

PIC24FJ128GC010 FAMILY

16-Bit Flash Microcontrollers with 12-Bit Pipeline A/D, Sigma-Delta A/D, USB On-The-Go and XLP Technology

Advanced Analog Features

- 12-Bit, up to 50-Channel, High-Speed, Pipelined Analog-to-Digital (A/D) Converter:
 - Conversion rates up to 10 Msps
 - Compatibility features for low conversion rates
 - Flexible operating modes with auto-accumulate, Threshold Detect and channel scan using sample lists
 - Conversion available during Sleep and Idle
- 16-Bit Sigma-Delta Analog-to-Digital (A/D) Converter:
 - Programmable data rate with dithering option and adjustable oversampling ratios
 - Two differential channels
 - Configurable input gain stage
- Two 10-Bit Digital-to-Analog Converters (DAC):
 - Fast settling time supports 1 Msps update rate
- Two Rail-to-Rail, Input/Output, General Purpose Operational Amplifiers:
 - 2.5 MHz gain bandwidth product (typical)
 - Flexible input multiplexing options
 - Optional Comparator mode
- Three Rail-to-Rail, Enhanced Analog Comparators with Programmable Input/Output Configuration
- Three On-Chip Programmable Voltage References
- Charge Time Measurement Unit (CTMU):
 - Used for capacitive touch sensing, up to 50 channels
 - Time measurement down to 100 ps resolution
 - Operation in Sleep mode

Extreme Low-Power Features

- Multiple Power Management Options for Extreme Power Reduction:
 - VBAT allows for lowest power consumption on backup battery (with or without RTCC)
 - Deep Sleep allows near total power-down, with the ability to wake-up on internal or external triggers
 - Full RAM and state retention in select Deep Sleep and VBAT modes
 - Sleep and Idle modes selectively shut down peripherals and/or core for substantial power reduction and fast wake-up
 - Doze mode allows CPU to run at a lower clock speed than peripherals
- Alternate Clock modes Allow On-the-Fly Switching to a Lower Clock Speed for Selective Power Reduction
- Extreme Low-Power Current Consumption for Deep Sleep:
 - WDT: 270 nA @ 3.3V, typical
 - RTCC: 350 nA @ 32 kHz, 3.3V, typical
 - Deep Sleep current, 75 nA, 3.3V, typical

PIC24FJ128GC010 FAMILY

Universal Serial Bus Features

- USB v2.0 On-The-Go (OTG) Compliant
- USB Device mode Operation from FRC Oscillator – No Crystal Oscillator Required
- Dual Role Capable – Can Act as Either Host or Peripheral
- Low-Speed (1.5 Mb/s) and Full-Speed (12 Mb/s) USB Operation in Host mode
- Full-Speed USB Operation in Device mode
- Low Jitter PLL for USB
- Supports up to 32 Endpoints (16 bidirectional):
 - USB module can use any RAM location on the device as USB endpoint buffers
- On-Chip USB Transceiver with Interface for Off-Chip USB Transceiver
- Supports Control, Interrupt, Isochronous and Bulk Transfers
- On-Chip Pull-up and Pull-Down Resistors

Peripheral Features

- LCD Display Controller:
 - Up to 59 segments by 8 commons
 - Internal charge pump and low-power, internal resistor biasing
 - Operation in Sleep mode
- Up to Five External Interrupt Sources
- Peripheral Pin Select (PPS); Allows Independent I/O Mapping of Many Peripherals
- Five 16-Bit Timers/Counters with Prescaler:
 - Can be paired as 32-bit timers/counters
- Six-Channel DMA Supports All Peripheral modules:
 - Minimizes CPU overhead, increases data throughput and lowers power consumption
- Nine Input Capture modules, Each with a Dedicated 16-Bit Timer
- Nine Output Compare/PWM modules, Each with a Dedicated 16-Bit Timer
- Enhanced Parallel Master/Slave Port (EPMP/EPSP)
- Hardware Real-Time Clock/Calendar (RTCC):
 - Run, Sleep, Deep Sleep and VBAT modes
- Two 3-Wire/4-Wire SPI modules (support 4 Frame modes) with 8-Level FIFO Buffer
- Two I²C™ modules Support Multi-Master/Slave mode and 7-Bit/10-Bit Addressing
- Four UART modules:
 - Support RS-485, RS-232 and LIN/J2602
 - On-chip hardware encoder/decoder for IrDA®
 - Auto-wake-up on Auto-Baud Detect (ABD)
 - 4-level deep FIFO buffer
- Programmable, 32-Bit Cyclic Redundancy Check (CRC) Generator
- Digital Signal Modulator (DSM) Provides On-Chip FSK and PSK Modulation for a Digital Signal Stream
- High-Current Sink/Source (18 mA/18 mA) on All I/O Pins
- Configurable Open-Drain Outputs on Digital I/O Pins
- 5.5V Tolerant Inputs on Select Pins

High-Performance CPU

- Modified Harvard Architecture
- Up to 16 MIPS Operation @ 32 MHz
- C Compiler Optimized Instruction Set Architecture (ISA)
- 8 MHz Internal Oscillator:
 - 96 MHz PLL option for USB clocking
 - Multiple clock divide options
 - Run-time self-calibration capability for maintaining better than ±0.20% accuracy
 - Fast start-up
- 17-Bit x 17-Bit Single-Cycle Hardware Fractional/Integer Multiplier
- 32-Bit by 16-Bit Hardware Divider
- 16 x 16-Bit Working Register Array
- Two Address Generation Units (AGUs) for Separate Read and Write Addressing of Data Memory

Special Microcontroller Features

- Supply Voltage Range of 2.0V to 3.6V
- Two On-Chip Voltage Regulators (1.8V and 1.2V) for Regular and eXtreme Low-Power Operation
- 20,000 Erase/Write Cycle Endurance Flash Program Memory, Typical
- Flash Data Retention: 20 Years Minimum
- Self-Programmable under Software Control
- Programmable Reference Clock Output
- In-Circuit Serial Programming™ (ICSP™) and In-Circuit Emulation (ICE) via 2 Pins
- JTAG Boundary Scan Support
- Fail-Safe Clock Monitor Operation:
 - Detects clock failure and switches to on-chip, low-power RC oscillator
- Power-on Reset (POR), Power-up Timer (PWRT) and Oscillator Start-up Timer (OST)
- Separate Brown-out Reset (BOR) and Deep Sleep Brown-out Reset (DSBOR) Circuits
- Programmable High/Low-Voltage Detect (HLVD)
- Flexible Watchdog Timer (WDT) with its Own RC Oscillator for Reliable Operation
- Standard and Ultra Low-Power Watchdog Timers for Reliable Operation in Standard and Deep Sleep modes

PIC24FJ128GC010 FAMILY

Pin Diagrams

64-Pin TQFP (10 mm x 10 mm)

64-Pin QFN (9 mm x 9 mm)⁽¹⁾

Legend: Shaded pins indicate pins tolerant to up to +5.5 VDC.

See [Table 1](#) for a complete description of pin functions.

Note 1: It is recommended to connect the metal pad on the bottom of the 64-pin QFN package to Vss.

PIC24FJ128GC010 FAMILY

PIC24FJ128GC010 FAMILY

TO OUR VALUED CUSTOMERS

It is our intention to provide our valued customers with the best documentation possible to ensure successful use of your Microchip products. To this end, we will continue to improve our publications to better suit your needs. Our publications will be refined and enhanced as new volumes and updates are introduced.

If you have any questions or comments regarding this publication, please contact the Marketing Communications Department via E-mail at docerrors@microchip.com or fax the **Reader Response Form** in the back of this data sheet to (480) 792-4150. We welcome your feedback.

Most Current Data Sheet

To obtain the most up-to-date version of this data sheet, please register at our Worldwide Web site at:

<http://www.microchip.com>

You can determine the version of a data sheet by examining its literature number found on the bottom outside corner of any page. The last character of the literature number is the version number, (e.g., DS30000A is version A of document DS30000).

Errata

An errata sheet, describing minor operational differences from the data sheet and recommended workarounds, may exist for current devices. As device/documentation issues become known to us, we will publish an errata sheet. The errata will specify the revision of silicon and revision of document to which it applies.

To determine if an errata sheet exists for a particular device, please check with one of the following:

- Microchip's Worldwide Web site; <http://www.microchip.com>
- Your local Microchip sales office (see last page)

When contacting a sales office, please specify which device, revision of silicon and data sheet (include literature number) you are using.

Customer Notification System

Register on our web site at www.microchip.com to receive the most current information on all of our products.

PIC24FJ128GC010 FAMILY

1.0 DEVICE OVERVIEW

This document contains device-specific information for the following devices:

- PIC24FJ64GC006
- PIC24FJ128GC006
- PIC24FJ64GC010
- PIC24FJ128GC010

The PIC24FJ128GC010 family expands the capabilities of the PIC24F family by adding a complete selection of advanced analog peripherals to its existing digital features. This combination, along with its ultra low-power features, Direct Memory Access (DMA) for peripherals, USB On-The-Go (OTG) and a built-in LCD controller and driver, makes this family the new standard for mixed-signal PIC® microcontrollers in one economical and power-saving package.

1.1 Core Features

1.1.1 16-BIT ARCHITECTURE

Central to all PIC24F devices is the 16-bit modified Harvard architecture, first introduced with Microchip's dsPIC® Digital Signal Controllers (DSCs). The PIC24F CPU core offers a wide range of enhancements, such as:

- 16-bit data and 24-bit address paths with the ability to move information between data and memory spaces
- Linear addressing of up to 12 Mbytes (program space) and 32 Kbytes (data)
- A 16-element working register array with built-in software stack support
- A 17 x 17 hardware multiplier with support for integer math
- Hardware support for 32 by 16-bit division
- An instruction set that supports multiple addressing modes and is optimized for high-level languages, such as 'C'
- Operational performance up to 16 MIPS

1.1.2 XLP POWER-SAVING TECHNOLOGY

The PIC24FJ128GC010 family of devices introduces a greatly expanded range of power-saving operating modes for the ultimate in power conservation. The new modes include:

- Retention Sleep, with essential circuits being powered from a separate low-voltage regulator
- Retention Deep Sleep, a lower power mode that maintains data RAM for fast start-up
- Deep Sleep without RTCC, for the lowest possible power consumption under software control
- VBAT mode (with or without RTCC), to continue limited operation from a backup battery when VDD is removed

Many of these new low-power modes also support the continuous operation of the low-power, on-chip Real-Time Clock/Calendar (RTCC), making it possible for an application to keep time while the device is otherwise asleep.

Aside from these new features, PIC24FJ128GC010 family devices also include all of the legacy power-saving features of previous PIC24F microcontrollers, such as:

- On-the-Fly Clock Switching, allowing the selection of a lower power clock during run time
- Doze Mode Operation, for maintaining peripheral clock speed while slowing the CPU clock
- Instruction-Based Power-Saving Modes, for quick invocation of Idle and the many Sleep modes.

1.1.3 OSCILLATOR OPTIONS AND FEATURES

All of the devices in the PIC24FJ128GC010 family offer five different oscillator options, allowing users a range of choices in developing application hardware. These include:

- Two Crystal modes
- Two External Clock modes
- A Phase Lock Loop (PLL) frequency multiplier, which allows clock speeds of up to 32 MHz
- A Fast Internal Oscillator (FRC) – nominal 8 MHz output, with multiple frequency divider options and automatic frequency self-calibration during run time
- A separate Low-Power Internal RC Oscillator (LPRC) – 31 kHz nominal, for low-power, timing-insensitive applications.

The internal oscillator block also provides a stable reference source for the Fail-Safe Clock Monitor (FSCM). This option constantly monitors the main clock source against a reference signal provided by the internal oscillator and enables the controller to switch to the internal oscillator, allowing for continued low-speed operation or a safe application shutdown.

1.1.4 EASY MIGRATION

Regardless of the memory size, all devices share the same rich set of peripherals, allowing for a smooth migration path as applications grow and evolve. This extends the ability of applications to grow from the relatively simple, to the powerful and complex, while still selecting a Microchip device.

PIC24FJ128GC010 FAMILY

1.2 Advanced Analog Features

The centerpiece of the PIC24FJ128GC010 family is the advanced analog block. This feature set provides application developers with all the tools they need for single chip applications that demand high analog performance. Included in the advanced analog block are:

- A new 12-bit, pipelined A/D Converter (A/D) module. A major departure from previous PIC24F A/D Converters, this module offers up to 50 single-ended input channels (or up to 25 differential channel pairs) and conversion rates of up to ten million samples per second. It also provides a wider range of new features that allow the converter to assess and make decisions on incoming data without CPU intervention.
- A dual differential channel, Sigma-Delta A/D Converter, for applications requiring high-precision conversions (up to 16-bit resolution). The Sigma-Delta Converter also offers programmable gain on each channel pair, and user-configurable data rate, between 976 samples per second and 62.5 ksp/s.
- Two independent, 10-bit Digital-to-Analog Converters (DACs), each capable of conversion rates up to one million samples per second.
- A comparator module with three analog comparators that are configurable for a wide range of operations. The comparators also have their own independent, configurable voltage reference.
- A dual operational amplifier module with multiple input options, selectable power modes, and rail-to-rail operation on the inputs and outputs. Each of the op amps can also be configured to function as a comparator, complete with interrupt generation.
- A dedicated, integrated band gap voltage reference for all analog modules, providing a range of on-chip reference voltages and two buffered reference outputs.
- Flexible multiplexing options for the entire analog block, allowing for the convenient sharing of signals between the analog modules.

1.3 DMA Controller

PIC24FJ128GC010 family devices also add a Direct Memory Access (DMA) controller to the existing PIC24F architecture. The DMA acts in concert with the CPU, allowing data to move between data memory and peripherals without the intervention of the CPU, increasing data throughput, and decreasing execution time overhead. Six independently programmable channels make it possible to service multiple peripherals at virtually the same time, with each channel peripheral performing a different operation. Many types of data transfer operations are supported.

1.4 USB On-The-Go (OTG)

USB On-The-Go provides on-chip functionality as a target device compatible with the USB 2.0 standard, as well as limited stand-alone functionality as a USB embedded host. By implementing USB Host Negotiation Protocol (HNP), the module can also dynamically switch between device and host operation, allowing for a much wider range of versatile USB-enabled applications on a microcontroller platform.

PIC24FJ128GC010 family devices also incorporate an integrated USB transceiver and precision oscillator, minimizing the required complexity of implementing a complete USB device, embedded host, dual role or On-The-Go application.

1.5 LCD Controller

With the PIC24FJ128GC010 family of devices, Microchip introduces its versatile Liquid Crystal Display (LCD) controller and driver to the PIC24F family. The on-chip LCD driver includes many features that make the integration of displays in low-power applications easier. These include an integrated voltage regulator with charge pump and an integrated internal resistor ladder that allows contrast control in software, and display operation above device V_{DD} .

PIC24FJ128GC010 FAMILY

1.6 Other Special Features

- **Peripheral Pin Select (PPS):** The Peripheral Pin Select feature allows most digital peripherals to be mapped over a fixed set of digital I/O pins. Users may independently map the input and/or output of any one of the many digital peripherals to any one of the I/O pins.
- **Communications:** The PIC24FJ128GC010 family incorporates several different serial communication peripherals to handle a range of application requirements. There are two independent I²C™ modules that support both Master and Slave modes of operation. Devices also have, through the PPS feature, four independent UARTs with built-in IrDA® encoders/decoders and two SPI modules.
- **CTMU Interface:** In addition to their other analog features, members of the PIC24FJ128GC010 family include the CTMU interface module. This provides a convenient method for precision time measurement and pulse generation, and can serve as an interface for capacitive sensors.
- **Enhanced Parallel Master/Parallel Slave Port:** This module allows rapid and transparent access to the microcontroller data bus, and enables the CPU to directly address external data memory. The parallel port can function in Master or Slave mode, accommodating data widths of 4, 8 or 16 bits, and address widths of up to 23 bits in Master modes.
- **Real-Time Clock and Calendar (RTCC):** This module implements a full-featured clock and calendar with alarm functions in hardware, freeing up timer resources and program memory space for use of the core application.
- **Data Signal Modulator (DSM):** The Data Signal Modulator (DSM) allows the user to mix a digital data stream (the “modulator signal”) with a carrier signal to produce a modulated output.

1.7 Details on Individual Family Members

Devices in the PIC24FJ128GC010 family are available in 64-pin and 100/121-pin packages. The general block diagram for all devices is shown in [Figure 1-1](#).

The devices are differentiated from each other in six ways:

1. Flash program memory (64 Kbytes for PIC24FJ64GC0XX devices and 128 Kbytes for PIC24FJ128GC0XX devices).
2. Available I/O pins and ports (53 pins on 6 ports for 64-pin devices and 85 pins on 7 ports for 100/121-pin devices).
3. Available Interrupt-on-Change Notification (ICN) inputs (52 on 64-pin devices and 82 on 100/121-pin devices).
4. Available remappable pins (29 pins on 64-pin devices and 44 pins on 100/121-pin devices).
5. Maximum available drivable LCD pixels (196 for 64-pin devices and 472 on 100/121-pin devices.)
6. Analog input channels for the pipeline A/D Converter (29 channels for 64-pin devices and 50 channels for 100/121-pin devices).

All other features for devices in this family are identical. These are summarized in [Table 1-1](#) and [Table 1-2](#).

A list of pin features available on the PIC24FJ128GC010 family devices, sorted by function, is shown in [Table 1-3](#). Note that this table shows the pin location of individual peripheral features and not how they are multiplexed on the same pin. This information is provided in the pinout diagrams in the beginning of the data sheet. Multiplexed features are sorted by the priority given to a feature, with the highest priority peripheral being listed first.

PIC24FJ128GC010 FAMILY

NOTES:

PIC24FJ128GC010 FAMILY

2.0 GUIDELINES FOR GETTING STARTED WITH 16-BIT MICROCONTROLLERS

2.1 Basic Connection Requirements

Getting started with the PIC24FJ128GC010 family of 16-bit microcontrollers requires attention to a minimal set of device pin connections before proceeding with development.

The following pins must always be connected:

- All VDD and VSS pins (see [Section 2.2 “Power Supply Pins”](#))
- All analog power pins (AVDD, SVDD, AVSS and SVSS), regardless of whether or not the analog device features are used (see [Section 2.2 “Power Supply Pins”](#))
- The USB transceiver supply, VUSB3V3, regardless of whether or not the USB module is used (see [Section 2.2 “Power Supply Pins”](#))
- MCLR pin (see [Section 2.3 “Master Clear \(MCLR\) Pin”](#))
- VCAP pin (see [Section 2.4 “Voltage Regulator Pin \(VCAP\)”](#))

These pins must also be connected if they are being used in the end application:

- PGECx/PGEDx pins used for In-Circuit Serial Programming™ (ICSP™) and debugging purposes (see [Section 2.5 “ICSP Pins”](#))
- OSCI and OSCO pins when an external oscillator source is used (see [Section 2.6 “External Oscillator Pins”](#))

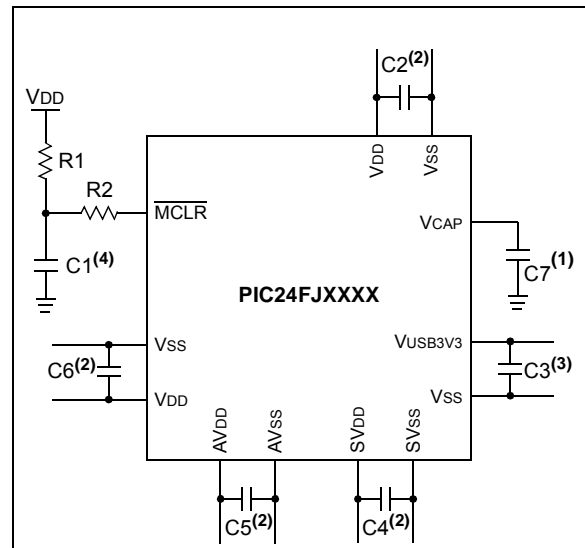

Additionally, the following pins may be required:

- Any voltage reference pins used when external voltage reference for analog modules is implemented (AVREF+/AVREF-, CVREF+/CVREF-, DVREF+ and SVREF+/SVREF-)

Note: All analog power supply and return pins must always be connected, regardless of whether any of the analog modules are being used.

The minimum mandatory connections are shown in [Figure 2-1](#).

FIGURE 2-1: RECOMMENDED MINIMUM CONNECTIONS

Key (all values are recommendations):

C1 through C6: 0.1 μ F, 20V ceramic

C7: 10 μ F, 6.3V or greater, tantalum or ceramic

R1: 10 k Ω

R2: 100 Ω to 470 Ω

- Note**
- 1: See [Section 2.4 “Voltage Regulator Pin \(VCAP\)”](#) for details on selecting the proper capacitor for VCAP.
 - 2: The example shown is for a PIC24F device with five power and ground pairs (including analog and USB). Other devices may have more or less pairs; adjust the number of decoupling capacitors appropriately.
 - 3: See [Section 19.1 “Hardware Configuration”](#) for details on connecting the pins for USB operation.
 - 4: C1 is optional, see [Section 2.3 “Master Clear \(MCLR\) Pin”](#) and [Section 2.5 “ICSP Pins”](#) for more information.

PIC24FJ128GC010 FAMILY

2.2 Power Supply Pins

2.2.1 DECOUPLING CAPACITORS

The use of decoupling capacitors on every pair of power supply pins is required. This includes digital supply (VDD and VSS) and all analog supplies (AVDD, SVDD, AVSS and SVSS).

Consider the following criteria when using decoupling capacitors:

- **Value and type of capacitor:** A 0.1 μF (100 nF), 10-20V capacitor is recommended. The capacitor should be a low-ESR device with a resonance frequency in the range of 200 MHz and higher. Ceramic capacitors are recommended.
- **Placement on the printed circuit board:** The decoupling capacitors should be placed as close to the pins as possible. It is recommended to place the capacitors on the same side of the board as the device. If space is constricted, the capacitor can be placed on another layer on the PCB using a via; however, ensure that the trace length from the pin to the capacitor is no greater than 0.25 inch (6 mm).
- **Handling high-frequency noise:** If the board is experiencing high-frequency noise (upward of tens of MHz), add a second ceramic type capacitor in parallel to the above described decoupling capacitor. The value of the second capacitor can be in the range of 0.01 μF to 0.001 μF . Place this second capacitor next to each primary decoupling capacitor. In high-speed circuit designs, consider implementing a pair of capacitances as close to the power and ground pins as possible (e.g., 0.1 μF in parallel with 0.001 μF).
- **Maximizing performance:** On the board layout from the power supply circuit, run the power and return traces to the decoupling capacitors first, and then to the device pins. This ensures that the decoupling capacitors are first in the power chain. Equally important is to keep the trace length between the capacitor and the power pins to a minimum, thereby reducing PCB trace inductance.

2.2.2 BULK CAPACITORS

On boards with power traces running longer than six inches in length, it is suggested to use a tank capacitor for integrated circuits including microcontrollers to supply a local power source. The value of the tank capacitor should be determined based on the trace resistance that connects the power supply source to the device, and the maximum current drawn by the device in the application. In other words, select the tank capacitor so that it meets the acceptable voltage sag at the device. Typical values range from 4.7 μF to 47 μF .

2.3 Master Clear ($\overline{\text{MCLR}}$) Pin

The $\overline{\text{MCLR}}$ pin provides two specific device functions: device Reset, and device programming and debugging. If programming and debugging are not required in the end application, a direct connection to VDD may be all that is required. The addition of other components, to help increase the application's resistance to spurious Resets from voltage sags, may be beneficial. A typical configuration is shown in Figure 2-1. Other circuit designs may be implemented, depending on the application's requirements.

During programming and debugging, the resistance and capacitance that can be added to the pin must be considered. Device programmers and debuggers drive the $\overline{\text{MCLR}}$ pin. Consequently, specific voltage levels (V_{IH} and V_{IL}) and fast signal transitions must not be adversely affected. Therefore, specific values of R1 and C1 will need to be adjusted based on the application and PCB requirements. For example, it is recommended that the capacitor, C1, be isolated from the $\overline{\text{MCLR}}$ pin during programming and debugging operations by using a jumper (Figure 2-2). The jumper is replaced for normal run-time operations.

Any components associated with the $\overline{\text{MCLR}}$ pin should be placed within 0.25 inch (6 mm) of the pin.

FIGURE 2-2: EXAMPLE OF $\overline{\text{MCLR}}$ PIN CONNECTIONS

PIC24FJ128GC010 FAMILY

2.4 Voltage Regulator Pin (VCAP)

A low-ESR ($< 5\Omega$) capacitor is required on the VCAP pin to stabilize the output voltage of the on-chip voltage regulator. The VCAP pin must not be connected to VDD and must use a capacitor of $10\ \mu\text{F}$ connected to ground. The type can be ceramic or tantalum. Suitable examples of capacitors are shown in Table 2-1. Capacitors with equivalent specification can be used.

The placement of this capacitor should be close to VCAP. It is recommended that the trace length not exceed 0.25 inch (6 mm). Refer to Section 37.0 “Electrical Characteristics” for additional information.

Designers may use Figure 2-3 to evaluate ESR equivalence of candidate devices.

Refer to Section 34.2 “On-Chip Voltage Regulator” for details on connecting and using the on-chip regulator.

FIGURE 2-3: FREQUENCY vs. ESR PERFORMANCE FOR SUGGESTED VCAP

TABLE 2-1: SUITABLE CAPACITOR EQUIVALENTS

| Make | Part # | Nominal Capacitance | Base Tolerance | Rated Voltage | Temp. Range |
|-----------|--------------------|---------------------|----------------|---------------|---------------|
| TDK | C3216X7R1C106K | 10 μF | $\pm 10\%$ | 16V | -55 to +125°C |
| TDK | C3216X5R1C106K | 10 μF | $\pm 10\%$ | 16V | -55 to +85°C |
| Panasonic | ECJ-3YX1C106K | 10 μF | $\pm 10\%$ | 16V | -55 to +125°C |
| Panasonic | ECJ-4YB1C106K | 10 μF | $\pm 10\%$ | 16V | -55 to +85°C |
| Murata | GRM32DR71C106KA01L | 10 μF | $\pm 10\%$ | 16V | -55 to +125°C |
| Murata | GRM31CR61C106KC31L | 10 μF | $\pm 10\%$ | 16V | -55 to +85°C |

2.4.1 CONSIDERATIONS FOR CERAMIC CAPACITORS

In recent years, large value, low-voltage, surface-mount ceramic capacitors have become very cost effective in sizes up to a few tens of microfarad. The low-ESR, small physical size and other properties make ceramic capacitors very attractive in many types of applications.

Ceramic capacitors are suitable for use with the internal voltage regulator of this microcontroller. However, some care is needed in selecting the capacitor to ensure that it maintains sufficient capacitance over the intended operating range of the application.

Typical low-cost, 10 μF ceramic capacitors are available in X5R, X7R and Y5V dielectric ratings (other types are also available, but are less common). The initial tolerance specifications for these types of capacitors are often specified as $\pm 10\%$ to $\pm 20\%$ (X5R and X7R), or $-20\%/+80\%$ (Y5V). However, the effective capacitance that these capacitors provide in an application circuit will also vary based on additional factors, such as the applied DC bias voltage and the temperature. The total in-circuit tolerance is, therefore, much wider than the initial tolerance specification.

The X5R and X7R capacitors typically exhibit satisfactory temperature stability (ex: $\pm 15\%$ over a wide temperature range, but consult the manufacturer's data sheets for exact specifications). However, Y5V capacitors typically have extreme temperature tolerance specifications of $+22\%/ -82\%$. Due to the extreme temperature tolerance, a 10 μF nominal rated Y5V type capacitor may not deliver enough total capacitance to meet minimum internal voltage regulator stability and transient response requirements. Therefore, Y5V capacitors are not recommended for use with the internal regulator if the application must operate over a wide temperature range.

In addition to temperature tolerance, the effective capacitance of large value ceramic capacitors can vary substantially, based on the amount of DC voltage applied to the capacitor. This effect can be very significant, but is often overlooked or is not always documented.

Typical DC bias voltage vs. capacitance graph for X7R type capacitors is shown in [Figure 2-4](#).

FIGURE 2-4: DC BIAS VOLTAGE vs. CAPACITANCE CHARACTERISTICS

When selecting a ceramic capacitor to be used with the internal voltage regulator, it is suggested to select a high-voltage rating, so that the operating voltage is a small percentage of the maximum rated capacitor voltage. For example, choose a ceramic capacitor rated at 16V for the 2.5V or 1.8V core voltage. Suggested capacitors are shown in [Table 2-1](#).

2.5 ICSP Pins

The PGECx and PGEDx pins are used for In-Circuit Serial Programming (ICSP) and debugging purposes. It is recommended to keep the trace length between the ICSP connector and the ICSP pins on the device as short as possible. If the ICSP connector is expected to experience an ESD event, a series resistor is recommended, with the value in the range of a few tens of ohms, not to exceed 100 Ω .

Pull-up resistors, series diodes and capacitors on the PGECx and PGEDx pins are not recommended as they will interfere with the programmer/debugger communications to the device. If such discrete components are an application requirement, they should be removed from the circuit during programming and debugging. Alternatively, refer to the AC/DC characteristics and timing requirements information in the respective device Flash programming specification for information on capacitive loading limits and pin Voltage Input High (VIH) and Voltage Input Low (VIL) requirements.

For device emulation, ensure that the "Communication Channel Select" (i.e., PGECx/PGEDx pins), programmed into the device, matches the physical connections for the ICSP to the Microchip debugger/emulator tool.

The $\overline{\text{MCLR}}$ connection from the ICSP header should connect directly to the $\overline{\text{MCLR}}$ pin on the device. A capacitor to ground (C1 in [Figure 2-2](#)) is optional, but if used, may interfere with ICSP operation if the value exceeds 0.01 μF . In most cases, this capacitor is not required.

For more information on available Microchip development tools connection requirements, refer to [Section 35.0 "Development Support"](#).

2.6 External Oscillator Pins

Many microcontrollers have options for at least two oscillators: a high-frequency primary oscillator and a low-frequency secondary oscillator (refer to [Section 9.0 “Oscillator Configuration”](#) for details).

The oscillator circuit should be placed on the same side of the board as the device. Place the oscillator circuit close to the respective oscillator pins with no more than 0.5 inch (12 mm) between the circuit components and the pins. The load capacitors should be placed next to the oscillator itself, on the same side of the board.

Use a grounded copper pour around the oscillator circuit to isolate it from surrounding circuits. The grounded copper pour should be routed directly to the MCU ground. Do not run any signal traces or power traces inside the ground pour. Also, if using a two-sided board, avoid any traces on the other side of the board where the crystal is placed.

Layout suggestions are shown in [Figure 2-5](#). In-line packages may be handled with a single-sided layout that completely encompasses the oscillator pins. With fine-pitch packages, it is not always possible to completely surround the pins and components. A suitable solution is to tie the broken guard sections to a mirrored ground layer. In all cases, the guard trace(s) must be returned to ground.

In planning the application's routing and I/O assignments, ensure that adjacent port pins, and other signals in close proximity to the oscillator, are benign (i.e., free of high frequencies, short rise and fall times and other similar noise).

For additional information and design guidance on oscillator circuits, please refer to these Microchip Application Notes, available at the corporate web site (www.microchip.com):

FIGURE 2-5: SUGGESTED PLACEMENT OF THE OSCILLATOR CIRCUIT

PIC24FJ128GC010 FAMILY

2.7 Configuration of Analog and Digital Pins During ICSP Operations

If an ICSP compliant emulator is selected as a debugger, it automatically initializes all of the A/D input pins (ANx) as “digital” pins. Depending on the particular device, this is done by setting all bits in the ADnPCFG register(s), or clearing all bit in the ANSx registers.

