranges by setting the R[2:0] control bits with DIF/$\overline{SGL}$ = 1.

Regardless of the specified input voltage range and whether the channel is selected, each analog input is ±6V fault tolerant. The analog input fault protection is active whether the device is unpowered or powered.

Any voltage beyond FSR, but within the ±6V fault-tolerant range, applied to an analog input results in a full-scale output voltage for that channel.

Clamping diodes with breakdown thresholds in excess of 6V protect the MAX1302 analog inputs during ESD and other transient events (Figure 6). The clamping diodes do not conduct during normal device operation, nor do they limit the current during such transients. When operating in an environment with the potential for high-energy voltage and/or current transients, protect the MAX1302 externally.

Differential Common-Mode Range

The MAX1302 differential common-mode range (V_{CMDR}) must remain within -4.75V to +5.5V to obtain valid conversion results. The differential common-mode range is defined as:

$$V_{CMDR} = \frac{(CH\_+) + (CH\_-)}{2}$$

In addition to the common-mode input voltage limitations, each individual analog input must be limited to ±6V with respect to AGND1.

The range-select bits R[2:0] in the analog input configuration bytes determine the full-scale range for the corresponding channel (Tables 2 and 6). Figures 9, 10, and 11 show the valid analog input voltage ranges for the MAX1302 when operating with FSR = V_{REF}/2, FSR = V_{REF}, and FSR = 2 x V_{REF}, respectively. The shaded area contains the valid common-mode voltage ranges that support the entire FSR.

Digital Interface

The MAX1302 features a serial interface that is compatible with SPI/QSPI and MICROWIRE devices. DIN, DOUT, SCLK, $\overline{CS}$, and SSTRB facilitate bidirectional communication between the MAX1302 and the master at SCLK rates up to 10MHz (internal clock mode, mode 2), 3.67MHz (external clock mode, mode 0), or 4.39MHz (external acquisition mode, mode 1). The master, typically a microcontroller, should use the CPOL = 0, CPHA = 0, SPI transfer format, as shown in the timing diagrams of Figures 2, 3, and 4.

The digital interface is used to:

- Select single-ended or true-differential input channel configurations
- Select the unipolar or bipolar input range
- Select the mode of operation:
  - External clock (mode 0)
  - External acquisition (mode 1)
  - Internal clock (mode 2)
  - Reset (mode 4)
  - Partial power-down (mode 6)
  - Full power-down (mode 7)
- Initiate conversions and read results

Chip Select ($\overline{CS}$)

$\overline{CS}$ enables communication with the MAX1302. When $\overline{CS}$ is low, data is clocked into the device from DIN on the rising edge of SCLK and data is clocked out of DOUT on the falling edge of SCLK. When $\overline{CS}$ is high, activity on SCLK and DIN is ignored and DOUT is high impedance allowing DOUT to be shared with other peripherals. SSTRB is never high impedance and therefore cannot be shared with other peripherals.

Serial Strobe Output (SSTRB)

As shown in Figures 3 and 4, the SSTRB transitions high to indicate that the ADC has completed a conversion and results are ready to be read by the master. SSTRB remains low in the external clock mode (Figure 2) and consequently may be left unconnected. SSTRB is driven high or low regardless of the state of $\overline{CS}$, therefore SSTRB cannot be shared with other peripherals.

Start Bit

Communication with the MAX1302 is accomplished using the three input data word formats shown in Table 3. Each input data word begins with a start bit. The start bit is defined as the first high bit clocked into DIN with $\overline{CS}$ low when any of the following are true:

- Data conversion is not in process and all data from the previous conversion has clocked out of DOUT.
- The device is configured for operation in external clock mode (mode 0) and previous conversion-result bits B15–B3 have clocked out of DOUT.
- The device is configured for operation in external acquisition mode (mode 1) and previous conversion-result bits B15–B7 have clocked out of DOUT.
- The device is configured for operation in internal clock mode, (mode 2) and previous conversion-result bits B15–B4 have clocked out of DOUT.

