## Qorivva MPC5606BK Microcontroller Data Sheet

# 1 Introduction

## 1.1 Document overview

This document describes the features of the family and options available within the family members, and highlights important electrical and physical characteristics of the device.

## 1.2 Description

This family of 32-bit system-on-chip (SoC) microcontrollers is the latest achievement in integrated automotive application controllers. It belongs to an expanding family of automotive-focused products designed to address the next wave of body electronics applications within the vehicle.

The advanced and cost-efficient e200z0 host processor core of this automotive controller family complies with the Power Architecture® technology and only implements the VLE (variable-length encoding) APU (Auxiliary Processor Unit), providing improved code density. It operates at speeds of up to 64 MHz and offers high performance processing optimized for low power consumption. It capitalizes on the available development infrastructure of current Power Architecture devices and is supported with software drivers, operating systems and configuration code to assist with users implementations.

<sup>3</sup> Not shared with 12-bit ADC, but possibly shared with other alternate functions.

<sup>4</sup> Not shared with 10-bit ADC, but possibly shared with other alternate functions.

<sup>5</sup> Refer to eMIOS section of device reference manual for information on the channel configuration and functions.

<sup>6</sup> Each channel supports a range of modes including Modulus counters, PWM generation, Input Capture, Output Compare.

<sup>7</sup> Each channel supports a range of modes including PWM generation with dead time, Input Capture, Output Compare.

<sup>8</sup> Each channel supports a range of modes including PWM generation, Input Capture, Output Compare, Period and Pulse width measurement.

<sup>9</sup> Each channel supports a range of modes including PWM generation, Input Capture, and Output Compare.

<sup>10</sup> Maximum I/O count based on multiplexing with peripherals.

## 2.2 Pin muxing

Table 2 defines the pin list and muxing for this device.

Each entry of Table 2 shows all the possible configurations for each pin, via the alternate functions. The default function assigned to each pin after reset is indicated by AF0.

<sup>1</sup> Alternate functions are chosen by setting the values of the PCR.PA bitfields inside the SIUL module. PCR.PA = 00 → AF0; PCR.PA = 01 → AF1; PCR.PA = 10 → AF2; PCR.PA = 11 → AF3. This is intended to select the output functions; to use one of the input functions, the PCR.IBE bit must be written to ‘1’, regardless of the values selected in the PCR.PA bitfields. For this reason, the value corresponding to an input only function is reported as “—”.

<sup>2</sup> See [Table 3](#).

<sup>3</sup> The RESET configuration applies during and after reset.

- <sup>4</sup> All WKUP pins also support external interrupt capability. See the WKPU chapter of the *MPC5606BK Microcontroller Reference Manual* for further details.
- <sup>5</sup> NMI has higher priority than alternate function. When NMI is selected, the PCR.AF field is ignored.
- <sup>6</sup> “Not applicable” because these functions are available only while the device is booting. See the BAM chapter of the *MPC5606BK Microcontroller Reference Manual* for details.
- <sup>7</sup> Value of PCR.IBE bit must be 0.
- <sup>8</sup> Out of reset all the functional pins except PC[0:1] and PH[9:10] are available to the user as GPIO.  
PC[0:1] are available as JTAG pins (TDI and TDO respectively).  
PH[9:10] are available as JTAG pins (TCK and TMS respectively).  
It is up to the user to configure these pins as GPIO when needed.
- <sup>9</sup> PC[1] is a fast/medium pad but is in medium configuration by default. This pad is in Alternate Function 2 mode after reset which has TDO functionality. The reset value of PCR.OBE is 1, but this setting has no impact as long as this pad stays in AF2 mode. After configuring this pad as GPIO (PCR.PA = 0), output buffer is enabled as reset value of PCR.OBE = 1.
- <sup>10</sup> Not available in 100LQFP package.

## 3 Electrical characteristics

This section contains electrical characteristics of the device as well as temperature and power considerations.

This product contains devices to protect the inputs against damage due to high static voltages. However, it is advisable to take precautions to avoid application of any voltage higher than the specified maximum rated voltages.

To enhance reliability, unused inputs can be driven to an appropriate logic voltage level ( $V_{DD}$  or  $V_{SS}$ ). This could be done by the internal pull-up and pull-down, which is provided by the product for most general purpose pins.

The parameters listed in the following tables represent the characteristics of the device and its demands on the system.

In the tables where the device logic provides signals with their respective timing characteristics, the symbol “CC” for Controller Characteristics is included in the Symbol column.

In the tables where the external system must provide signals with their respective timing characteristics to the device, the symbol “SR” for System Requirement is included in the Symbol column.

### 3.1 Parameter classification

The electrical parameters shown in this supplement are guaranteed by various methods. To give the customer a better understanding, the classifications listed in [Table 4](#) are used and the parameters are tagged accordingly in the tables where appropriate.

**Table 4. Parameter classifications**

Classification tag	Tag description
P	Those parameters are guaranteed during production testing on each individual device.
C	Those parameters are achieved by the design characterization by measuring a statistically relevant sample size across process variations.
T	Those parameters are achieved by design characterization on a small sample size from typical devices under typical conditions unless otherwise noted. All values shown in the typical column are within this category.
D	Those parameters are derived mainly from simulations.

### NOTE

The classification is shown in the column labeled “C” in the parameter tables where appropriate.

## 3.2 NVUSRO register

Portions of the device configuration, such as high voltage supply, oscillator margin, and watchdog enable/disable after reset are controlled via bit values in the Non-Volatile User Options Register (NVUSRO) register.

For a detailed description of the NVUSRO register, please refer to the *MPC5606BK Microcontroller Reference Manual*.

### 3.2.1 NVUSRO[PAD3V5V] field description

Table 5 shows how NVUSRO[PAD3V5V] controls the device configuration.

**Table 5. PAD3V5V field description<sup>1</sup>**

Value <sup>2</sup>	Description
0	High voltage supply is 5.0 V
1	High voltage supply is 3.3 V

<sup>1</sup> See the *MPC5606BK Microcontroller Reference Manual* for more information on the NVUSRO register.

<sup>2</sup> The default manufacturing value is ‘1’. This value can be programmed by the customer in Shadow Flash.

The DC electrical characteristics are dependent on the PAD3V5V bit value.

### 3.2.2 NVUSRO[OSCILLATOR\_MARGIN] field description

Table 6 shows how NVUSRO[OSCILLATOR\_MARGIN] controls the device configuration.

**Table 6. OSCILLATOR\_MARGIN field description<sup>1</sup>**

Value <sup>2</sup>	Description
0	Low consumption configuration (4 MHz/8 MHz)
1	High margin configuration (4 MHz/16 MHz)

<sup>1</sup> See the *MPC5606BK Microcontroller Reference Manual* for more information on the NVUSRO register.

<sup>2</sup> The default manufacturing value is ‘1’. This value can be programmed by the customer in Shadow Flash.

The fast external crystal oscillator consumption is dependent on the OSCILLATOR\_MARGIN bit value.

### 3.2.3 NVUSRO[WATCHDOG\_EN] field description

The watchdog enable/disable configuration after reset is dependent on the WATCHDOG\_EN bit value. Table 7 shows how NVUSRO[WATCHDOG\_EN] controls the device configuration.

**Table 7. WATCHDOG\_EN field description<sup>1</sup>**

Value <sup>2</sup>	Description
0	Disable after reset
1	Enable after reset

<sup>1</sup> See the *MPC5606BK Microcontroller Reference Manual* for more information on the NVUSRO register.

<sup>2</sup> The default manufacturing value is '1'. This value can be programmed by the customer in Shadow Flash.

## NOTE

Stresses exceeding the recommended absolute maximum ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification are not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability. During overload conditions ( $V_{IN} > V_{DD}$  or  $V_{IN} < V_{SS}$ ), the voltage on pins with respect to ground ( $V_{SS}$ ) must not exceed the recommended values.

While the supply voltage ramps up, the slope on  $V_{DD\_BV}$  should be less than  $0.9V_{DD\_HV}$  in order to ensure the device does not enter regulator bypass mode.