All PIC24F devices will have either one or more ADnPCFG registers or several ANSx registers (one for each port); no device will have both. Refer to [Section 11.2 “Configuring Analog Port Pins \(ANSx\)”](#) for more specific information.

The bits in these registers that correspond to the A/D pins that initialized the emulator must not be changed by the user application firmware; otherwise, communication errors will result between the debugger and the device.

If your application needs to use certain A/D pins as analog input pins during the debug session, the user application must modify the appropriate bits during initialization of the A/D module, as follows:

- For devices with an ADnPCFG register, clear the bits corresponding to the pin(s) to be configured as analog. Do not change any other bits, particularly those corresponding to the PGECx/PGEDx pair, at any time.
- For devices with ANSx registers, set the bits corresponding to the pin(s) to be configured as analog. Do not change any other bits, particularly those corresponding to the PGECx/PGEDx pair, at any time.

When a Microchip debugger/emulator is used as a programmer, the user application firmware must correctly configure the ADnPCFG or ANSx registers. Automatic initialization of this register is only done during debugger operation. Failure to correctly configure the register(s) will result in all A/D pins being recognized as analog input pins, resulting in the port value being read as a logic ‘0’, which may affect user application functionality.

2.8 Sigma-Delta A/D Connections

The Sigma-Delta A/D Converter has input and power connections that are independent from the rest of the microcontroller. These connections are required to use the converter, and are in addition to the connection and layout connections provided in [Section 2.1 “Basic Connection Requirements”](#) and [Section 2.2 “Power Supply Pins”](#).

2.8.1 VOLTAGE AND GROUND CONNECTIONS

To minimize noise interference, the Sigma-Delta A/D Converter has independent voltage pins. Converter circuits are supplied through the SVDD pin. Independent ground return is provided through the SVSS pin.

As with the microcontroller’s VDD/VSS and AVDD/AVSS pins, bypass capacitors are required on SVDD and SVSS. Requirements for these capacitors are identical to those for the VDD/VSS and AVDD/AVSS pins.

It is recommended that designs using the Sigma-Delta A/D Converter incorporate a separate ground return path for analog circuits. The analog and digital grounds may be tied to a single point at the power source. Analog pins that require grounding should be tied to this analog return. SVSS can be tied to the digital ground, along with VSS and AVSS.

2.8.2 ANALOG INPUTS

The analog signals to be converted are connected to the pins of CH0 and/or CH1. Each channel has inverting and non-inverting inputs (CHn- and CHn+, respectively), and is fully differential.

If not used for conversion, CH1+ and CH1- can be used to supply an external voltage reference to the converter. If an external reference is not used and CH1 is not needed as a conversion input, both pins should be connected to the analog ground return.

2.9 Unused I/Os

Unused I/O pins should be configured as outputs and driven to a logic low state. Alternatively, connect a 1 k Ω to 10 k Ω resistor to VSS on unused pins and drive the output to logic low.

PIC24FJ128GC010 FAMILY

3.0 CPU

Note: This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “PIC24F Family Reference Manual”, “CPU with Extended Data Space (EDS)” (DS39732). The information in this data sheet supersedes the information in the FRM.

The PIC24F CPU has a 16-bit (data) modified, Harvard architecture with an enhanced instruction set and a 24-bit instruction word with a variable length opcode field. The Program Counter (PC) is 23 bits wide and addresses up to 4M instructions of user program memory space. A single-cycle instruction prefetch mechanism is used to help maintain throughput and provides predictable execution. All instructions execute in a single cycle, with the exception of instructions that change the program flow, the double-word move (MOV.D) instruction and the table instructions. Overhead-free program loop constructs are supported using the REPEAT instructions, which are interruptible at any point.

PIC24F devices have sixteen, 16-bit working registers in the programmer's model. Each of the working registers can act as a data, address or address offset register. The 16th working register (W15) operates as a Software Stack Pointer for interrupts and calls.

The lower 32 Kbytes of the Data Space can be accessed linearly. The upper 32 Kbytes of the Data Space are referred to as Extended Data Space to which the extended data RAM, EPMP memory space or program memory can be mapped.

The Instruction Set Architecture (ISA) has been significantly enhanced beyond that of the PIC18, but maintains an acceptable level of backward compatibility. All PIC18 instructions and addressing modes are supported, either directly, or through simple macros. Many of the ISA enhancements have been driven by compiler efficiency needs.

The core supports Inherent (no operand), Relative, Literal and Memory Direct Addressing modes, along with three groups of addressing modes. All modes support Register Direct and various Register Indirect modes. Each group offers up to seven addressing modes. Instructions are associated with predefined addressing modes, depending upon their functional requirements.

For most instructions, the core is capable of executing a data (or program data) memory read, a working register (data) read, a data memory write and a program (instruction) memory read per instruction cycle. As a result, three parameter instructions can be supported, allowing trinary operations (that is, $A + B = C$) to be executed in a single cycle.

A high-speed, 17-bit x 17-bit multiplier has been included to significantly enhance the core arithmetic capability and throughput. The multiplier supports Signed, Unsigned and Mixed mode, 16-bit x 16-bit or 8-bit x 8-bit, integer multiplication. All multiply instructions execute in a single cycle.

The 16-bit ALU has been enhanced with integer divide assist hardware that supports an iterative non-restoring divide algorithm. It operates in conjunction with the REPEAT instruction looping mechanism and a selection of iterative divide instructions to support 32-bit (or 16-bit), divided by 16-bit, integer signed and unsigned division. All divide operations require 19 cycles to complete but are interruptible at any cycle boundary.

The PIC24F has a vectored exception scheme with up to 8 sources of non-maskable traps and up to 118 interrupt sources. Each interrupt source can be assigned to one of seven priority levels.

A block diagram of the CPU is shown in [Figure 3-1](#).

3.1 Programmer's Model

The programmer's model for the PIC24F is shown in [Figure 3-2](#). All registers in the programmer's model are memory mapped and can be manipulated directly by instructions. A description of each register is provided in [Table 3-1](#). All registers associated with the programmer's model are memory mapped.

R = Readable bit

W = Writable bit

U = Unimplemented bit, read as '0'

-n = Value at POR

'1' = Bit is set

'0' = Bit is cleared

x = Bit is unknown

bit 15-9 **Unimplemented:** Read as '0'

bit 8 **DC:** ALU Half Carry/Borrow bit

1 = A carry out from the 4th low-order bit (for byte-sized data) or 8th low-order bit (for word-sized data) of the result occurred

0 = No carry out from the 4th or 8th low-order bit of the result has occurred

bit 7-5 **IPL<2:0>:** CPU Interrupt Priority Level (IPL) Status bits^(1,2)

111 = CPU Interrupt Priority Level is 7 (15); user interrupts are disabled

110 = CPU Interrupt Priority Level is 6 (14)

101 = CPU Interrupt Priority Level is 5 (13)

100 = CPU Interrupt Priority Level is 4 (12)

011 = CPU Interrupt Priority Level is 3 (11)

010 = CPU Interrupt Priority Level is 2 (10)

001 = CPU Interrupt Priority Level is 1 (9)

000 = CPU Interrupt Priority Level is 0 (8)

bit 4 **RA:** REPEAT Loop Active bit

1 = REPEAT loop is in progress

0 = REPEAT loop is not in progress

bit 3 **N:** ALU Negative bit

1 = Result was negative

0 = Result was not negative (zero or positive)

bit 2 **OV:** ALU Overflow bit

1 = Overflow occurred for signed (2's complement) arithmetic in this arithmetic operation

0 = No overflow has occurred

bit 1 **Z:** ALU Zero bit

1 = An operation, which affects the Z bit, has set it at some time in the past

0 = The most recent operation, which affects the Z bit, has cleared it (i.e., a non-zero result)

bit 0 **C:** ALU Carry/Borrow bit

1 = A carry out from the Most Significant bit (MSb) of the result occurred

0 = No carry out from the Most Significant bit of the result occurred

Note 1: The IPLx Status bits are read-only when NSTDIS (INTCON1<15>) = 1.

Note 2: The IPLx Status bits are concatenated with the IPL3 (CORCON<3>) bit to form the CPU Interrupt Priority Level (IPL). The value in parentheses indicates the IPL when IPL3 = 1.

Note 1: The IPL3 bit is concatenated with the IPL<2:0> bits (SR<7:5>) to form the CPU Interrupt priority Level; see [Register 3-1](#) for bit description.

PIC24FJ128GC010 FAMILY

3.3 Arithmetic Logic Unit (ALU)

The PIC24F ALU is 16 bits wide and is capable of addition, subtraction, bit shifts and logic operations. Unless otherwise mentioned, arithmetic operations are 2's complement in nature. Depending on the operation, the ALU may affect the values of the Carry (C), Zero (Z), Negative (N), Overflow (OV) and Digit Carry (DC) Status bits in the SR register. The C and DC Status bits operate as Borrow and Digit Borrow bits, respectively, for subtraction operations.

The ALU can perform 8-bit or 16-bit operations, depending on the mode of the instruction that is used. Data for the ALU operation can come from the W register array, or data memory, depending on the addressing mode of the instruction. Likewise, output data from the ALU can be written to the W register array or a data memory location.

The PIC24F CPU incorporates hardware support for both multiplication and division. This includes a dedicated hardware multiplier and support hardware for 16-bit divisor division.

3.3.1 MULTIPLIER

The ALU contains a high-speed, 17-bit x 17-bit multiplier. It supports unsigned, signed or mixed sign operation in several multiplication modes:

1. 16-bit x 16-bit signed
2. 16-bit x 16-bit unsigned
3. 16-bit signed x 5-bit (literal) unsigned
4. 16-bit unsigned x 16-bit unsigned
5. 16-bit unsigned x 5-bit (literal) unsigned
6. 16-bit unsigned x 16-bit signed
7. 8-bit unsigned x 8-bit unsigned

3.3.2 DIVIDER

The divide block supports signed and unsigned integer divide operations with the following data sizes:

1. 32-bit signed/16-bit signed divide
2. 32-bit unsigned/16-bit unsigned divide
3. 16-bit signed/16-bit signed divide
4. 16-bit unsigned/16-bit unsigned divide

The quotient for all divide instructions ends up in W0 and the remainder in W1. Sixteen-bit signed and unsigned DIV instructions can specify any W register for both the 16-bit divisor (Wn), and any W register (aligned) pair (W(m + 1):Wm) for the 32-bit dividend. The divide algorithm takes one cycle per bit of divisor, so both 32-bit/16-bit and 16-bit/16-bit instructions take the same number of cycles to execute.

3.3.3 MULTIBIT SHIFT SUPPORT

The PIC24F ALU supports both single bit and single-cycle, multibit arithmetic and logic shifts. Multibit shifts are implemented using a shifter block, capable of performing up to a 15-bit arithmetic right shift, or up to a 15-bit left shift, in a single cycle. All multibit shift instructions only support Register Direct Addressing for both the operand source and result destination.

A full summary of instructions that use the shift operation is provided in [Table 3-2](#).

TABLE 3-2: INSTRUCTIONS THAT USE THE SINGLE BIT AND MULTIBIT SHIFT OPERATION

| Instruction | Description |
|-------------|---|
| ASR | Arithmetic shift right source register by one or more bits. |
| SL | Shift left source register by one or more bits. |
| LSR | Logical shift right source register by one or more bits. |

PIC24FJ128GC010 FAMILY

4.0 MEMORY ORGANIZATION

As Harvard architecture devices, PIC24F microcontrollers feature separate program and data memory spaces and buses. This architecture also allows direct access of program memory from the Data Space (DS) during code execution.

4.1 Program Memory Space

The program address memory space of the PIC24FJ128GC010 family devices is 4M instructions. The space is addressable by a 24-bit value derived

from either the 23-bit Program Counter (PC) during program execution, or from table operation or Data Space remapping, as described in [Section 4.3 “Interfacing Program and Data Memory Spaces”](#).

User access to the program memory space is restricted to the lower half of the address range (000000h to 7FFFFFFh). The exception is the use of TBLRD/TBLWT operations, which use TBLPAG<7> to permit access to the Configuration bits and Device ID sections of the configuration memory space.

Memory maps for the PIC24FJ128GC010 family of devices are shown in [Figure 4-1](#).

FIGURE 4-1: PROGRAM SPACE MEMORY MAP FOR PIC24FJ128GC010 FAMILY DEVICES

PIC24FJ128GC010 FAMILY

4.1.1 PROGRAM MEMORY ORGANIZATION

The program memory space is organized in word-addressable blocks. Although it is treated as 24 bits wide, it is more appropriate to think of each address of the program memory as a lower and upper word, with the upper byte of the upper word being unimplemented. The lower word always has an even address, while the upper word has an odd address (Figure 4-2).

Program memory addresses are always word-aligned on the lower word and addresses are incremented or decremented by two during code execution. This arrangement also provides compatibility with data memory space addressing and makes it possible to access data in the program memory space.

4.1.2 HARD MEMORY VECTORS

All PIC24F devices reserve the addresses between 000000h and 000200h for hard-coded program execution vectors. A hardware Reset vector is provided to redirect code execution from the default value of the PC on device Reset to the actual start of code. A GOTO instruction is programmed by the user at 000000h with the actual address for the start of code at 000002h.

PIC24F devices also have two Interrupt Vector Tables (IVTs), located from 000004h to 0000FFh and 000100h to 0001FFh. These vector tables allow each of the many device interrupt sources to be handled by separate ISRs. A more detailed discussion of the Interrupt Vector Tables is provided in Section 8.1 “Interrupt Vector Table”.

4.1.3 FLASH CONFIGURATION WORDS

In PIC24FJ128GC010 family devices, the top four words of on-chip program memory are reserved for configuration information. On device Reset, the configuration information is copied into the appropriate Configuration register. The addresses of the Flash Configuration Word for devices in the PIC24FJ128GC010 family are shown in Table 4-1. Their location in the memory map is shown with the other memory vectors in Figure 4-1.

The Configuration Words in program memory are a compact format. The actual Configuration bits are mapped in several different registers in the configuration memory space. Their order in the Flash Configuration Words does not reflect a corresponding arrangement in the configuration space. Additional details on the device Configuration Words are provided in Section 34.0 “Special Features”.

TABLE 4-1: FLASH CONFIGURATION WORDS FOR PIC24FJ128GC010 FAMILY DEVICES

| Device | Program Memory (Words) | Configuration Word Addresses |
|-----------------|------------------------|------------------------------|
| PIC24FJ64GC0XX | 22,016 | 00ABF8h:00ABFEh |
| PIC24FJ128GC0XX | 44,032 | 0157F8h:0157FEh |

FIGURE 4-2: PROGRAM MEMORY ORGANIZATION

PIC24FJ128GC010 FAMILY

4.2 Data Memory Space

Note: This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “PIC24F Family Reference Manual”, **Section 45. “Data Memory with Extended Data Space (EDS)”** (DS39733). The information in this data sheet supersedes the information in the FRM.

The PIC24F core has a 16-bit wide data memory space, addressable as a single linear range. The Data Space (DS) is accessed using two Address Generation Units (AGUs), one each for read and write operations. The Data Space memory map is shown in [Figure 4-3](#).

The 16-bit wide data addresses in the data memory space point to bytes within the Data Space. This gives a DS address range of 64 Kbytes or 32K words. The lower half (0000h to 7FFFh) is used for implemented (on-chip) memory addresses.

The upper half of data memory address space (8000h to FFFFh) is used as a window into the Extended Data Space (EDS). This allows the microcontroller to directly access a greater range of data beyond the standard 16-bit address range. EDS is discussed in detail in [Section 4.2.5 “Extended Data Space \(EDS\)”](#).

The lower half of DS is compatible with previous PIC24F microcontrollers without EDS. All PIC24FJ128GC010 family devices implement 8 Kbytes of data RAM in the lower half of the DS, from 0800h to 27FFh.

4.2.1 DATA SPACE WIDTH

The data memory space is organized in byte-addressable, 16-bit wide blocks. Data is aligned in data memory and registers as 16-bit words, but all Data Space Effective Addresses (EAs) resolve to bytes. The Least Significant Bytes (LSBs) of each word have even addresses, while the Most Significant Bytes (MSBs) have odd addresses.

FIGURE 4-3: DATA SPACE MEMORY MAP FOR PIC24FJ128GC010 FAMILY DEVICES

PIC24FJ128GC010 FAMILY

4.2.2 DATA MEMORY ORGANIZATION AND ALIGNMENT

To maintain backward compatibility with PIC® MCUs and improve Data Space memory usage efficiency, the PIC24F instruction set supports both word and byte operations. As a consequence of byte accessibility, all EA calculations are internally scaled to step through word-aligned memory. For example, the core recognizes that Post-Modified Register Indirect Addressing mode [Ws++] will result in a value of Ws + 1 for byte operations and Ws + 2 for word operations.

Data byte reads will read the complete word, which contains the byte, using the LSB of any EA to determine which byte to select. The selected byte is placed onto the LSB of the data path. That is, data memory and registers are organized as two parallel, byte-wide entities with shared (word) address decode but separate write lines. Data byte writes only write to the corresponding side of the array or register which matches the byte address.

All word accesses must be aligned to an even address. Misaligned word data fetches are not supported, so care must be taken when mixing byte and word operations or translating from 8-bit MCU code. If a misaligned read or write is attempted, an address error trap will be generated. If the error occurred on a read, the instruction underway is completed; if it occurred on a write, the instruction will be executed but the write will not occur. In either case, a trap is then executed, allowing the system and/or user to examine the machine state prior to execution of the address Fault.

All byte loads into any W register are loaded into the LSB. The Most Significant Byte (MSB) is not modified.

A Sign-Extend (SE) instruction is provided to allow users to translate 8-bit signed data to 16-bit signed values. Alternatively, for 16-bit unsigned data, users can clear the MSB of any W register by executing a Zero-Extend (ZE) instruction on the appropriate address.

Although most instructions are capable of operating on word or byte data sizes, it should be noted that some instructions operate only on words.

4.2.3 NEAR DATA SPACE

The 8-Kbyte area between 0000h and 1FFFh is referred to as the Near Data Space. Locations in this space are directly addressable via a 13-bit absolute address field within all memory direct instructions. The remainder of the Data Space is addressable indirectly. Additionally, the whole Data Space is addressable using MOV instructions, which support Memory Direct Addressing with a 16-bit address field.

4.2.4 SPECIAL FUNCTION REGISTER (SFR) SPACE

The first 2 Kbytes of the Near Data Space, from 0000h to 07FFh, are primarily occupied with Special Function Registers (SFRs). These are used by the PIC24F core and peripheral modules for controlling the operation of the device.

SFRs are distributed among the modules that they control and are generally grouped together by module. Much of the SFR space contains unused addresses; these are read as '0'. A diagram of the SFR space, showing where the SFRs are actually implemented, is shown in Table 4-2. Each implemented area indicates a 32-byte region where at least one address is implemented as an SFR. A complete list of implemented SFRs, including their addresses, is shown in Tables 4-3 through 4-39.

TABLE 4-2: IMPLEMENTED REGIONS OF SFR DATA SPACE

| SFR Space Address | | | | | | | | | | |
|-------------------|-------------------|------------------------|------------------------|---------|------------|---------|------|------|-----|---|
| | xx00 | xx20 | xx40 | xx60 | xx80 | xxA0 | xxC0 | xxE0 | | |
| 000h | Core | | | ICN | Interrupts | | | | | |
| 100h | Timers | — | Capture | | | Compare | | | — | |
| 200h | I ² C™ | URT | SPI/URT ⁽¹⁾ | SPI | — | — | — | URT | I/O | |
| 300h | A/D | | | DMA | | | | — | | |
| 400h | A/D | DAC | — | — | USB | | | S/D | ANA | — |
| 500h | A/D | | | — | LCD | | | — | | |
| 600h | EPMP | RTC/CMP ⁽²⁾ | CRC | — | AVR | PPS | | | | — |
| 700h | — | — | System | NVM/PMD | CTM | — | — | — | — | |

Legend: — = No implemented SFRs in this block; URT = UART; S/D = Sigma-Delta A/D; AVR = Analog Reference

Note 1: This region includes registers for the op amp module.

2: This region includes registers for the Digital Signal Modulator (DSM) module.

Legend: — = unimplemented, read as '0'. Reset values are shown in hexadecimal. Reset values shown are for 100/121-pin devices.

Note 1: These bits are unimplemented in 64-pin devices, read as '0'.

Note 2: RC12 and RC15 are only available when the primary oscillator is disabled or when EC mode is selected (POSCMD<1:0> Configuration bits = 11 or 00); otherwise read as '0'.

Note 3: RC15 is only available when the POSCMD<1:0> Configuration bits = 11 or 00 and the OSCIOFN Configuration bit = 1.

Note 4: RC13 and RC14 are input ports only and cannot be used as output ports.

PIC24FJ128GC010 FAMILY

4.2.5 EXTENDED DATA SPACE (EDS)

The Extended Data Space (EDS) allows PIC24F devices to address a much larger range of data than would otherwise be possible with a 16-bit address range. EDS includes any additional internal data memory not directly accessible by the lower 32-Kbyte data address space and any external memory through the Enhanced Parallel Master Port (EPMP).

In addition, EDS also allows read access to the program memory space. This feature is called Program Space Visibility (PSV) and is discussed in detail in [Section 4.3.3 “Reading Data from Program Memory Using EDS”](#).

[Figure 4-4](#) displays the entire EDS space. The EDS is organized as pages, called EDS pages, with one page equal to the size of the EDS window (32 Kbytes). A particular EDS page is selected through the Data Space Read register (DSRPAG) or Data Space Write register (DSWPAG). For PSV, only the DSRPAG register is used. The combination of the DSRPAG register value and the 16-bit wide data address forms a 24-bit Effective Address (EA).

The data addressing range of PIC24FJ128GC010 family devices depends on the version of the Enhanced Parallel Master Port (EPMP) implemented on a particular device; this is, in turn, is a function of the device pin count. [Table 4-40](#) lists the total memory accessible by each of the devices in this family. For more details on accessing external memory using EPMP, refer to the “PIC24F Family Reference Manual”, [Section 42. “Enhanced Parallel Master Port \(EPMP\)”](#) (DS39730).

TABLE 4-40: TOTAL ACCESSIBLE DATA MEMORY

| Family | Internal RAM | External RAM Access Using EPMP |
|-----------------|--------------|--------------------------------|
| PIC24FJXXXGC010 | 8K | Up to 16 Mbytes |
| PIC24FJXXXGC006 | 8K | Up to 64K |

Note: Accessing Page 0 in the EDS window will generate an address error trap as Page 0 is the base data memory (data locations, 0800h to 7FFFh, in the lower Data Space).

FIGURE 4-4: EXTENDED DATA SPACE

PIC24FJ128GC010 FAMILY

4.2.5.1 Data Read from EDS

In order to read the data from the EDS space, first, an Address Pointer is set up by loading the required EDS page number into the DSRPAG register and assigning the offset address to one of the W registers. Once the above assignment is done, the EDS window is enabled by setting bit 15 of the working register, assigned with the offset address; then, the contents of the pointed EDS location can be read.

Figure 4-5 illustrates how the EDS space address is generated for read operations.

When the Most Significant bit (MSb) of EA is '1' and DSRPAG<9> = 0, the lower 9 bits of DSRPAG are concatenated to the lower 15 bits of the EA to form a 24-bit EDS space address for read operations.

Example 4-1 shows how to read a byte, word and double-word from EDS.

Note: All read operations from EDS space have an overhead of one instruction cycle. Therefore, a minimum of two instruction cycles is required to complete an EDS read. EDS reads under the REPEAT instruction; the first two accesses take three cycles and the subsequent accesses take one cycle.

FIGURE 4-5: EDS ADDRESS GENERATION FOR READ OPERATIONS

EXAMPLE 4-1: EDS READ CODE IN ASSEMBLY

```
; Set the EDS page from where the data to be read
mov    #0x0002, w0
mov    w0, DSRPAG    ;page 2 is selected for read
mov    #0x0800, w1    ;select the location (0x800) to be read
bset   w1, #15       ;set the MSB of the base address, enable EDS mode

;Read a byte from the selected location
mov.b  [w1++], w2    ;read Low byte
mov.b  [w1++], w3    ;read High byte

;Read a word from the selected location
mov    [w1], w2      ;

;Read Double - word from the selected location
mov.d  [w1], w2      ;two word read, stored in w2 and w3
```

PIC24FJ128GC010 FAMILY

4.2.5.2 Data Write into EDS

In order to write data to EDS space, such as in EDS reads, an Address Pointer is set up by loading the required EDS page number into the DSWPAG register and assigning the offset address to one of the W registers. Once the above assignment is done, then the EDS window is enabled by setting bit 15 of the working register, assigned with the offset address, and the accessed location can be written.

Figure 4-6 illustrates how the EDS space address is generated for write operations.

When the MSb of EA is '1', the lower 9 bits of DSWPAG are concatenated to the lower 15 bits of EA to form a 24-bit EDS address for write operations. Example 4-2 shows how to write a byte, word and double-word to EDS.

The Page registers (DSRPAG/DSWPAG) do not update automatically while crossing a page boundary when the rollover happens from 0xFFFF to 0x8000.

While developing code in assembly, care must be taken to update the Page registers when an Address Pointer crosses the page boundary. The 'C' compiler keeps track of the addressing, and increments or decrements the Page registers accordingly, while accessing contiguous data memory locations.

Note 1: All write operations to EDS are executed in a single cycle.

2: Use of Read/Modify/Write operation on any EDS location under a REPEAT instruction is not supported. For example, BCLR, BSW, BTG, RLC f, RLNC f, RRC f, RRNC f, ADD f, SUB f, SUBR f, AND f, IOR f, XOR f, ASR f, ASL f.

3: Use the DSRPAG register while performing Read/Modify/Write operations.

FIGURE 4-6: EDS ADDRESS GENERATION FOR WRITE OPERATIONS

EXAMPLE 4-2: EDS WRITE CODE IN ASSEMBLY

```
; Set the EDS page where the data to be written
mov    #0x0002, w0
mov    w0, DSWPAG           ;page 2 is selected for write
mov    #0x0800, w1         ;select the location (0x800) to be written
bset   w1, #15             ;set the MSB of the base address, enable EDS mode

;Write a byte to the selected location
mov    #0x00A5, w2
mov    #0x003C, w3
mov.b  w2, [w1++]          ;write Low byte
mov.b  w3, [w1++]          ;write High byte

;Write a word to the selected location
mov    #0x1234, w2        ;
mov    w2, [w1]           ;

;Write a Double - word to the selected location
mov    #0x1122, w2
mov    #0x4455, w3
mov.d  w2, [w1]          ;2 EDS writes
```

PIC24FJ128GC010 FAMILY

TABLE 4-41: EDS MEMORY ADDRESS WITH DIFFERENT PAGES AND ADDRESSES

| DSRPAG (Data Space Read Register) | DSWPAG (Data Space Write Register) | Source/Destination Address While Indirect Addressing | 24-Bit EA Pointing to EDS | Comment |
|--------------------------------------|---------------------------------------|--|---------------------------|-----------------------------------|
| x ⁽¹⁾ | x ⁽¹⁾ | 0000h to 1FFFh | 000000h to 001FFFh | Near Data Space ⁽²⁾ |
| | | 2000h to 7FFFh | 002000h to 007FFFh | |
| 001h | 001h | 8000h to FFFFh | 008000h to 00FFFEh | EPMP Memory Space |
| 002h | 002h | | 010000h to 017FFEh | |
| 003h | 003h | | 018000h to 0187FEh | |
| • | • | | • | |
| • | • | | • | |
| • | • | • | | |
| • | • | • | | |
| 1FFh | 1FFh | | FF8000h to FFFFh | |
| 000h | 000h | | Invalid Address | Address Error Trap ⁽³⁾ |

- Note 1:** If the source/destination address is below 8000h, the DSRPAG and DSWPAG registers are not considered.
Note 2: This Data Space can also be accessed by Direct Addressing.
Note 3: When the source/destination address is above 8000h and DSRPAG/DSWPAG are '0', an address error trap will occur.

4.2.6 SOFTWARE STACK

Apart from its use as a working register, the W15 register in PIC24F devices is also used as a Software Stack Pointer (SSP). The pointer always points to the first available free word and grows from lower to higher addresses. It decrements for stack pops and post-increments for stack pushes, as shown in Figure 4-7. Note that for a PC push during any CALL instruction, the MSB of the PC is zero-extended before the push, ensuring that the MSB is always clear.

Note: A PC push during exception processing will concatenate the SRL register to the MSB of the PC prior to the push.

The Stack Pointer Limit Value register (SPLIM), associated with the Stack Pointer, sets an upper address boundary for the stack. SPLIM is uninitialized at Reset. As is the case for the Stack Pointer, SPLIM<0> is forced to '0' as all stack operations must be word-aligned. Whenever an EA is generated using W15 as a source or destination pointer, the resulting address is compared with the value in SPLIM. If the contents of the Stack Pointer (W15) and the SPLIM register are equal, and a push operation is performed, a stack error trap will not occur. The stack error trap will occur on a subsequent push operation. Thus, for

example, if it is desirable to cause a stack error trap when the stack grows beyond address, 2000h in RAM, initialize the SPLIM with the value, 1FFEh.

Similarly, a Stack Pointer underflow (stack error) trap is generated when the Stack Pointer address is found to be less than 0800h. This prevents the stack from interfering with the SFR space.

A write to the SPLIM register should not be immediately followed by an indirect read operation using W15.

FIGURE 4-7: CALL STACK FRAME

PIC24FJ128GC010 FAMILY

4.3 Interfacing Program and Data Memory Spaces

The PIC24F architecture uses a 24-bit wide program space and 16-bit wide Data Space. The architecture is also a modified Harvard scheme, meaning that data can also be present in the program space. To use this data successfully, it must be accessed in a way that preserves the alignment of information in both spaces.

Aside from normal execution, the PIC24F architecture provides two methods by which program space can be accessed during operation:

- Using table instructions to access individual bytes or words anywhere in the program space
- Remapping a portion of the program space into the Data Space (Program Space Visibility)

Table instructions allow an application to read or write to small areas of the program memory. This makes the method ideal for accessing data tables that need to be updated from time to time. It also allows access to all bytes of the program word. The remapping method allows an application to access a large block of data on a read-only basis, which is ideal for look-ups from a large table of static data. It can only access the least significant word of the program word.

4.3.1 ADDRESSING PROGRAM SPACE

Since the address ranges for the data and program spaces are 16 and 24 bits, respectively, a method is needed to create a 23-bit or 24-bit program address from 16-bit data registers. The solution depends on the interface method to be used.

For table operations, the 8-bit Table Memory Page Address register (TBLPAG) is used to define a 32K word region within the program space. This is concatenated with a 16-bit EA to arrive at a full 24-bit program space address. In this format, the MSBs of TBLPAG are used to determine if the operation occurs in the user memory (TBLPAG<7> = 0) or the configuration memory (TBLPAG<7> = 1).

For remapping operations, the 10-bit Extended Data Space Read register (DSRPAG) is used to define a 16K word page in the program space. When the Most Significant bit (MSb) of the EA is '1', and the MSb (bit 9) of DSRPAG is '1', the lower 8 bits of DSRPAG are concatenated with the lower 15 bits of the EA to form a 23-bit program space address. The DSRPAG<8> bit decides whether the lower word (when the bit is '0') or the higher word (when the bit is '1') of program memory is mapped. Unlike table operations, this strictly limits remapping operations to the user memory area.

Table 4-42 and Figure 4-8 show how the program EA is created for table operations, and remapping accesses from the data EA. Here, P<23:0> refer to a program space word, whereas D<15:0> refer to a Data Space word.