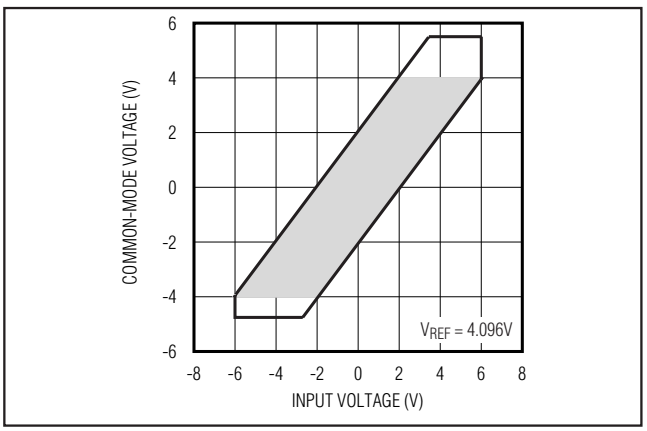

Figure 10. Common-Mode Voltage vs. Input Voltage (FSR = 2 x V_{REF})

Output Data Format

Output data is clocked out of DOUT in offset binary format on the falling edge of SCLK, MSB first (B15). For output binary codes, see the *Transfer Function* section and Figures 12, 13, and 14.

Configuring Analog Inputs

Each analog input has two configurable parameters:

- Single-ended or true-differential input
- Input voltage range

These parameters are configured using the analog input configuration byte as shown in Table 2. Each analog input has a dedicated register to store its input configuration information. The timing diagram of Figure 15 shows how to write to the analog input configuration registers. Figure 16 shows DOUT and SSTRB timing.

Transfer Function

An ADC's transfer function defines the relationship between the analog input voltage and the digital output code. Figures 12, 13, and 14 show the MAX1302 transfer functions. The transfer function is determined by the following characteristics:

- Analog input voltage range
- Single-ended or differential configuration
- Reference voltage

The axes of an ADC transfer function are typically in least significant bits (LSBs). For the MAX1302, an LSB is calculated using the following equation:

$$1\ LSB = \frac{FSR \times V_{REF}}{2^N \times 4.096V}$$

where N is the number of bits (N = 16) and FSR is the full-scale range (see Figures 7 and 8).

Mode Control

The MAX1302 contains one byte-wide mode-control register. The timing diagram of Figure 15 shows how to use the mode-control byte, and the mode-control byte format is shown in Table 7. The mode-control byte is used to select the conversion method and to control the power modes of the MAX1302.

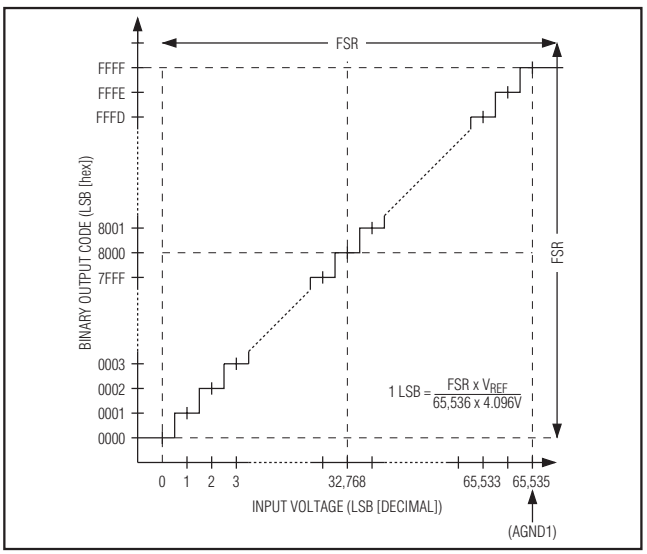

Figure 13. Ideal Unipolar Transfer Function, Single-Ended Input, -FSR to 0

Selecting the Conversion Method

The conversion method is selected using the mode-control byte (see the *Mode Control* section), and the conversion is initiated using a conversion start command (Table 3, and Figures 2, 3, and 4). The MAX1302 converts analog signals to digital data using one of three methods:

- External Clock Mode, Mode 0 (Figure 2)
  - Highest maximum throughput (see the *Electrical Characteristics* table)
  - User controls the sample instant
  - $\overline{CS}$ remains low during the conversion
  - User supplies SCLK throughout the ADC conversion and reads data at DOUT
- External Acquisition Mode, Mode 1 (Figure 3)
  - Lowest maximum throughput (see the *Electrical Characteristics* table)
  - User controls the sample instant
  - User supplies two bytes of SCLK, then drives $\overline{CS}$ high to relieve processor load while the ADC converts
  - After SSTRB transitions high, the user supplies two bytes of SCLK and reads data at DOUT
- Internal Clock Mode, Mode 2 (Figure 4)
  - High maximum throughput (see the *Electrical Characteristics* table)
  - The internal clock controls the sampling instant