<sup>5</sup> 100 nF capacitance needs to be provided between  $V_{DD\_ADC}/V_{SS\_ADC}$  pair.

<sup>6</sup> Guaranteed by device validation. Please refer to [Section 3.5.1, External ballast resistor recommendations](#) for minimum  $V_{DD}$  slope to be guaranteed to ensure correct power up in case of external resistor usage.

<sup>7</sup> This frequency includes the 4% frequency modulation guard band.

## NOTE

RAM data retention is guaranteed with  $V_{DD\_LV}$  not below 1.08 V.

## 3.5 Thermal characteristics

### 3.5.1 External ballast resistor recommendations

External ballast resistor on V<sub>DD\_BV</sub> pin helps in reducing the overall power dissipation inside the device. This resistor is required only when maximum power consumption exceeds the limit imposed by package thermal characteristics.

As stated in [Table 11](#) LQFP thermal characteristics, considering a thermal resistance of 144 LQFP as 48.3 °C/W, at ambient temperature T<sub>A</sub> = 125 °C, the junction temperature T<sub>j</sub> will cross 150 °C if the total power dissipation is greater than (150 – 125)/48.3 = 517 mW. Therefore, the total device current I<sub>DDMAX</sub> at 125 °C/5.5 V must not exceed 94.1 mA (i.e., PD/VDD). Assuming an average I<sub>DD(V<sub>DD\_HV</sub>)</sub> of 15–20 mA consumption typically during device RUN mode, the LV domain consumption I<sub>DD(V<sub>DD\_BV</sub>)</sub> is thus limited to I<sub>DDMAX</sub> – I<sub>DD(V<sub>DD\_HV</sub>)</sub>, i.e., 80 mA.

Therefore, respecting the maximum power allowed as explained in [Section 3.5.2, Package thermal characteristics](#), it is recommended to use this resistor only in the 125 °C/5.5 V operating corner as per the following guidelines:

- If I<sub>DD(V<sub>DD\_BV</sub>)</sub> < 80 mA, then no resistor is required.
- If 80 mA < I<sub>DD(V<sub>DD\_BV</sub>)</sub> < 90 mA, then 4 Ω resistor can be used.
- If I<sub>DD(V<sub>DD\_BV</sub>)</sub> > 90 mA, then 8 Ω resistor can be used.

Using resistance in the range of 4–8 Ω, the gain will be around 10–20% of total consumption on V<sub>DD\_BV</sub>. For example, if 8 Ω resistor is used, then power consumption when I<sub>DD(V<sub>DD\_BV</sub>)</sub> is 110 mA is equivalent to power consumption when I<sub>DD(V<sub>DD\_BV</sub>)</sub> is 90 mA (approximately) when resistor not used.

In order to ensure correct power up, the minimum V<sub>DD\_BV</sub> to be guaranteed is 30 ms/V. If the supply ramp is slower than this value, then LVDHV3B monitoring ballast supply V<sub>DD\_BV</sub> pin gets triggered leading to device reset. Until the supply reaches certain threshold, this low voltage monitor generates destructive reset event in the system. This threshold depends on the maximum I<sub>DD(V<sub>DD\_BV</sub>)</sub> possible across the external resistor.

### 3.5.3 Power considerations

The average chip-junction temperature,  $T_J$ , in degrees Celsius, may be calculated using [Equation 1](#):

$$T_J = T_A + (P_D \times R_{\theta JA}) \quad \text{Eqn. 1}$$

Where:

$T_A$  is the ambient temperature in °C.

$R_{\theta JA}$  is the package junction-to-ambient thermal resistance, in °C/W.

$P_D$  is the sum of  $P_{INT}$  and  $P_{I/O}$  ( $P_D = P_{INT} + P_{I/O}$ ).

$P_{INT}$  is the product of  $I_{DD}$  and  $V_{DD}$ , expressed in watts. This is the chip internal power.

$P_{I/O}$  represents the power dissipation on input and output pins; user determined.

Most of the time for the applications,  $P_{I/O} < P_{INT}$  and may be neglected. On the other hand,  $P_{I/O}$  may be significant, if the device is configured to continuously drive external modules and/or memories.

An approximate relationship between  $P_D$  and  $T_J$  (if  $P_{I/O}$  is neglected) is given by:

$$P_D = K / (T_J + 273 \text{ °C}) \quad \text{Eqn. 2}$$

Therefore, solving equations 1 and 2:

$$K = P_D \times (T_A + 273 \text{ °C}) + R_{\theta JA} \times P_D^2 \quad \text{Eqn. 3}$$

Where:

$K$  is a constant for the particular part, which may be determined from [Equation 3](#) by measuring  $P_D$  (at equilibrium) for a known  $T_A$ . Using this value of  $K$ , the values of  $P_D$  and  $T_J$  may be obtained by solving equations [1](#) and [2](#) iteratively for any value of  $T_A$ .

## 3.6 I/O pad electrical characteristics

### 3.6.1 I/O pad types

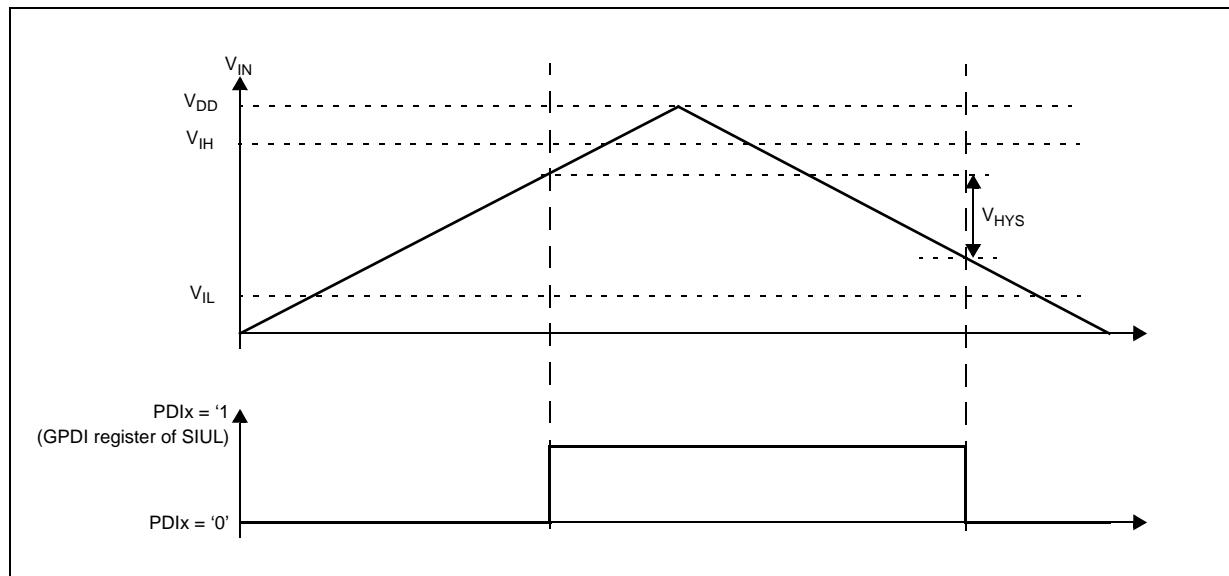

The device provides four main I/O pad types depending on the associated alternate functions:

- Slow pads — are the most common pads, providing a good compromise between transition time and low electromagnetic emission.
- Medium pads — provide transition fast enough for the serial communication channels with controlled current to reduce electromagnetic emission.
- Fast pads — provide maximum speed. These are used for improved debugging capability.
- Input only pads — are associated with ADC channels and 32 kHz low power external crystal oscillator providing low input leakage.

Medium and Fast pads can use slow configuration to reduce electromagnetic emission, at the cost of reducing AC performance.

### 3.6.2 I/O input DC characteristics

[Table 12](#) provides input DC electrical characteristics as described in [Figure 5](#).

<sup>2</sup> In the range from 40 to 1000 ns, pulses can be filtered or not filtered, according to operating temperature and voltage.