TABLE 4-42: PROGRAM SPACE ADDRESS CONSTRUCTION

| Access Type | Access Space | Program Space Address | | | | |
|--|---------------|------------------------------|----------------------------|---------------------|------------------------------|-----|
| | | <23> | <22:16> | <15> | <14:1> | <0> |
| Instruction Access (Code Execution) | User | 0 | PC<22:1> | | | 0 |
| | | 0xx xxxx xxxx xxxx xxxx xxx0 | | | | |
| TBLRD/TBLWT (Byte/Word Read/Write) | User | TBLPAG<7:0> | | Data EA<15:0> | | |
| | | 0xxx xxxx | | xxxx xxxx xxxx xxxx | | |
| | Configuration | TBLPAG<7:0> | | Data EA<15:0> | | |
| | | 1xxx xxxx | | xxxx xxxx xxxx xxxx | | |
| Program Space Visibility (Block Remap/Read) | User | 0 | DSRPAG<7:0> ⁽²⁾ | | Data EA<14:0> ⁽¹⁾ | |
| | | 0 | xxxx xxxx | | xxx xxxx xxxx xxxx | |

Note 1: Data EA<15> is always '1' in this case, but is not used in calculating the program space address. Bit 15 of the address is DSRPAG<0>.

2: DSRPAG<9> is always '1' in this case. DSRPAG<8> decides whether the lower word or higher word of program memory is read. When DSRPAG<8> is '0', the lower word is read and when it is '1', the higher word is read.

PIC24FJ128GC010 FAMILY

FIGURE 4-8: DATA ACCESS FROM PROGRAM SPACE ADDRESS GENERATION

PIC24FJ128GC010 FAMILY

4.3.2 DATA ACCESS FROM PROGRAM MEMORY USING TABLE INSTRUCTIONS

The `TBLRDL` and `TBLWTL` instructions offer a direct method of reading or writing the lower word of any address within the program space without going through Data Space. The `TBLRDH` and `TBLWTH` instructions are the only method to read or write the upper 8 bits of a program space word as data.

The PC is incremented by two for each successive 24-bit program word. This allows program memory addresses to directly map to Data Space addresses. Program memory can thus be regarded as two, 16-bit word-wide address spaces, residing side by side, each with the same address range. `TBLRDL` and `TBLWTL` access the space which contains the least significant data word, and `TBLRDH` and `TBLWTH` access the space which contains the upper data byte.

Two table instructions are provided to move byte or word-sized (16-bit) data to and from program space. Both function as either byte or word operations.

1. `TBLRDL` (Table Read Low): In Word mode, it maps the lower word of the program space location ($P<15:0>$) to a data address ($D<15:0>$). In Byte mode, either the upper or lower byte of the lower program word is mapped to the lower byte of a data address. The upper byte is selected when byte select is '1'; the lower byte is selected when it is '0'.

2. `TBLRDH` (Table Read High): In Word mode, it maps the entire upper word of a program address ($P<23:16>$) to a data address. Note that $D<15:8>$, the 'phantom' byte, will always be '0'. In Byte mode, it maps the upper or lower byte of the program word to $D<7:0>$ of the data address, as above. Note that the data will always be '0' when the upper 'phantom' byte is selected (Byte Select = 1).

In a similar fashion, two table instructions, `TBLWTH` and `TBLWTL`, are used to write individual bytes or words to a program space address. The details of their operation are described in [Section 6.0 "Flash Program Memory"](#).

For all table operations, the area of program memory space to be accessed is determined by the Table Memory Page Address register (`TBLPAG`). `TBLPAG` covers the entire program memory space of the device, including user and configuration spaces. When `TBLPAG<7> = 0`, the table page is located in the user memory space. When `TBLPAG<7> = 1`, the page is located in configuration space.

Note: Only table read operations will execute in the configuration memory space where Device IDs are located. Table write operations are not allowed.

FIGURE 4-9: ACCESSING PROGRAM MEMORY WITH TABLE INSTRUCTIONS

PIC24FJ128GC010 FAMILY

4.3.3 READING DATA FROM PROGRAM MEMORY USING EDS

The upper 32 Kbytes of Data Space may optionally be mapped into any 16K word page of the program space. This provides transparent access of stored constant data from the Data Space without the need to use special instructions (i.e., TBLRDL/H).

Program space access through the Data Space occurs when the MSb of EA is '1' and the DSRPAG<9> is also '1'. The lower 8 bits of DSRPAG are concatenated to the Wn<14:0> bits to form a 23-bit EA to access program memory. The DSRPAG<8> decides which word should be addressed; when the bit is '0', the lower word and when '1', the upper word of the program memory is accessed.

The entire program memory is divided into 512 EDS pages, from 200h to 3FFh, each consisting of 16K words of data. Pages, 200h to 2FFh, correspond to the lower words of the program memory, while 300h to 3FFh correspond to the upper words of the program memory.

Using this EDS technique, the entire program memory can be accessed. Previously, the access to the upper word of the program memory was not supported.

Table 4-43 provides the corresponding 23-bit EDS address for program memory with EDS page and source addresses.

For operations that use PSV and are executed outside a REPEAT loop, the MOV and MOV.D instructions will require one instruction cycle in addition to the specified execution time. All other instructions will require two instruction cycles in addition to the specified execution time.

For operations that use PSV, which are executed inside a REPEAT loop, there will be some instances that require two instruction cycles in addition to the specified execution time of the instruction:

- Execution in the first iteration
- Execution in the last iteration
- Execution prior to exiting the loop due to an interrupt
- Execution upon re-entering the loop after an interrupt is serviced

Any other iteration of the REPEAT loop will allow the instruction accessing data, using PSV, to execute in a single cycle.

TABLE 4-43: EDS PROGRAM ADDRESS WITH DIFFERENT PAGES AND ADDRESSES

| DSRPAG (Data Space Read Register) | Source Address While Indirect Addressing | 23-Bit EA Pointing to EDS | Comment |
|--------------------------------------|---|---|--|
| 200h • • • 2FFh | 8000h to FFFFh | 000000h to 007FFEh • • • 7F8000h to 7FFFFEh | Lower words of 4M program instructions; (8 Mbytes) for read operations only. |
| 300h • • • 3FFh | | 000001h to 007FFFh • • • 7F8001h to 7FFFFFh | Upper words of 4M program instructions (4 Mbytes remaining, 4 Mbytes are phantom bytes); for read operations only. |
| 000h | | Invalid Address | Address error trap ⁽¹⁾ |

Note 1: When the source/destination address is above 8000h and DSRPAG/DSWPAG are '0', an address error trap will occur.

EXAMPLE 4-3: EDS READ CODE FROM PROGRAM MEMORY IN ASSEMBLY

```

; Set the EDS page from where the data to be read

PIC24FJ128GC010 FAMILY

5.0 DIRECT MEMORY ACCESS CONTROLLER (DMA)

Note: This data sheet summarizes the features of the PIC24FJ128GC010 family of devices. It is not intended to be a comprehensive reference source. To complement the information in this data sheet, refer to the “PIC24F Family Reference Manual”, “Direct Memory Access Controller (DMA)” (DS39742). The information in this data sheet supersedes the information in the FRM.

The Direct Memory Access (DMA) controller is designed to service high data throughput peripherals operating on the SFR bus, allowing them to access data memory directly and alleviating the need for CPU intensive management. By allowing these data intensive peripherals to share their own data path, the main data bus is also deloaded, resulting in additional power savings.

The DMA controller functions both as a peripheral and a direct extension of the CPU. It is located on the microcontroller data bus, between the CPU and DMA controller-enabled peripherals, with direct access to SRAM. This partitions the SFR bus into two buses, allowing the DMA controller access to the DMA capable peripherals located on the new DMA SFR bus. The controller serves as a master device on the DMA SFR bus, controlling data flow from DMA capable peripherals.

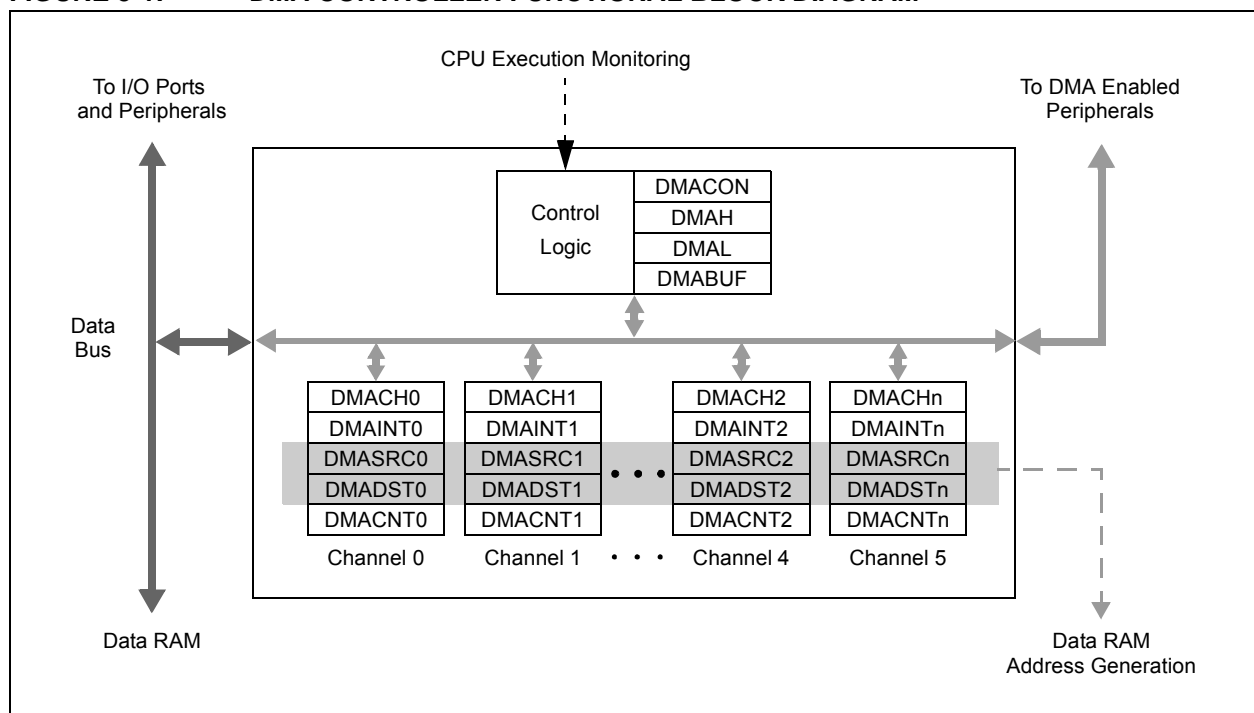

The controller also monitors CPU instruction processing directly, allowing it to be aware of when the CPU requires access to peripherals on the DMA bus, and automatically relinquishing control to the CPU as needed. This increases the effective bandwidth for handling data without DMA operations, causing a processor Stall. This makes the controller essentially transparent to the user.

The DMA controller includes these features:

- Six multiple independent and independently programmable channels
- Concurrent operation with the CPU (no DMA caused Wait states)
- DMA bus arbitration
- Five Programmable Address modes
- Four Programmable Transfer modes
- Four Flexible Internal Data Transfer modes
- Byte or word support for data transfer
- 16-Bit Source and Destination Address register for each channel, dynamically updated and reloadable
- 16-Bit Transaction Count register, dynamically updated and reloadable
- Upper and Lower Address Limit registers
- Counter half-full level interrupt
- Software triggered transfer
- Null Write mode for symmetric buffer operations

A simplified block diagram of the DMA controller is shown in [Figure 5-1](#).

FIGURE 5-1: DMA CONTROLLER FUNCTIONAL BLOCK DIAGRAM

PIC24FJ128GC010 FAMILY

5.1 Summary of DMA Operations

The DMA controller is capable of moving data between addresses according to a number of different parameters. Each of these parameters can be independently configured for any transaction. In addition, any or all of the DMA channels can independently perform a different transaction at the same time. Transactions are classified by these parameters:

- Source and destination (SFRs and data RAM)
- Data size (byte or word)
- Trigger source
- Transfer mode (One-Shot, Repeated or Continuous)
- Addressing modes (Fixed Address or Address Blocks, with or without Address Increment/Decrement)

In addition, the DMA controller provides channel priority arbitration for all channels.

5.1.1 SOURCE AND DESTINATION

Using the DMA controller, data may be moved between any two addresses in the Data Space. The SFR space (0000h to 07FFh) or the data RAM space (0800h to FFFFh) can serve as either the source or the destination. Data can be moved between these areas in either direction, or between addresses in either area. The four different combinations are shown in [Figure 5-2](#).

If it is necessary to protect areas of data RAM, the DMA controller allows the user to set upper and lower address boundaries for operations in the Data Space above the SFR space. The boundaries are set by the DMAH and DMAL Limit registers. If a DMA channel attempts an operation outside of the address boundaries, the transaction is terminated and an interrupt is generated.

5.1.2 DATA SIZE

The DMA controller can handle both 8-bit and 16-bit transactions. Size is user-selectable using the SIZE bit (DMACHn<1>). By default, each channel is configured for word-size transactions. When byte-size transactions are chosen, the LSb of the source and/or destination address determines if the data represents the upper or lower byte of the data RAM location.

5.1.3 TRIGGER SOURCE

The DMA controller can use 63 of the device's interrupt sources to initiate a transaction. The DMA trigger sources occur in reverse order of their natural interrupt priority and are shown in [Table 5-1](#).

These sources cannot be used as DMA triggers:

- Input Capture 8 and 9
- Output Compare 7, 8 and 9
- USB

Since the source and destination addresses for any transaction can be programmed independently of the trigger source, the DMA controller can use any trigger to perform an operation on any peripheral. This also allows DMA channels to be cascaded to perform more complex transfer operations.

5.1.4 TRANSFER MODE

The DMA controller supports four types of data transfers, based on the volume of data to be moved for each trigger.

- One-Shot: A single transaction occurs for each trigger.
- Continuous: A series of back-to-back transactions occur for each trigger. The number of transactions is determined by the DMACNTn Transaction Counter register.
- Repeated One-Shot: A single transaction is performed repeatedly, once per trigger, until the DMA channel is disabled.
- Repeated Continuous: A series of transactions are performed repeatedly, one cycle per trigger, until the DMA channel is disabled.

All transfer modes allow the option to have the source and destination addresses, and counter value automatically reloaded after the completion of a transaction. Repeated mode transfers do this automatically.

5.1.5 ADDRESSING MODES

The DMA controller also supports transfers between single addresses or address ranges. The four basic options are:

- Fixed-to-Fixed: Between two constant addresses
- Fixed-to-Block: From a constant source address to a range of destination addresses
- Block-to-Fixed: From a range of source addresses to a single, constant destination address
- Block-to-Block: From a range to source addresses to a range of destination addresses

The option to select auto-increment or auto-decrement of source and/or destination addresses is available for Block Addressing modes.

In addition to the four basic modes, the DMA controller also supports Peripheral Indirect Addressing (PIA) mode, where the source or destination address is generated jointly by the DMA controller and a PIA capable peripheral. When enabled, the DMA channel provides a base source and/or destination address, while the peripheral provides a fixed range, offset address.

For PIC24FJ128GC010 family devices, the 12-bit A/D Converter module is the only PIA capable peripheral. Details for its use in PIA mode are provided in [Section 26.0 “12-Bit High-Speed, Pipeline A/D Converter”](#).

PIC24FJ128GC010 FAMILY

FIGURE 5-2: TYPES OF DMA DATA TRANSFERS

PIC24FJ128GC010 FAMILY

5.1.6 CHANNEL PRIORITY

Each DMA channel functions independently of the others, but also competes with the others for access to the data and DMA buses. When access collisions occur, the DMA controller arbitrates between the channels using a user-selectable priority scheme. Two schemes are available:

- Round Robin: When two or more channels collide, the lower numbered channel receives priority on the first collision. On subsequent collisions, the higher numbered channels each receive priority based on their channel number.
- Fixed: When two or more channels collide, the lowest numbered channel always receives priority, regardless of past history.

5.2 Typical Setup

To set up a DMA channel for a basic data transfer:

1. Enable the DMA controller (DMAEN = 1) and select an appropriate channel priority scheme by setting or clearing PRSSEL.
2. Program DMAH and DMAL with appropriate upper and lower address boundaries for data RAM operations.
3. Select the DMA channel to be used and disable its operation (CHEN = 0).
4. Program the appropriate source and destination addresses for the transaction into the channel's DMASRCn and DMADSTn registers. For PIA Mode Addressing, use the base address value.
5. Program the DMACNTn register for the number of triggers per transfer (One-Shot or Continuous modes) or the number of words (bytes) to be transferred (Repeated modes).
6. Set or clear the SIZE bit to select the data size.
7. Program the TRMODEx bits to select the Data Transfer mode.
8. Program the SAMODEx and DAMODEx bits to select the addressing mode.
9. Enable the DMA channel by setting CHEN.
10. Enable the trigger source interrupt.

5.3 Peripheral Module Disable

Unlike other peripheral modules, the channels of the DMA controller cannot be individually powered down using the Peripheral Module Disable (PMD) registers. Instead, the channels are controlled as two groups. The DMA0MD bit (PMD7<4>) selectively controls DMACH0 through DMACH3. The DMA1MD bit (PMD7<5>) controls DMACH4 and DMACH5. Setting both bits effectively disables the DMA controller.

5.4 Registers

The DMA controller uses a number of registers to control its operation. The number of registers depends on the number of channels implemented for a particular device.

There are always four module level registers (one control and three buffer/address):

- DMACON: DMA Control Register ([Register 5-1](#))
- DMAH and DMAL: DMA High and Low Address Limit Registers
- DMABUF: DMA Data Buffer Register

Each of the DMA channels implements five registers (two control and three buffer/address):

- DMACHn: DMA Channel n Control Register ([Register 5-2](#))
- DMAINTn: DMA Channel n Interrupt Control Register ([Register 5-3](#))
- DMASRCn: DMA Data Source Address Pointer for Channel n Register
- DMADSTn: DMA Data Destination Source for Channel n Register
- DMACNTn: DMA Transaction Counter for Channel n Register

For PIC24FJ128GC010 family devices, there are a total of 34 DMA registers.

PIC24FJ128GC010 FAMILY

6.0 FLASH PROGRAM MEMORY

Note: This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “PIC24F Family Reference Manual”, “Program Memory” (DS39715). The information in this data sheet supersedes the information in the FRM.

The PIC24FJ128GC010 family of devices contains internal Flash program memory for storing and executing application code. The program memory is readable, writable and erasable. The Flash can be programmed in three ways:

- In-Circuit Serial Programming™ (ICSP™)
- Run-Time Self-Programming (RTSP)
- Enhanced In-Circuit Serial Programming (Enhanced ICSP)

ICSP allows a PIC24FJ128GC010 family device to be serially programmed while in the end application circuit. This is simply done with two lines for the programming clock and programming data (named PGECx and PGEDx, respectively), and three other lines for power (VDD), ground (VSS) and Master Clear (MCLR). This allows customers to manufacture boards with unprogrammed devices and then program the microcontroller just before shipping the product. This also allows the most recent firmware or a custom firmware to be programmed.

RTSP is accomplished using TBLRD (Table Read) and TBLWT (Table Write) instructions. With RTSP, the user may write program memory data in blocks of 64 instructions (192 bytes) at a time and erase program memory in blocks of 512 instructions (1536 bytes) at a time.

6.1 Table Instructions and Flash Programming

Regardless of the method used, all programming of Flash memory is done with the table read and write instructions. These allow direct read and write access to the program memory space from the data memory while the device is in normal operating mode. The 24-bit target address in the program memory is formed using the TBLPAG<7:0> bits and the Effective Address (EA) from a W register, specified in the table instruction, as shown in Figure 6-1.

The TBLRDL and the TBLWTL instructions are used to read or write to bits<15:0> of program memory. TBLRDL and TBLWTL can access program memory in both Word and Byte modes.

The TBLRDH and TBLWTH instructions are used to read or write to bits<23:16> of program memory. TBLRDH and TBLWTH can also access program memory in Word or Byte mode.

FIGURE 6-1: ADDRESSING FOR TABLE REGISTERS

PIC24FJ128GC010 FAMILY

6.2 RTSP Operation

The PIC24F Flash program memory array is organized into rows of 64 instructions or 192 bytes. RTSP allows the user to erase blocks of eight rows (512 instructions) at a time and to program one row at a time. It is also possible to program single words.

The 8-row erase blocks and single row write blocks are edge-aligned, from the beginning of program memory, on boundaries of 1536 bytes and 192 bytes, respectively.

When data is written to program memory using TBLWT instructions, the data is not written directly to memory. Instead, data written using table writes is stored in holding latches until the programming sequence is executed.

Any number of TBLWT instructions can be executed and a write will be successfully performed. However, 64 TBLWT instructions are required to write the full row of memory.

To ensure that no data is corrupted during a write, any unused address should be programmed with FFFFFFFh. This is because the holding latches reset to an unknown state, so if the addresses are left in the Reset state, they may overwrite the locations on rows which were not rewritten.

The basic sequence for RTSP programming is to set up a Table Pointer, then do a series of TBLWT instructions to load the buffers. Programming is performed by setting the control bits in the NVMCON register.

Data can be loaded in any order and the holding registers can be written to multiple times before performing a write operation. Subsequent writes, however, will wipe out any previous writes.

Note: Writing to a location multiple times without erasing is *not* recommended.

All of the table write operations are single-word writes (2 instruction cycles), because only the buffers are written. A programming cycle is required for programming each row.

6.3 Enhanced In-Circuit Serial Programming

Enhanced In-Circuit Serial Programming uses an on-board bootloader, known as the Program Executive (PE), to manage the programming process. Using an SPI data frame format, the Program Executive can erase, program and verify program memory. For more information on Enhanced ICSP, see the device programming specification.

6.4 Control Registers

There are two SFRs used to read and write the program Flash memory: NVMCON and NVMKEY.

The NVMCON register ([Register 6-1](#)) controls which blocks are to be erased, which memory type is to be programmed and when the programming cycle starts.

NVMKEY is a write-only register that is used for write protection. To start a programming or erase sequence, the user must consecutively write 55h and AAh to the NVMKEY register. Refer to [Section 6.5 “Programming Operations”](#) for further details.

PIC24FJ128GC010 FAMILY

6.5 Programming Operations

A complete programming sequence is necessary for programming or erasing the internal Flash in RTSP mode. During a programming or erase operation, the processor stalls (Waits) until the operation is finished. Setting the WR bit (NVMCON<15>) starts the operation and the WR bit is automatically cleared when the operation is finished.

6.5.1 PROGRAMMING ALGORITHM FOR FLASH PROGRAM MEMORY

The user can program one row of Flash program memory at a time. To do this, it is necessary to erase the 8-row erase block containing the desired row. The general process is:

1. Read eight rows of program memory (512 instructions) and store in data RAM.
2. Update the program data in RAM with the desired new data.
3. Erase the block (see [Example 6-1](#)):
 - a) Set the NVMOPx bits (NVMCON<3:0>) to '0010' to configure for block erase. Set the ERASE (NVMCON<6>) and WREN (NVMCON<14>) bits.
 - b) Write the starting address of the block to be erased into the TBLPAG and W registers.
 - c) Write 55h to NVMKEY.
 - d) Write AAh to NVMKEY.
 - e) Set the WR bit (NVMCON<15>). The erase cycle begins and the CPU stalls for the duration of the erase cycle. When the erase is done, the WR bit is cleared automatically.

4. Write the first 64 instructions from data RAM into the program memory buffers (see [Example 6-3](#)).
5. Write the program block to Flash memory:
 - a) Set the NVMOPx bits to '0001' to configure for row programming. Clear the ERASE bit and set the WREN bit.
 - b) Write 55h to NVMKEY.
 - c) Write AAh to NVMKEY.
 - d) Set the WR bit. The programming cycle begins and the CPU stalls for the duration of the write cycle. When the write to Flash memory is done, the WR bit is cleared automatically.
6. Repeat Steps 4 and 5, using the next available 64 instructions from the block in data RAM by incrementing the value in TBLPAG, until all 512 instructions are written back to Flash memory.

For protection against accidental operations, the write initiate sequence for NVMKEY must be used to allow any erase or program operation to proceed. After the programming command has been executed, the user must wait for the programming time until programming is complete. The two instructions following the start of the programming sequence should be NOPs, as shown in [Example 6-4](#).

EXAMPLE 6-1: ERASING A PROGRAM MEMORY BLOCK (ASSEMBLY LANGUAGE CODE)

```
; Set up NVMCON for block erase operation
MOV    #0x4042, W0                ;
MOV    W0, NVMCON                 ; Initialize NVMCON
; Init pointer to row to be ERASED
MOV    #tblpage(PROG_ADDR), W0    ;
MOV    W0, TBLPAG                 ; Initialize Program Memory (PM) Page Boundary SFR
MOV    #tbloffset(PROG_ADDR), W0  ; Initialize in-page EA<15:0> pointer
TBLWTL W0, [W0]                   ; Set base address of erase block
DISI   #5                          ; Block all interrupts with priority <7
                                           ; for next 5 instructions

MOV.B  #0x55, W0                   ; Write the 0x55 key
MOV    W0, NVMKEY                 ;
MOV.B  #0xAA, W1                   ;
MOV    W1, NVMKEY                 ; Write the 0xAA key
BSET   NVMCON, #WR                 ; Start the erase sequence
NOP                                         ; Insert two NOPs after the erase
NOP                                         ; command is asserted
```

PIC24FJ128GC010 FAMILY

EXAMPLE 6-2: ERASING A PROGRAM MEMORY BLOCK ('C' LANGUAGE CODE)

```
// C example using MPLAB C30
unsigned long progAddr = 0xXXXXXX;      // Address of row to write
unsigned int offset;
//Set up pointer to the first memory location to be written
TBLPAG = progAddr>>16;                 // Initialize PM Page Boundary SFR
offset = progAddr & 0xFFFF;           // Initialize lower word of address
__builtin_tblwtl(offset, 0x0000);     // Set base address of erase block
                                        // with dummy latch write
NVMCON = 0x4042;                       // Initialize NVMCON
asm("DISI #5");                         // Block all interrupts with priority <7
                                        // for next 5 instructions
__builtin_write_NVM();                 // check function to perform unlock
                                        // sequence and set WR
```

EXAMPLE 6-3: LOADING THE WRITE BUFFERS

```
; Set up NVMCON for row programming operations
MOV    #0x4001, W0                      ;

```

PIC24FJ128GC010 FAMILY

6.5.2 PROGRAMMING A SINGLE WORD OF FLASH PROGRAM MEMORY

If a Flash location has been erased, it can be programmed using table write instructions to write an instruction word (24-bit) into the write latch. The TBLPAG register is loaded with the 8 Most Significant Bytes (MSBs) of the Flash address. The TBLWTL and TBLWTH instructions write the desired data into the

write latches and specify the lower 16 bits of the program memory address to write to. To configure the NVMCON register for a word write, set the NVMOPx bits (NVMCON<3:0>) to '0011'. The write is performed by executing the unlock sequence and setting the WR bit (see [Example 6-5](#)). An equivalent procedure in 'C' compiler, using the MPLAB® C30 compiler and built-in hardware functions, is shown in [Example 6-6](#).

EXAMPLE 6-5: PROGRAMMING A SINGLE WORD OF FLASH PROGRAM MEMORY

```
; Setup a pointer to data Program Memory
MOV   #tblpage(PROG_ADDR), W0   ;
MOV   W0, TBLPAG                ;Initialize PM Page Boundary SFR
MOV   #tbloffset(PROG_ADDR), W0 ;Initialize a register with program memory address

MOV   #LOW_WORD_N, W2           ;
MOV   #HIGH_BYTE_N, W3         ;
TBLWTL W2, [W0]                 ; Write PM low word into program latch
TBLWTH W3, [W0++]              ; Write PM high byte into program latch

; Setup NVMCON for programming one word to data Program Memory
MOV   #0x4003, W0               ;
MOV   W0, NVMCON                ; Set NVMOP bits to 0011

DISI   #5                       ; Disable interrupts while the KEY sequence is written
MOV.B  #0x55, W0                 ; Write the key sequence
MOV   W0, NVMKEY
MOV.B  #0xAA, W0
MOV   W0, NVMKEY
BSET   NVMCON, #WR              ; Start the write cycle
NOP                                         ; Required delays
NOP
```

EXAMPLE 6-6: PROGRAMMING A SINGLE WORD OF FLASH PROGRAM MEMORY ('C' LANGUAGE CODE)

```
// C example using MPLAB C30
unsigned int offset;
unsigned long progAddr = 0xFFFFFFFF; // Address of word to program
unsigned int progDataL = 0xFFFF; // Data to program lower word
unsigned char progDataH = 0xFF; // Data to program upper byte

//Set up NVMCON for word programming
NVMCON = 0x4003; // Initialize NVMCON

//Set up pointer to the first memory location to be written
TBLPAG = progAddr>>16; // Initialize PM Page Boundary SFR
offset = progAddr & 0xFFFF; // Initialize lower word of address