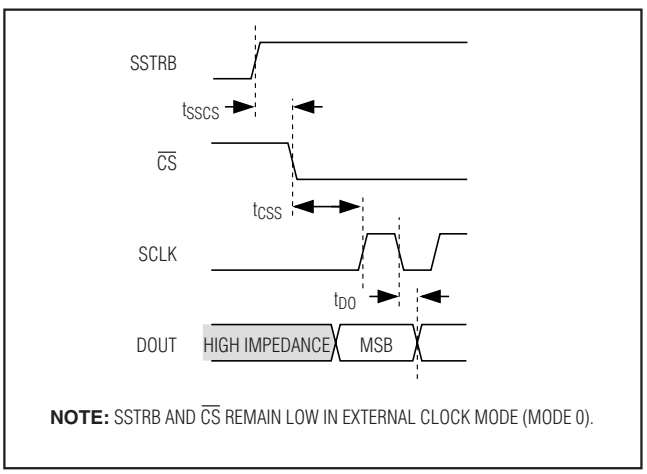

Figure 16. DOUT and SSTRB Timing

- User supplies one byte of SCLK, then drives $\overline{CS}$ high to relieve processor load while the ADC converts
- After SSTRB transitions high, the user supplies two bytes of SCLK and reads data at DOUT

External Clock Mode (Mode 0)

The MAX1302's fastest maximum throughput rate is achieved operating in external clock mode. SCLK controls both the acquisition and conversion of the analog signal, facilitating precise control over when the analog signal is captured. The analog input sampling instant is at the falling edge of the 14th SCLK (Figure 2).

Since SCLK drives the conversion in external clock mode, the SCLK frequency should remain constant while the conversion is clocked. The minimum SCLK frequency prevents droop in the internal sampling capacitor voltages during conversion.

SSTRB remains low in the external clock mode, and as a result may be left unconnected if the MAX1302 will always be used in the external clock mode.

External Acquisition Mode (Mode 1)

The slowest maximum throughput rate is achieved with the external acquisition method. SCLK controls the acquisition of the analog signal in external acquisition mode, facilitating precise control over when the analog signal is captured. The internal clock controls the conversion of the analog input voltage. The analog input sampling instant is at the falling edge of the 16th SCLK (Figure 3).

For the external acquisition mode, $\overline{CS}$ must remain low for the first 15 clock cycles and then rise on or after the falling edge of the 16th SCLK cycle as shown in Figure 3. For optimal performance, idle DIN and SCLK during the conversion. With careful board layout, transitions at DIN and SCLK during the conversion have a minimal impact on the conversion result.

After the conversion is complete, SSTRB asserts high and $\overline{CS}$ can be brought low to read the conversion result. SSTRB returns low on the rising SCLK edge of the subsequent start bit.

Internal Clock Mode (Mode 2)

In internal clock mode, the internal clock controls both acquisition and conversion of the analog signal. The internal clock starts approximately 100ns to 400ns after the falling edge of the eighth SCLK and has a rate of about 4.5MHz. The analog input sampling instant occurs at the falling edge of the 11th internal clock signal (Figure 4).

For the internal clock mode, $\overline{CS}$ must remain low for the first seven SCLK cycles and then rise on or after the falling edge of the eighth SCLK cycle. After the conversion is complete, SSTRB asserts high and $\overline{CS}$ can be brought low to read the conversion result. SSTRB returns low on the rising SCLK edge of the subsequent start bit.

Reset (Mode 4)

As shown in Table 8, set M[2:0] = 100 to reset the MAX1302 to its default conditions. The default conditions are full power operation with each channel configured for ±V_{REF}, bipolar, single-ended conversions using external clock mode (mode 0).

Partial Power-Down Mode (Mode 6)

As shown in Table 8, when M[2:0] = 110, the device enters partial power-down mode. In partial power-down, all analog portions of the device are powered down except for the reference voltage generator and bias supplies.

To exit partial power-down, change the mode by issuing one of the following mode-control bytes (see the *Mode Control* section):

- External-clock-mode control byte
- External-acquisition-mode control byte
- Internal-clock-mode control byte
- Reset byte
- Full power-down-mode control byte

This prevents the MAX1302 from inadvertently exiting partial power-down mode because of a $\overline{CS}$ glitch in a noisy digital environment.