### 3.6.3 I/O output DC characteristics

The following tables provide DC characteristics for bidirectional pads:

- Table 13 provides weak pull figures. Both pull-up and pull-down resistances are supported.
- Table 14 provides output driver characteristics for I/O pads when in SLOW configuration.
- Table 15 provides output driver characteristics for I/O pads when in MEDIUM configuration.

### 3.6.5 I/O pad current specification

The I/O pads are distributed across the I/O supply segment. Each I/O supply segment is associated to a  $V_{DD}/V_{SS}$  supply pair as described in Table 18.

Table 19 provides I/O consumption figures.

In order to ensure device reliability, the average current of the I/O on a single segment should remain below the  $I_{AVGSEG}$  maximum value.

<sup>2</sup> Stated maximum values represent peak consumption that lasts only a few ns during I/O transition.

Table 20 provides the weight of concurrent switching I/Os.

In order to ensure device functionality, the sum of the weight of concurrent switching I/Os on a single segment should remain below the 100%.

<sup>3</sup> C<sub>L</sub> includes device and package capacitance (C<sub>PKG</sub> < 5 pF).

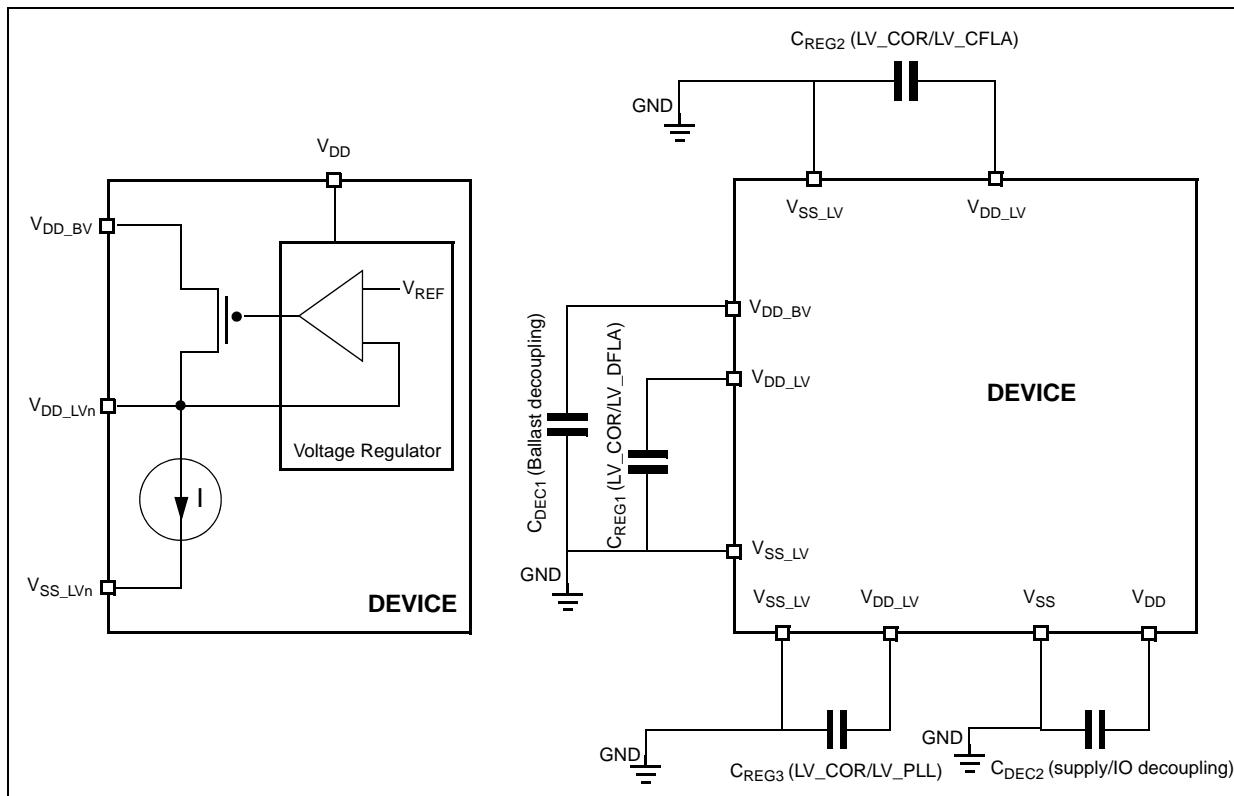

<sup>4</sup> The configuration PAD3V5 = 1 when V<sub>DD</sub> = 5 V is only transient configuration during power-up. All pads but RESET are configured in input or in high impedance state.

## 3.8 Power management electrical characteristics

### 3.8.1 Voltage regulator electrical characteristics

The device implements an internal voltage regulator to generate the low voltage core supply  $V_{DD\_LV}$  from the high voltage ballast supply  $V_{DD\_BV}$ . The regulator itself is supplied by the common I/O supply  $V_{DD}$ . The following supplies are involved:

- HV: High voltage external power supply for voltage regulator module. This must be provided externally through  $V_{DD}$  power pin.
- BV: High voltage external power supply for internal ballast module. This must be provided externally through  $V_{DD\_BV}$  power pin. Voltage values should be aligned with  $V_{DD}$ .
- LV: Low voltage internal power supply for core, FMPLL and Flash digital logic. This is generated by the internal voltage regulator but provided outside to connect stability capacitor. It is further split into four main domains to ensure noise isolation between critical LV modules within the device:
  - LV\_COR: Low voltage supply for the core. It is also used to provide supply for FMPLL through double bonding.
  - LV\_CFLA: Low voltage supply for code Flash module. It is supplied with dedicated ballast and shorted to LV\_COR through double bonding.
  - LV\_DFLA: Low voltage supply for data Flash module. It is supplied with dedicated ballast and shorted to LV\_COR through double bonding.
  - LV\_PLL: Low voltage supply for FMPLL. It is shorted to LV\_COR through double bonding.

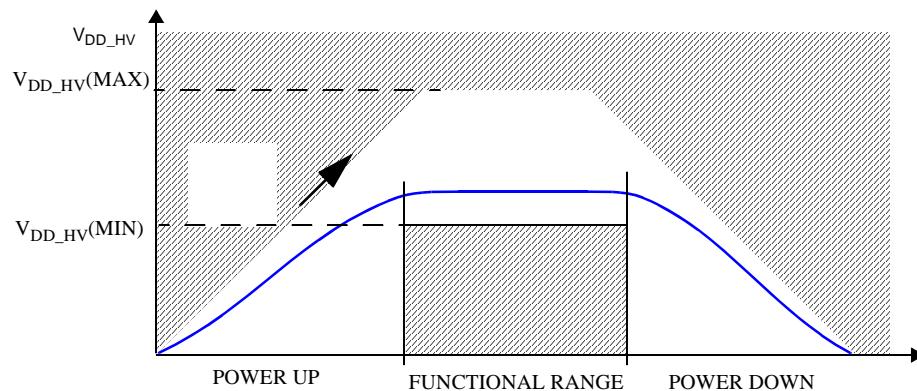

**Figure 8. Voltage regulator capacitance connection**

The internal voltage regulator requires external capacitance ( $C_{REGn}$ ) to be connected to the device in order to provide a stable low voltage digital supply to the device. Capacitances should be placed on the board as near as possible to the associated pins. Care should also be taken to limit the serial inductance of the board to less than 5 nH.

Each decoupling capacitor must be placed between each of the three  $V_{DD\_LV}/V_{SS\_LV}$  supply pairs to ensure stable voltage (see [Section 3.4, Recommended operating conditions](#)).

