### DESCRIPTION

The PL133-67 is an advanced fanout buffer design for high performance, low-power, small form factor applications. The PL133-67 accepts a reference clock input from DC to 150MHz and provides 6 outputs of the same frequency.

The PL133-67 is offered in a TSSOP-16L package and it offers the best phase noise, additive jitter performance, and lowest power consumption of any comparable IC.

The PL133-67 outputs can be disabled to a high impedance (tri-state) by pulling low the OE pin. When the OE pin is high, the outputs are enabled and follow the REF input signal. When the OE pin is left open, a pull-up resistor on the chip will default the OE pin to logic 1 so the outputs are enabled.

**LAYOUT RECOMMENDATIONS**

The following guidelines are to assist you with a performance optimized PCB design:

**Signal Integrity and Termination Considerations**

- Keep traces short!
- Trace = Inductor. With a capacitive load this equals ringing!
- Long trace = Transmission Line. Without proper termination this will cause reflections ( looks like ringing ).
- Design long traces (> 1 inch) as "striplines" or "microstrips" with defined impedance.
- Match trace at one side to avoid reflections bouncing back and forth.

**Decoupling and Power Supply Considerations**

- Place decoupling capacitors as close as possible to the VDD pin(s) to limit noise from the power supply
- Addition of a ferrite bead in series with VDD can help prevent noise from other board sources
- Value of decoupling capacitor is frequency dependant. Typical values to use are 0.1μF for designs using frequencies < 50MHz and 0.01μF for designs using frequencies > 50MHz.

**Typical CMOS termination**

Place Series Resistor as close as possible to CMOS output

CMOS Output Buffer  
( Typical buffer impedance 20 ohm)

To CMOS Input

Connect a 33 ohm series resistor at each of the output clocks to enhance the stability of the output signal

### NOISE CHARACTERISTICS (Commercial and Industrial Temperature Devices)

Parameter	Description	Test Conditions	Min.	Typ.	Max.	Unit
	Additive Phase Jitter	$V_{DD}=3.3V$ , Frequency=100MHz Offset=12KHz ~ 20MHz		60		fs

PL133-67 Additive Phase Jitter:  
 $V_{DD}=3.3V$ , CLK=100MHz, Integration Range 12KHz to 20MHz: 0.059ps typical.

When a buffer is used to pass a signal then the buffer will add a little bit of its own noise. The phase noise on the output of the buffer will be a little bit more than the phase noise in the input signal. To quantify the noise addition in the buffer we compare the Phase Jitter numbers from the input and the output. The difference is called "Additive Phase Jitter". The formula for the Additive Phase Jitter is as follows:

$$\text{Additive Phase Jitter} = \sqrt{(\text{Output Phase Jitter})^2 - (\text{Input Phase Jitter})^2}$$