Full Power-Down Mode (Mode 7)

When M[2:0] = 111, the device enters full power-down mode and the total supply current falls to 1µA (typ). In full power-down, all analog portions of the device are powered down. When using the internal reference, upon exiting full power-down mode, allow 10ms for the internal reference voltage to stabilize prior to initiating a conversion.

To exit full power-down, change the mode by issuing one of the following mode-control bytes (see the *Mode Control* section):

- External-clock-mode control byte

- External-acquisition-mode control byte
- Internal-clock-mode control byte
- Reset byte
- Partial power-down-mode control byte

This prevents the MAX1302 from inadvertently exiting full power-down mode because of a $\overline{CS}$ glitch in a noisy digital environment.

Power-On Reset

The MAX1302 powers up in normal operation configured for external clock mode with all circuitry active (Tables 7 and 8). Each analog input channel (CH0–CH7) is set for single-ended conversions with a ±V_{REF} bipolar input range (Table 6).

Allow the power supplies to stabilize after power-up. Do not initiate any conversions until the power supplies have stabilized. Additionally, allow 10ms for the internal reference to stabilize when C_{REF} = 1.0µF and C_{RECAP} = 0.1µF. Larger reference capacitors require longer stabilization times.

Internal or External Reference

The MAX1302 operates with either an internal or external reference. The reference voltage impacts the ADC's FSR (Figures 12, 13, and 14). An external reference is recommended if more accuracy is required than the internal reference provides, and/or multiple converters require the same reference voltage.

Internal Reference

The MAX1302 contains an internal 4.096V bandgap reference. This bandgap reference is connected to REFCAP through a nominal 5kΩ resistor (Figure 17). The voltage at REFCAP is buffered creating 4.096V at REF. When using the internal reference, bypass REFCAP with a 0.1µF or greater capacitor to AGND1 and bypass REF with a 1.0µF or greater capacitor to AGND1.

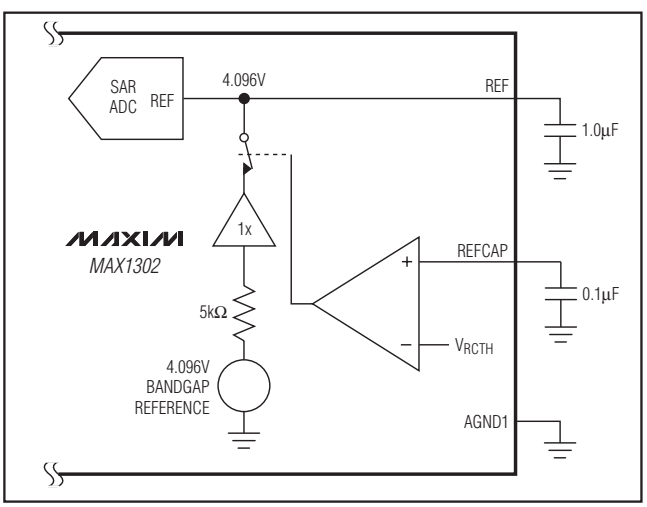

Figure 17. Internal Reference Operation

External Reference

For external reference operation, disable the internal reference and reference buffer by connecting REFCAP to AVDD1. With AVDD1 connected to REFCAP, REF becomes a high-impedance input and accepts an external reference voltage. The MAX1302 external reference current varies depending on the applied reference voltage and the operating mode (see the External Reference Input Current vs. External Reference Input Voltage in the *Typical Operating Characteristics*).

Applications Information

Noise Reduction

Additional samples can be taken and averaged (oversampling) to remove the effect of transition noise on conversion results. The square root of the number of samples determines the improvement in performance. For example, with 2/3 LSB_{RMS} (4 LSB_{P-P}) transition noise, 16 (4^2 = 16) samples must be taken to reduce the noise to 1 LSB_{P-P}.

Interface with 4–20mA Signals

Figure 19 illustrates a simple interface between the MAX1302 and a 4–20mA signal. 4–20mA signaling can be used as a binary switch (4mA represents a logic-low signal, 20mA represents a logic-high signal), or for precision communication where currents between 4mA and 20mA represent intermediate analog data. For binary switch applications, connect the 4–20mA signal to the MAX1302 with a resistor to ground. For example, a 200Ω resistor converts the 4–20mA signal to a 0.8V to 4V signal. Adjust the resistor value so the parallel combination of the resistor and the MAX1302 source impedance is 200Ω. In this application, select the single-ended 0V to V_{REF} range (R[2:0] = 011, Table 6). For applications that require precision measurements of continuous analog currents between 4mA and 20mA, use a buffer to prevent the MAX1302 input from diverting current from the 4–20mA signal.