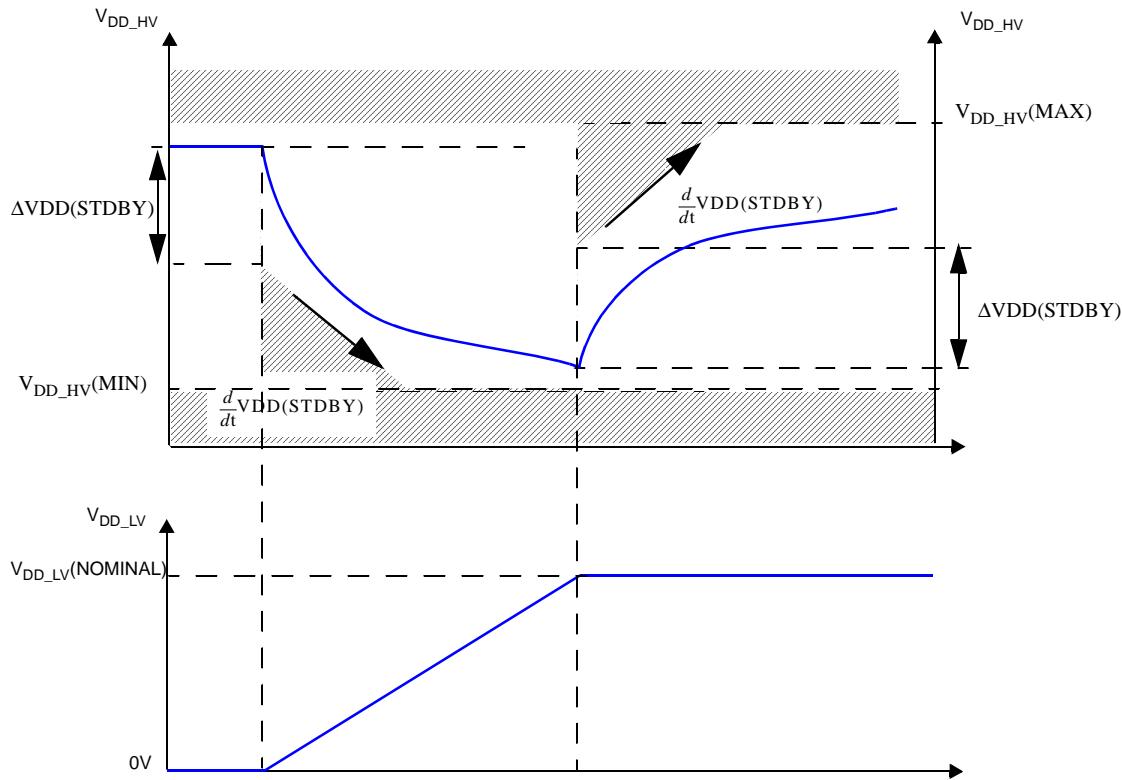

The internal voltage regulator requires controlled slew rate of  $V_{DD}/V_{DD\_BV}$  as described in [Figure 9](#).

**Figure 9.  $V_{DD}$  and  $V_{DD\_BV}$  maximum slope**

When STANDBY mode is used, further constraints apply to the  $V_{DD}/V_{DD\_BV}$  in order to guarantee correct regulator functionality during STANDBY exit. This is described in [Figure 10](#).

STANDBY regulator constraints should normally be guaranteed by implementing equivalent of  $C_{STDBY}$  capacitance on application board (capacitance and ESR typical values), but would actually depend on the exact characteristics of the application's external regulator.

**Figure 10.  $V_{DD}$  and  $V_{DD\_BV}$  supply constraints during STANDBY mode exit**

<sup>1</sup>  $V_{DD} = 3.3 \text{ V} \pm 10\% / 5.0 \text{ V} \pm 10\%$ ,  $T_A = -40$  to  $125^\circ\text{C}$ , unless otherwise specified

<sup>2</sup> This capacitance value is driven by the constraints of the external voltage regulator supplying the  $V_{DD\_BV}$  voltage. A typical value is in the range of 470 nF.

<sup>3</sup> This value is acceptable to guarantee operation from 4.5 V to 5.5 V

<sup>4</sup> External regulator and capacitance circuitry must be capable of providing  $I_{DD\_BV}$  while maintaining supply  $V_{DD\_BV}$  in operating range.

<sup>5</sup> Inrush current is seen only for short time during power-up and on standby exit (max 20  $\mu\text{s}$ , depending on external capacitances to be load).

<sup>6</sup> The duration of the inrush current depends on the capacitance placed on LV pins. BV decoupling capacitors must be sized accordingly. Refer to  $I_{MREG}$  value for minimum amount of current to be provided in cc.

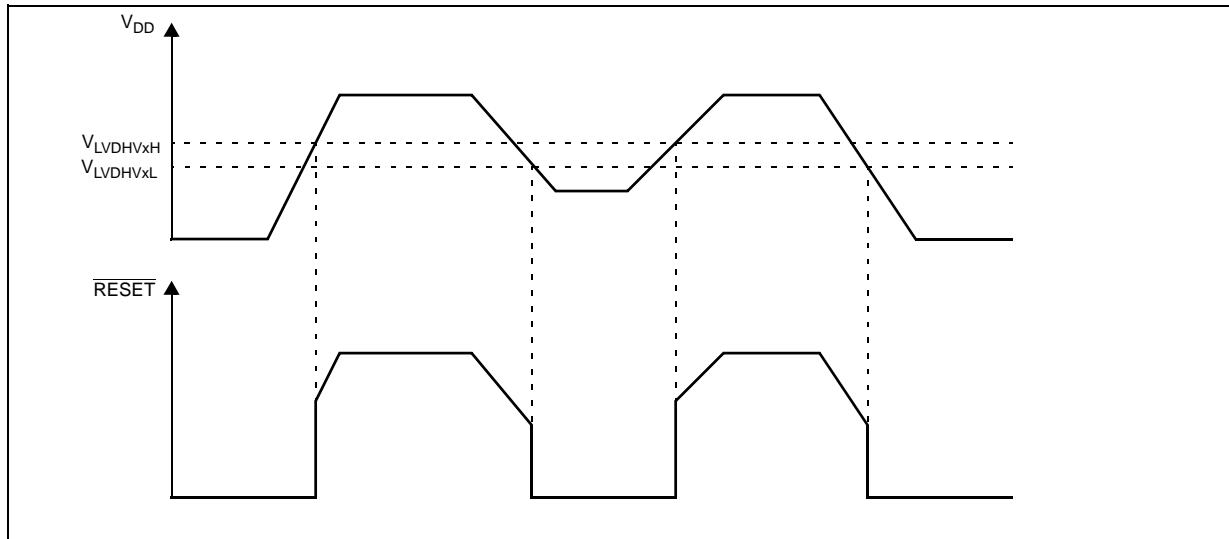

### 3.8.2 Voltage monitor electrical characteristics

The device implements a Power-on Reset module to ensure correct power-up initialization, as well as four low voltage detectors to monitor the  $V_{DD}$  and the  $V_{DD\_LV}$  voltage while device is supplied:

- POR monitors  $V_{DD}$  during the power-up phase to ensure device is maintained in a safe reset state
- LVDHV3 monitors  $V_{DD}$  to ensure device reset below minimum functional supply
- LVDHV3B monitors  $V_{DD\_BV}$  to ensure device reset below minimum functional supply
- LVDHV5 monitors  $V_{DD}$  when application uses device in the  $5.0\text{ V} \pm 10\%$  range
- LVDLVCOR monitors power domain No. 1
- LVDLVBKP monitors power domain No. 0

### NOTE

When enabled, power domain No. 2 is monitored through LVDLVBKP.

<sup>1</sup> Except for I<sub>DDMAX</sub>, all consumptions in this table apply to V<sub>DD\_BV</sub> only and do not include V<sub>DD\_HV</sub>.

<sup>2</sup> V<sub>DD</sub> = 3.3 V ± 10% / 5.0 V ± 10%, T<sub>A</sub> = –40 to 125 °C, unless otherwise specified

<sup>3</sup> Running consumption is given on voltage regulator supply (V<sub>DDREG</sub>). I<sub>DDMAX</sub> is composed of three components: I<sub>DDMAX</sub> = I<sub>DD(V<sub>DD\_BV</sub>)</sub> + I<sub>DD(V<sub>DD\_HV</sub>)</sub> + I<sub>DD(V<sub>DD\_HV\_ADC</sub>)</sub>. It does not include a fourth component linked to I/Os toggling which is **highly** dependent on the application. The given value is thought to be a **worst case value** (64 MHz at 125 °C) with all peripherals running, and code fetched from code flash while modify operation on-going on data flash. Note that this value can be significantly reduced by the application: switch off unused peripherals (default), reduce peripheral frequency through internal prescaler, fetch from RAM most used functions, use low power mode when possible.