//Perform TBLWT instructions to write latches
__builtin_tblwtl(offset, progDataL); // Write to address low word
__builtin_tblwth(offset, progDataH); // Write to upper byte
asm("DISI #5"); // Block interrupts with priority <7
// for next 5 instructions
__builtin_write_NVM(); // C30 function to perform unlock
// sequence and set WR
```

PIC24FJ128GC010 FAMILY

7.0 RESETS

Note: This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “PIC24F Family Reference Manual”, “Reset” (DS39712). The information in this data sheet supersedes the information in the FRM.

The Reset module combines all Reset sources and controls the device Master Reset Signal, $\overline{\text{SYSRST}}$. The following is a list of device Reset sources:

- POR: Power-on Reset
- MCLR: Pin Reset
- SWR: RESET Instruction
- WDT: Watchdog Timer Reset
- BOR: Brown-out Reset
- CM: Configuration Mismatch Reset
- TRAPR: Trap Conflict Reset
- IOPUWR: Illegal Opcode Reset
- UWR: Uninitialized W Register Reset

A simplified block diagram of the Reset module is shown in [Figure 7-1](#).

Any active source of Reset will make the $\overline{\text{SYSRST}}$ signal active. Many registers associated with the CPU and peripherals are forced to a known Reset state. Most registers are unaffected by a Reset; their status is unknown on POR and unchanged by all other Resets.

Note: Refer to the specific peripheral or CPU section of this manual for register Reset states.

All types of device Reset will set a corresponding status bit in the RCON register to indicate the type of Reset (see [Register 7-1](#)). In addition, Reset events occurring while an extreme power-saving feature is in use (such as VBAT) will set one or more status bits in the RCON2 register ([Register 7-2](#)). A POR will clear all bits, except for the BOR and POR (RCON<1:0>) bits, which are set. The user may set or clear any bit at any time during code execution. The RCON bits only serve as status bits. Setting a particular Reset status bit in software will not cause a device Reset to occur.

The RCON register also has other bits associated with the Watchdog Timer and device power-saving states. The function of these bits is discussed in other sections of this data sheet.

Note: The status bits in the RCON registers should be cleared after they are read so that the next RCON register values after a device Reset will be meaningful.

| EXTR ⁽¹⁾ | SWR ⁽¹⁾ | SWDTEN ⁽⁴⁾ | WDTO ⁽¹⁾ | SLEEP ⁽¹⁾ | IDLE ⁽¹⁾ | BOR ⁽¹⁾ | POR ⁽¹⁾ |
| bit 7 | | | | | | | bit 0 |

Legend:

R = Readable bit

W = Writable bit

U = Unimplemented bit, read as '0'

-n = Value at POR

'1' = Bit is set

'0' = Bit is cleared

x = Bit is unknown

- bit 15 **TRAPR:** Trap Reset Flag bit⁽¹⁾
 1 = A Trap Conflict Reset has occurred
 0 = A Trap Conflict Reset has not occurred
- bit 14 **IOPUWR:** Illegal Opcode or Uninitialized W Access Reset Flag bit⁽¹⁾
 1 = An illegal opcode detection, an illegal address mode or Uninitialized W register is used as an Address Pointer and caused a Reset
 0 = An illegal opcode or Uninitialized W Reset has not occurred
- bit 13 **Unimplemented:** Read as '0'
- bit 12 **RETEN:** Retention Mode Enable bit⁽²⁾
 1 = Retention mode is enabled while device is in Sleep modes (1.2V regulator supplies to the core)
 0 = Retention mode is disabled; normal voltage levels are present
- bit 11 **Unimplemented:** Read as '0'
- bit 10 **DPSLP:** Deep Sleep Flag bit⁽¹⁾
 1 = Device has been in Deep Sleep mode
 0 = Device has not been in Deep Sleep mode
- bit 9 **CM:** Configuration Word Mismatch Reset Flag bit⁽¹⁾
 1 = A Configuration Word Mismatch Reset has occurred
 0 = A Configuration Word Mismatch Reset has not occurred
- bit 8 **PMSLP:** Program Memory Power During Sleep bit⁽³⁾
 1 = Program memory bias voltage remains powered during Sleep
 0 = Program memory bias voltage is powered down during Sleep
- bit 7 **EXTR:** External Reset ($\overline{\text{MCLR}}$) Pin bit⁽¹⁾
 1 = A Master Clear (pin) Reset has occurred
 0 = A Master Clear (pin) Reset has not occurred
- bit 6 **SWR:** Software Reset (Instruction) Flag bit⁽¹⁾
 1 = A RESET instruction has been executed
 0 = A RESET instruction has not been executed

Note 1: All of the Reset status bits may be set or cleared in software. Setting one of these bits in software does not cause a device Reset.

2: If the $\overline{\text{LPCFG}}$ Configuration bit is '1' (unprogrammed), the retention regulator is disabled and the RETEN bit has no effect.

3: Re-enabling the regulator after it enters Standby mode will add a delay, T_{VREG} , when waking up from Sleep. Applications that do not use the voltage regulator should set this bit to prevent this delay from occurring.

4: If the FWDTEN Configuration bit is '1' (unprogrammed), the WDT is always enabled, regardless of the SWDTEN bit setting.

| POR (RCON<0>) | POR | — |

Note: All Reset flag bits may be set or cleared by the user software.

PIC24FJ128GC010 FAMILY

7.1 Special Function Register Reset States

Most of the Special Function Registers (SFRs) associated with the PIC24F CPU and peripherals are reset to a particular value at a device Reset. The SFRs are grouped by their peripheral or CPU function and their Reset values are specified in each section of this manual.

The Reset value for each SFR does not depend on the type of Reset, with the exception of four registers. The Reset value for the Reset Control register, RCON, will depend on the type of device Reset. The Reset value for the Oscillator Control register, OSCCON, will depend on the type of Reset and the programmed values of the FNOSC_x bits in Flash Configuration Word 2 (CW2) (see [Table 7-2](#)). The RCFGAL and NVMCON registers are only affected by a POR.

7.2 Device Reset Times

The Reset times for various types of device Reset are summarized in [Table 7-3](#). Note that the System Reset signal, $\overline{\text{SYSRST}}$, is released after the POR delay time expires.

The time at which the device actually begins to execute code will also depend on the system oscillator delays, which include the Oscillator Start-up Timer (OST) and the PLL lock time. The OST and PLL lock times occur in parallel with the applicable $\overline{\text{SYSRST}}$ delay times.

The Fail-Safe Clock Monitor (FSCM) delay determines the time at which the FSCM begins to monitor the system clock source after the $\overline{\text{SYSRST}}$ signal is released.

7.3 Brown-out Reset (BOR)

PIC24FJ128GC010 family devices implement a BOR circuit that provides the user with several configuration and power-saving options. The BOR is controlled by the BOREN (CW3<12>) Configuration bit.

When BOR is enabled, any drop of V_{DD} below the BOR threshold results in a device BOR. Threshold levels are described in [Section 37.1 “DC Characteristics”](#) (Parameter DC17B).

7.4 Clock Source Selection at Reset

If clock switching is enabled, the system clock source at device Reset is chosen, as shown in [Table 7-2](#). If clock switching is disabled, the system clock source is always selected according to the Oscillator Configuration bits. Refer to the “*PIC24F Family Reference Manual*”, [Section 6.0 “Oscillator”](#) (DS39700) for further details.

TABLE 7-2: OSCILLATOR SELECTION vs. TYPE OF RESET (CLOCK SWITCHING ENABLED)

| Reset Type | Clock Source Determinant |
|--------------------------|--|
| POR | FNOSC<2:0> Configuration bits (CW2<10:8>) |
| BOR | |
| $\overline{\text{MCLR}}$ | COSC<2:0> Control bits (OSCCON<14:12>) |
| WDTO | |
| SWR | |

| | FRCPLL | $\text{TSTARTUP} + \text{TRST}$ | $\text{TFRC} + \text{TLOCK}$ | 2, 3, 5, 6 |
| | LPRC | $\text{TSTARTUP} + \text{TRST}$ | TLPRC | 2, 3, 6 |
| MCLR | Any Clock | TRST | — | 3 |
| WDT | Any Clock | TRST | — | 3 |
| Software | Any clock | TRST | — | 3 |
| Illegal Opcode | Any Clock | TRST | — | 3 |
| Uninitialized W | Any Clock | TRST | — | 3 |
| Trap Conflict | Any Clock | TRST | — | 3 |

Note 1: TPOR = Power-on Reset delay (10 μs nominal).

2: TSTARTUP = TVREG.

3: TRST = Internal State Reset time (2 μs nominal).

4: TOST = Oscillator Start-up Timer (OST). A 10-bit counter counts 1024 oscillator periods before releasing the oscillator clock to the system.

5: TLOCK = PLL lock time.

6: TFRC and TLPRC = RC oscillator start-up times.

7: If Two-Speed Start-up is enabled, regardless of the primary oscillator selected, the device starts with FRC, so the system clock delay is just TFRC and in such cases, FRC start-up time is valid. It switches to the primary oscillator after its respective clock delay.

7.4.1 POR AND LONG OSCILLATOR START-UP TIMES

The oscillator start-up circuitry and its associated delay timers are not linked to the device Reset delays that occur at power-up. Some crystal circuits (especially low-frequency crystals) will have a relatively long start-up time. Therefore, one or more of the following conditions is possible after $\overline{\text{SYSRST}}$ is released:

- The oscillator circuit has not begun to oscillate.
- The Oscillator Start-up Timer has not expired (if a crystal oscillator is used).
- The PLL has not achieved a lock (if PLL is used).

The device will not begin to execute code until a valid clock source has been released to the system. Therefore, the oscillator and PLL start-up delays must be considered when the Reset delay time must be known.

7.4.2 FAIL-SAFE CLOCK MONITOR (FSCM) AND DEVICE RESETS

If the FSCM is enabled, it will begin to monitor the system clock source when $\overline{\text{SYSRST}}$ is released. If a valid clock source is not available at this time, the device will automatically switch to the FRC oscillator and the user can switch to the desired crystal oscillator in the Trap Service Routine (TSR).

PIC24FJ128GC010 FAMILY

8.0 INTERRUPT CONTROLLER

Note: This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “PIC24F Family Reference Manual”, “Interrupts” (DS39707). The information in this data sheet supersedes the information in the FRM.

The PIC24F interrupt controller reduces the numerous peripheral interrupt request signals to a single interrupt request signal to the PIC24F CPU. It has the following features:

- Up to 8 processor exceptions and software traps
- Seven user-selectable priority levels
- Interrupt Vector Table (IVT) with up to 118 vectors
- Unique vector for each interrupt or exception source
- Fixed priority within a specified user priority level
- Alternate Interrupt Vector Table (AIVT) for debug support
- Fixed interrupt entry and return latencies

8.1 Interrupt Vector Table

The Interrupt Vector Table (IVT) is shown in [Figure 8-1](#). The IVT resides in program memory, starting at location, 000004h. The IVT contains 126 vectors, consisting of 8 non-maskable trap vectors, plus up to 118 source interrupts. In general, each interrupt source has its own vector. Each interrupt vector contains a 24-bit wide address. The value programmed into each interrupt vector location is the starting address of the associated Interrupt Service Routine (ISR).

Interrupt vectors are prioritized in terms of their natural priority; this is linked to their position in the vector table. All other things being equal, lower addresses have a higher natural priority. For example, the interrupt associated with Vector 0 will take priority over interrupts at any other vector address.

PIC24FJ128GC010 family devices implement non-maskable traps and unique interrupts. These are summarized in [Table 8-1](#) and [Table 8-2](#).

8.1.1 ALTERNATE INTERRUPT VECTOR TABLE

The Alternate Interrupt Vector Table (AIVT) is located after the IVT, as shown in [Figure 8-1](#). The ALTIVT (INTCON2<15>) control bit provides access to the AIVT. If the ALTIVT bit is set, all interrupt and exception processes will use the alternate vectors instead of the default vectors. The alternate vectors are organized in the same manner as the default vectors.

The AIVT supports emulation and debugging efforts by providing a means to switch between an application, and a support environment, without requiring the interrupt vectors to be reprogrammed. This feature also enables switching between applications for evaluation of different software algorithms at run time. If the AIVT is not needed, the AIVT should be programmed with the same addresses used in the IVT.

8.2 Reset Sequence

A device Reset is not a true exception because the interrupt controller is not involved in the Reset process. The PIC24F devices clear their registers in response to a Reset, which forces the PC to zero. The microcontroller then begins program execution at location, 000000h. The user programs a GOTO instruction at the Reset address, which redirects program execution to the appropriate start-up routine.

Note: Any unimplemented or unused vector locations in the IVT and AIVT should be programmed with the address of a default interrupt handler routine that contains a RESET instruction.

8.3 Interrupt Control and Status Registers

The PIC24FJ128GC010 family of devices implements a total of 44 registers for the interrupt controller:

- INTCON1
- INTCON2
- IFS0 through IFS7
- IEC0 through IEC7
- IPC0 through IPC13, ICP15, ICP16, ICP18 through ICP23, ICP25, ICP26 and ICP29
- INTTREG

Global interrupt control functions are controlled from INTCON1 and INTCON2. INTCON1 contains the Interrupt Nesting Disable (NSTDIS) bit, as well as the control and status flags for the processor trap sources. The INTCON2 register controls the external interrupt request signal behavior and the use of the Alternate Interrupt Vector Table (AIVT).

The IFSx registers maintain all of the interrupt request flags. Each source of interrupt has a status bit, which is set by the respective peripherals or an external signal and is cleared via software.

The IECx registers maintain all of the interrupt enable bits. These control bits are used to individually enable interrupts from the peripherals or external signals.

The IPCx registers are used to set the Interrupt Priority Level (IPL) for each source of interrupt. Each user interrupt source can be assigned to one of eight priority levels.

The INTTREG register contains the associated interrupt vector number and the new CPU Interrupt Priority Level, which are latched into the Vector Number (VECNUM<6:0>) and the Interrupt Level (ILR<3:0>) bit fields in the INTTREG register. The new Interrupt Priority Level is the priority of the pending interrupt.

The interrupt sources are assigned to the IFSx, IECx and IPCx registers in the order of their vector numbers, as shown in [Table 8-2](#). For example, the INT0 (External Interrupt 0) is shown as having a vector number and a natural order priority of 0. Thus, the INT0IF status bit is found in IFS0<0>, the INT0IE enable bit in IEC0<0> and the INT0IP<2:0> priority bits in the first position of IPC0 (IPC0<2:0>).

Although they are not specifically part of the interrupt control hardware, two of the CPU Control registers contain bits that control interrupt functionality. The ALU STATUS Register (SR) contains the IPL<2:0> bits (SR<7:5>). These indicate the current CPU Interrupt Priority Level. The user can change the current CPU priority level by writing to the IPLx bits.

The CORCON register contains the IPL3 bit, which together with the IPL<2:0> bits, indicates the current CPU priority level. IPL3 is a read-only bit so that trap events cannot be masked by the user software.

The interrupt controller has the Interrupt Controller Test register, INTTREG, which displays the status of the interrupt controller. When an interrupt request occurs, its associated vector number and the new Interrupt Priority Level are latched into INTTREG. This information can be used to determine a specific interrupt source if a generic ISR is used for multiple vectors (such as when ISR remapping is used in bootloader applications) or to check if another interrupt is pending while in an ISR.

All Interrupt registers are described in [Register 8-1](#) through [Register 8-46](#) in the succeeding pages.

- bit 7 **Unimplemented:** Read as '0'
- bit 6-0 **VECNUM<6:0>:** Vector Number of Pending Interrupt or Last Acknowledged Interrupt bits
When VHOLD = 1:
 Indicates the vector number (from 0 to 118) of the last interrupt to occur.
When VHOLD = 0:
 Indicates the vector number (from 0 to 118) of the interrupt request currently being handled.

PIC24FJ128GC010 FAMILY

8.4 Interrupt Setup Procedures

8.4.1 INITIALIZATION

To configure an interrupt source:

1. Set the NSTDIS (INTCON1<15>) control bit if nested interrupts are not desired.
2. Select the user-assigned priority level for the interrupt source by writing the control bits in the appropriate IPCx register. The priority level will depend on the specific application and type of interrupt source. If multiple priority levels are not desired, the IPCx register control bits, for all enabled interrupt sources, may be programmed to the same non-zero value.

Note: At a device Reset, the IPCx registers are initialized, such that all user interrupt sources are assigned to Priority Level 4.

3. Clear the interrupt flag status bit associated with the peripheral in the associated IFSx register.
4. Enable the interrupt source by setting the interrupt enable control bit associated with the source in the appropriate IECx register.

8.4.2 INTERRUPT SERVICE ROUTINE (ISR)

The method that is used to declare an Interrupt Service Routine (ISR) and initialize the IVT with the correct vector address will depend on the programming language (i.e., 'C' or assembler), and the language development toolsuite that is used to develop the application. In general, the user must clear the interrupt flag in the appropriate IFSx register for the source of the interrupt that the ISR handles; otherwise, the ISR will be re-entered immediately after exiting the routine. If the ISR is coded in assembly language, it must be terminated using a `RETFIE` instruction to unstack the saved PC value, SRL value and old CPU priority level.

8.4.3 TRAP SERVICE ROUTINE (TSR)

A Trap Service Routine (TSR) is coded like an ISR, except that the appropriate trap status flag in the INTCON1 register must be cleared to avoid re-entry into the TSR.

8.4.4 INTERRUPT DISABLE

All user interrupts can be disabled using the following procedure:

1. Push the current SR value onto the software stack using the `PUSH` instruction.
2. Force the CPU to Priority Level 7 by inclusive ORing the value, 0Eh, with SRL.

To enable user interrupts, the `POP` instruction may be used to restore the previous SR value.

Note that only user interrupts with a priority level of 7 or less can be disabled. Trap sources (Levels 8-15) cannot be disabled.

The `DISI` instruction provides a convenient way to disable interrupts of Priority Levels 1-6 for a fixed period of time. Level 7 interrupt sources are not disabled by the `DISI` instruction.

PIC24FJ128GC010 FAMILY

9.0 OSCILLATOR CONFIGURATION

Note: This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the "PIC24F Family Reference Manual", "Oscillator" (DS39700).

The oscillator system for PIC24FJ128GC010 family devices has the following features:

- A total of four external and internal oscillator options as clock sources, providing 11 different clock modes

- An on-chip USB PLL block to provide a stable 48 MHz clock for the USB module, as well as a range of frequency options for the system clock
- Software-controllable switching between various clock sources
- Software-controllable postscaler for selective clocking of CPU for system power savings
- A Fail-Safe Clock Monitor (FSCM) that detects clock failure and permits safe application recovery or shutdown
- A separate and independently configurable system clock output for synchronizing external hardware

A simplified diagram of the oscillator system is shown in Figure 9-1.

FIGURE 9-1: PIC24FJ128GC010 FAMILY CLOCK DIAGRAM

PIC24FJ128GC010 FAMILY

9.1 CPU Clocking Scheme

The system clock source can be provided by one of four sources:

- Primary Oscillator (POSC) on the OSCI and OSCO pins
- Secondary Oscillator (SOSC) on the SOSCI and SOSCO pins
- Fast Internal RC (FRC) Oscillator
- Low-Power Internal RC (LPRC) Oscillator

The Primary Oscillator and FRC sources have the option of using the internal USB PLL block, which generates both the USB module clock and a separate system clock from the 96 MHz PLL. Refer to [Section 9.6 “Oscillator Modes and USB Operation”](#) for additional information.

The internal FRC provides an 8 MHz clock source. It can optionally be reduced by the programmable clock divider to provide a range of system clock frequencies.

The selected clock source generates the processor and peripheral clock sources. The processor clock source is divided by two to produce the internal instruction cycle clock, Fcy. In this document, the instruction cycle clock is also denoted by Fosc/2. The internal instruction cycle clock, Fosc/2, can be provided on the OSCO I/O pin for some operating modes of the Primary Oscillator.

9.2 Initial Configuration on POR

The oscillator source (and operating mode) that is used at a device Power-on Reset event is selected using Configuration bit settings. The Oscillator Configuration bit settings are located in the Configuration registers in the program memory (refer to [Section 34.1 “Configuration Bits”](#) for further details). The Primary Oscillator Configuration bits, POSCMD<1:0> (Configuration Word 2<1:0>), and the Initial Oscillator Select Configuration bits, FNOSC<2:0> (Configuration Word 2<10:8>), select the oscillator source that is used at a Power-on Reset. The FRC Primary Oscillator with Postscaler (FRCDIV) is the default (unprogrammed) selection. The Secondary Oscillator (SOSC), or one of the internal oscillators, may be chosen by programming these bit locations.

The Configuration bits allow users to choose between the various clock modes, shown in [Table 9-1](#).

9.2.1 CLOCK SWITCHING MODE CONFIGURATION BITS

The FCKSM<1:0> Configuration bits (Configuration Word 2<7:6>) are used to jointly configure device clock switching and the Fail-Safe Clock Monitor (FSCM). Clock switching is enabled only when FCKSM1 is programmed ('0'). The FSCM is enabled only when FCKSM<1:0> are both programmed ('00').

TABLE 9-1: CONFIGURATION BIT VALUES FOR CLOCK SELECTION

| Oscillator Mode | Oscillator Source | POSCMD<1:0> | FNOSC<2:0> | Notes |
|---|-------------------|-------------|------------|---------------------------------------|
| Fast RC Oscillator with Postscaler (FRCDIV) | Internal | 11 | 111 | 1 , 2 |
| (Reserved) | Internal | xx | 110 | 1 |
| Low-Power RC Oscillator (LPRC) | Internal | 11 | 101 | 1 |
| Secondary (Timer1) Oscillator (SOSC) | Secondary | 11 | 100 | 1 |
| Primary Oscillator (XT) with PLL Module (XTPLL) | Primary | 01 | 011 | |
| Primary Oscillator (EC) with PLL Module (ECPLL) | Primary | 00 | 011 | |
| Primary Oscillator (HS) | Primary | 10 | 010 | |
| Primary Oscillator (XT) | Primary | 01 | 010 | |
| Primary Oscillator (EC) | Primary | 00 | 010 | |
| Fast RC Oscillator with PLL Module (FRCPLL) | Internal | 11 | 001 | 1 |
| Fast RC Oscillator (FRC) | Internal | 11 | 000 | 1 |

Note 1: OSCO pin function is determined by the OSCIOFCN Configuration bit.

2: This is the default oscillator mode for an unprogrammed (erased) device.

PIC24FJ128GC010 FAMILY

9.3 Control Registers

The operation of the oscillator is controlled by three Special Function Registers:

- OSCCON
- CLKDIV
- OSCTUN

The OSCCON register (Register 9-1) is the main control register for the oscillator. It controls clock source switching and allows the monitoring of clock sources.

OSCCON is protected by a write lock to prevent inadvertent clock switches. See Section 9.4 “Clock Switching Operation” for more information.

The CLKDIV register (Register 9-2) controls the features associated with Doze mode, as well as the postscaler for the FRC Oscillator.

The OSCTUN register (Register 9-3) allows the user to fine-tune the FRC Oscillator over a range of approximately $\pm 1.5\%$. It also controls the FRC self-tuning features, described in Section 9.5 “FRC Active Clock Tuning”.

| -n = Value at POR | '1' = Bit is set | '0' = Bit is cleared |
| | | x = Bit is unknown |

bit 15 **Unimplemented:** Read as '0'

bit 14-12 **COSC<2:0>:** Current Oscillator Selection bits

- 111 = Fast RC Oscillator with Postscaler (FRCDIV)
- 110 = Reserved
- 101 = Low-Power RC Oscillator (LPRC)
- 100 = Secondary Oscillator (SOSC)
- 011 = Primary Oscillator with PLL module (XTPLL, HSPLL, ECPLL)
- 010 = Primary Oscillator (XT, HS, EC)
- 001 = Fast RC Oscillator with Postscaler and PLL module (FRCPLL)⁽⁴⁾
- 000 = Fast RC Oscillator (FRC)

bit 11 **Unimplemented:** Read as '0'

bit 10-8 **NOSC<2:0>:** New Oscillator Selection bits⁽¹⁾

- 111 = Fast RC Oscillator with Postscaler (FRCDIV)
- 110 = Reserved
- 101 = Low-Power RC Oscillator (LPRC)
- 100 = Secondary Oscillator (SOSC)
- 011 = Primary Oscillator with PLL module (XTPLL, HSPLL, ECPLL)
- 010 = Primary Oscillator (XT, HS, EC)
- 001 = Fast RC Oscillator with Postscaler and PLL module (FRCPLL)⁽⁴⁾
- 000 = Fast RC Oscillator (FRC)

Note 1: Reset values for these bits are determined by the FNOSCx Configuration bits.

2: The state of the IOLOCK bit can only be changed once an unlocking sequence has been executed. In addition, if the IOL1WAY Configuration bit is '1', once the IOLOCK bit is set, it cannot be cleared.

3: This bit also resets to '0' during any valid clock switch or whenever a non-PLL Clock mode is selected.

4: The default divisor of the postscaler is 2, which will generate a 4 MHz clock to the PLL module.

 000000 = Center frequency, oscillator is running at factory calibrated frequency
 1111111 =
 ...
 100001 =
 100000 = Minimum frequency deviation

Note 1: Use of either clock tuning reference source has specific application requirements. See [Section 9.5 “FRC Active Clock Tuning”](#) for details.
Note 2: These bits are read-only when STEN = 1.

9.4 Clock Switching Operation

With few limitations, applications are free to switch between any of the four clock sources (POSC, SOSC, FRC and LPRC) under software control and at any time. To limit the possible side effects that could result from this flexibility, PIC24F devices have a safeguard lock built into the switching process.

Note: The Primary Oscillator mode has three different submodes (XT, HS and EC) which are determined by the POSCMDx Configuration bits. While an application can switch to and from Primary Oscillator mode in software, it cannot switch between the different primary submodes without reprogramming the device.

9.4.1 ENABLING CLOCK SWITCHING

To enable clock switching, the FCKSM1 Configuration bit in CW2 must be programmed to '0'. (Refer to [Section 34.1 "Configuration Bits"](#) for further details.) If the FCKSM1 Configuration bit is unprogrammed ('1'), the clock switching function and Fail-Safe Clock Monitor function are disabled; this is the default setting.

The NOSCx control bits (OSCCON<10:8>) do not control the clock selection when clock switching is disabled. However, the COSCx<2:0> bits (OSCCON<14:12>) will reflect the clock source selected by the FNOSCx Configuration bits.

The OSWEN control bit (OSCCON<0>) has no effect when clock switching is disabled; it is held at '0' at all times.

9.4.2 OSCILLATOR SWITCHING SEQUENCE

At a minimum, performing a clock switch requires this basic sequence:

1. If desired, read the COSCx bits (OSCCON<14:12>) to determine the current oscillator source.
2. Perform the unlock sequence to allow a write to the OSCCON register high byte.
3. Write the appropriate value to the NOSCx bits (OSCCON<10:8>) for the new oscillator source.
4. Perform the unlock sequence to allow a write to the OSCCON register low byte.
5. Set the OSWEN bit to initiate the oscillator switch.

Once the basic sequence is completed, the system clock hardware responds automatically as follows:

1. The clock switching hardware compares the COSCx bits with the new value of the NOSCx bits. If they are the same, then the clock switch is a redundant operation. In this case, the OSWEN bit is cleared automatically and the clock switch is aborted.
2. If a valid clock switch has been initiated, the LOCK (OSCCON<5>) and CF (OSCCON<3>) bits are cleared.
3. The new oscillator is turned on by the hardware if it is not currently running. If a crystal oscillator must be turned on, the hardware will wait until the OST expires. If the new source is using the PLL, then the hardware waits until a PLL lock is detected (LOCK = 1).
4. The hardware waits for 10 clock cycles from the new clock source and then performs the clock switch.
5. The hardware clears the OSWEN bit to indicate a successful clock transition. In addition, the NOSCx bit values are transferred to the COSCx bits.
6. The old clock source is turned off at this time, with the exception of LPRC (if WDT or FSCM is enabled) or SOSC (if SOSSEN remains set).

Note 1: The processor will continue to execute code throughout the clock switching sequence. Timing-sensitive code should not be executed during this time.

- 2: Direct clock switches between any Primary Oscillator mode with PLL and FRCPLL mode are not permitted. This applies to clock switches in either direction. In these instances, the application must switch to FRC mode as a transitional clock source between the two PLL modes.

PIC24FJ128GC010 FAMILY

A recommended code sequence for a clock switch includes the following:

1. Disable interrupts during the OSCCON register unlock and write sequence.
2. Execute the unlock sequence for the OSCCON high byte by writing 78h and 9Ah to OSCCON<15:8> in two back-to-back instructions.
3. Write the new oscillator source to the NOSCx bits in the instruction immediately following the unlock sequence.
4. Execute the unlock sequence for the OSCCON low byte by writing 46h and 57h to OSCCON<7:0> in two back-to-back instructions.
5. Set the OSWEN bit in the instruction immediately following the unlock sequence.
6. Continue to execute code that is not clock-sensitive (optional).
7. Invoke an appropriate amount of software delay (cycle counting) to allow the selected oscillator and/or PLL to start and stabilize.
8. Check to see if OSWEN is '0'. If it is, the switch was successful. If OSWEN is still set, then check the LOCK bit to determine the cause of the failure.

The core sequence for unlocking the OSCCON register and initiating a clock switch is shown in [Example 9-1](#).

EXAMPLE 9-1: BASIC CODE SEQUENCE FOR CLOCK SWITCHING

```
;Place the new oscillator selection in W0
;OSCCONH (high byte) Unlock Sequence
MOV     #OSCCONH, w1
MOV     #0x78, w2
MOV     #0x9A, w3