8-Channel, ±V_{REF} Multirange Inputs, Serial 16-Bit ADC

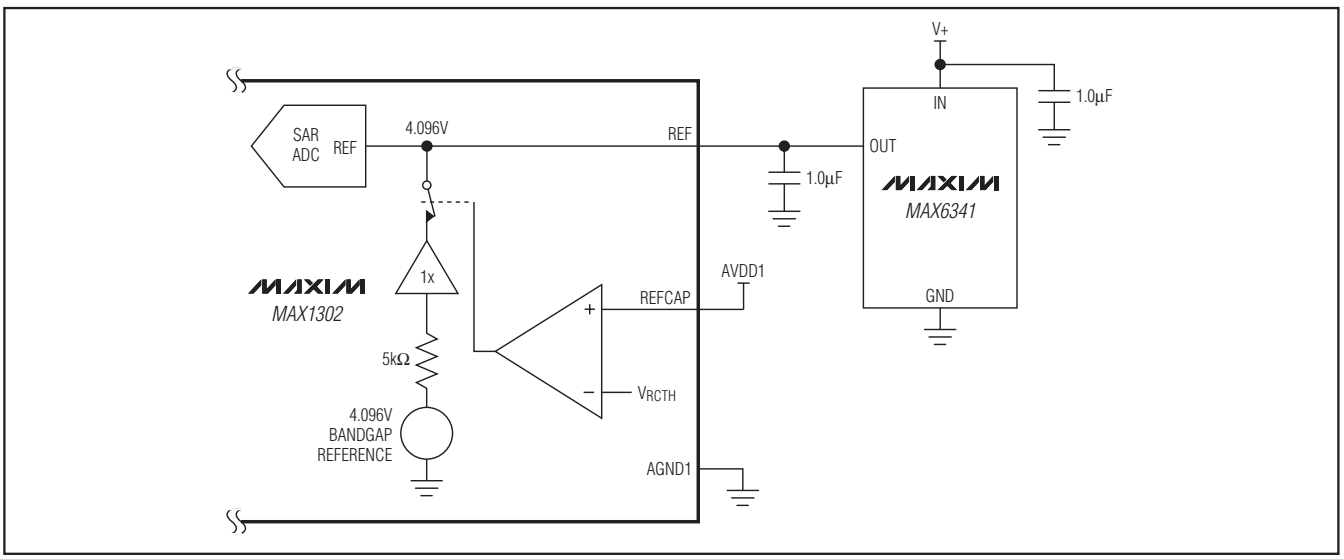

Figure 18. External Reference Operation

Bridge Application

The MAX1302 converts 1kHz signals more accurately than a similar sigma-delta converter that might be considered in bridge applications. The input impedance of the MAX1302, in combination with the current-limiting resistors, can affect the gain of the MAX1302. In many applications this error is acceptable, but for applications that cannot tolerate this error, the MAX1302 inputs can be buffered (Figure 20). Connect the bridge to a low-offset differential amplifier and then the true differential inputs of the MAX1302. Larger excitation voltages take advantage of more of the ±V_{REF}/2 differential input voltage range. Select an input voltage range that matches the amplifier output. Be aware of the amplifier offset and offset-drift errors when selecting an appropriate amplifier.

Dynamically Adjusting the Input Range

Software control of each channel's analog input range and the unipolar endpoint overlap specification make it possible for the user to change the input range for a channel dynamically and improve performance in some applications. Changing the input range results in a small LSB step-size over a wider output voltage range. For example, by switching between a -V_{REF}/2 to 0V range and a 0V to V_{REF}/2 range, an LSB is:

$$\frac{(V_{REF}/2) \times V_{REF}}{65,536 \times 4.096}$$

but the input voltage range effectively spans from -V_{REF}/2 to +V_{REF}/2 (FSR = +V_{REF}).

Layout, Grounding, and Bypassing

Careful PCB layout is essential for best system performance. Boards should have separate analog and digital ground planes and ensure that digital and analog signals are separated from each other. Do not run analog and digital (especially clock) lines parallel to one another, or digital lines underneath the device package.