- <sup>4</sup> Higher current may be sunk by device during power-up and standby exit. Please refer to inrush current in [Table 22](#).
- <sup>5</sup> RUN current measured with typical application with accesses on both Flash and RAM.
- <sup>6</sup> Only for the “P” classification: Data and Code Flash in Normal Power. Code fetched from RAM: Serial IPs CAN and LIN in loop back mode, DSPI as Master, PLL as system clock (4 x Multiplier) peripherals on (eMIOs/CTU/ADC) and running at max frequency, periodic SW/WDG timer reset enabled.

## 3.11 Electromagnetic compatibility (EMC) characteristics

Susceptibility tests are performed on a sample basis during product characterization.

### 3.11.1 Designing hardened software to avoid noise problems

EMC characterization and optimization are performed at component level with a typical application environment and simplified MCU software. It should be noted that good EMC performance is highly dependent on the user application and the software in particular.

Therefore it is recommended that the user apply EMC software optimization and prequalification tests in relation with the EMC level requested for the application.

- Software recommendations – The software flowchart must include the management of runaway conditions such as:
  - Corrupted program counter
  - Unexpected reset
  - Critical data corruption (control registers...)
- Prequalification trials – Most of the common failures (unexpected reset and program counter corruption) can be reproduced by manually forcing a low state on the reset pin or the oscillator pins for 1 second.  
To complete these trials, ESD stress can be applied directly on the device. When unexpected behavior is detected, the software can be hardened to prevent unrecoverable errors occurring.

### 3.11.2 Electromagnetic interference (EMI)

The product is monitored in terms of emission based on a typical application. This emission test conforms to the IEC61967-1 standard, which specifies the general conditions for EMI measurements.

### 3.11.3 Absolute maximum ratings (electrical sensitivity)

Based on two different tests (ESD and LU) using specific measurement methods, the product is stressed in order to determine its performance in terms of electrical sensitivity.

#### 3.11.3.1 Electrostatic discharge (ESD)

Electrostatic discharges (a positive then a negative pulse separated by 1 second) are applied to the pins of each sample according to each pin combination. The sample size depends on the number of supply pins in the device (3 parts $\times$ (n + 1) supply pin). This test conforms to the AEC-Q100-002/-003/-011 standard.

**Table 31. ESD absolute maximum ratings<sup>1,2</sup>**

$V_{ESD(CDM)}$	Electrostatic discharge voltage (Charged Device Model)	$T_A = 25^\circ\text{C}$ conforming to AEC-Q100-011	C3A	500 750 (corners)	

<sup>1</sup> All ESD testing is in conformity with CDF-AEC-Q100 Stress Test Qualification for Automotive Grade Integrated Circuits.

<sup>2</sup> A device will be defined as a failure if after exposure to ESD pulses the device no longer meets the device specification requirements. Complete DC parametric and functional testing shall be performed per applicable device specification at room temperature followed by hot temperature, unless specified otherwise in the device specification.

<sup>3</sup> Data based on characterization results, not tested in production

### 3.11.3.2 Static latch-up (LU)

Two complementary static tests are required on six parts to assess the latch-up performance:

- A supply overvoltage is applied to each power supply pin.
- A current injection is applied to each input, output and configurable I/O pin.

These tests are compliant with the EIA/JESD 78 IC latch-up standard.

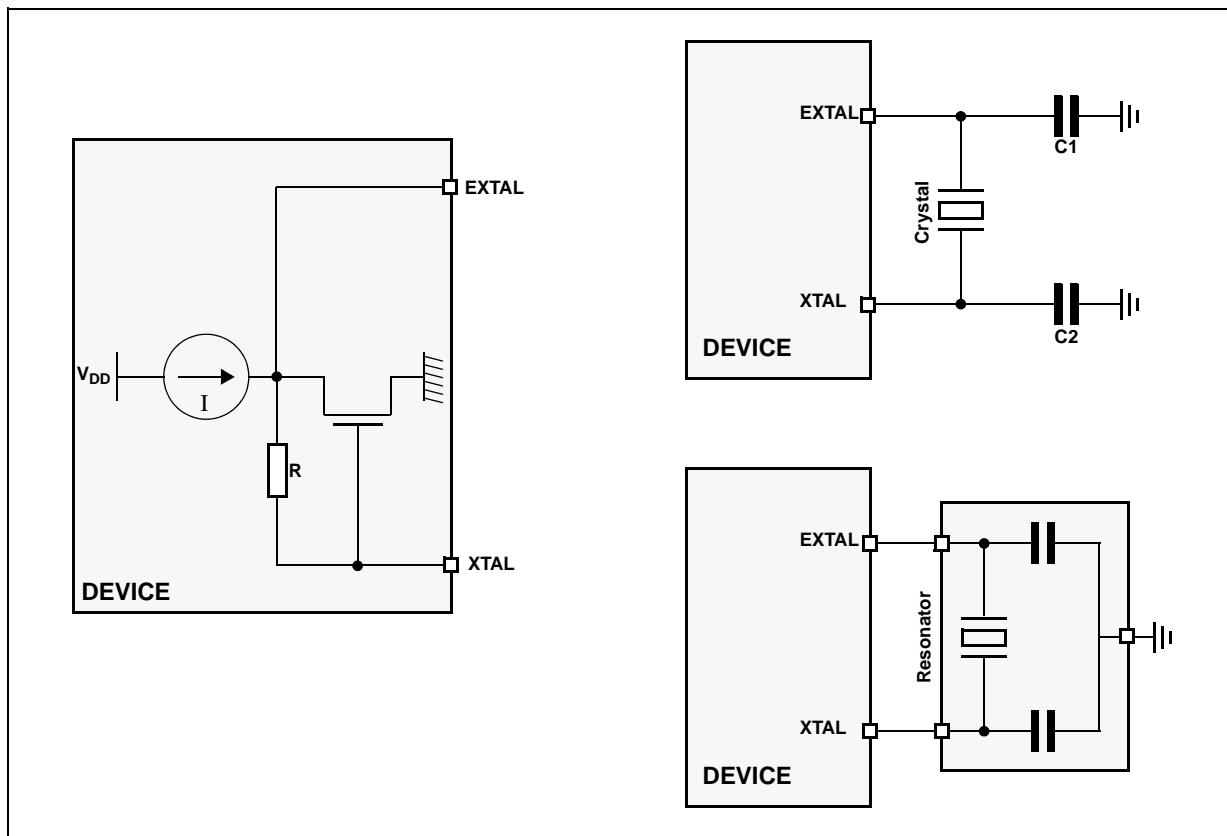

**Table 32. Latch-up results**

## 3.17 ADC electrical characteristics

### 3.17.1 Introduction

The device provides two Successive Approximation Register (SAR) analog-to-digital converters (10-bit and 12-bit).