MOV     #0x57, w3
MOV.b   w2, [w1]
MOV.b   w3, [w1]
;Start oscillator switch operation
BSET    OSCCON,#0
```

9.5 FRC Active Clock Tuning

PIC24FJ128GC010 family devices include an automatic mechanism to calibrate the FRC during run time. This system uses active clock tuning from a source of known accuracy to maintain the FRC within a very narrow margin of its nominal 8 MHz frequency. This allows for a frequency accuracy that is well within the requirements of the “*USB 2.0 Specification*”, regarding full-speed USB devices.

Note: The self-tune feature maintains sufficient accuracy for operation in USB Device mode. For applications that function as a USB host, a high-accuracy clock source ($\pm 0.05\%$) is still required.

The self-tune system is controlled by the bits in the upper half of the OSCTUN register. Setting the STEN bit (OSCTUN<15>) enables the self-tuning feature, allowing the hardware to calibrate to a source selected by the STSRC bit (OSCTUN<12>). When STSRC = 1, the system uses the Start-of-Frame (SOF) packets from an external USB host for its source. When STSRC = 0, the system uses the crystal-controlled SOSC for its calibration source. Regardless of the source, the system uses the TUN<5:0> bits (OSCTUN<5:0>) to change the FRC Oscillator's frequency. Frequency monitoring and adjustment is dynamic, occurring continuously during run time. While the system is active, the TUNx bits cannot be written to by software.

Note: To use the USB as a reference clock tuning source (STSRC = 1), the microcontroller must be configured for USB device operation and connected to a non-suspended USB host or hub port.

If the SOSC is to be used as the reference clock tuning source (STSRC = 0), the SOSC must also be enabled for clock tuning to occur.

The self-tune system can generate a hardware interrupt, FSTIF. The interrupt can result from a drift of the FRC from the reference by greater than 0.2% in either direction, or whenever the frequency deviation is beyond the ability of the TUNx bits to correct (i.e., greater than 1.5%). The STLOCK and STOR status bits (OSCTUN<11,9>) are used to indicate these conditions.

The STLPOL and STORPOL bits (OSCTUN<10,8>) configure the FSTIF interrupt to occur in the presence or the absence of the conditions. It is the user's responsibility to monitor both the STLOCK and STOR bits to determine the exact cause of the interrupt.

Note: The STLPOL and STORPOL bits should be ignored when the self-tune system is disabled (STEN = 0).

PIC24FJ128GC010 FAMILY

9.6 Oscillator Modes and USB Operation

Because of the timing requirements imposed by USB, an internal clock of 48 MHz is required at all times while the USB module is enabled and not in a suspended operating state. Since this is well beyond the maximum CPU clock speed, a method is provided to internally generate both the USB and system clocks from a single oscillator source. PIC24FJ128GC010 family devices use the same clock structure as most other PIC24FJ devices, but include a two-branch PLL system to generate the two clock signals.

The USB PLL block is shown in Figure 9-2. In this system, the input from the Primary Oscillator is divided down by a PLL prescaler to generate a 4 MHz output. This is used to drive an on-chip, 96 MHz PLL frequency multiplier to drive the two clock branches. One branch uses a fixed, divide-by-2 frequency divider to generate the 48 MHz USB clock. The other branch uses a fixed, divide-by-3 frequency divider and configurable PLL prescaler/divider to generate a range of system clock frequencies. The CPDIV<1:0> bits select the system clock speed; available clock options are listed in Table 9-2.

The USB PLL prescaler does not automatically sense the incoming oscillator frequency. The user must manually configure the PLL divider to generate the required 4 MHz output, using the PLLDIV<3:0> Configuration bits. This limits the choices for Primary Oscillator frequency to a total of 8 possibilities, shown in Table 9-3.

TABLE 9-2: SYSTEM CLOCK OPTIONS DURING USB OPERATION

| MCU Clock Division (CPDIV<1:0>) | Microcontroller Clock Frequency |
|---------------------------------|---------------------------------|
| None (00) | 32 MHz |
| ÷2 (01) | 16 MHz |
| ÷4 (10) ⁽¹⁾ | 8 MHz |
| ÷8 (11) ⁽¹⁾ | 4 MHz |

Note 1: This is not compatible with USB operation. The USB module must be disabled to use this system clock option.

TABLE 9-3: VALID PRIMARY OSCILLATOR CONFIGURATIONS FOR USB OPERATIONS

| Input Oscillator Frequency | Clock Mode | PLL Division (PLLDIV<3:0>) |
|----------------------------|-------------------------------------|----------------------------|
| 48 MHz | ECPLL | ÷12 (0111) |
| 32 MHz | HSPLL, ECPLL | ÷8 (0110) |
| 24 MHz | HSPLL, ECPLL | ÷6 (0101) |
| 20 MHz | HSPLL, ECPLL | ÷5 (0100) |
| 16 MHz | HSPLL, ECPLL | ÷4 (0011) |
| 12 MHz | HSPLL, ECPLL | ÷3 (0010) |
| 8 MHz | ECPLL, XTPLL, FRCPLL ⁽¹⁾ | ÷2 (0001) |
| 4 MHz | ECPLL, XTPLL, FRCPLL ⁽¹⁾ | ÷1 (0000) |

Note 1: This requires the use of the FRC self-tune feature to maintain required clock accuracy.

FIGURE 9-2: PLL BLOCK

PIC24FJ128GC010 FAMILY

9.6.1 CONSIDERATIONS FOR USB OPERATION

When using the USB On-The-Go module in PIC24FJ128GC010 family devices, users must always observe these rules in configuring the system clock:

- The oscillator modes listed in [Table 9-3](#) are the only oscillator configurations that permit USB operation. There is no provision to provide a separate external clock source to the USB module.
- For USB operation, the selected clock source (EC, HS or XT) must meet the USB clock tolerance requirements.
- When the FRCPLL Oscillator mode is used for USB applications, the FRC self-tune system should be used as well. While the FRC is accurate, the only two ways to ensure the level of accuracy required by the “*USB 2.0 Specification*”, throughout the application’s operating range, are either the self-tune system or manually changing the TUN<5:0> bits.
- The user must always ensure that the FRC source is configured to provide a frequency of 4 MHz or 8 MHz (RCDIV<2:0> = 001 or 000) and that the USB PLL prescaler is configured appropriately.
- All other oscillator modes are available; however, USB operation is not possible when these modes are selected. They may still be useful in cases where other power levels of operation are desirable and the USB module is not needed (e.g., the application is Sleeping and waiting for a bus attachment).

9.7 Reference Clock Output

In addition to the CLKO output (Fosc/2) available in certain oscillator modes, the device clock in the PIC24FJ128GC010 family devices can also be configured to provide a reference clock output signal to a port pin. This feature is available in all oscillator configurations and allows the user to select a greater range of clock submultiples to drive external devices in the application.

This reference clock output is controlled by the REFOCON register ([Register 9-4](#)). Setting the ROEN bit (REFOCON<15>) makes the clock signal available on the REFO pin. The RODIV<3:0> bits (REFOCON<11:8>) enable the selection of 16 different clock divider options.

The ROSSLP and ROSEL bits (REFOCON<13:12>) control the availability of the reference output during Sleep mode. The ROSEL bit determines if the oscillator on OSC1 and OSC2, or the current system clock source, is used for the reference clock output. The ROSSLP bit determines if the reference source is available on REFO when the device is in Sleep mode.

To use the reference clock output in Sleep mode, both the ROSSLP and ROSEL bits must be set. The device clock must also be configured for one of the primary modes (EC, HS or XT); otherwise, if the POSCEN bit is not also set, the oscillator on OSC1 and OSC2 will be powered down when the device enters Sleep mode. Clearing the ROSEL bit allows the reference output frequency to change as the system clock changes during any clock switches.

9.8 Secondary Oscillator

9.8.1 BASIC SOSC OPERATION

PIC24FJ128GC010 family devices do not have to set the SOSSEN bit to use the Secondary Oscillator. Any module requiring the SOSC (such as RTCC, Timer1 or DSWDT) will automatically turn on the SOSC when the clock signal is needed. The SOSC, however, has a long start-up time (as long as 1 second). To avoid delays for peripheral start-up, the SOSC can be manually started using the SOSSEN bit.

To use the Secondary Oscillator, the SOSCSEL bit (CW3<8>) must be set to ‘1’. Programming the SOSCSEL bit to ‘0’ configures the SOSC pins for Digital mode, enabling digital I/O functionality on the pins.

9.8.2 CRYSTAL SELECTION

The 32.768 kHz crystal used for the SOSC must have the following specifications in order to properly start up and run at the correct frequency:

- 12.5 pF loading capacitance
- 1.0 pF shunt capacitance
- A typical ESR of 50K; 70K maximum

In addition, the two external crystal loading capacitors should be in the range of 22-27 pF, which will be based on the PC board layout. The capacitors should be C0G, 5% tolerance and rated 25V or greater.

The accuracy and duty cycle of the SOSC can be measured on the REFO pin and is recommended to be in the range of 40-60% and accurate to ±0.65Hz.

Note: Do not enable the LCD segment pin, SEG17, on RD0 when using the 64-pin package if the SOSC is used for time-sensitive applications. Avoid high-frequency traces adjacent to the SOSCO and SOSCI pins as this can cause errors in the SOSC frequency and/or duty cycle.

PIC24FJ128GC010 FAMILY

NOTES:

PIC24FJ128GC010 FAMILY

10.0 POWER-SAVING FEATURES

Note: This data sheet summarizes the features of this group of PIC24FJ devices. It is not intended to be a comprehensive reference source. For more information, refer to the “PIC24F Family Reference Manual”, “Power-Saving Features with Deep Sleep” (DS39727).

The PIC24FJ128GC010 family of devices provides the ability to manage power consumption by selectively managing clocking to the CPU and the peripherals. In general, a lower clock frequency and a reduction in the number of circuits being clocked reduces consumed power.

PIC24FJ128GC010 family devices manage power consumption with five strategies:

- Instruction-Based Power Reduction Modes
- Hardware-Based Power Reduction Features
- Clock Frequency Control
- Software Controlled Doze Mode
- Selective Peripheral Control in Software

Combinations of these methods can be used to selectively tailor an application’s power consumption, while still maintaining critical application features, such as timing-sensitive communications.

10.1 Overview of Power-Saving Modes

In addition to full-power operation, otherwise known as Run mode, the PIC24FJ128GC010 family of devices offers three Instruction-Based Power-Saving modes and one Hardware-Based mode:

- Idle
- Sleep (Sleep and Low-Voltage Sleep)
- Deep Sleep (with and without retention)
- VBAT (with and without RTCC)

All four modes can be activated by powering down different functional areas of the microcontroller, allowing progressive reductions of operating and Idle power consumption. In addition, three of the modes can be tailored for more power reduction, at a trade-off of some operating features. [Table 10-1](#) lists all of the operating modes, in order of increasing power savings. [Table 10-2](#) summarizes how the microcontroller exits the different modes. Specific information is provided in the following sections.

TABLE 10-1: OPERATING MODES FOR PIC24FJ128GC010 FAMILY DEVICES

| Mode | Entry | Active Systems | | | | |
|----------------------|------------------------------------|----------------|------------------|--------------------|---------------------|-------------------------|
| | | Core | Peripherals | Data RAM Retention | RTCC ⁽¹⁾ | DSGPR0/DSGPR1 Retention |
| Run (default) | N/A | Y | Y | Y | Y | Y |
| Idle | Instruction | N | Y | Y | Y | Y |
| Sleep: | | | | | | |
| Sleep | Instruction | N | S ⁽²⁾ | Y | Y | Y |
| Low-Voltage Sleep | Instruction + RETEN bit | N | S ⁽²⁾ | Y | Y | Y |
| Deep Sleep: | | | | | | |
| Retention Deep Sleep | Instruction + DSEN bit + RETEN bit | N | N | Y | Y | Y |
| Deep Sleep | Instruction + DSEN bit | N | N | N | Y | Y |
| VBAT: | | | | | | |
| with RTCC | Hardware | N | N | N | Y | Y |
| w/o RTCC | Hardware + RTCBAT Config. bit | N | N | N | N | Y |

Note 1: If RTCC is otherwise enabled in firmware.

2: A select peripheral can operate during this mode from LPRC or some external clock.

PIC24FJ128GC010 FAMILY

TABLE 10-2: EXITING POWER SAVING MODES

| Mode | Exit Conditions | | | | | | | Code Execution Resumes | |
|----------------------|-----------------|------|--------|-----|------|------------|------------------|------------------------|----------------------------|
| | Interrupts | | Resets | | | RTCC Alarm | WDT | | VDD Restore ⁽²⁾ |
| | All | INT0 | All | POR | MCLR | | | | |
| Idle | Y | Y | Y | Y | Y | Y | Y | N/A | Next instruction |
| Sleep (all modes) | Y | Y | Y | Y | Y | Y | Y | N/A | |
| Deep Sleep | N | Y | N | Y | Y | Y | Y ⁽¹⁾ | N/A | Reset vector |
| Retention Deep Sleep | N | Y | N | Y | Y | Y | Y ⁽¹⁾ | N/A | Next instruction |
| VBAT | N | N | N | N | N | N | N | Y | Reset vector |

Note 1: Deep Sleep WDT.

2: A POR or POR-like Reset results whenever VDD is removed and restored in any mode except for Retention Deep Sleep.

10.1.1 INSTRUCTION-BASED POWER-SAVING MODES

Three of the power-saving modes are entered through the execution of the `PWRSVAV` instruction. Sleep mode stops clock operation and halts all code execution. Idle mode halts the CPU and code execution, but allows peripheral modules to continue operation. Deep Sleep mode stops clock operation, code execution and all peripherals, except RTCC and DSWDT. It also freezes I/O states and removes power to Flash memory, and may remove power to SRAM.

The assembly syntax of the `PWRSVAV` instruction is shown in [Example 10-1](#). Sleep and Idle modes are entered directly with a single assembler command. Deep Sleep requires an additional sequence to unlock and enable the entry into Deep Sleep, which is described in [Section 10.4.2 “Entering Deep Sleep Mode”](#).

Note: `SLEEP_MODE` and `IDLE_MODE` are constants defined in the assembler include file for the selected device.

Sleep and Idle modes can be exited as a result of an enabled interrupt, WDT time-out or a device Reset. When the device exits these modes, it is said to “wake-up”.

The features enabled with the low-voltage/retention regulator result in some changes to the way that Sleep and Deep Sleep modes behave. See [Section 10.3 “Sleep Mode”](#) and [Section 10.4 “Deep Sleep Mode”](#) for additional information.

10.1.1.1 Interrupts Coincident with Power Save Instructions

Any interrupt that coincides with the execution of a `PWRSVAV` instruction will be held off until entry into Sleep or Idle mode has completed. The device will then wake-up from Sleep or Idle mode.

For Deep Sleep mode, interrupts that coincide with the execution of the `PWRSVAV` instruction may be lost. If the low-voltage/retention regulator is not enabled, the microcontroller resets on leaving Deep Sleep and the interrupt will be lost. If the low-voltage/retention regulator is enabled, the microcontroller will exit Deep Sleep and the interrupt will then be handled.

Interrupts that occur during the Deep Sleep unlock sequence will interrupt the mandatory five-instruction cycle sequence timing and cause a failure to enter Deep Sleep. For this reason, it is recommended to disable all interrupts during the Deep Sleep unlock sequence.

EXAMPLE 10-1: `PWRSVAV` INSTRUCTION SYNTAX

```
// Syntax to enter Sleep mode:
PWRSVAV    #SLEEP_MODE        ; Put the device into SLEEP mode
//
//Syntax to enter Idle mode:
PWRSVAV    #IDLE_MODE         ; Put the device into IDLE mode
//
// Syntax to enter Deep Sleep mode:
// First use the unlock sequence to set the DSEN bit (see Example 10-2)
BSET       DSCON, #DSEN        ; Enable Deep Sleep
BSET       DSCON, #DSEN        ; Enable Deep Sleep(repeat the command)
PWRSVAV    #SLEEP_MODE        ; Put the device into Deep SLEEP mode
```

10.1.2 HARDWARE-BASED POWER-SAVING MODE

The hardware-based VBAT mode does not require any action by the user during code development. Instead, it is a hardware design feature that allows the microcontroller to retain critical data (using the DSGPRx registers) and maintain the RTCC when VDD is removed from the application. This is accomplished by supplying a backup power source to a specific power pin. VBAT mode is described in more detail in [Section 10.5 “Vbat Mode”](#).

10.1.3 LOW-VOLTAGE/RETENTION REGULATOR

PIC24FJ128GC010 family devices incorporate a second on-chip voltage regulator, designed to provide power to select microcontroller features at 1.2V, nominal. This regulator allows features, such as data RAM and the WDT, to be maintained in power-saving modes where they would otherwise be inactive, or maintain them at a lower power than would otherwise be the case.

The low-voltage/retention regulator is only available when Sleep or Deep Sleep modes are invoked. It is controlled by the LPCFG Configuration bit (CW1<10>) and in firmware by the RETEN bit (RCON<12>). LPCFG must be programmed (= 0) and the RETEN bit must be set (= 1) for the regulator to be enabled.

10.2 Idle Mode

Idle mode provides these features:

- The CPU will stop executing instructions.
- The WDT is automatically cleared.
- The system clock source remains active. By default, all peripheral modules continue to operate normally from the system clock source, but can also be selectively disabled (see [Section 10.8 “Selective Peripheral Module Control”](#)).
- If the WDT or FSCM is enabled, the LPRC will also remain active.

The device will wake from Idle mode on any of these events:

- Any interrupt that is individually enabled
- Any device Reset
- A WDT time-out

On wake-up from Idle, the clock is re-applied to the CPU and instruction execution begins immediately, starting with the instruction following the PWRSAV instruction or the first instruction in the Interrupt Service Routine (ISR).

10.3 Sleep Mode

Sleep mode includes these features:

- The system clock source is shut down. If an on-chip oscillator is used, it is turned off.
- The device current consumption will be reduced to a minimum provided that no I/O pin is sourcing current.
- The I/O pin directions and states are frozen.
- The Fail-Safe Clock Monitor does not operate during Sleep mode since the system clock source is disabled.
- The LPRC clock will continue to run in Sleep mode if the WDT or RTCC, with LPRC as the clock source, is enabled.
- The WDT, if enabled, is automatically cleared prior to entering Sleep mode.
- Some device features or peripherals may continue to operate in Sleep mode. This includes items, such as the Input Change Notification (ICN) on the I/O ports, or peripherals that use an external clock input. Any peripheral that requires the system clock source for its operation will be disabled in Sleep mode.

The device will wake-up from Sleep mode on any of these events:

- On any interrupt source that is individually enabled
- On any form of device Reset
- On a WDT time-out

On wake-up from Sleep, the processor will restart with the same clock source that was active when Sleep mode was entered.

10.3.1 LOW-VOLTAGE/RETENTION SLEEP MODE

Low-Voltage/Retention Sleep mode functions as Sleep mode with the same features and wake-up triggers. The difference is that the low-voltage/retention regulator allows Core Digital Logic Voltage (VCORE) to drop to 1.2V nominal. This permits an incremental reduction of power consumption over what would be required if VCORE was maintained at a 1.8V (minimum) level.

Low-Voltage Sleep mode requires a longer wake-up time than Sleep mode, due to the additional time required to bring VCORE back to 1.8V (known as TREG). In addition, the use of the low-voltage/retention regulator limits the amount of current that can be sourced to any active peripherals, such as the RTCC/LCD, etc.

PIC24FJ128GC010 FAMILY

10.4 Deep Sleep Mode

Deep Sleep mode provides the lowest levels of power consumption available from the Instruction-Based modes. PIC24FJ128GC010 family devices have two Deep Sleep modes: Legacy Deep Sleep, found in other PIC24F devices, and Retention Deep Sleep, described below.

Deep Sleep modes have these features:

- The system clock source is shut down. If an on-chip oscillator is used, it is turned off.
- The device current consumption will be reduced to a minimum.
- The I/O pin directions and states are frozen.
- The Fail-Safe Clock Monitor does not operate during Sleep mode since the system clock source is disabled.
- The LPRC clock will continue to run in Deep Sleep mode if the WDT, or RTCC with LPRC as the clock source, is enabled.
- The dedicated Deep Sleep WDT and BOR systems, if enabled, are used.
- The RTCC and its clock source continue to run, if enabled. All other peripherals are disabled.

Entry into Deep Sleep mode is completely under software control. Exit from the Deep Sleep modes can be triggered from any of the following events:

- POR event
- MCLR event
- RTCC alarm (if the RTCC is present)
- External Interrupt 0
- Deep Sleep Watchdog Timer (DSWDT) time-out

10.4.1 RETENTION DEEP SLEEP

Unlike Deep Sleep mode, Retention Deep Sleep mode represents an incremental increase in power consumption. Although it also allows the device to operate at a V_{CORE} of 1.2V, the low-voltage/retention regulator is used in this mode to maintain the contents of the data RAM, which slightly increases current consumption. Maintaining data RAM (including the SFRs) has several effects that make Retention Deep Sleep different from Deep Sleep:

- The wake-up sources are the same as those for Deep Sleep mode.
- Wake-up from Retention Deep Sleep allows the device to resume its previous state and start code execution where it left off, instead of restarting at the Reset vector (as with Deep Sleep).

10.4.2 ENTERING DEEP SLEEP MODE

Deep Sleep mode is entered by setting the DSEN bit in the DSCON register and then executing a Sleep command (`PWRSV #SLEEP_MODE`) within one instruction cycle to minimize the chance that Deep Sleep will be spuriously entered. If the low-voltage/retention regulator is already enabled, prior to setting the DSEN bit, the device will enter Retention Deep Sleep.

If the `PWRSV` command is not given within one instruction cycle, the DSEN bit will be cleared by the hardware and must be set again by the software before entering Deep Sleep mode. The DSEN bit is also automatically cleared when exiting Deep Sleep mode.

Note: To re-enter Deep Sleep after a Deep Sleep wake-up, allow a delay of at least 3 Tcy after clearing the RELEASE bit.

The sequence to enter Deep Sleep mode is:

1. If the application requires the Deep Sleep WDT, enable it and configure its clock source. For more information on Deep Sleep WDT, see [Section 10.4.6 “Deep Sleep WDT”](#).
2. If the application requires Deep Sleep BOR, enable it by programming the DSBORN Configuration bit (CW4<6>).
3. If the application requires wake-up from Deep Sleep on RTCC alarm, enable and configure the RTCC module. For more information on RTCC, see [Section 23.0 “Real-Time Clock and Calendar \(RTCC\)”](#).
4. If needed, save any critical application context data by writing it to the DSGPR0 and DSGPR1 registers (optional).
5. Enable Deep Sleep mode by setting the DSEN bit (DSCON<15>).

Note: A repeat sequence is required to set the DSEN bit. The repeat sequence (repeating the instruction twice) is required to write to any of the Deep Sleep registers (DSCON, DSWAKE, DSGPR0, DSGPR1). This is required to prevent the user from entering Deep Sleep by mistake. Any write to these registers has to be done twice to actually complete the write (see [Example 10-2](#)).

6. Enter Deep Sleep mode by issuing 3 `NOP` commands and then a `PWRSV #0` instruction.

PIC24FJ128GC010 FAMILY

Any time the DSEN bit is set, all bits in the DSWAKE register will be automatically cleared.

EXAMPLE 10-2: THE REPEAT SEQUENCE

Example 1:

```
mov    #8000, w2    ; enable DS
mov    w2, DSCON
mov    w2, DSCON    ; second write required to
                   ; actually write to DSCON
```

Example 2:

```
bset   DSCON, #15
nop
nop
nop
bset   DSCON, #15    ; enable DS (two writes required)
```

10.4.3 EXITING DEEP SLEEP MODES

Deep Sleep modes exit on any one of the following events:

- POR event on VDD supply. If there is no DSBOR circuit to re-arm the VDD supply POR circuit, the external VDD supply must be lowered to the natural arming voltage of the POR circuit.
- DSWDT time-out. When the DSWDT timer times out, the device exits Deep Sleep.
- RTCC alarm (if $\overline{\text{RTCEN}} = 1$).
- Assertion ('0') of the $\overline{\text{MCLR}}$ pin.
- Assertion of the INT0 pin (if the interrupt was enabled before Deep Sleep mode was entered). The polarity configuration is used to determine the assertion level ('0' or '1') of the pin that will cause an exit from Deep Sleep mode. Exiting from Deep Sleep mode requires a change on the INT0 pin while in Deep Sleep mode.

Note: Any interrupt pending when entering Deep Sleep mode is cleared.

Exiting Deep Sleep generally does not retain the state of the device and is equivalent to a Power-on Reset (POR) of the device. Exceptions to this include the RTCC (if present), which remains operational through the wake-up, the DSGPRx registers and DSWDT.

Wake-up events that occur from the time Deep Sleep exits, until the time the POR sequence completes, are not ignored. The DSWAKE register will capture ALL wake-up events, from setting DSEN to clearing RELEASE.

The sequence for exiting Deep Sleep mode is:

1. After a wake-up event, the device exits Deep Sleep and performs a POR. The DSEN bit is cleared automatically. Code execution resumes at the Reset vector.
2. To determine if the device exited Deep Sleep, read the Deep Sleep bit, DPSLP (RCON<10>). This bit will be set if there was an exit from Deep Sleep mode. If the bit is set, clear it.
3. Determine the wake-up source by reading the DSWAKE register.
4. Determine if a DSBOR event occurred during Deep Sleep mode by reading the DSBOR bit (DSCON<1>).
5. If application context data has been saved, read it back from the DSGPR0 and DSGPR1 registers.
6. Clear the RELEASE bit (DSCON<0>).

10.4.4 SAVING CONTEXT DATA WITH THE DSGPRx REGISTERS

As exiting Deep Sleep mode causes a POR, most Special Function Registers reset to their default POR values. In addition, because V_{CORE} power is not supplied in Deep Sleep mode, information in data RAM may be lost when exiting this mode.

Applications which require critical data to be saved, prior to Deep Sleep, may use the Deep Sleep General Purpose registers, DSGPR0 and DSGPR1, or data EEPROM (if available). Unlike other SFRs, the contents of these registers are preserved while the device is in Deep Sleep mode. After exiting Deep Sleep, software can restore the data by reading the registers and clearing the RELEASE bit (DSCON<0>).

10.4.5 I/O PINS IN DEEP SLEEP MODES

During Deep Sleep, the general purpose I/O pins retain their previous states and the Secondary Oscillator (SOSC) will remain running, if enabled. Pins that are configured as inputs (TRISx bit set), prior to entry into Deep Sleep, remain high-impedance during Deep Sleep. Pins that are configured as outputs (TRISx bit clear), prior to entry into Deep Sleep, remain as output pins during Deep Sleep. While in this mode, they continue to drive the output level determined by their corresponding LATx bit at the time of entry into Deep Sleep.

PIC24FJ128GC010 FAMILY

Once the device wakes back up, all I/O pins continue to maintain their previous states, even after the device has finished the POR sequence and is executing application code again. Pins configured as inputs during Deep Sleep remain high-impedance and pins configured as outputs continue to drive their previous value. After waking up, the TRIS and LAT registers, and the SOSCEN bit (OSCCON<1>), are reset. If firmware modifies any of these bits or registers, the I/O will not immediately go to the newly configured states. Once the firmware clears the RELEASE bit (DSCON<0>), the I/O pins are “released”. This causes the I/O pins to take the states configured by their respective TRISx and LATx bit values.

This means that keeping the SOSC running after waking up requires the SOSCEN bit to be set before clearing RELEASE.

If the Deep Sleep BOR (DSBOR) is enabled, and a DSBOR or a true POR event occurs during Deep Sleep, the I/O pins will be immediately released, similar to clearing the RELEASE bit. All previous state information will be lost, including the general purpose DSGPR0 and DSGPR1 contents.

If a MCLR Reset event occurs during Deep Sleep, the DSGPRx, DSCON and DSWAKE registers will remain valid, and the RELEASE bit will remain set. The state of the SOSC will also be retained. The I/O pins, however, will be reset to their MCLR Reset state. Since RELEASE is still set, changes to the SOSCEN bit (OSCCON<1>) cannot take effect until the RELEASE bit is cleared.

In all other Deep Sleep wake-up cases, application firmware must clear the RELEASE bit in order to reconfigure the I/O pins.

10.4.6 DEEP SLEEP WDT

To enable the DSWDT in Deep Sleep mode, program the Configuration bit, DSWDTEN (CW4<7>). The device WDT need not be enabled for the DSWDT to function. Entry into Deep Sleep modes automatically resets the DSWDT.

The DSWDT clock source is selected by the DSWDTOSC Configuration bit (CW4<5>). The post-scaler options are programmed by the DSWDPS<4:0> Configuration bits (CW4<4:0>). The minimum time-out period that can be achieved is 1 ms and the maximum is 25.7 days. For more details on DSWDT configuration options, refer to [Section 34.0 “Special Features”](#).

10.4.6.1 Switching Clocks in Deep Sleep Mode

Both the RTCC and the DSWDT may run from either SOSC or the LPRC clock source. This allows both the RTCC and DSWDT to run without requiring both the LPRC and SOSC to be enabled together, reducing power consumption.

Running the RTCC from LPRC will result in a loss of accuracy in the RTCC, of approximately 5 to 10%. If a more accurate RTCC is required, it must be run from the SOSC clock source. The RTCC clock source is selected with the RTCLK<1:0> bits (RTCPWC<11:10>).

Under certain circumstances, it is possible for the DSWDT clock source to be off when entering Deep Sleep mode. In this case, the clock source is turned on automatically (if DSWDT is enabled) without the need for software intervention. However, this can cause a delay in the start of the DSWDT counters. In order to avoid this delay when using SOSC as a clock source, the application can activate SOSC prior to entering Deep Sleep mode.

10.4.7 CHECKING AND CLEARING THE STATUS OF DEEP SLEEP

Upon entry into Deep Sleep mode, the status bit, DPSLP (RCON<10>), becomes set and must be cleared by the software.

On power-up, the software should read this status bit to determine if the Reset was due to an exit from Deep Sleep mode and clear the bit if it is set. Of the four possible combinations of DPSLP and POR bit states, three cases can be considered:

- Both the DPSLP and POR bits are cleared. In this case, the Reset was due to some event other than a Deep Sleep mode exit.
- The DPSLP bit is clear, but the POR bit is set; this is a normal POR.
- Both the DPSLP and POR bits are set. This means that Deep Sleep mode was entered, the device was powered down and Deep Sleep mode was exited.

10.4.8 POWER-ON RESETS (PORs)

VDD voltage is monitored to produce PORs. Since exiting from Deep Sleep mode functionally looks like a POR, the technique described in [Section 10.4.7 “Checking and Clearing the Status of Deep Sleep”](#) should be used to distinguish between Deep Sleep and a true POR event. When a true POR occurs, the entire device, including all Deep Sleep logic (Deep Sleep registers, RTCC, DSWDT, etc.), is reset.

10.5 VBAT Mode

This mode represents the lowest power state that the microcontroller can achieve and still resume operation. VBAT mode is automatically triggered when the microcontroller's main power supply on VDD fails. When this happens, the microcontroller's on-chip power switch connects to a backup power source, such as a battery, supplied to the VBAT pin. This maintains a few key systems at an extremely low-power draw until VDD is restored.

The power supplied on VBAT only runs two systems: the RTCC and the Deep Sleep Semaphore registers (DSGPR0 and DSGPR1). To maintain these systems during a sudden loss of VDD, it is essential to connect a power source, other than VDD or AVDD, to the VBAT pin.

When the RTCC is enabled, it continues to operate with the same clock source (SOSC or LPRC) that was selected prior to entering VBAT mode. There is no provision to switch to a lower power clock source after the mode switch.

Since the loss of VDD is usually an unforeseen event, it is recommended that the contents of the Deep Sleep Semaphore registers be loaded with the data to be retained at an early point in code execution.

10.5.1 VBAT MODE WITH NO RTCC

By disabling RTCC operation during VBAT mode, power consumption is reduced to the lowest of all power-saving modes. This is done by programming the RTCBAT Configuration bit (CW4<9>) to '0'. In this mode, only the Deep Sleep Semaphore registers are maintained.

10.5.2 WAKE-UP FROM VBAT MODES

When VDD is restored to a device in VBAT mode, it automatically wakes. Wake-up occurs with a POR, after which, the device starts executing code from the Reset vector. All SFRs, except the Deep Sleep Semaphore registers, are reset to their POR values. If the RTCC was not configured to run during VBAT mode, it will remain disabled and RTCC will not run. Wake-up timing is similar to that for a normal POR.

To differentiate a wake-up from VBAT mode from other POR states, check the VBAT status bit (RCON2<0>). If this bit is set while the device is starting to execute the code from the Reset vector, it indicates that there has been an exit from VBAT mode. The application must clear the VBAT bit to ensure that future VBAT wake-up events are captured.

If a POR occurs without a power source connected to the VBAT pin, the VBPOR bit (RCON2<1>) is set. If this bit is set on a POR, it indicates that a battery needs to be connected to the VBAT pin.

In addition, if the VBAT power source falls below the level needed for Deep Sleep Semaphore operation while in VBAT mode (e.g., the battery has been drained), the VBPOR bit will be set. VBPOR is also set when the microcontroller is powered up the very first time, even if power is supplied to VBAT.

10.5.3 I/O PINS DURING VBAT MODES

All I/O pins switch to Input mode during VBAT mode. The only exceptions are the SOSCI and SOSCO pins, which maintain their states if the Secondary Oscillator is being used as the RTCC clock source. It is the user's responsibility to restore the I/O pins to their proper states, using the TRISx and LATx bits, once VDD has been restored.

10.5.4 SAVING CONTEXT DATA WITH THE DSGPRx REGISTERS

As with Deep Sleep mode (i.e., without the low-voltage/retention regulator), all SFRs are reset to their POR values after VDD has been restored. Only the Deep Sleep Semaphore registers are preserved. Applications which require critical data to be saved should save it in DSGPR0 and DSGPR1.

| |
|--|
| Note: If the VBAT mode is not used, it is recommended to connect the VBAT pin to VDD. |
|--|

The POR should be enabled for the reliable operation of the VBAT.

- 3:** This bit is set when the device is originally powered up, even if power is present on VBAT.

10.6 Clock Frequency and Clock Switching

In Run and Idle modes, all PIC24FJ devices allow for a wide range of clock frequencies to be selected under application control. If the system clock configuration is not locked, users can choose low-power or high-precision oscillators by simply changing the NOSCx bits. The process of changing a system clock during operation, as well as limitations to the process, are discussed in more detail in [Section 9.0 “Oscillator Configuration”](#).

10.7 Doze Mode

Generally, changing clock speed and invoking one of the power-saving modes are the preferred strategies for reducing power consumption. There may be circumstances, however, where this is not practical. For example, it may be necessary for an application to maintain uninterrupted synchronous communication, even while it is doing nothing else. Reducing system clock speed may introduce communication errors, while using a power-saving mode may stop communications completely.

Doze mode is a simple and effective alternative method to reduce power consumption while the device is still executing code. In this mode, the system clock continues to operate from the same source and at the same speed. Peripheral modules continue to be clocked at the same speed, while the CPU clock speed is reduced. Synchronization between the two clock domains is maintained, allowing the peripherals to access the SFRs while the CPU executes code at a slower rate.

Doze mode is enabled by setting the DOZEN bit (CLKDIV<11>). The ratio between peripheral and core clock speed is determined by the DOZE<2:0> bits (CLKDIV<14:12>). There are eight possible configurations, from 1:1 to 1:128, with 1:8 being the default.

It is also possible to use Doze mode to selectively reduce power consumption in event driven applications. This allows clock-sensitive functions, such as synchronous communications, to continue without interruption while the CPU Idles, waiting for something to invoke an interrupt routine. Enabling the automatic return to full-speed CPU operation on interrupts is enabled by setting the ROI bit (CLKDIV<15>). By default, interrupt events have no effect on Doze mode operation.

10.8 Selective Peripheral Module Control

Idle and Doze modes allow users to substantially reduce power consumption by slowing or stopping the CPU clock. Even so, peripheral modules still remain clocked, and thus, consume power. There may be cases where the application needs what these modes do not provide: the allocation of power resources to the CPU processing with minimal power consumption from the peripherals.

PIC24F devices address this requirement by allowing peripheral modules to be selectively disabled, reducing or eliminating their power consumption. This can be done with two control bits:

- The Peripheral Enable bit, generically named, “XXXEN”, located in the module’s main control SFR.
- The Peripheral Module Disable (PMD) bit, generically named, “XXXMD”, located in one of the PMDn Control registers (XXXMD bits are in PMDn registers, shown in [Table 4-39](#)).

Both bits have similar functions in enabling or disabling its associated module. Setting the PMD bit for a module disables all clock sources to that module, reducing its power consumption to an absolute minimum. In this state, the control and status registers associated with the peripheral will also be disabled, so writes to those registers will have no effect and read values will be invalid. Many peripheral modules have a corresponding PMD bit.

In contrast, disabling a module by clearing its XXXEN bit disables its functionality, but leaves its registers available to be read and written to. Power consumption is reduced, but not by as much as when the PMD bits are used. Most peripheral modules have an enable bit; exceptions include capture, compare and RTCC.

To achieve more selective power savings, peripheral modules can also be selectively disabled when the device enters Idle mode. This is done through the control bit of the generic name format, “XXXIDL”. By default, all modules that can operate during Idle mode will do so. Using the disable on Idle feature disables the module while in Idle mode, allowing further reduction of power consumption during Idle mode, enhancing power savings for extremely critical power applications.

PIC24FJ128GC010 FAMILY

NOTES:

PIC24FJ128GC010 FAMILY

11.0 I/O PORTS

Note: This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “PIC24F Family Reference Manual”, “I/O Ports with Peripheral Pin Select (PPS)” (DS39711). The information in this data sheet supersedes the information in the FRM.

All of the device pins (except VDD, VSS, MCLR and OSC/CLKI) are shared between the peripherals and the Parallel I/O ports. All I/O input ports feature Schmitt Trigger (ST) inputs for improved noise immunity.

11.1 Parallel I/O (PIO) Ports

A Parallel I/O port that shares a pin with a peripheral is, in general, subservient to the peripheral. The peripheral’s output buffer data and control signals are provided to a pair of multiplexers. The multiplexers select whether the peripheral or the associated port has ownership of the output data and control signals of the I/O pin. The logic also prevents “loop through”, in which a port’s digital output can drive the input of a peripheral that shares the same pin. Figure 11-1 shows how ports are shared with other peripherals and the associated I/O pin to which they are connected.

When a peripheral is enabled and the peripheral is actively driving an associated pin, the use of the pin as a general purpose output pin is disabled. The I/O pin may be read, but the output driver for the parallel port bit will be disabled. If a peripheral is enabled, but the peripheral is not actively driving a pin, that pin may be driven by a port.

All port pins have three registers directly associated with their operation as digital I/O and one register associated with their operation as analog inputs. The Data Direction register (TRISx) determines whether the pin is an input or an output. If the data direction bit is a ‘1’, then the pin is an input. All port pins are defined as inputs after a Reset. Reads from the Output Latch register (LATx), read the latch; writes to the latch, write the latch. Reads from the port (PORTx), read the port pins; writes to the port pins, write the latch.

Any bit and its associated data and control registers that are not valid for a particular device will be disabled. That means the corresponding LATx and TRISx registers, and the port pin will read as zeros.

When a pin is shared with another peripheral or function that is defined as an input only, it is regarded as a dedicated port because there is no other competing source of inputs. RC13 and RC14 can be input ports only; they cannot be configured as outputs.

FIGURE 11-1: BLOCK DIAGRAM OF A TYPICAL SHARED PORT STRUCTURE

PIC24FJ128GC010 FAMILY

11.1.1 I/O PORT WRITE/READ TIMING

One instruction cycle is required between a port direction change or port write operation and a read operation of the same port. Typically, this instruction would be a `NOP`.

11.1.2 OPEN-DRAIN CONFIGURATION

In addition to the `PORTx`, `LATx` and `TRISx` registers for data control, each port pin can also be individually configured for either a digital or open-drain output. This is controlled by the Open-Drain Control register, `ODCx`, associated with each port. Setting any of the bits configures the corresponding pin to act as an open-drain output.

The open-drain feature allows the generation of outputs higher than V_{DD} (e.g., 5V) on any desired digital only pins by using external pull-up resistors. The maximum open-drain voltage allowed is the same as the maximum V_{IH} specification.

11.1.3 GPIO FUNCTIONS ON THE USB PINS

When the USB module is enabled, the USB module controls the `RG2/RG3/RF7` port pins. General purpose input/output and related interrupt-on-change functionality can be made available on the `RG2/RG3/RF7` pins when the USB module is disabled and the `UTRDIS` (`U1CNFG2<0>`) bit is set. Additionally, for general purpose digital input function on `RF7/VBUS`, the `ANSF7` bit must be cleared.

11.2 Configuring Analog Port Pins (ANSx)

The `ANSx` and `TRISx` registers control the operation of the pins with analog function. Each port pin with analog function is associated with one of the `ANSx` bits (see [Register 11-1](#) through [Register 11-7](#)), which decides if the pin function should be analog or digital. Refer to [Table 11-1](#) for detailed behavior of the pin for different `ANSx` and `TRISx` bit settings.

When reading the `PORTx` register, all pins configured as analog input channels will read as cleared (a low level).

11.2.1 ANALOG INPUT PINS AND VOLTAGE CONSIDERATIONS

The voltage tolerance of pins used as device inputs is dependent on the pin's input function. Most input pins are able to handle DC voltages of up to 5.5V, a level typical for digital logic circuits. However, several pins can only tolerate voltages up to V_{DD} . Voltage excursions beyond V_{DD} on these pins should always be avoided.

[Table 11-2](#) summarizes the different voltage tolerances. Refer to [Section 37.0 "Electrical Characteristics"](#) for more details.

TABLE 11-1: CONFIGURING ANALOG/DIGITAL FUNCTION OF AN I/O PIN

| Pin Function | ANSx Setting | TRISx Setting | Comments |
|----------------|--------------|---------------|--|
| Analog Input | 1 | 1 | It is recommended to keep <code>ANSx = 1</code> . |
| Analog Output | 1 | 1 | It is recommended to keep <code>ANSx = 1</code> . |
| Digital Input | 0 | 1 | Firmware must wait at least one instruction cycle after configuring a pin as a digital input before a valid input value can be read. |
| Digital Output | 0 | 0 | Make sure to disable the analog output function on the pin if any is present. |

PIC24FJ128GC010 FAMILY

TABLE 11-2: INPUT VOLTAGE LEVELS FOR PORT OR PIN TOLERATED DESCRIPTION INPUT

| Port or Pin | Tolerated Input | Description |
|-------------------------------------|-----------------|---|
| PORTA<15:14,7:0> ⁽¹⁾ | 5.5V | Tolerates input levels above VDD; useful for most standard logic. |
| PORTB<15:14,12,7,4,2> | | |
| PORTC<4:1> ⁽¹⁾ | | |
| PORTD<15:0> ⁽¹⁾ | | |
| PORTE<9:8,4:0> ⁽¹⁾ | | |
| PORTF<13:12,8:7,5:0> ⁽¹⁾ | | |
| PORTG<15:12,1:0> ⁽¹⁾ | | |
| PORTA<10:9> | VDD | Only VDD input levels are tolerated. |
| PORTB<13,6:5,3,1:0> | | |
| PORTC<15:12> ⁽¹⁾ | | |
| PORTE<7:5> | | |
| PORTG<9:6,3:2> | | |

Note 1: Not all of these pins are implemented in 64-pin devices. Refer to [Section 1.0 “Device Overview”](#) for a complete description of port pin implementation.

PIC24FJ128GC010 FAMILY

11.3 Input Change Notification (ICN)

The Input Change Notification function of the I/O ports allows the PIC24FJ128GC010 family of devices to generate interrupt requests to the processor in response to a Change-of-State (COS) on selected input pins. This feature is capable of detecting input Change-of-States, even in Sleep mode, when the clocks are disabled. Depending on the device pin count, there are up to 82 external inputs that may be selected (enabled) for generating an interrupt request on a Change-of-State.

Registers, CNEN1 through CNEN6, contain the interrupt enable control bits for each of the Change Notification (CN) input pins. Setting any of these bits enables a CN interrupt for the corresponding pins.

Each CN pin has both a weak pull-up and a weak pull-down connected to it. The pull-ups act as a current source that is connected to the pin, while the pull-downs act as a current sink that is connected to the pin. These eliminate the need for external resistors when push button or keypad devices are connected. The pull-ups and pull-downs are separately enabled using the CNPU1 through CNPU6 registers (for pull-ups) and the CNPD1 through CNPD6 registers (for pull-downs). Each CN pin has individual control bits for its pull-up and pull-down. Setting a control bit enables the weak pull-up or pull-down for the corresponding pin.

When the internal pull-up is selected, the pin pulls up to $V_{DD} - 1.1V$ (typical). When the internal pull-down is selected, the pin pulls down to V_{SS} .

Note: Pull-ups on Change Notification pins should always be disabled whenever the port pin is configured as a digital output.

EXAMPLE 11-1: PORT WRITE/READ IN ASSEMBLY