Figure 1 shows the recommended system ground connections. Establish an analog ground point at AGND1 and a digital ground point at DGND. Connect all analog grounds to the star analog ground. Connect the digital grounds to the star digital ground. Connect the digital ground plane to the analog ground plane at one point. For lowest noise operation, make the ground return to the star ground's power-supply low impedance and as short as possible.

High-frequency noise in the AVDD1 power supply degrades the ADC's high-speed comparator performance. Bypass AVDD1 to AGND1 with a 0.1µF ceramic surface-mount capacitor. Make bypass capacitor connections as short as possible.

Parameter Definitions

Integral Nonlinearity (INL)

INL is the deviation of the values on an actual transfer function from a straight line. This straight line is either a best straight-line fit or a line drawn between the endpoints of the transfer function once offset and gain errors have been nullified. The MAX1302 INL is measured using the endpoint method.

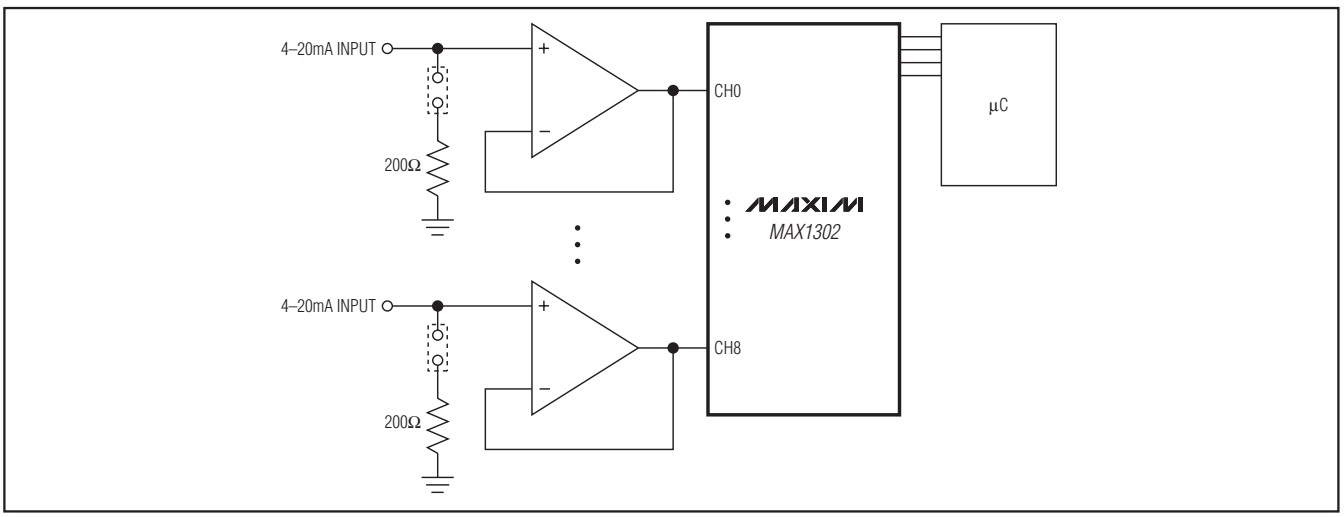

Figure 19. 4–20mA Application

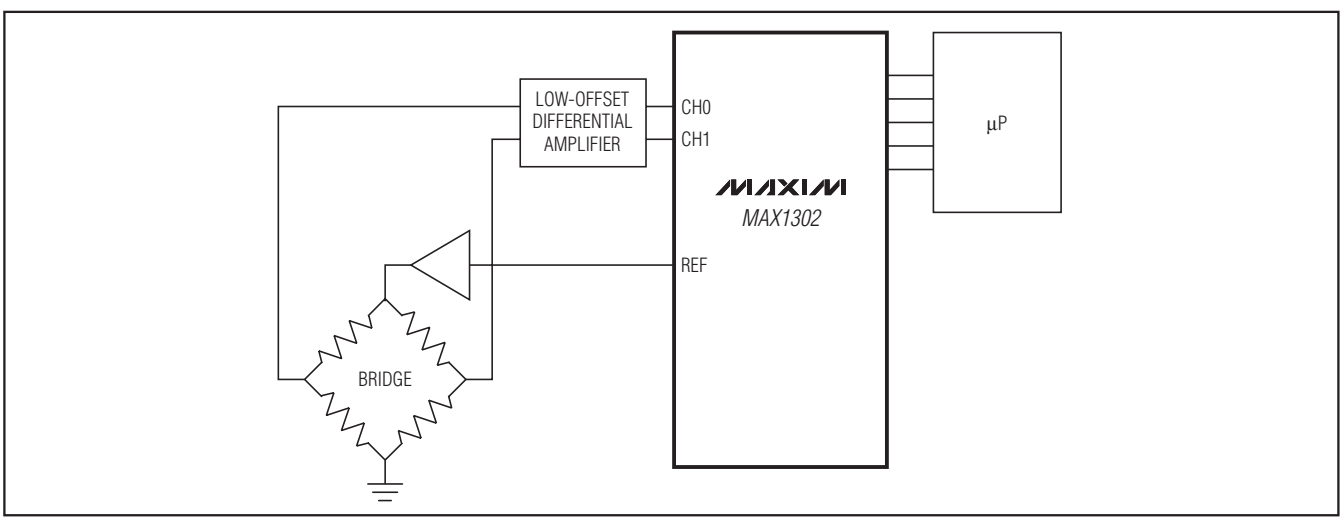

Figure 20. Bridge Application

Differential Nonlinearity (DNL)

DNL is the difference between an actual step width and the ideal value of 1 LSB. A DNL error specification of greater than -1 LSB guarantees no missing codes and a monotonic transfer function.

Transition Noise

Transition noise is the amount of noise that appears at a code transition on the ADC transfer function. Conversions performed with the analog input right at the code transition can result in code flickering in the LSBs.

Channel-to-Channel Isolation

Channel-to-channel isolation indicates how well each analog input is isolated from the others. The channel-to-channel isolation for these devices is measured by applying a near full-scale magnitude 5kHz sine wave to the selected analog input channel while applying an equal magnitude sine wave of a different frequency to all unselected channels. An FFT of the selected channel output is used to determine the ratio of the magnitudes of the signal applied to the unselected channels and the 5kHz signal applied to the selected analog input channel. This ratio is reported, in dB, as channel-to-channel isolation.

8-Channel, ±V_{REF} Multirange Inputs, Serial 16-Bit ADC