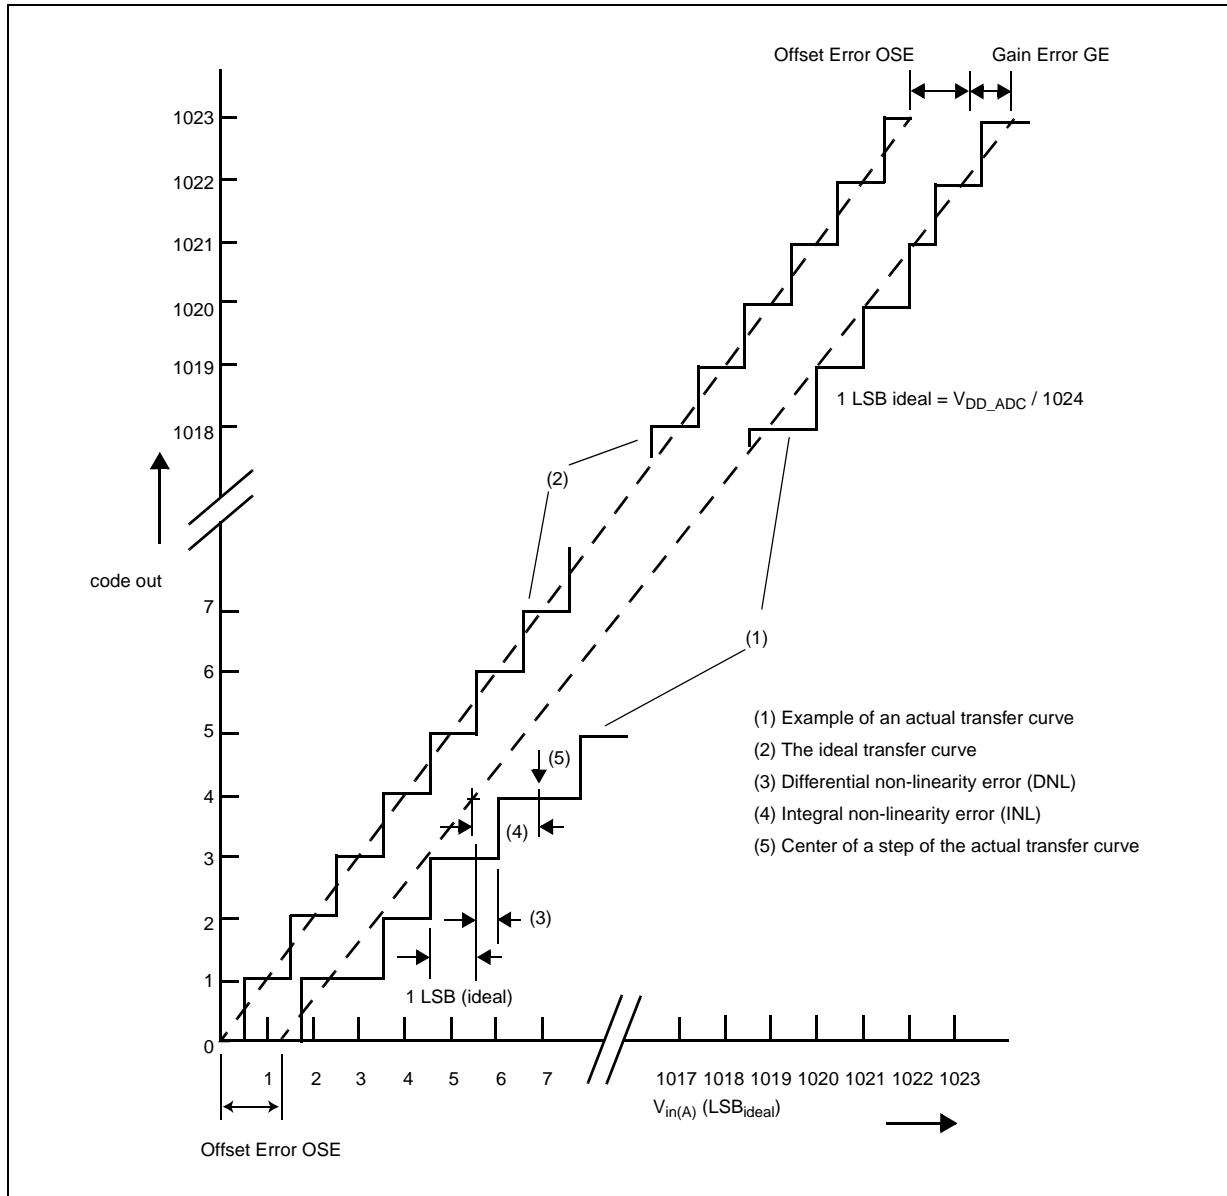

Figure 17. ADC\_0 characteristic and error definitions

### 3.17.2 Input impedance and ADC accuracy

In the following analysis, the input circuit corresponding to the precise channels is considered.

To preserve the accuracy of the A/D converter, it is necessary that analog input pins have low AC impedance. Placing a capacitor with good high frequency characteristics at the input pin of the device can be effective: the capacitor should be as large as

possible, ideally infinite. This capacitor contributes to attenuating the noise present on the input pin; furthermore, it sources charge during the sampling phase, when the analog signal source is a high-impedance source.

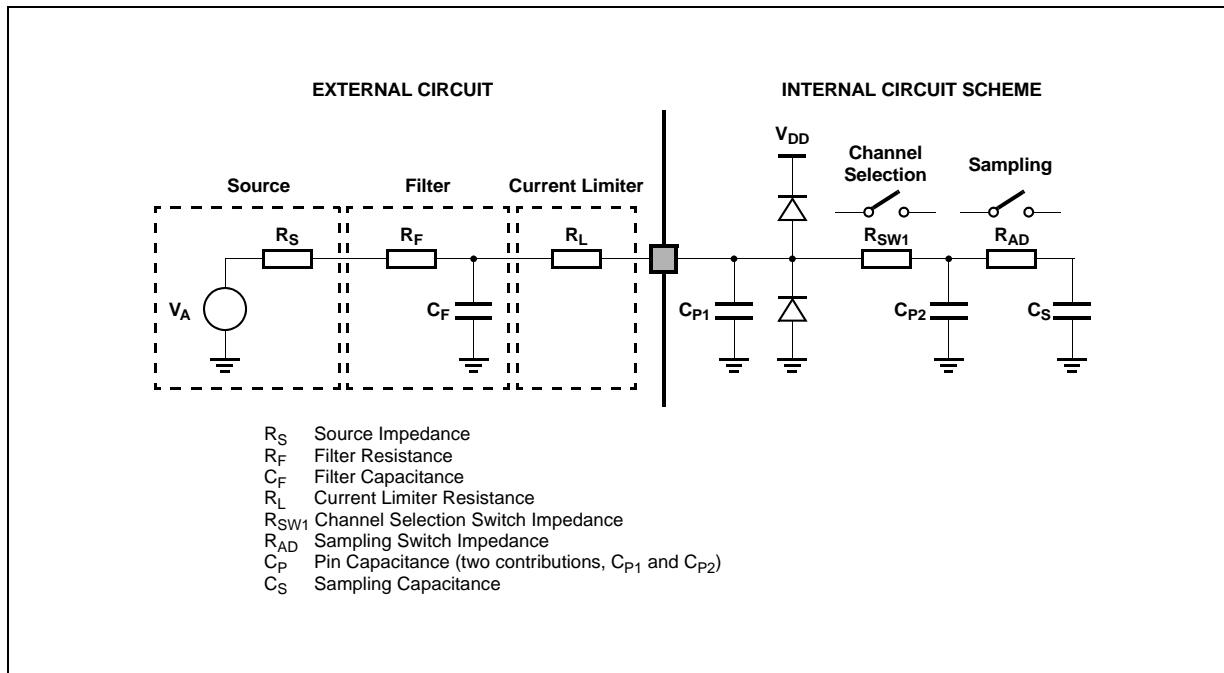

A real filter can typically be obtained by using a series resistance with a capacitor on the input pin (simple RC filter). The RC filtering may be limited according to the value of source impedance of the transducer or circuit supplying the analog signal to be measured. The filter at the input pins must be designed taking into account the dynamic characteristics of the input signal (bandwidth) and the equivalent input impedance of the ADC itself.

In fact a current sink contributor is represented by the charge sharing effects with the sampling capacitance:  $C_S$  being substantially a switched capacitance, with a frequency equal to the conversion rate of the ADC, it can be seen as a resistive path to ground. For instance, assuming a conversion rate of 1 MHz, with  $C_S$  equal to 3 pF, a resistance of 330 kΩ is obtained ( $R_{EQ} = 1 / (fc \times C_S)$ , where  $fc$  represents the conversion rate at the considered channel). To minimize the error induced by the voltage partitioning between this resistance (sampled voltage on  $C_S$ ) and the sum of  $R_S + R_F + R_L + R_{SW} + R_{AD}$ , the external circuit must be designed to respect the [Equation 4](#):

**Eqn. 4**

$$V_A \cdot \frac{R_S + R_F + R_L + R_{SW} + R_{AD}}{R_{EQ}} < \frac{1}{2} \text{ LSB}$$

[Equation 4](#) generates a constraint for external network design, in particular on resistive path. Internal switch resistances ( $R_{SW}$  and  $R_{AD}$ ) can be neglected with respect to external resistances.