```
MOV    0xFF00, W0    ; Configure PORTB<15:8> as inputs
MOV    W0, TRISB     ; and PORTB<7:0> as outputs
NOP                      ; Delay 1 cycle
BTSS   PORTB, #13    ; Next Instruction
```

EXAMPLE 11-2: PORT WRITE/READ IN 'C'

```
TRISB = 0xFF00;           // Configure PORTB<15:8> as inputs and PORTB<7:0> as outputs
Nop();                    // Delay 1 cycle
If (PORTBbits.RB13){ };   // Next Instruction
```

PIC24FJ128GC010 FAMILY

11.4 Peripheral Pin Select (PPS)

A major challenge in general purpose devices is providing the largest possible set of peripheral features while minimizing the conflict of features on I/O pins. In an application that needs to use more than one peripheral multiplexed on a single pin, inconvenient work arounds in application code, or a complete redesign, may be the only option.

The Peripheral Pin Select (PPS) feature provides an alternative to these choices by enabling the user's peripheral set selection and its placement on a wide range of I/O pins. By increasing the pinout options available on a particular device, users can better tailor the microcontroller to their entire application, rather than trimming the application to fit the device.

The Peripheral Pin Select feature operates over a fixed subset of digital I/O pins. Users may independently map the input and/or output of any one of many digital peripherals to any one of these I/O pins. PPS is performed in software and generally does not require the device to be reprogrammed. Hardware safeguards are included that prevent accidental or spurious changes to the peripheral mapping once it has been established.

11.4.1 AVAILABLE PINS

The PPS feature is used with a range of up to 44 pins, depending on the particular device and its pin count. Pins that support the Peripheral Pin Select feature include the designation, "RPn" or "RPI n", in their full pin designation, where "n" is the remappable pin number. "RP" is used to designate pins that support both remappable input and output functions, while "RPI" indicates pins that support remappable input functions only.

PIC24FJ128GC010 family devices support a larger number of remappable input only pins than remappable input/output pins. In this device family, there are up to 32 remappable input/output pins, depending on the pin count of the particular device selected. These pins are numbered, RP0 through RP31. Remappable input only pins are numbered above this range, from RPI32 to RPI43 (or the upper limit for that particular device).

See [Table 1-3](#) for a summary of pinout options in each package offering.

11.4.2 AVAILABLE PERIPHERALS

The peripherals managed by the PPS are all digital only peripherals. These include general serial communications (UART and SPI), general purpose timer clock inputs, timer related peripherals (input capture and output compare) and external interrupt inputs. Also included are the outputs of the comparator module, since these are discrete digital signals.

PPS is not available for these peripherals:

- I²C™ (input and output)
- USB (all module inputs and outputs)
- Change Notification inputs
- RTCC alarm output(s)
- EPMP signals (input and output)
- LCD signals
- Analog (inputs and outputs)
- INT0

A key difference between pin select and non-pin select peripherals is that pin select peripherals are not associated with a default I/O pin. The peripheral must always be assigned to a specific I/O pin before it can be used. In contrast, non-pin select peripherals are always available on a default pin, assuming that the peripheral is active and not conflicting with another peripheral.

11.4.2.1 Peripheral Pin Select Function Priority

Pin-selectable peripheral outputs (e.g., OC, UART transmit) will take priority over general purpose digital functions on a pin, such as EPMP and port I/O. Specialized digital outputs (e.g., USB on USB-enabled devices) will take priority over PPS outputs on the same pin. The pin diagrams list peripheral outputs in the order of priority. Refer to them for priority concerns on a particular pin.

Unlike PIC24F devices with fixed peripherals, pin-selectable peripheral inputs will never take ownership of a pin. The pin's output buffer will be controlled by the TRISx setting or by a fixed peripheral on the pin. If the pin is configured in Digital mode, then the PPS input will operate correctly. If an analog function is enabled on the pin, the PPS input will be disabled.

11.4.3 CONTROLLING PERIPHERAL PIN SELECT

PPS features are controlled through two sets of Special Function Registers (SFRs): one to map peripheral inputs and one to map the outputs. Because they are separately controlled, a particular peripheral's input and output (if the peripheral has both) can be placed on any selectable function pin without constraint.

The association of a peripheral to a peripheral-selectable pin is handled in two different ways, depending on if an input or an output is being mapped.

PIC24FJ128GC010 FAMILY

11.4.3.1 Input Mapping

The inputs of the Peripheral Pin Select options are mapped on the basis of the peripheral; that is, a control register associated with a peripheral dictates the pin it will be mapped to. The RPINRx registers are used to configure peripheral input mapping (see [Register 11-8](#) through [Register 11-26](#)).

Each register contains two sets of 6-bit fields, with each set associated with one of the pin-selectable peripherals. Programming a given peripheral's bit field, with an appropriate 6-bit value, maps the RPN/RPIn pin with that value to that peripheral. For any given device, the valid range of values for any of the bit fields corresponds to the maximum number of Peripheral Pin Selections supported by the device.

TABLE 11-3: SELECTABLE INPUT SOURCES (MAPS INPUT TO FUNCTION)⁽¹⁾

Note 1: Unless otherwise noted, all inputs use the Schmitt Trigger (ST) input buffers.

PIC24FJ128GC010 FAMILY

11.4.3.2 Output Mapping

In contrast to inputs, the outputs of the Peripheral Pin Select options are mapped on the basis of the pin. In this case, a control register associated with a particular pin dictates the peripheral output to be mapped. The RPORx registers are used to control output mapping. Each register contains two 6-bit fields, with each field being associated with one RPn pin (see [Register 11-27](#) through [Register 11-42](#)). The value of the bit field

corresponds to one of the peripherals and that peripheral's output is mapped to the pin (see [Table 11-4](#)).

Because of the mapping technique, the list of peripherals for output mapping also includes a null value of '000000'. This permits any given pin to remain disconnected from the output of any of the pin-selectable peripherals.

TABLE 11-4: SELECTABLE OUTPUT SOURCES (MAPS FUNCTION TO OUTPUT)

| Output Function Number ⁽¹⁾ | Function | Output Name |
|---------------------------------------|-----------------------------------|--------------------------|
| 0 | NULL ⁽²⁾ | Null |
| 1 | C1OUT | Comparator 1 Output |
| 2 | C2OUT | Comparator 2 Output |
| 3 | U1TX | UART1 Transmit |
| 4 | $\overline{U1RTS}$ ⁽³⁾ | UART1 Request-to-Send |
| 5 | U2TX | UART2 Transmit |
| 6 | $\overline{U2RTS}$ ⁽³⁾ | UART2 Request-to-Send |
| 7 | SDO1 | SPI1 Data Output |
| 8 | SCK1OUT | SPI1 Clock Output |
| 9 | SS1OUT | SPI1 Slave Select Output |
| 10 | SDO2 | SPI2 Data Output |
| 11 | SCK2OUT | SPI2 Clock Output |
| 12 | SS2OUT | SPI2 Slave Select Output |
| 18 | OC1 | Output Compare 1 |
| 19 | OC2 | Output Compare 2 |
| 20 | OC3 | Output Compare 3 |
| 21 | OC4 | Output Compare 4 |
| 22 | OC5 | Output Compare 5 |
| 23 | OC6 | Output Compare 6 |
| 24 | OC7 | Output Compare 7 |
| 25 | OC8 | Output Compare 8 |
| 28 | U3TX | UART3 Transmit |
| 29 | $\overline{U3RTS}$ ⁽³⁾ | UART3 Request-to-Send |
| 30 | U4TX | UART4 Transmit |
| 31 | $\overline{U4RTS}$ ⁽³⁾ | UART4 Request-to-Send |
| 35 | OC9 | Output Compare 9 |
| 36 | C3OUT | Comparator 3 Output |
| 37 | MDOUT | DSM Modulator Output |
| 38-63 | (unused) | NC |

- Note 1:** Setting the RPORx register with the listed value assigns that output function to the associated RPn pin.
Note 2: The NULL function is assigned to all RPn outputs at device Reset and disables the RPn output function.
Note 3: IrDA[®] BCLKx functionality uses this output.

PIC24FJ128GC010 FAMILY

11.4.3.3 Mapping Limitations

The control schema of the Peripheral Pin Select is extremely flexible. Other than systematic blocks that prevent signal contention, caused by two physical pins being configured as the same functional input or two functional outputs configured as the same pin, there are no hardware enforced lockouts. The flexibility extends to the point of allowing a single input to drive multiple peripherals or a single functional output to drive multiple output pins.

11.4.3.4 Mapping Exceptions for PIC24FJ128GC010 Family Devices

Although the PPS registers theoretically allow for up to 64 remappable I/O pins, not all of these are implemented in all devices. For PIC24FJ128GC010 family devices, the maximum number of remappable pins available is 44, which includes 12 input only pins. In addition, some pins in the RP and RPI sequences are unimplemented in lower pin count devices. The differences in available remappable pins are summarized in [Table 11-5](#).

When developing applications that use remappable pins, users should also keep these things in mind:

- For the RPINRx registers, bit combinations corresponding to an unimplemented pin for a particular device are treated as invalid; the corresponding module will not have an input mapped to it. For all PIC24FJ128GC010 family devices, this includes all values greater than 43 ('101011').
- For RPORx registers, the bit fields corresponding to an unimplemented pin will also be unimplemented. Writing to these fields will have no effect.

11.4.4 CONTROLLING CONFIGURATION CHANGES

Because peripheral remapping can be changed during run time, some restrictions on peripheral remapping are needed to prevent accidental configuration changes. PIC24F devices include three features to prevent alterations to the peripheral map:

- Control register lock sequence
- Continuous state monitoring
- Configuration bit remapping lock

11.4.4.1 Control Register Lock

Under normal operation, writes to the RPINRx and RPORx registers are not allowed. Attempted writes will appear to execute normally, but the contents of the registers will remain unchanged. To change these registers, they must be unlocked in hardware. The register lock is controlled by the IOLOCK bit (OSCCON<6>). Setting IOLOCK prevents writes to the control registers; clearing IOLOCK allows writes.

To set or clear IOLOCK, a specific command sequence must be executed:

1. Write 46h to OSCCON<7:0>.
2. Write 57h to OSCCON<7:0>.
3. Clear (or set) IOLOCK as a single operation.

Unlike the similar sequence with the oscillator's LOCK bit, IOLOCK remains in one state until changed. This allows all of the Peripheral Pin Selects to be configured with a single unlock sequence, followed by an update to all control registers, then locked with a second lock sequence.

11.4.4.2 Continuous State Monitoring

In addition to being protected from direct writes, the contents of the RPINRx and RPORx registers are constantly monitored in hardware by shadow registers. If an unexpected change in any of the registers occurs (such as cell disturbances caused by ESD or other external events), a Configuration Mismatch Reset will be triggered.

11.4.4.3 Configuration Bit Pin Select Lock

As an additional level of safety, the device can be configured to prevent more than one write session to the RPINRx and RPORx registers. The IOL1WAY (CW4<15>) Configuration bit blocks the IOLOCK bit from being cleared after it has been set once. If IOLOCK remains set, the register unlock procedure will not execute and the Peripheral Pin Select Control registers cannot be written to. The only way to clear the bit and re-enable peripheral remapping is to perform a device Reset.

In the default (unprogrammed) state, IOL1WAY is set, restricting users to one write session. Programming IOL1WAY allows users unlimited access (with the proper use of the unlock sequence) to the Peripheral Pin Select registers.

TABLE 11-5: REMAPPABLE PIN EXCEPTIONS FOR PIC24FJ128GC010 FAMILY DEVICES

| Device | RP Pins (I/O) | | RPI Pins | |
|-----------------|---------------|-----------------------|----------|--------------------|
| | Total | Unimplemented | Total | Unimplemented |
| PIC24FJXXXGC006 | 28 | RP5, RP15, RP30, RP31 | 1 | RPI32-36, RPI38-43 |
| PIC24FJXXXGC010 | 32 | — | 12 | — |

PIC24FJ128GC010 FAMILY

11.4.5 CONSIDERATIONS FOR PERIPHERAL PIN SELECTION

The ability to control Peripheral Pin Selection introduces several considerations into application design that could be overlooked. This is particularly true for several common peripherals that are available only as remappable peripherals.

The main consideration is that the Peripheral Pin Selects are not available on default pins in the device's default (Reset) state. Since all RPINRx registers reset to '111111' and all RPORx registers reset to '000000', all Peripheral Pin Select inputs are tied to Vss and all Peripheral Pin Select outputs are disconnected.

Note: In tying Peripheral Pin Select inputs to RP63, the RP63 pin need not exist on a device for the registers to be reset to it.

This situation requires the user to initialize the device with the proper peripheral configuration before any other application code is executed. Since the IOLOCK bit resets in the unlocked state, it is not necessary to execute the unlock sequence after the device has come out of Reset. For application safety, however, it is best to set IOLOCK and lock the configuration after writing to the control registers.

Because the unlock sequence is timing-critical, it must be executed as an assembly language routine in the same manner as changes to the oscillator configuration. If the bulk of the application is written in 'C', or another high-level language, the unlock sequence should be performed by writing in-line assembly.

Choosing the configuration requires a review of all Peripheral Pin Selects and their pin assignments, especially those that will not be used in the application. In all cases, unused pin-selectable peripherals should be disabled completely. Unused peripherals should have their inputs assigned to an unused RPn/RPIn pin function. I/O pins with unused RPn functions should be configured with the null peripheral output.

The assignment of a peripheral to a particular pin does not automatically perform any other configuration of the pin's I/O circuitry. In theory, this means adding a pin-selectable output to a pin may mean inadvertently driving an existing peripheral input when the output is driven. Users must be familiar with the behavior of other fixed peripherals that share a remappable pin and know when to enable or disable them. To be safe, fixed digital peripherals that share the same pin should be disabled when not in use.

Along these lines, configuring a remappable pin for a specific peripheral does not automatically turn that feature on. The peripheral must be specifically configured for operation and enabled as if it were tied to a fixed pin. Where this happens in the application code (immediately following a device Reset and peripheral configuration or inside the main application routine) depends on the peripheral and its use in the application.

A final consideration is that Peripheral Pin Select functions neither override analog inputs nor reconfigure pins with analog functions for digital I/O. If a pin is configured as an analog input on device Reset, it must be explicitly reconfigured as digital I/O when used with a Peripheral Pin Select.

Example 11-3 shows a configuration for bidirectional communication with flow control using UART1. The following input and output functions are used:

- Input Functions: U1RX, U1CTS
- Output Functions: U1TX, U1RTS

EXAMPLE 11-3: CONFIGURING UART1 INPUT AND OUTPUT FUNCTIONS

```
// Unlock Registers
asm volatile ("MOV #OSCCON, w1 \n"
             "MOV #0x46, w2 \n"
             "MOV #0x57, w3 \n"
             "MOV.b w2, [w1] \n"
             "MOV.b w3, [w1] \n"
             "BCLR OSCCON, #6");

// or use C30 built-in macro:
// __builtin_write_OSCCONL(OSCCON & 0xbf);

// Configure Input Functions (Table 11-2)
// Assign U1RX To Pin RP0
RPINR18bits.U1RXR = 0;

// Assign U1CTS To Pin RP1
RPINR18bits.U1CTSR = 1;

// Configure Output Functions (Table 11-4)
// Assign U1TX To Pin RP2
RPOR1bits.RP2R = 3;

// Assign U1RTS To Pin RP3
RPOR1bits.RP3R = 4;

// Lock Registers
asm volatile ("MOV #OSCCON, w1 \n"
             "MOV #0x46, w2 \n"
             "MOV #0x57, w3 \n"
             "MOV.b w2, [w1] \n"
             "MOV.b w3, [w1] \n"
             "BSET OSCCON, #6");