Unipolar Offset Error

-FSR to 0V

When a zero-scale analog input voltage is applied to the converter inputs, the digital output is all ones (0xFFFF). Ideally, the transition from 0xFFFF to 0xFFFE occurs at AGND1 - 0.5 LSB. Unipolar offset error is the amount of deviation between the measured zero-scale transition point and the ideal zero-scale transition point, with all untested channels grounded.

0V to +FSR

When a zero-scale analog input voltage is applied to the converter inputs, the digital output is all zeros (0x0000). Ideally, the transition from 0x0000 to 0x0001 occurs at AGND1 + 0.5 LSB. Unipolar offset error is the amount of deviation between the measured zero-scale transition point and the ideal zero-scale transition point, with all untested channels grounded.

Bipolar Offset Error

When a zero-scale analog input voltage is applied to the converter inputs, the digital output is a one followed by all zeros (0x8000). Ideally, the transition from 0x7FFF to 0x8000 occurs at (2^{N-1} - 0.5) LSB. Bipolar offset error is the amount of deviation between the measured midscale transition point and the ideal midscale transition point, with untested channels grounded.

Gain Error

When a positive full-scale voltage is applied to the converter inputs, the digital output is all ones (0xFFFF). The transition from 0xFFFE to 0xFFFF occurs at 1.5 LSB below full scale. Gain error is the amount of deviation between the measured full-scale transition point and the ideal full-scale transition point with the offset error removed and all untested channels grounded.

Unipolar Endpoint Overlap

Unipolar endpoint overlap is the change in offset when switching between complementary input voltage ranges. For example, the difference between the voltage that results in a 0xFFFF output in the -V_{REF}/2 to 0V input voltage range and the voltage that results in a 0x0000 output in the 0V to +V_{REF}/2 input voltage range is the unipolar endpoint overlap. The unipolar endpoint overlap is positive for the MAX1302, preventing loss of signal or a dead zone when switching between adjacent analog input voltage ranges.

Small-Signal Bandwidth

A 100mV_{P-P} sine wave is applied to the ADC, and the input frequency is then swept up to the point where the amplitude of the digitized conversion result has decreased by -3dB.