**Figure 18. Input equivalent circuit (precise channels)**

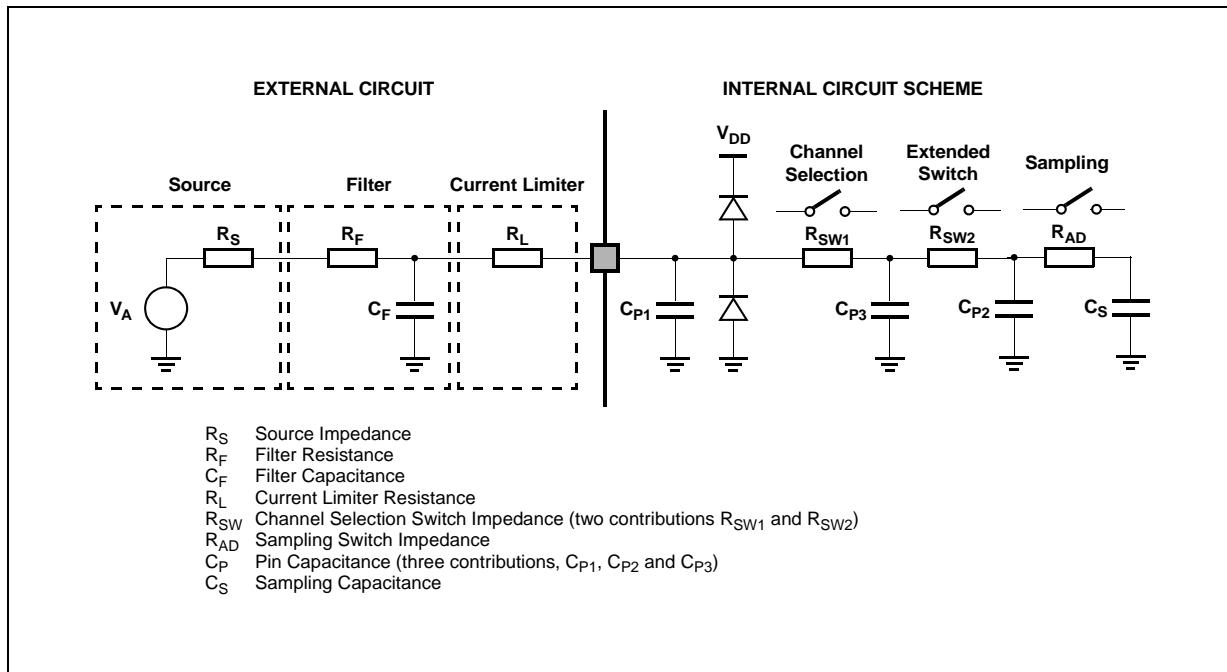

Figure 19. Input equivalent circuit (extended channels)

A second aspect involving the capacitance network shall be considered. Assuming the three capacitances  $C_F$ ,  $C_{P1}$  and  $C_{P2}$  are initially charged at the source voltage  $V_A$  (refer to the equivalent circuit reported in Figure 18): A charge sharing phenomenon is installed when the sampling phase is started (A/D switch close).

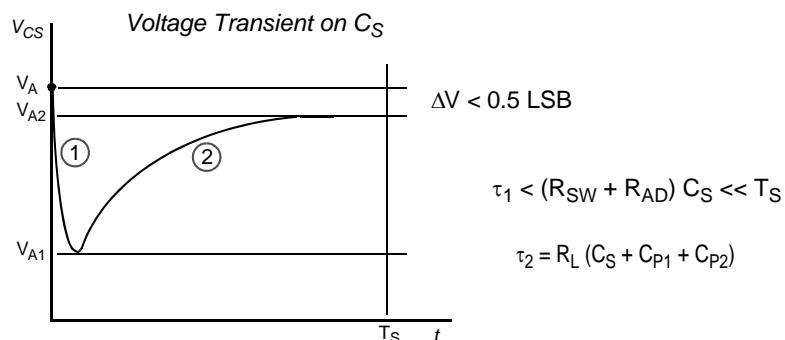

Figure 20. Transient behavior during sampling phase

In particular two different transient periods can be distinguished:

1. A first and quick charge transfer from the internal capacitance  $C_{P1}$  and  $C_{P2}$  to the sampling capacitance  $C_S$  occurs ( $C_S$  is supposed initially completely discharged): considering a worst case (since the time constant in reality would be faster) in which  $C_{P2}$  is reported in parallel to  $C_{P1}$  (call  $C_P = C_{P1} + C_{P2}$ ), the two capacitances  $C_P$  and  $C_S$  are in series, and the time constant is

**Eqn. 5**

$$\tau_1 = (R_{SW} + R_{AD}) \cdot \frac{C_P \cdot C_S}{C_P + C_S}$$

Equation 5 can again be simplified considering only  $C_S$  as an additional worst condition. In reality, the transient is faster, but the A/D converter circuitry has been designed to be robust also in the very worst case: the sampling time  $T_S$  is always much longer than the internal time constant:

**Eqn. 6**

$$\tau_1 < (R_{SW} + R_{AD}) \cdot C_S \ll T_S$$

The charge of  $C_{P1}$  and  $C_{P2}$  is redistributed also on  $C_S$ , determining a new value of the voltage  $V_{A1}$  on the capacitance according to Equation 7:

**Eqn. 7**

$$V_{A1} \cdot (C_S + C_{P1} + C_{P2}) = V_A \cdot (C_{P1} + C_{P2})$$

2. A second charge transfer involves also  $C_F$  (that is typically bigger than the on-chip capacitance) through the resistance  $R_L$ : again considering the worst case in which  $C_{P2}$  and  $C_S$  were in parallel to  $C_{P1}$  (since the time constant in reality would be faster), the time constant is:

**Eqn. 8**

$$\tau_2 < R_L \cdot (C_S + C_{P1} + C_{P2})$$

In this case, the time constant depends on the external circuit: in particular imposing that the transient is completed well before the end of sampling time  $T_S$ , a constraint on  $R_L$  sizing is obtained:

**Eqn. 9**

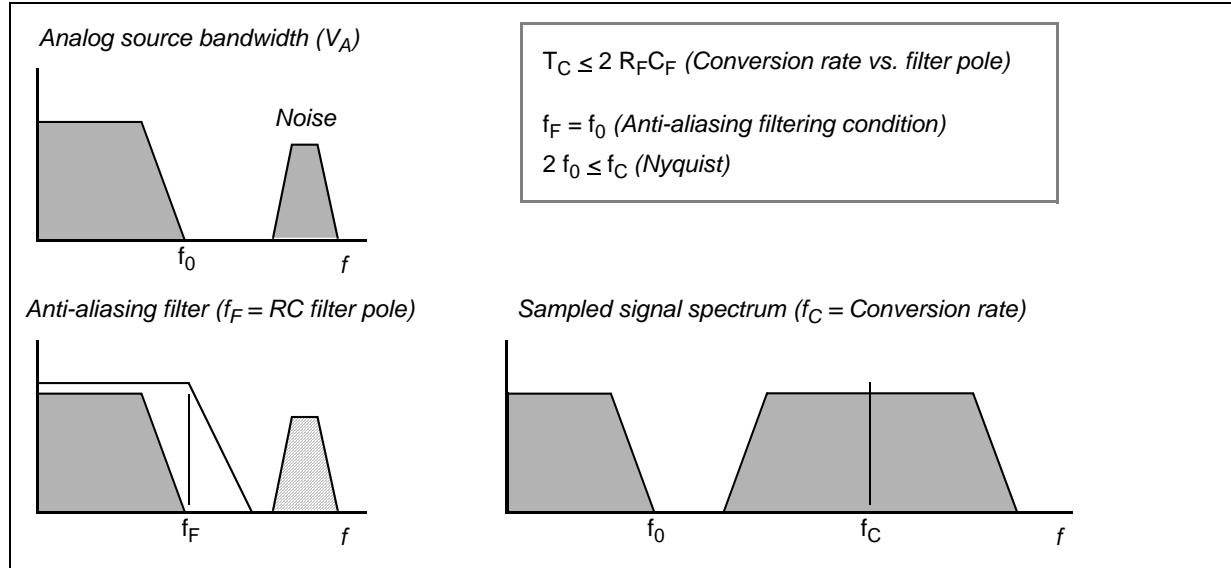

$$10 \cdot \tau_2 = 10 \cdot R_L \cdot (C_S + C_{P1} + C_{P2}) < T_S$$

Of course,  $R_L$  shall be sized also according to the current limitation constraints, in combination with  $R_S$  (source impedance) and  $R_F$  (filter resistance). Being  $C_F$  definitively bigger than  $C_{P1}$ ,  $C_{P2}$  and  $C_S$ , then the final voltage  $V_{A2}$  (at the end of the charge transfer transient) will be much higher than  $V_{A1}$ . Equation 10 must be respected (charge balance assuming now  $C_S$  already charged at  $V_{A1}$ ):