// or use C30 built-in macro:
// __builtin_write_OSCCONL(OSCCON | 0x40);
```

PIC24FJ128GC010 FAMILY

11.4.6 PERIPHERAL PIN SELECT REGISTERS

The PIC24FJ128GC010 family of devices implements a total of 35 registers for remappable peripheral configuration:

- Input Remappable Peripheral Registers (19)
- Output Remappable Peripheral Registers (16)

Note: Input and output register values can only be changed if IOLOCK (OSCCON<6>) = 0. See [Section 11.4.4.1 “Control Register Lock”](#) for a specific command sequence.

PIC24FJ128GC010 FAMILY

12.0 TIMER1

Note: This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “PIC24F Family Reference Manual”, “Timers” (DS39704). The information in this data sheet supersedes the information in the FRM.

The Timer1 module is a 16-bit timer, which can serve as the time counter for the Real-Time Clock (RTC) or operate as a free-running, interval timer/counter. Timer1 can operate in three modes:

- 16-Bit Timer
- 16-Bit Synchronous Counter
- 16-Bit Asynchronous Counter

Timer1 also supports these features:

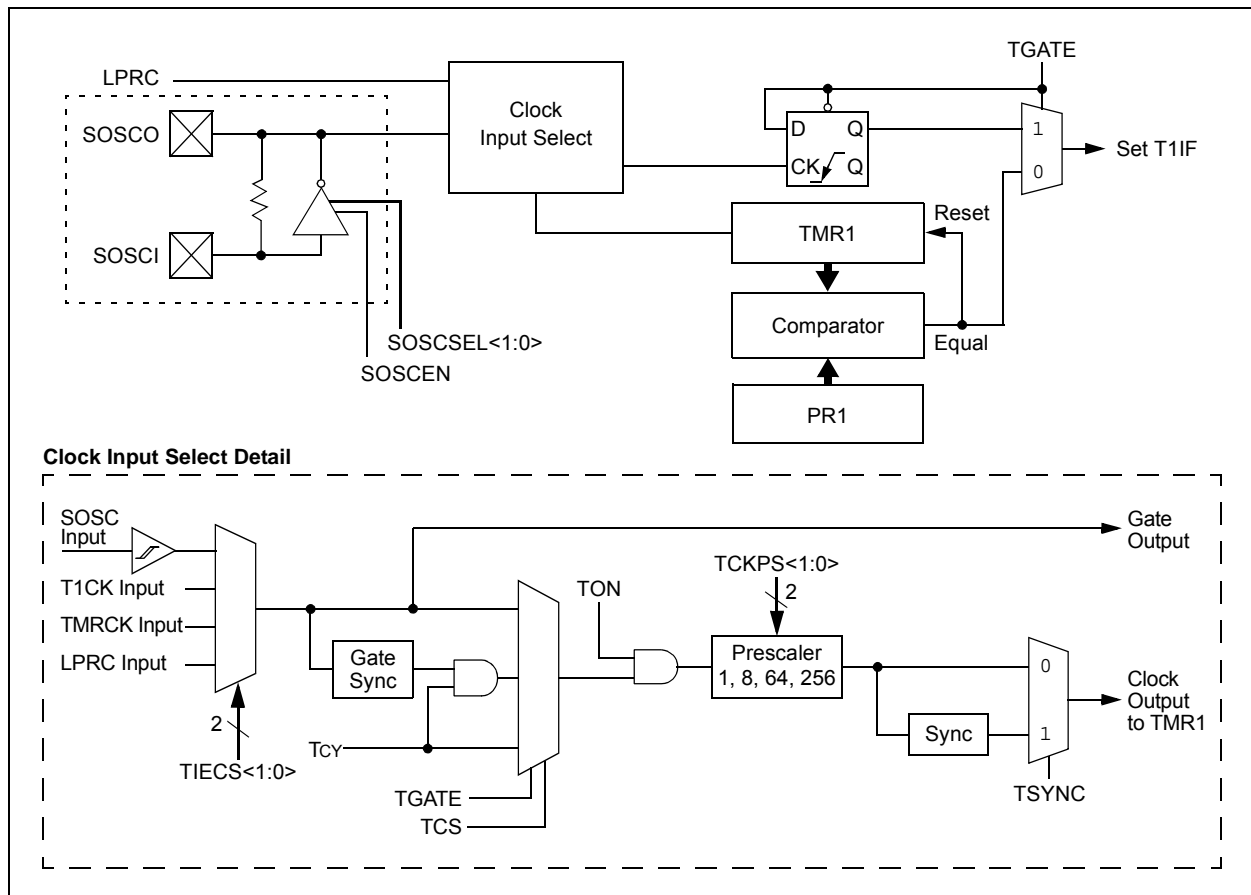

- Timer Gate Operation
- Selectable Prescaler Settings
- Timer Operation During CPU Idle and Sleep modes
- Interrupt on 16-Bit Period Register Match or Falling Edge of External Gate Signal

Figure 12-1 presents a block diagram of the 16-bit timer module.

To configure Timer1 for operation:

1. Set the TON bit (= 1).
2. Select the timer prescaler ratio using the TCKPS<1:0> bits.
3. Set the Clock and Gating modes using the TCS, TIECS<1:0> and TGATE bits.
4. Set or clear the TSYNC bit to configure synchronous or asynchronous operation.
5. Load the timer period value into the PR1 register.
6. If interrupts are required, set the Timer1 Interrupt Enable bit, T1IE. Use the Timer1 Interrupt Priority bits, T1IP<2:0>, to set the interrupt priority.

 0 = Internal clock (Fosc/2)
- bit 0 **Unimplemented:** Read as '0'

Note 1: Changing the value of T1CON while the timer is running (TON = 1) causes the timer prescale counter to reset and is not recommended.

13.0 TIMER2/3 AND TIMER4/5

Note: This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “PIC24F Family Reference Manual”, “Timers” (DS39704). The information in this data sheet supersedes the information in the FRM.

The Timer2/3 and Timer4/5 modules are 32-bit timers, which can also be configured as four independent, 16-bit timers with selectable operating modes.

As 32-bit timers, Timer2/3 and Timer4/5 can each operate in three modes:

- Two Independent 16-Bit Timers with All 16-Bit Operating modes (except Asynchronous Counter mode)
- Single 32-Bit Timer
- Single 32-Bit Synchronous Counter

They also support these features:

- Timer Gate Operation
- Selectable Prescaler Settings
- Timer Operation During Idle and Sleep modes
- Interrupt on a 32-Bit Period Register Match
- A/D Event Trigger (only on Timer2/3 in 32-bit mode and Timer3 in 16-bit mode)

Individually, all four of the 16-bit timers can function as synchronous timers or counters. They also offer the features listed above, except for the A/D Event Trigger. This trigger is implemented only on Timer2/3 in 32-bit mode and Timer3 in 16-bit mode. The operating modes and enabled features are determined by setting the appropriate bit(s) in the T2CON, T3CON, T4CON and T5CON registers. T2CON and T4CON are shown in generic form in [Register 13-1](#); T3CON and T5CON are shown in [Register 13-2](#).

For 32-bit timer/counter operation, Timer2 and Timer4 are the least significant word; Timer3 and Timer5 are the most significant word of the 32-bit timers.

Note: For 32-bit operation, T3CON and T5CON control bits are ignored. Only T2CON and T4CON control bits are used for setup and control. Timer2 and Timer4 clock and gate inputs are utilized for the 32-bit timer modules, but an interrupt is generated with the Timer3 or Timer5 interrupt flags.

To configure Timer2/3 or Timer4/5 for 32-bit operation:

1. Set the T32 or T45 bit (T2CON<3> or T4CON<3> = 1).
2. Select the prescaler ratio for Timer2 or Timer4 using the TCKPS<1:0> bits.
3. Set the Clock and Gating modes using the TCS and TGATE bits. If TCS is set to an external clock, RPINRx (TxCK) must be configured to an available RPn/RPIn pin. For more information, see [Section 11.4 “Peripheral Pin Select \(PPS\)”](#).
4. Load the timer period value. PR3 (or PR5) will contain the most significant word (msw) of the value, while PR2 (or PR4) contains the least significant word (lsw).
5. If interrupts are required, set the interrupt enable bit, T3IE or T5IE. Use the priority bits, T3IP<2:0> or T5IP<2:0>, to set the interrupt priority. Note that while Timer2 or Timer4 controls the timer, the interrupt appears as a Timer3 or Timer5 interrupt.
6. Set the TON bit (= 1).

The timer value, at any point, is stored in the register pair, TMR<3:2> (or TMR<5:4>). TMR3 (TMR5) always contains the most significant word of the count, while TMR2 (TMR4) contains the least significant word.

To configure any of the timers for individual 16-bit operation:

1. Clear the T32 bit corresponding to that timer (T2CON<3> for Timer2 and Timer3 or T4CON<3> (T45) for Timer4 and Timer5).
2. Select the timer prescaler ratio using the TCKPS<1:0> bits.
3. Set the Clock and Gating modes using the TCS and TGATE bits. See [Section 11.4 “Peripheral Pin Select \(PPS\)”](#) for more information.
4. Load the timer period value into the PRx register.
5. If interrupts are required, set the interrupt enable bit, TxIE. Use the priority bits, TxIP<2:0>, to set the interrupt priority.
6. Set the TON (TxCON<15> = 1) bit.

 1 = External clock from pin, TyCK (on the rising edge)
 0 = Internal clock (FOSC/2)
- bit 0 **Unimplemented:** Read as '0'

- Note 1:** Changing the value of TyCON while the timer is running (TON = 1) causes the timer prescale counter to reset and is not recommended.
- 2:** When 32-bit operation is enabled (T2CON<3> or T4CON<3> = 1), these bits have no effect on Timery operation; all timer functions are set through T2CON and T4CON.
- 3:** If TCS = 1 and TIECS<1:0> = x1, the selected external timer input (TMRCK or TyCK) must be configured to an available RPN/RPI pin. For more information, see [Section 11.4 "Peripheral Pin Select \(PPS\)"](#).

PIC24FJ128GC010 FAMILY

14.0 INPUT CAPTURE WITH DEDICATED TIMERS

Note: This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “PIC24F Family Reference Manual”, “Input Capture with Dedicated Timer” (DS39722). The information in this data sheet supersedes the information in the FRM.

Devices in the PIC24FJ128GC010 family contain seven independent input capture modules. Each of the modules offers a wide range of configuration and operating options for capturing external pulse events and generating interrupts.

Key features of the input capture module include:

- Hardware-configurable for 32-bit operation in all modes by cascading two adjacent modules
- Synchronous and Trigger modes of output compare operation, with up to 30 user-selectable sync/trigger sources available
- A 4-level FIFO buffer for capturing and holding timer values for several events
- Configurable interrupt generation
- Up to 6 clock sources available for each module, driving a separate internal 16-bit counter

The module is controlled through two registers: ICxCON1 (Register 14-1) and ICxCON2 (Register 14-2). A general block diagram of the module is shown in Figure 14-1.

14.1 General Operating Modes

14.1.1 SYNCHRONOUS AND TRIGGER MODES

When the input capture module operates in a Free-Running mode, the internal 16-bit counter, ICxTMR, counts up continuously, wrapping around from FFFFh to 0000h on each overflow. Its period is synchronized to the selected external clock source. When a capture event occurs, the current 16-bit value of the internal counter is written to the FIFO buffer.

In Synchronous mode, the module begins capturing events on the ICx pin as soon as its selected clock source is enabled. Whenever an event occurs on the selected sync source, the internal counter is reset. In Trigger mode, the module waits for a sync event from another internal module to occur before allowing the internal counter to run.

Standard, free-running operation is selected by setting the SYNCSELx bits (ICxCON2<4:0>) to ‘00000’ and clearing the ICTRIG bit (ICxCON2<7>). Synchronous and Trigger modes are selected any time the SYNCSELx bits are set to any value except ‘00000’. The ICTRIG bit selects either Synchronous or Trigger mode; setting the bit selects Trigger mode operation. In both modes, the SYNCSEL<4:0> bits determine the sync/trigger source.

When the SYNCSELx bits are set to ‘00000’ and ICTRIG is set, the module operates in Software Trigger mode. In this case, capture operations are started by manually setting the TRIGSTAT bit (ICxCON2<6>).

FIGURE 14-1: INPUT CAPTURE x BLOCK DIAGRAM

PIC24FJ128GC010 FAMILY

14.1.2 CASCADED (32-BIT) MODE

By default, each module operates independently with its own 16-bit timer. To increase resolution, adjacent even and odd modules can be configured to function as a single 32-bit module. (For example, Modules 1 and 2 are paired, as are Modules 3 and 4, and so on.) The odd numbered module (ICx) provides the Least Significant 16 bits of the 32-bit register pairs and the even module (ICy) provides the Most Significant 16 bits. Wrap-arounds of the ICx registers cause an increment of their corresponding ICy registers.

Cascaded operation is configured in hardware by setting the IC32 bits (ICxCON2<8>) for both modules.

14.2 Capture Operations

The input capture module can be configured to capture timer values and generate interrupts on rising edges on ICx or all transitions on ICx. Captures can be configured to occur on all rising edges or just some (every 4th or 16th). Interrupts can be independently configured to generate on each event or a subset of events.

To set up the module for capture operations:

1. Configure the ICx input for one of the available Peripheral Pin Select pins.
2. If Synchronous mode is to be used, disable the sync source before proceeding.
3. Make sure that any previous data has been removed from the FIFO by reading ICxBUF until the ICBNE bit (ICxCON1<3>) is cleared.
4. Set the SYNCSEL<4:0> bits (ICxCON2<4:0>) to the desired sync/trigger source.
5. Set the ICTSEL<2:0> bits (ICxCON1<12:10>) for the desired clock source.
6. Set the ICI<1:0> bits (ICxCON1<6:5>) to the desired interrupt frequency
7. Select Synchronous or Trigger mode operation:
 - a) Check that the SYNCSELx bits are not set to '00000'.
 - b) For Synchronous mode, clear the ICTRIG bit (ICxCON2<7>).
 - c) For Trigger mode, set ICTRIG and clear the TRIGSTAT bit (ICxCON2<6>).
8. Set the ICM<2:0> bits (ICxCON1<2:0>) to the desired operational mode.
9. Enable the selected sync/trigger source.

For 32-bit cascaded operations, the setup procedure is slightly different:

1. Set the IC32 bits for both modules (ICyCON2<8>) and (ICxCON2<8>), enabling the even numbered module first. This ensures the modules will start functioning in unison.
2. Set the ICTSELx and SYNCSELx bits for both modules to select the same sync/trigger and time base source. Set the even module first, then the odd module. Both modules must use the same ICTSELx and SYNCSELx bits settings.
3. Clear the ICTRIG bit of the even module (ICyCON2<7>). This forces the module to run in Synchronous mode with the odd module, regardless of its trigger setting.
4. Use the odd module's ICx bits (ICxCON1<6:5>) to set the desired interrupt frequency.
5. Use the ICTRIG bit of the odd module (ICxCON2<7>) to configure Trigger or Synchronous mode operation.

Note: For Synchronous mode operation, enable the sync source as the last step. Both input capture modules are held in Reset until the sync source is enabled.

6. Use the ICMx bits of the odd module (ICxCON1<2:0>) to set the desired Capture mode.

The module is ready to capture events when the time base and the sync/trigger source are enabled. When the ICBNE bit (ICxCON1<3>) becomes set, at least one capture value is available in the FIFO. Read input capture values from the FIFO until the ICBNE clears to '0'.

For 32-bit operation, read both the ICxBUF and ICyBUF for the full 32-bit timer value (ICxBUF for the lsw, ICyBUF for the msw). At least one capture value is available in the FIFO buffer when the odd module's ICBNE bit (ICxCON1<3>) becomes set. Continue to read the buffer registers until ICBNE is cleared (performed automatically by hardware).

15.0 OUTPUT COMPARE WITH DEDICATED TIMERS

Note: This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “PIC24F Family Reference Manual”, “Output Compare with Dedicated Timer” (DS39723). The information in this data sheet supersedes the information in the FRM.

Devices in the PIC24FJ128GC010 family all feature seven independent output compare modules. Each of these modules offers a wide range of configuration and operating options for generating pulse trains on internal device events, and can produce Pulse-Width Modulated (PWM) waveforms for driving power applications.

Key features of the output compare module include:

- Hardware-configurable for 32-bit operation in all modes by cascading two adjacent modules
- Synchronous and Trigger modes of output compare operation, with up to 31 user-selectable trigger/sync sources available
- Two separate Period registers (a main register, OCxR, and a secondary register, OCxRS) for greater flexibility in generating pulses of varying widths
- Configurable for single pulse or continuous pulse generation on an output event, or continuous PWM waveform generation
- Up to 6 clock sources available for each module, driving a separate internal 16-bit counter

15.1 General Operating Modes

15.1.1 SYNCHRONOUS AND TRIGGER MODES

When the output compare module operates in a Free-Running mode, the internal 16-bit counter, OCxTMR, runs counts up continuously, wrapping around from 0xFFFF to 0x0000 on each overflow. Its period is synchronized to the selected external clock source. Compare or PWM events are generated each time a match between the internal counter and one of the Period registers occurs.

In Synchronous mode, the module begins performing its compare or PWM operation as soon as its selected clock source is enabled. Whenever an event occurs on the selected sync source, the module's internal counter is reset. In Trigger mode, the module waits for a sync event from another internal module to occur before allowing the counter to run.

Free-Running mode is selected by default or any time that the SYNCSEL<4:0> bits (OCxCON2<4:0>) are set to '00000'. Synchronous or Trigger modes are selected any time the SYNCSELx bits are set to any value except '00000'. The OCTRIG bit (OCxCON2<7>) selects either Synchronous or Trigger mode; setting the bit selects Trigger mode operation. In both modes, the SYNCSELx bits determine the sync/trigger source.

15.1.2 CASCADED (32-BIT) MODE

By default, each module operates independently with its own set of 16-bit Timer and Duty Cycle registers. To increase resolution, adjacent even and odd modules can be configured to function as a single 32-bit module. (For example, Modules 1 and 2 are paired, as are Modules 3 and 4, and so on.) The odd numbered module (OCx) provides the Least Significant 16 bits of the 32-bit register pairs and the even numbered module (OCy) provides the Most Significant 16 bits. Wrap-arounds of the OCx registers cause an increment of their corresponding OCy registers.

Cascaded operation is configured in hardware by setting the OC32 bit (OCxCON2<8>) for both modules. For more details on cascading, refer to the “PIC24F Family Reference Manual”, Section 35. “Output Compare with Dedicated Timer” (DS39723).

PIC24FJ128GC010 FAMILY

FIGURE 15-1: OUTPUT COMPARE x BLOCK DIAGRAM (16-BIT MODE)

15.2 Compare Operations

In Compare mode ([Figure 15-1](#)), the output compare module can be configured for single-shot or continuous pulse generation. It can also repeatedly toggle an output pin on each timer event.

To set up the module for compare operations:

1. Configure the OCx output for one of the available Peripheral Pin Select pins.
2. Calculate the required values for the OCxR and (for Double Compare modes) OCxRS Duty Cycle registers:
 - a) Determine the instruction clock cycle time. Take into account the frequency of the external clock to the timer source (if one is used) and the timer prescaler settings.
 - b) Calculate time to the rising edge of the output pulse relative to the timer start value (0000h).
 - c) Calculate the time to the falling edge of the pulse based on the desired pulse width and the time to the rising edge of the pulse.
3. Write the rising edge value to OCxR and the falling edge value to OCxRS.
4. Set the Timer Period register, PRy, to a value equal to or greater than the value in OCxRS.
5. Set the OCM<2:0> bits for the appropriate compare operation (= 0xx).
6. For Trigger mode operations, set OCTRIG to enable Trigger mode. Set or clear TRIGMODE to configure trigger operation and TRIGSTAT to select a hardware or software trigger. For Synchronous mode, clear OCTRIG.
7. Set the SYNCSEL<4:0> bits to configure the trigger or synchronization source. If free-running timer operation is required, set the SYNCSELx bits to '00000' (no sync/trigger source).
8. Select the time base source with the OCTSEL<2:0> bits. If necessary, set the TON bit for the selected timer, which enables the compare time base to count. Synchronous mode operation starts as soon as the time base is enabled; Trigger mode operation starts after a trigger source event occurs.

PIC24FJ128GC010 FAMILY

For 32-bit cascaded operation, these steps are also necessary:

1. Set the OC32 bits for both registers (OCyCON2<8>) and (OCxCON2<8>). Enable the even numbered module first to ensure the modules will start functioning in unison.
2. Clear the OCTRIG bit of the even module (OCyCON2<7>), so the module will run in Synchronous mode.
3. Configure the desired output and Fault settings for OCy.
4. Force the output pin for OCx to the output state by clearing the OCTRIS bit.
5. If Trigger mode operation is required, configure the trigger options in OCx by using the OCTRIG (OCxCON2<7>), TRIGMODE (OCxCON1<3>) and SYNCSELx (OCxCON2<4:0>) bits.
6. Configure the desired Compare or PWM mode of operation (OCM<2:0>) for OCy first, then for OCx.

Depending on the output mode selected, the module holds the OCx pin in its default state and forces a transition to the opposite state when OCxR matches the timer. In Double Compare modes, OCx is forced back to its default state when a match with OCxRS occurs. The OCxIF interrupt flag is set after an OCxR match in Single Compare modes and after each OCxRS match in Double Compare modes.

Single-shot pulse events only occur once, but may be repeated by simply rewriting the value of the OCxCON1 register. Continuous pulse events continue indefinitely until terminated.

15.3 Pulse-Width Modulation (PWM) Mode

In PWM mode, the output compare module can be configured for edge-aligned or center-aligned pulse waveform generation. All PWM operations are double-buffered (buffer registers are internal to the module and are not mapped into SFR space).

To configure the output compare module for PWM operation:

1. Configure the OCx output for one of the available Peripheral Pin Select pins.
2. Calculate the desired duty cycles and load them into the OCxR register.
3. Calculate the desired period and load it into the OCxRS register.
4. Select the current OCx as the synchronization source by writing 0x1F to the SYNCSEL<4:0> bits (OCxCON2<4:0>) and '0' to the OCTRIG bit (OCxCON2<7>).
5. Select a clock source by writing to the OCTSEL<2:0> bits (OCxCON1<12:10>).
6. Enable interrupts, if required, for the timer and output compare modules. The output compare interrupt is required for PWM Fault pin utilization.
7. Select the desired PWM mode in the OCM<2:0> bits (OCxCON1<2:0>).
8. Appropriate Fault inputs may be enabled by using the ENFLT<2:0> bits as described in [Register 15-1](#).
9. If a timer is selected as a clock source, set the selected timer prescale value. The selected timer's prescaler output is used as the clock input for the OCx timer and not the selected timer output.

Note: This peripheral contains input and output functions that may need to be configured by the Peripheral Pin Select. See [Section 11.4 "Peripheral Pin Select \(PPS\)"](#) for more information.

PIC24FJ128GC010 FAMILY

FIGURE 15-2: OUTPUT COMPARE x BLOCK DIAGRAM (DOUBLE-BUFFERED, 16-BIT PWM MODE)

15.3.1 PWM PERIOD

The PWM period is specified by writing to PRy, the Timer Period register. The PWM period can be calculated using Equation 15-1.

EQUATION 15-1: CALCULATING THE PWM PERIOD⁽¹⁾

$$\text{PWM Period} = [(PRy) + 1] \cdot T_{CY} \cdot (\text{Timer Prescale Value})$$

Where:

$$\text{PWM Frequency} = 1/[\text{PWM Period}]$$

Note 1: Based on $T_{CY} = T_{OSC} \cdot 2$; Doze mode and PLL are disabled.

Note: A PRy value of N will produce a PWM period of N + 1 time base count cycles. For example, a value of 7, written into the PRy register, will yield a period consisting of 8 time base cycles.

PIC24FJ128GC010 FAMILY

15.3.2 PWM DUTY CYCLE

The PWM duty cycle is specified by writing to the OCxRS and OCxR registers. The OCxRS and OCxR registers can be written to at any time, but the duty cycle value is not latched until a match between PRy and TMRy occurs (i.e., the period is complete). This provides a double buffer for the PWM duty cycle and is essential for glitchless PWM operation.

Some important boundary parameters of the PWM duty cycle include:

- If OCxR, OCxRS and PRy are all loaded with 0000h, the OCx pin will remain low (0% duty cycle).
- If OCxRS is greater than PRy, the pin will remain high (100% duty cycle).

See [Example 15-1](#) for PWM mode timing details. [Table 15-1](#) and [Table 15-2](#) show example PWM frequencies and resolutions for a device operating at 4 MIPS and 10 MIPS, respectively.

EQUATION 15-2: CALCULATION FOR MAXIMUM PWM RESOLUTION⁽¹⁾

$$\text{Maximum PWM Resolution (bits)} = \frac{\log_{10} \left(\frac{FCY}{FPWM \cdot (\text{Timer Prescale Value})} \right)}{\log_{10}^{(2)}} \text{ bits}$$

Note 1: Based on FCY = FOSC/2; Doze mode and PLL are disabled.

EXAMPLE 15-1: PWM PERIOD AND DUTY CYCLE CALCULATIONS⁽¹⁾

1. Find the Timer Period register value for a desired PWM frequency of 52.08 kHz, where FOSC = 8 MHz with PLL (32 MHz device clock rate) and a Timer2 prescaler setting of 1:1.

$$TCY = 2 * TOSC = 62.5 \text{ ns}$$

$$\text{PWM Period} = 1/\text{PWM Frequency} = 1/52.08 \text{ kHz} = 19.2 \text{ ms}$$

$$\text{PWM Period} = (PR2 + 1) * TCY * (\text{Timer2 Prescale Value})$$

$$19.2 \text{ ms} = (PR2 + 1) * 62.5 \text{ ns} * 1$$

$$PR2 = 306$$

2. Find the maximum resolution of the duty cycle that can be used with a 52.08 kHz frequency and a 32 MHz device clock rate:

$$\text{PWM Resolution} = \log_{10}(FCY/FPWM)/\log_{10}2 \text{ bits}$$

$$= (\log_{10}(16 \text{ MHz}/52.08 \text{ kHz})/\log_{10}2) \text{ bits}$$

$$= 8.3 \text{ bits}$$

Note 1: Based on TCY = 2 * TOSC; Doze mode and PLL are disabled.

PIC24FJ128GC010 FAMILY

NOTES:

16.0 SERIAL PERIPHERAL INTERFACE (SPI)

Note: This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “PIC24F Family Reference Manual”, “Serial Peripheral Interface (SPI)” (DS39699). The information in this data sheet supersedes the information in the FRM.

The Serial Peripheral Interface (SPI) module is a synchronous serial interface useful for communicating with other peripheral or microcontroller devices. These peripheral devices may be serial EEPROMs, shift registers, display drivers, A/D Converters, etc. The SPI module is compatible with the SPI and SIOP Motorola® interfaces. All devices of the PIC24FJ128GC010 family include two SPI modules.

The module supports operation in two buffer modes. In Standard Buffer mode, data is shifted through a single serial buffer. In Enhanced Buffer mode, data is shifted through an 8-level FIFO buffer.

Note: Do not perform Read/Modify/Write operations (such as bit-oriented instructions) on the SPIxBUF register in either Standard or Enhanced Buffer mode.

The module also supports a basic framed SPI protocol while operating in either Master or Slave mode. A total of four framed SPI configurations are supported.

The SPI serial interface consists of four pins:

- SDIx: Serial Data Input
- SDOx: Serial Data Output
- SCKx: Shift Clock Input or Output
- $\overline{\text{SSx}}$: Active-Low Slave Select or Frame Synchronization I/O Pulse

The SPI module can be configured to operate using 2, 3 or 4 pins. In the 3-pin mode, $\overline{\text{SSx}}$ is not used; in the 2-pin mode, both SDOx and $\overline{\text{SSx}}$ are not used.

Block diagrams of the module in Standard and Enhanced modes are shown in [Figure 16-1](#) and [Figure 16-2](#).

Note: In this section, the SPI modules are referred to together as SPIx, or separately as SPI1 or SPI2. Special Function Registers will follow a similar notation. For example, SPIxCON1 and SPIxCON2 refer to the control registers for any of the two SPI modules.

PIC24FJ128GC010 FAMILY

To set up the SPI module for the Standard Master mode of operation:

1. If using interrupts:
 - a) Clear the SPIxIF bit in the respective IFSx register.
 - b) Set the SPIxIE bit in the respective IECx register.
 - c) Write the SPIxIP bits in the respective IPCx register to set the interrupt priority.
2. Write the desired settings to the SPIxCON1 and SPIxCON2 registers with MSTEN (SPIxCON1<5>) = 1.
3. Clear the SPIROV bit (SPIxSTAT<6>).
4. Enable SPI operation by setting the SPIEN bit (SPIxSTAT<15>).
5. Write the data to be transmitted to the SPIxBUF register. Transmission (and reception) will start as soon as data is written to the SPIxBUF register.

To set up the SPI module for the Standard Slave mode of operation:

1. Clear the SPIxBUF register.
2. If using interrupts:
 - a) Clear the SPIxIF bit in the respective IFSx register.
 - b) Set the SPIxIE bit in the respective IECx register.
 - c) Write the SPIxIP bits in the respective IPCx register to set the interrupt priority.
3. Write the desired settings to the SPIxCON1 and SPIxCON2 registers with MSTEN (SPIxCON1<5>) = 0.
4. Clear the SMP bit.
5. If the CKE bit (SPIxCON1<8>) is set, then the SSx pin (SPIxCON1<7>) must be set to enable the SSx pin.
6. Clear the SPIROV bit (SPIxSTAT<6>).
7. Enable SPI operation by setting the SPIEN bit (SPIxSTAT<15>).

FIGURE 16-1: SPIx MODULE BLOCK DIAGRAM (STANDARD MODE)

PIC24FJ128GC010 FAMILY

To set up the SPI module for the Enhanced Buffer Master mode of operation:

1. If using interrupts:
 - a) Clear the SPIxIF bit in the respective IFSx register.
 - b) Set the SPIxIE bit in the respective IECx register.
 - c) Write the SPIxIP bits in the respective IPCx register.
2. Write the desired settings to the SPIxCON1 and SPIxCON2 registers with MSTEN (SPIxCON1<5>) = 1.
3. Clear the SPIROV bit (SPIxSTAT<6>).
4. Select Enhanced Buffer mode by setting the SPIBEN bit (SPIxCON2<0>).
5. Enable SPI operation by setting the SPIEN bit (SPIxSTAT<15>).
6. Write the data to be transmitted to the SPIxBUF register. Transmission (and reception) will start as soon as data is written to the SPIxBUF register.

To set up the SPI module for the Enhanced Buffer Slave mode of operation:

1. Clear the SPIxBUF register.
2. If using interrupts:
 - a) Clear the SPIxIF bit in the respective IFSx register.
 - b) Set the SPIxIE bit in the respective IECx register.
 - c) Write the SPIxIP bits in the respective IPCx register to set the interrupt priority.
3. Write the desired settings to the SPIxCON1 and SPIxCON2 registers with MSTEN (SPIxCON1<5>) = 0.
4. Clear the SMP bit.
5. If the CKE bit is set, then the SSx pin must be set, thus enabling the SSx pin.
6. Clear the SPIROV bit (SPIxSTAT<6>).
7. Select Enhanced Buffer mode by setting the SPIBEN bit (SPIxCON2<0>).
8. Enable SPI operation by setting the SPIEN bit (SPIxSTAT<15>).

 1 = Enables module and configures SCKx, SDOx, SDIx and \overline{SSx} as serial port pins
 0 = Disables module
- bit 14 **Unimplemented:** Read as '0'
- bit 13 **SPISIDL:** SPIx Stop in Idle Mode bit
 1 = Discontinues module operation when device enters Idle mode
 0 = Continues module operation in Idle mode
- bit 12-11 **Unimplemented:** Read as '0'
- bit 10-8 **SPIBEC<2:0>:** SPIx Buffer Element Count bits (valid in Enhanced Buffer mode)
Master mode:
 The number of SPI transfers pending.
Slave mode:
 The number of SPI transfers unread.
- bit 7 **SRMPT:** SPIx Shift Register (SPIxSR) Empty bit (valid in Enhanced Buffer mode)
 1 = SPIx Shift register is empty and ready to send or receive
 0 = SPIx Shift register is not empty
- bit 6 **SPIROV:** SPIx Receive Overflow Flag bit
 1 = A new byte/word is completely received and discarded; the user software has not read the previous data in the SPIxBUF register.
 0 = No overflow has occurred
- bit 5 **SRXMPT:** SPIx Receive FIFO Empty bit (valid in Enhanced Buffer mode)
 1 = Receive FIFO is empty
 0 = Receive FIFO is not empty
- bit 4-2 **SISEL<2:0>:** SPIx Buffer Interrupt Mode bits (valid in Enhanced Buffer mode)
 111 = Interrupt when the SPIx transmit buffer is full (SPITBF bit is set)
 110 = Interrupt when the last bit is shifted into SPIxSR; as a result, the TX FIFO is empty
 101 = Interrupt when the last bit is shifted out of SPIxSR; now the transmit is complete
 100 = Interrupt when one data is shifted into the SPIxSR; as a result, the TX FIFO has one open spot
 011 = Interrupt when the SPIx receive buffer is full (SPIRBF bit is set)
 010 = Interrupt when the SPIx receive buffer is 3/4 or more full
 001 = Interrupt when data is available in the receive buffer (SRMPT bit is set)
 000 = Interrupt when the last data in the receive buffer is read; as a result, the buffer is empty (SRXMPT bit is set)

Note 1: If SPIEN = 1, these functions must be assigned to available RPN/RPIN pins before use. See [Section 11.4 “Peripheral Pin Select \(PPS\)”](#) for more information.

PIC24FJ128GC010 FAMILY

REGISTER 16-1: SPIxSTAT: SPIx STATUS AND CONTROL REGISTER (CONTINUED)

- bit 1 **SPITBF:** SPIx Transmit Buffer Full Status bit
1 = Transmit has not yet started, SPIxTXB is full
0 = Transmit has started, SPIxTXB is empty
In Standard Buffer mode:
Automatically set in hardware when the CPU writes to the SPIxBUF location, loading the SPIxTXB. Automatically cleared in hardware when the SPIx module transfers data from SPIxTXB to SPIxSR.
In Enhanced Buffer mode:
Automatically set in hardware when the CPU writes to the SPIxBUF location, loading the last available buffer location. Automatically cleared in hardware when a buffer location is available for a CPU write.
- bit 0 **SPIRBF:** SPIx Receive Buffer Full Status bit
1 = Receive is complete, SPIxRXB is full
0 = Receive is not complete, SPIxRXB is empty
In Standard Buffer mode:
Automatically set in hardware when SPIx transfers data from SPIxSR to SPIxRXB. Automatically cleared in hardware when the core reads the SPIxBUF location, reading SPIxRXB.
In Enhanced Buffer mode:
Automatically set in hardware when SPIx transfers data from the SPIxSR to the buffer, filling the last unread buffer location. Automatically cleared in hardware when a buffer location is available for a transfer from SPIxSR.

Note 1: If SPIEN = 1, these functions must be assigned to available RPN/RPIN pins before use. See [Section 11.4 “Peripheral Pin Select \(PPS\)”](#) for more information.

NOTES:

17.0 INTER-INTEGRATED CIRCUIT™ (I²C™)

Note: This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “PIC24F Family Reference Manual”, “Inter-Integrated Circuit™ (I²C™)” (DS39702). The information in this data sheet supersedes the information in the FRM.