Full-Power Bandwidth

A 95% of full-scale sine wave is applied to the ADC, and the input frequency is then swept up to the point where the amplitude of the digitized conversion result has decreased by -3dB.

Common-Mode Rejection Ratio (CMRR)

CMRR is the ability of a device to reject a signal that is "common" to or applied to both input terminals. The common-mode signal can be either an AC or a DC signal or a combination of the two. CMR is expressed in decibels. Common-mode rejection ratio is the ratio of the differential signal gain to the common-mode signal gain. CMRR applies only to differential operation.

Power-Supply Rejection Ratio (PSRR)

PSRR is the ratio of the output-voltage shift to the power-supply-voltage shift for a fixed input voltage. For the MAX1302, AVDD1 can vary from 4.75V to 5.25V. PSRR is expressed in decibels and is calculated using the following equation:

$$PSRR[dB] = 20 \times \log\left(\frac{5.25V - 4.75V}{V_{OUT}(5.25V) - V_{OUT}(4.75V)}\right)$$

For the MAX1302, PSRR is tested in bipolar operation with the analog inputs grounded.

Aperture Jitter

Aperture jitter, t_{AJ}, is the statistical distribution of the variation in the sampling instant (Figure 21).

Aperture Delay

Aperture delay, t_{AD}, is the time from the falling edge of SCLK to the sampling instant (Figure 21).

Signal-to-Noise Ratio (SNR)

SNR is computed by taking the ratio of the RMS signal to the RMS noise. RMS noise includes all spectral components to the Nyquist frequency excluding the fundamental, the first five harmonics, and the DC offset.

Signal-to-Noise Plus Distortion (SINAD)

SINAD is computed by taking the ratio of the RMS signal to the RMS noise plus distortion. RMS noise plus distortion includes all spectral components to the Nyquist frequency excluding the fundamental and the DC offset.

$$SINAD(dB) = 20 \times \log\left(\frac{Signal_{RMS}}{Noise_{RMS}}\right)$$

Effective Number of Bits (ENOB)

ENOB indicates the global accuracy of an ADC at a specific input frequency and sampling rate. With an input range equal to the ADC's full-scale range, calculate the ENOB as follows:

$$ENOB = \left(\frac{SINAD - 1.76}{6.02}\right)$$

Total Harmonic Distortion (THD)

For the MAX1302, THD is the ratio of the RMS sum of the input signal's first four harmonic components to the fundamental itself. This is expressed as:

$$THD = 20 \times \log\left(\frac{\sqrt{V_2^2 + V_3^2 + V_4^2 + V_5^2}}{V_1}\right)$$

where V_1 is the fundamental amplitude, and V_2 through V_5 are the amplitudes of the 2nd- through 5th-order harmonic components.

Spurious-Free Dynamic Range (SFDR)

SFDR is the ratio of RMS amplitude of the fundamental (maximum signal component) to the RMS value of the next-largest spectral component.

Компания «ЭлектроПласт» предлагает заключение долгосрочных отношений при поставках импортных электронных компонентов на взаимовыгодных условиях!

Наши преимущества:

- Оперативные поставки широкого спектра электронных компонентов отечественного и импортного производства напрямую от производителей и с крупнейших мировых складов;
- Поставка более 17-ти миллионов наименований электронных компонентов;
- Поставка сложных, дефицитных, либо снятых с производства позиций;
- Оперативные сроки поставки под заказ (от 5 рабочих дней);
- Экспресс доставка в любую точку России;
- Техническая поддержка проекта, помощь в подборе аналогов, поставка прототипов;
- Система менеджмента качества сертифицирована по Международному стандарту ISO 9001;
- Лицензия ФСБ на осуществление работ с использованием сведений, составляющих государственную тайну;
- Поставка специализированных компонентов (Xilinx, Altera, Analog Devices, Intersil, Interpoint, Microsemi, Aeroflex, Peregrine, Syfer, Eurofarad, Texas Instrument, Miteq, Cobham, E2V, MA-COM, Hittite, Mini-Circuits,General Dynamics и др.);

Помимо этого, одним из направлений компании «ЭлектроПласт» является направление «Источники питания». Мы предлагаем Вам помощь Конструкторского отдела:

- Подбор оптимального решения, техническое обоснование при выборе компонента;
- Подбор аналогов;
- Консультации по применению компонента;
- Поставка образцов и прототипов;
- Техническая поддержка проекта;
- Защита от снятия компонента с производства.