**Eqn. 10**

$$V_{A2} \cdot (C_S + C_{P1} + C_{P2} + C_F) = V_A \cdot C_F + V_{A1} \cdot (C_{P1} + C_{P2} + C_S)$$

The two transients above are not influenced by the voltage source that, due to the presence of the  $R_F C_F$  filter, is not able to provide the extra charge to compensate the voltage drop on  $C_S$  with respect to the ideal source  $V_A$ ; the time constant  $R_F C_F$  of the filter is very high with respect to the sampling time ( $T_S$ ). The filter is typically designed to act as antialiasing.

**Figure 21. Spectral representation of input signal**

Calling  $f_0$  the bandwidth of the source signal (and as a consequence the cut-off frequency of the antialiasing filter,  $f_F$ ), according to the Nyquist theorem the conversion rate  $f_C$  must be at least  $2f_0$ ; it means that the constant time of the filter is greater than or at least equal to twice the conversion period ( $T_C$ ). Again the conversion period  $T_C$  is longer than the sampling time  $T_S$ , which is just a portion of it, even when fixed channel continuous conversion mode is selected (fastest conversion rate at a specific channel): in conclusion it is evident that the time constant of the filter  $R_F C_F$  is definitely much higher than the sampling time  $T_S$ , so the charge level on  $C_S$  cannot be modified by the analog signal source during the time in which the sampling switch is closed.

The considerations above lead to impose new constraints on the external circuit, to reduce the accuracy error due to the voltage drop on  $C_S$ ; from the two charge balance equations above, it is simple to derive [Equation 11](#) between the ideal and real sampled voltage on  $C_S$ :

**Eqn. 11**

$$\frac{V_{A2}}{V_A} = \frac{C_{P1} + C_{P2} + C_F}{C_{P1} + C_{P2} + C_F + C_S}$$

From this formula, in the worst case (when  $V_A$  is maximum, that is for instance 5 V), assuming to accept a maximum error of half a count, a constraint is evident on  $C_F$  value:

**ADC\_0 (10-bit)**

**Eqn. 12**

$$C_F > 2048 \cdot C_S$$

**ADC\_1 (12-bit)**

**Eqn. 13**

$$C_F > 8192 \cdot C_S$$

Revision	Date	Description of changes
1	22 Apr 2011	Initial release.
2	15 May 2013	<p>Changed device number to MPC5606BK.</p> <p>In <a href="#">Table 2 (Functional port pins)</a>, updated PA[11] AF2, PD[13] AF2, and PH[11] AF3 I/O direction to “I/O”.</p> <p>In <a href="#">Table 3 (Pad types)</a>, corrected “Fast” in the “S” row to “Slow.”</p> <p>In <a href="#">Table 5 (PAD3V5V field description)</a>, updated footnote 2.</p> <p>In <a href="#">Table 6 (OSCILLATOR_MARGIN field description)</a>, updated footnote 2.</p> <p>Inserted <a href="#">Section 3.2.3, NVUSRO[WATCHDOG_EN] field description</a>.</p> <p>In <a href="#">Table 8 (Absolute maximum ratings)</a>, <a href="#">Table 9 (Recommended operating conditions (3.3 V))</a>, and <a href="#">Table 10 (Recommended operating conditions (5.0 V))</a>, corrected the parameter description for <math>V_{DD\_ADC}</math> to “Voltage on VDD_HV_ADC0, VDD_HV_ADC1 (ADC reference) with respect to ground (<math>V_{SS}</math>)”</p> <p>In <a href="#">Section 3.6.1, I/O pad types bullet item</a>, removed Nexus reference.</p> <p>In <a href="#">Table 12 (I/O input DC electrical characteristics)</a>, added specifications for 85 °C.</p> <p>In <a href="#">Table 13 (I/O pull-up/pull-down DC electrical characteristics)</a>, <a href="#">Table 14 (SLOW configuration output buffer electrical characteristics)</a>, <a href="#">Table 15 (MEDIUM configuration output buffer electrical characteristics)</a>, and <a href="#">Table 16 (FAST configuration output buffer electrical characteristics)</a>, changed sentence in footnote 2 to “All pads but RESET are configured in input or in high impedance state.”</p> <p>In <a href="#">Table 15 (MEDIUM configuration output buffer electrical characteristics)</a>, for <math>V_{OL}</math>, changed <math>I_{OH}</math> to <math>I_{OL}</math>.</p> <p>Updated <a href="#">Table 20 (I/O weight)</a>.</p> <p>In <a href="#">Table 21 (Reset electrical characteristics)</a> changed sentence in footnote 4 to “All pads but RESET are configured in input or in high impedance state.”</p> <p>In <a href="#">Table 22 (Voltage regulator electrical characteristics)</a>, corrected the maximum value for <math>I_{DD\_BV}</math> in <a href="#">Table 22 (Voltage regulator electrical characteristics)</a> to 300 mA.</p> <p>In <a href="#">Table 23 (Low voltage monitor electrical characteristics)</a>, changed <math>V_{PORUP}</math> classification tag from “P” (Production testing guaranteed) to “D” (Design simulation). Changed <math>V_{LVDHV3BH}</math> classification tag from “P” (Production testing guaranteed) to “T” (Design characterization).</p> <p>In <a href="#">Table 23 (Low voltage monitor electrical characteristics)</a>, changed <math>V_{LVDHV3L}</math>, <math>V_{LVDHV3BL}</math> minimums from 2.7 V to 2.6 V.</p>

Компания «ЭлектроПласт» предлагает заключение долгосрочных отношений при поставках импортных электронных компонентов на взаимовыгодных условиях!

#### Наши преимущества:

- Оперативные поставки широкого спектра электронных компонентов отечественного и импортного производства напрямую от производителей и с крупнейших мировых складов;
- Поставка более 17-ти миллионов наименований электронных компонентов;
- Поставка сложных, дефицитных, либо снятых с производства позиций;
- Оперативные сроки поставки под заказ (от 5 рабочих дней);
- Экспресс доставка в любую точку России;
- Техническая поддержка проекта, помошь в подборе аналогов, поставка прототипов;
- Система менеджмента качества сертифицирована по Международному стандарту ISO 9001;
- Лицензия ФСБ на осуществление работ с использованием сведений, составляющих государственную тайну;
- Поставка специализированных компонентов (Xilinx, Altera, Analog Devices, Intersil, Interpoint, Microsemi, Aeroflex, Peregrine, Syfer, Eurofarad, Texas Instrument, Miteq, Cobham, E2V, MA-COM, Hittite, Mini-Circuits, General Dynamics и др.);

Помимо этого, одним из направлений компании «ЭлектроПласт» является направление «Источники питания». Мы предлагаем Вам помошь Конструкторского отдела:

- Подбор оптимального решения, техническое обоснование при выборе компонента;
- Подбор аналогов;
- Консультации по применению компонента;
- Поставка образцов и прототипов;
- Техническая поддержка проекта;
- Защита от снятия компонента с производства.