The Inter-Integrated Circuit™ (I²C™) module is a serial interface useful for communicating with other peripheral or microcontroller devices. These peripheral devices may be serial EEPROMs, display drivers, A/D Converters, etc.

The I²C module supports these features:

- Independent master and slave logic
- 7-bit and 10-bit device addresses
- General call address as defined in the I²C protocol
- Clock stretching to provide delays for the processor to respond to a slave data request
- Both 100 kHz and 400 kHz bus specifications
- Configurable address masking
- Multi-Master modes to prevent loss of messages in arbitration
- Bus Repeater mode, allowing the acceptance of all messages as a slave regardless of the address
- Automatic SCL

A block diagram of the module is shown in [Figure 17-1](#).

17.1 Communicating as a Master in a Single Master Environment

The details of sending a message in Master mode depends on the communications protocol for the device being communicated with. Typically, the sequence of events is as follows:

1. Assert a Start condition on SDAx and SCLx.
2. Send the I²C device address byte to the slave with a write indication.
3. Wait for and verify an Acknowledge from the slave.
4. Send the first data byte (sometimes known as the command) to the slave.
5. Wait for and verify an Acknowledge from the slave.
6. Send the serial memory address low byte to the slave.
7. Repeat Steps 4 and 5 until all data bytes are sent.
8. Assert a Repeated Start condition on SDAx and SCLx.
9. Send the device address byte to the slave with a read indication.
10. Wait for and verify an Acknowledge from the slave.
11. Enable master reception to receive serial memory data.
12. Generate an ACK or NACK condition at the end of a received byte of data.
13. Generate a Stop condition on SDAx and SCLx.

FIGURE 17-1: I²C™ BLOCK DIAGRAM

PIC24FJ128GC010 FAMILY

17.2 Setting Baud Rate When Operating as a Bus Master

To compute the Baud Rate Generator reload value, use Equation 17-1.

EQUATION 17-1: COMPUTING BAUD RATE RELOAD VALUE^(1,2)

$$FSCL = \frac{FCY}{I2CxBRG + 1 + \frac{FCY}{10,000,000}}$$

or:

$$I2CxBRG = \left(\frac{FCY}{FSCL} - \frac{FCY}{10,000,000} - 1 \right)$$

Note 1: Based on FCY = FOSC/2; Doze mode and PLL are disabled.

2: These clock rate values are for guidance only. The actual clock rate can be affected by various system-level parameters. The actual clock rate should be measured in its intended application.

17.3 Slave Address Masking

The I2CxMSK register (Register 17-3) designates address bit positions as “don’t care” for both 7-Bit and 10-Bit Addressing modes. Setting a particular bit location (= 1) in the I2CxMSK register causes the slave module to respond, whether the corresponding address bit value is a ‘0’ or a ‘1’. For example, when I2CxMSK is set to ‘00100000’, the slave module will detect both addresses, ‘0000000’ and ‘0100000’.

To enable address masking, the Intelligent Peripheral Management Interface (IPMI) must be disabled by clearing the IPMIEN bit (I2CxCON<11>).

Note: As a result of changes in the I²C™ protocol, the addresses in Table 17-2 are reserved and will not be Acknowledged in Slave mode. This includes any address mask settings that include any of these addresses.

TABLE 17-1: I²C™ CLOCK RATES^(1,2)

| Required System F _{SCL} | FCY | I2CxBRG Value | | Actual F _{SCL} |
|----------------------------------|--------|---------------|---------------|-------------------------|
| | | (Decimal) | (Hexadecimal) | |
| 100 kHz | 16 MHz | 157 | 9D | 100 kHz |
| 100 kHz | 8 MHz | 78 | 4E | 100 kHz |
| 100 kHz | 4 MHz | 39 | 27 | 99 kHz |
| 400 kHz | 16 MHz | 37 | 25 | 404 kHz |
| 400 kHz | 8 MHz | 18 | 12 | 404 kHz |
| 400 kHz | 4 MHz | 9 | 9 | 385 kHz |
| 400 kHz | 2 MHz | 4 | 4 | 385 kHz |
| 1 MHz | 16 MHz | 13 | D | 1.026 MHz |
| 1 MHz | 8 MHz | 6 | 6 | 1.026 MHz |
| 1 MHz | 4 MHz | 3 | 3 | 0.909 MHz |

Note 1: Based on FCY = FOSC/2; Doze mode and PLL are disabled.

2: These clock rate values are for guidance only. The actual clock rate can be affected by various system-level parameters. The actual clock rate should be measured in its intended application.

TABLE 17-2: I²C™ RESERVED ADDRESSES⁽¹⁾

| Slave Address | R/W Bit | Description |
|---------------|---------|--|
| 0000 000 | 0 | General Call Address ⁽²⁾ |
| 0000 000 | 1 | Start Byte |
| 0000 001 | x | CBus Address |
| 0000 01x | x | Reserved |
| 0000 1xx | x | HS Mode Master Code |
| 1111 0xx | x | 10-Bit Slave Upper Byte ⁽³⁾ |
| 1111 1xx | x | Reserved |

Note 1: The address bits listed here will never cause an address match, independent of address mask settings.

2: The address will be Acknowledged only if GCEN = 1.

3: A match on this address can only occur on the upper byte in 10-Bit Addressing mode.

- bit 15 **I2CEN:** I2Cx Enable bit
 1 = Enables the I2Cx module and configures the SDAx and SCLx pins as serial port pins
 0 = Disables the I2Cx module; all I²C™ pins are controlled by port functions
- bit 14 **Unimplemented:** Read as '0'
- bit 13 **I2CSIDL:** I2Cx Stop in Idle Mode bit
 1 = Discontinues module operation when device enters an Idle mode
 0 = Continues module operation in Idle mode
- bit 12 **SCLREL:** SCLx Release Control bit (when operating as I²C slave)
 1 = Releases SCLx clock
 0 = Holds SCLx clock low (clock stretch)
If STREN = 1:
 Bit is R/W (i.e., software may write '0' to initiate stretch and write '1' to release clock). Hardware is clear at the beginning of slave transmission. Hardware is clear at the end of slave reception.
If STREN = 0:
 Bit is R/S (i.e., software may only write '1' to release clock). Hardware is clear at the beginning of slave transmission.
- bit 11 **IPMIEN:** Intelligent Platform Management Interface (IPMI) Enable bit
 1 = IPMI Support mode is enabled; all addresses are Acknowledged
 0 = IPMI Support mode is disabled
- bit 10 **A10M:** 10-Bit Slave Addressing bit
 1 = I2CxADD is a 10-bit slave address
 0 = I2CxADD is a 7-bit slave address
- bit 9 **DISSLW:** Disable Slew Rate Control bit
 1 = Slew rate control is disabled
 0 = Slew rate control is enabled
- bit 8 **SMEN:** SMBus Input Levels bit
 1 = Enables I/O pin thresholds compliant with SMBus specifications
 0 = Disables the SMBus input thresholds
- bit 7 **GCEN:** General Call Enable bit (when operating as I²C slave)
 1 = Enables interrupt when a general call address is received in the I2CxRSR (module is enabled for reception)
 0 = General call address is disabled
- bit 6 **STREN:** SCLx Clock Stretch Enable bit (when operating as I²C slave)
 Used in conjunction with the SCLREL bit.
 1 = Enables software or receive clock stretching
 0 = Disables software or receive clock stretching

PIC24FJ128GC010 FAMILY

REGISTER 17-1: I2CxCON: I2Cx CONTROL REGISTER (CONTINUED)

- bit 5 **ACKDT:** Acknowledge Data bit (when operating as I²C master; applicable during master receive)
Value that will be transmitted when the software initiates an Acknowledge sequence.
1 = Sends NACK during Acknowledge
0 = Sends ACK during Acknowledge
- bit 4 **ACKEN:** Acknowledge Sequence Enable bit (when operating as I²C master; applicable during master receive)
1 = Initiates Acknowledge sequence on SDAx and SCLx pins and transmits the ACKDT data bit. Hardware is clear at the end of the master Acknowledge sequence.
0 = Acknowledge sequence is not in progress
- bit 3 **RCEN:** Receive Enable bit (when operating as I²C master)
1 = Enables Receive mode for I²C. Hardware is clear at the end of the eighth bit of the master receive data byte.
0 = Receive sequence is not in progress
- bit 2 **PEN:** Stop Condition Enable bit (when operating as I²C master)
1 = Initiates Stop condition on the SDAx and SCLx pins. Hardware is clear at the end of the master Stop sequence.
0 = Stop condition is not in progress
- bit 1 **RSEN:** Repeated Start Condition Enable bit (when operating as I²C master)
1 = Initiates Repeated Start condition on the SDAx and SCLx pins. Hardware is clear at the end of the master Repeated Start sequence.
0 = Repeated Start condition is not in progress
- bit 0 **SEN:** Start Condition Enable bit (when operating as I²C master)
1 = Initiates Start condition on SDAx and SCLx pins. Hardware is clear at the end of the master Start sequence.

- bit 15 **ACKSTAT:** Acknowledge Status bit
1 = NACK was detected last
0 = ACK was detected last
Hardware is set or cleared at the end of Acknowledge.
- bit 14 **TRSTAT:** Transmit Status bit (when operating as I²C™ master; applicable to master transmit operation)
1 = Master transmit is in progress (8 bits + ACK)
0 = Master transmit is not in progress
Hardware is set at the beginning of master transmission; hardware is clear at the end of slave Acknowledge.
- bit 13-11 **Unimplemented:** Read as '0'
- bit 10 **BCL:** Master Bus Collision Detect bit
1 = A bus collision has been detected during a master operation
0 = No bus collision
Hardware is set at the detection of a bus collision.
- bit 9 **GCSTAT:** General Call Status bit
1 = General call address was received
0 = General call address was not received
Hardware is set when the address matches the general call address; hardware is clear at Stop detection.
- bit 8 **ADD10:** 10-Bit Address Status bit
1 = 10-bit address was matched
0 = 10-bit address was not matched
Hardware is set at the match of the 2nd byte of the matched 10-bit address; hardware is clear at Stop detection.
- bit 7 **IWCOL:** Write Collision Detect bit
1 = An attempt to write to the I2CxTRN register failed because the I²C module is busy
0 = No collision
Hardware is set at an occurrence of a write to I2CxTRN while busy (cleared by software).
- bit 6 **I2COV:** I2Cx Receive Overflow Flag bit
1 = A byte was received while the I2CxRCV register is still holding the previous byte
0 = No overflow
Hardware is set at an attempt to transfer I2CxRSR to I2CxRCV (cleared by software).
- bit 5 **DAC:** Data/Address bit (when operating as I²C slave)
1 = Indicates that the last byte received was data
0 = Indicates that the last byte received was a device address
Hardware is clear at the device address match. Hardware is set after a transmission finishes or by reception of a slave byte.

REGISTER 17-2: I2CxSTAT: I2Cx STATUS REGISTER (CONTINUED)

- bit 4 **P:** Stop bit
 1 = Indicates that a Stop bit has been detected last
 0 = Stop bit was not detected last
 Hardware is set or clear when Start, Repeated Start or Stop is detected.
- bit 3 **S:** Start bit
 1 = Indicates that a Start (or Repeated Start) bit has been detected last
 0 = Start bit was not detected last
 Hardware is set or clear when Start, Repeated Start or Stop is detected.
- bit 2 **R/W:** Read/Write Information bit (when operating as I²C slave)
 1 = Read: Indicates the data transfer is output from the slave
 0 = Write: Indicates the data transfer is input to the slave
 Hardware is set or clear after the reception of an I²C device address byte.
- bit 1 **RBF:** Receive Buffer Full Status bit
 1 = Receive is complete, I2CxRCV is full
 0 = Receive is not complete, I2CxRCV is empty
 Hardware is set when I2CxRCV is written with the received byte; hardware is clear when the software reads I2CxRCV.
- bit 0 **TBF:** Transmit Buffer Full Status bit
 1 = Transmit is in progress, I2CxTRN is full
 0 = Transmit is complete, I2CxTRN is empty
 Hardware is set when software writes to I2CxTRN; hardware is clear at the completion of data transmission.

PIC24FJ128GC010 FAMILY

NOTES:

PIC24FJ128GC010 FAMILY

18.0 UNIVERSAL ASYNCHRONOUS RECEIVER TRANSMITTER (UART)

Note: This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “PIC24F Family Reference Manual”, “UART” (DS39708). The information in this data sheet supersedes the information in the FRM.

The Universal Asynchronous Receiver Transmitter (UART) module is one of the serial I/O modules available in the PIC24F device family. The UART is a full-duplex, asynchronous system that can communicate with peripheral devices, such as personal computers, LIN/J2602, RS-232 and RS-485 interfaces. The module also supports a hardware flow control option with the UxCTS and UxRTS pins, and includes an IrDA® encoder and decoder.

The primary features of the UARTx module are:

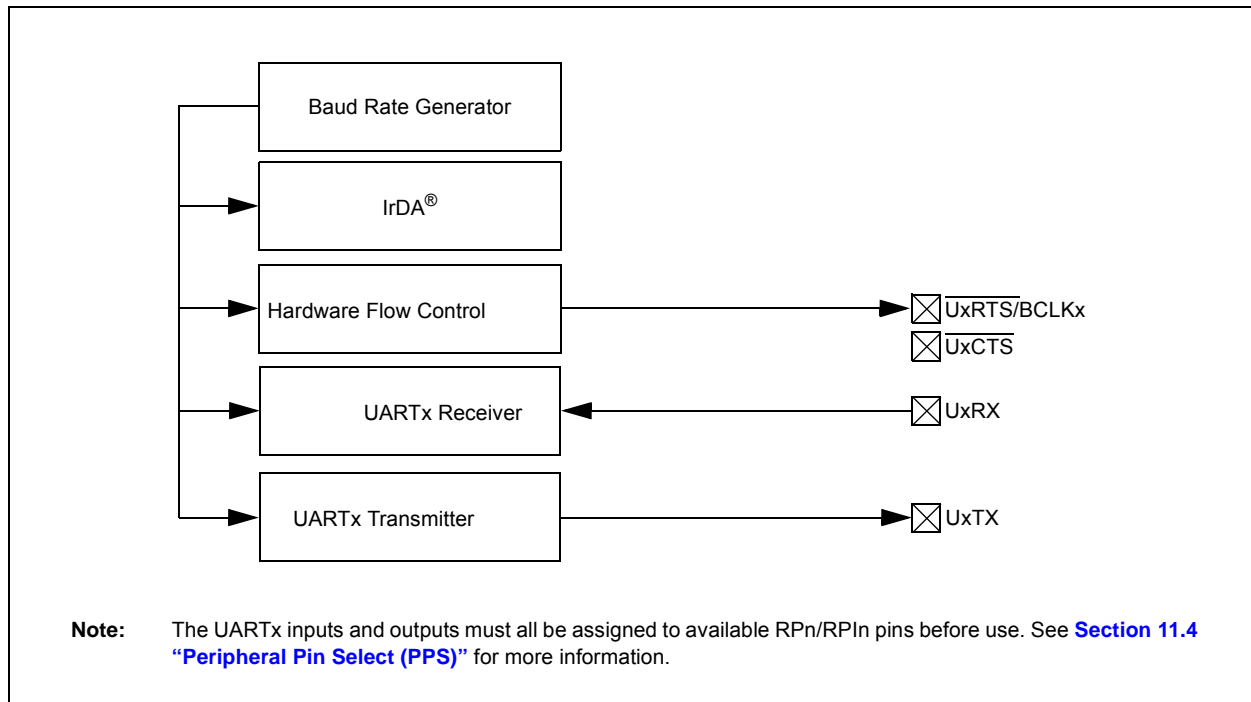

- Full-Duplex, 8 or 9-Bit Data Transmission Through the UxTX and UxRX Pins
- Even, Odd or No Parity Options (for 8-bit data)
- One or Two Stop bits
- Hardware Flow Control Option with the $\overline{\text{UxCTS}}$ and UxRTS Pins

- Fully Integrated Baud Rate Generator with 16-Bit Prescaler
- Baud Rates Ranging from 15 bps to 1 Mbps at 16 MIPS
- 4-Deep, First-In-First-Out (FIFO) Transmit Data Buffer
- 4-Deep FIFO Receive Data Buffer
- Parity, Framing and Buffer Overrun Error Detection
- Support for 9-Bit mode with Address Detect (9th bit = 1)
- Transmit and Receive Interrupts
- Loopback mode for Diagnostic Support
- Support for Sync and Break Characters
- Supports Automatic Baud Rate Detection
- IrDA® Encoder and Decoder Logic
- 16x Baud Clock Output for IrDA Support

A simplified block diagram of the UARTx is shown in Figure 18-1. The UARTx module consists of these key important hardware elements:

- Baud Rate Generator
- Asynchronous Transmitter
- Asynchronous Receiver

FIGURE 18-1: UARTx SIMPLIFIED BLOCK DIAGRAM

PIC24FJ128GC010 FAMILY

18.1 UARTx Baud Rate Generator (BRG)

The UARTx module includes a dedicated, 16-bit Baud Rate Generator. The UxBRG register controls the period of a free-running, 16-bit timer. Equation 18-1 shows the formula for computation of the baud rate with BRGH = 0.

EQUATION 18-1: UARTx BAUD RATE WITH BRGH = 0^(1,2)

$$\text{Baud Rate} = \frac{\text{FCY}}{16 \cdot (\text{UxBRG} + 1)}$$

$$\text{UxBRG} = \frac{\text{FCY}}{16 \cdot \text{Baud Rate}} - 1$$

- Note 1:** FCY denotes the instruction cycle clock frequency (FOSC/2).
- 2:** Based on FCY = FOSC/2; Doze mode and PLL are disabled.

Example 18-1 shows the calculation of the baud rate error for the following conditions:

- FCY = 4 MHz
- Desired Baud Rate = 9600

EXAMPLE 18-1: BAUD RATE ERROR CALCULATION (BRGH = 0)⁽¹⁾

$$\text{Desired Baud Rate} = \text{FCY}/(16 (\text{BRGx} + 1))$$

Solving for BRGx Value:

$$\text{BRGx} = ((\text{FCY}/\text{Desired Baud Rate})/16) - 1$$

$$\text{BRGx} = ((4000000/9600)/16) - 1$$

$$\text{BRGx} = 25$$

$$\begin{aligned} \text{Calculated Baud Rate} &= 4000000/(16 (25 + 1)) \\ &= 9615 \end{aligned}$$

$$\begin{aligned} \text{Error} &= (\text{Calculated Baud Rate} - \text{Desired Baud Rate})/\text{Desired Baud Rate} \\ &= (9615 - 9600)/9600 \\ &= 0.16\% \end{aligned}$$

- Note 1:** Based on FCY = FOSC/2; Doze mode and PLL are disabled.

The maximum baud rate (BRGH = 0) possible is FCY/16 (for UxBRG = 0) and the minimum baud rate possible is FCY/(16 * 65536).

Equation 18-2 shows the formula for computation of the baud rate with BRGH = 1.

EQUATION 18-2: UARTx BAUD RATE WITH BRGH = 1^(1,2)

$$\text{Baud Rate} = \frac{\text{FCY}}{4 \cdot (\text{UxBRG} + 1)}$$

$$\text{UxBRG} = \frac{\text{FCY}}{4 \cdot \text{Baud Rate}} - 1$$

- Note 1:** FCY denotes the instruction cycle clock frequency.
- 2:** Based on FCY = FOSC/2; Doze mode and PLL are disabled.

The maximum baud rate (BRGH = 1) possible is FCY/4 (for UxBRG = 0) and the minimum baud rate possible is FCY/(4 * 65536).

Writing a new value to the UxBRG register causes the BRG timer to be reset (cleared). This ensures the BRG does not wait for a timer overflow before generating the new baud rate.

18.2 Transmitting in 8-Bit Data Mode

1. Set up the UARTx:
 - a) Write appropriate values for data, parity and Stop bits.
 - b) Write appropriate baud rate value to the UxBRG register.
 - c) Set up transmit and receive interrupt enable and priority bits.
2. Enable the UARTx.
3. Set the UTXEN bit (causes a transmit interrupt, two cycles after being set).
4. Write a data byte to the lower byte of the UxTXREG word. The value will be immediately transferred to the Transmit Shift Register (TSR) and the serial bit stream will start shifting out with the next rising edge of the baud clock.
5. Alternatively, the data byte may be transferred while UTXEN = 0 and then the user may set UTXEN. This will cause the serial bit stream to begin immediately because the baud clock will start from a cleared state.
6. A transmit interrupt will be generated as per interrupt control bit, UTXISELx.

18.3 Transmitting in 9-Bit Data Mode

1. Set up the UARTx (as described in [Section 18.2 “Transmitting in 8-Bit Data Mode”](#)).
2. Enable the UARTx.
3. Set the UTXEN bit (causes a transmit interrupt).
4. Write UxTXREG as a 16-bit value only.
5. A word write to UxTXREG triggers the transfer of the 9-bit data to the TSR. The serial bit stream will start shifting out with the first rising edge of the baud clock.
6. A transmit interrupt will be generated as per the setting of control bit, UTXISELx.

18.4 Break and Sync Transmit Sequence

The following sequence will send a message frame header, made up of a Break, followed by an auto-baud Sync byte.

1. Configure the UARTx for the desired mode.
2. Set UTXEN and UTXBRK to set up the Break character.
3. Load the UxTXREG with a dummy character to initiate transmission (value is ignored).
4. Write '55h' to UxTXREG; this loads the Sync character into the transmit FIFO.
5. After the Break has been sent, the UTXBRK bit is reset by hardware. The Sync character now transmits.

18.5 Receiving in 8-Bit or 9-Bit Data Mode

1. Set up the UARTx (as described in [Section 18.2 “Transmitting in 8-Bit Data Mode”](#)).
2. Enable the UARTx.
3. A receive interrupt will be generated when one or more data characters have been received, as per interrupt control bit, URXISELx.
4. Read the OERR bit to determine if an overrun error has occurred. The OERR bit must be reset in software.
5. Read UxRXREG.

The act of reading the UxRXREG character will move the next character to the top of the receive FIFO, including a new set of PERR and FERR values.

18.6 Operation of $\overline{\text{UxCTS}}$ and $\overline{\text{UxRTS}}$ Control Pins

UARTx Clear-to-Send ($\overline{\text{UxCTS}}$) and Request-to-Send ($\overline{\text{UxRTS}}$) are the two hardware controlled pins that are associated with the UARTx module. These two pins allow the UARTx to operate in Simplex and Flow Control mode. They are implemented to control the transmission and reception between the Data Terminal Equipment (DTE). The UEN<1:0> bits in the UxMODE register configure these pins.

18.7 Infrared Support

The UARTx module provides two types of infrared UART support: one is the IrDA clock output to support an external IrDA encoder and decoder device (legacy module support), and the other is the full implementation of the IrDA encoder and decoder. Note that because the IrDA modes require a 16x baud clock, they will only work when the BRGH bit (UxMODE<3>) is '0'.

18.7.1 IrDA CLOCK OUTPUT FOR EXTERNAL IrDA SUPPORT

To support external IrDA encoder and decoder devices, the BCLKx pin (same as the UxRTS pin) can be configured to generate the 16x baud clock. With UEN<1:0> = 11, the BCLKx pin will output the 16x baud clock if the UARTx module is enabled. It can be used to support the IrDA codec chip.

18.7.2 BUILT-IN IrDA ENCODER AND DECODER

The UARTx has full implementation of the IrDA encoder and decoder as part of the UARTx module. The built-in IrDA encoder and decoder functionality is enabled using the IREN bit (UxMODE<12>). When enabled (IREN = 1), the receive pin (UxRX) acts as the input from the infrared receiver. The transmit pin (UxTX) acts as the output to the infrared transmitter.

PIC24FJ128GC010 FAMILY

NOTES:

PIC24FJ128GC010 FAMILY

19.0 UNIVERSAL SERIAL BUS WITH ON-THE-GO SUPPORT (USB OTG)

Note: This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “PIC24F Family Reference Manual”, “**USB On-The-Go (OTG)**” (DS39721). The information in this data sheet supersedes the information in the FRM.

PIC24FJ128GC010 family devices contain a full-speed and low-speed compatible, On-The-Go (OTG) USB Serial Interface Engine (SIE). The OTG capability allows the device to act as either a USB peripheral device or as a USB embedded host with limited host capabilities. The OTG capability allows the device to dynamically switch from device to host operation using OTG’s Host Negotiation Protocol (HNP).

For more details on OTG operation, refer to the “On-The-Go Supplement” to the “USB 2.0 Specification”, published by the USB-IF. For more details on USB operation, refer to the “Universal Serial Bus Specification”, v2.0.

The USB OTG module offers these features:

- USB functionality in Device and Host modes, and OTG capabilities for Application-Controlled mode switching
- Software-selectable module speeds of full speed (12 Mbps) or low speed (1.5 Mbps, available in Host mode only)
- Support for all four USB transfer types: control, interrupt, bulk and isochronous
- 16 bidirectional endpoints for a total of 32 unique endpoints
- DMA interface for data RAM access
- Queues up to sixteen unique endpoint transfers without servicing
- Integrated, on-chip USB transceiver with support for off-chip transceivers via a digital interface
- Integrated VBUS generation with on-chip comparators and boost generation, and support of external VBUS comparators and regulators through a digital interface
- Configurations for on-chip bus pull-up and pull-down resistors

A simplified block diagram of the USB OTG module is shown in [Figure 19-1](#).

The USB OTG module can function as a USB peripheral device or as a USB host, and may dynamically switch between Device and Host modes under software control. In either mode, the same data paths and Buffer Descriptors (BDs) are used for the transmission and reception of data.

In discussing USB operation, this section will use a controller-centric nomenclature for describing the direction of the data transfer between the microcontroller and the USB. RX (Receive) will be used to describe transfers that move data from the USB to the microcontroller and TX (Transmit) will be used to describe transfers that move data from the microcontroller to the USB. [Table 19-1](#) shows the relationship between data direction in this nomenclature and the USB tokens exchanged.

TABLE 19-1: CONTROLLER-CENTRIC DATA DIRECTION FOR USB HOST OR TARGET

| USB Mode | Direction | |
|----------|--------------|--------------|
| | RX | TX |
| Device | OUT or SETUP | IN |
| Host | IN | OUT or SETUP |

This chapter presents the most basic operations needed to implement USB OTG functionality in an application. A complete and detailed discussion of the USB protocol and its OTG supplement are beyond the scope of this data sheet. It is assumed that the user already has a basic understanding of USB architecture and the latest version of the protocol.

Not all steps for proper USB operation (such as device enumeration) are presented here. It is recommended that application developers use an appropriate device driver to implement all of the necessary features. Microchip provides a number of application-specific resources, such as USB firmware and driver support. Refer to www.microchip.com/usb for the latest firmware and driver support.

PIC24FJ128GC010 FAMILY

FIGURE 19-1: USB OTG MODULE BLOCK DIAGRAM

- Note 1:** Pins are multiplexed with digital I/O and other device features.
Note 2: Connecting VBUS3V3 to VDD is highly recommended, as floating this input can cause increased I_{PD} currents. The pin should be tied to VDD when the USB functions are not used.

PIC24FJ128GC010 FAMILY

19.1 Hardware Configuration

19.1.1 DEVICE MODE

19.1.1.1 D+ Pull-up Resistor

PIC24FJ128GC010 family devices have a built-in 1.5 k Ω resistor on the D+ line that is available when the microcontroller is operating in Device mode. This is used to signal an external host that the device is operating in Full-Speed Device mode. It is engaged by setting the USBEN bit (U1CON<0>) and powering up the USB module (USBPWR = 1). If the OTGEN bit (U1OTGCON<2>) is set, then the D+ pull-up is enabled through the DPPULUP bit (U1OTGCON<7>).

19.1.1.2 The VBUS Pin

In order to meet the USB 2.0 specification requirement, relating to the back drive voltage on the D+ /D- pins, the USB module incorporates VBUS level sensing comparators. When the comparators detect the VBUS level below the VA_SESS_VLD level, the hardware will automatically disable the D+ pull-up resistor described in [Section 19.1.1.1 “D+ Pull-up Resistor”](#). This allows the device to automatically meet the back drive requirement for D+ and D-, even if the application firmware does not explicitly monitor the VBUS level. Therefore, the VBUS microcontroller pin should not be left floating in USB Device mode application designs, and should normally be connected to the VBUS pin on the USB connector/cable (either directly or through a small resistance ≤ 100 ohms).

19.1.1.3 Power Modes

Many USB applications will likely have several different sets of power requirements and configuration. The most common power modes encountered are:

- Bus Power Only mode
- Self-Power Only mode
- Dual Power with Self-Power Dominance

Bus Power Only mode ([Figure 19-2](#)) is effectively the simplest method. All power for the application is drawn from the USB.

To meet the inrush current requirements of the “*USB 2.0 OTG Specification*”, the total effective capacitance, appearing across VBUS and ground, must be no more than 10 μ F.

In the USB Suspend mode, devices must consume no more than 2.5 mA from the 5V VBUS line of the USB cable. During the USB Suspend mode, the D+ or D- pull-up resistor must remain active, which will consume some of the allowed suspend current.

In Self-Power Only mode ([Figure 19-3](#)), the USB application provides its own power, with very little power being pulled from the USB. Note that an attach indication is added to indicate when the USB has been connected and the host is actively powering VBUS.

To meet compliance specifications, the USB module (and the D+ or D- pull-up resistor) should not be enabled until the host actively drives VBUS high. One of the 5.5V tolerant I/O pins may be used for this purpose.

The application should never source any current onto the 5V VBUS pin of the USB cable when the USB module is operated in USB Device mode.

The Dual Power mode with Self-Power Dominance ([Figure 19-4](#)) allows the application to use internal power primarily, but switch to power from the USB when no internal power is available. Dual power devices must also meet all of the special requirements for inrush current and Suspend mode current previously described, and must not enable the USB module until VBUS is driven high.

FIGURE 19-2: BUS-POWERED INTERFACE EXAMPLE

FIGURE 19-3: SELF-POWER ONLY

FIGURE 19-4: DUAL POWER EXAMPLE

PIC24FJ128GC010 FAMILY

19.1.2 HOST AND OTG MODES

19.1.2.1 D+ and D- Pull-Down Resistors

PIC24FJ128GC010 family devices have a built-in 15 kΩ pull-down resistor on the D+ and D- lines. These are used in tandem to signal to the bus that the microcontroller is operating in Host mode. They are engaged by setting the HOSTEN bit (U1CON<3>). If the OTGEN bit (U1OTGCON<2>) is set, then these pull-downs are enabled by setting the DPPULDWN and DMPULDWN bits (U1OTGCON<5:4>).

19.1.2.2 Power Configurations

In Host mode, as well as Host mode in On-The-Go operation, the “USB 2.0 OTG Specification” requires that the host application should supply power on VBUS. Since the microcontroller is running below VBUS, and is not able to source sufficient current, a separate power supply must be provided.

When the application is always operating in Host mode, a simple circuit can be used to supply VBUS and regulate current on the bus (Figure 19-5). For OTG operation, it is necessary to be able to turn VBUS on or off as needed, as the microcontroller switches between Device and Host modes. A typical example using an external charge pump is shown in Figure 19-6.

FIGURE 19-5: HOST INTERFACE EXAMPLE

FIGURE 19-6: OTG INTERFACE EXAMPLE

PIC24FJ128GC010 FAMILY

19.1.3 USING AN EXTERNAL INTERFACE

Some applications may require the USB interface to be isolated from the rest of the system. PIC24FJ128GC010 family devices include a complete interface to communicate with and control an external USB transceiver, including the control of data line pull-ups and pull-downs. The VBUS voltage generation control circuit can also be configured for different VBUS generation topologies.

Refer to the “*PIC24F Family Reference Manual*”, **Section 27. “USB On-The-Go (OTG)”** for information on using the external interface.

19.1.4 CALCULATING TRANSCEIVER POWER REQUIREMENTS

The USB transceiver consumes a variable amount of current depending on the characteristic impedance of the USB cable, the length of the cable, the VUSB supply voltage and the actual data patterns moving across the USB cable. Longer cables have larger capacitances and consume more total energy when switching output states. The total transceiver current consumption will be application-specific. [Equation 19-1](#) can help estimate how much current actually may be required in full-speed applications.

Refer to the “*PIC24F Family Reference Manual*”, **Section 27. “USB On-The-Go (OTG)”** for a complete discussion on transceiver power consumption.

EQUATION 19-1: ESTIMATING USB TRANSCEIVER CURRENT CONSUMPTION

$$I_{XCVR} = \frac{40 \text{ mA} \cdot V_{USB} \cdot P_{ZERO} \cdot P_{IN} \cdot L_{CABLE}}{3.3\text{V} \cdot 5\text{m}} + I_{PULLUP}$$

Legend: V_{USB} – Voltage applied to the VUSB3V3 pin in volts (3.0V to 3.6V).

P_{ZERO} – Percentage (in decimal) of the IN traffic bits sent by the PIC[®] microcontroller that are a value of ‘0’.

P_{IN} – Percentage (in decimal) of total bus bandwidth that is used for IN traffic.

L_{CABLE} – Length (in meters) of the USB cable. The “*USB 2.0 OTG Specification*” requires that full-speed applications use cables no longer than 5m.

I_{PULLUP} – Current which the nominal, 1.5 kΩ pull-up resistor (when enabled) must supply to the USB cable.

PIC24FJ128GC010 FAMILY

19.2 USB Buffer Descriptors and the BDT

Endpoint buffer control is handled through a structure called the Buffer Descriptor Table (BDT). This provides a flexible method for users to construct and control endpoint buffers of various lengths and configurations.

The BDT can be located in any available 512-byte, aligned block of data RAM. The BDT Pointer (U1BDTP1) contains the upper address byte of the BDT and sets the location of the BDT in RAM. The user must set this pointer to indicate the table's location.

The BDT is composed of Buffer Descriptors (BDs) which are used to define and control the actual buffers in the USB RAM space. Each BD consists of two 16-bit, "soft" (non-fixed-address) registers, BDNSTAT and BDNADR, where n represents one of the 64 possible BDs (range of 0 to 63). BDNSTAT is the status register for BDN, while BDNADR specifies the starting address for the buffer associated with BDN.

Note: Since BDNADR is a 16-bit register, only the first 64 Kbytes of RAM can be accessed by the USB module.

Depending on the endpoint buffering configuration used, there are up to 64 sets of Buffer Descriptors, for a total of 256 bytes. At a minimum, the BDT must be at least 8 bytes long. This is because the "USB 2.0 OTG Specification" mandates that every device must have Endpoint 0 with both input and output for initial setup.

Endpoint mapping in the BDT is dependent on three variables:

- Endpoint number (0 to 15)
- Endpoint direction (RX or TX)
- Ping-pong settings (U1CNFG1<1:0>)

Figure 19-7 illustrates how these variables are used to map endpoints in the BDT.

In Host mode, only Endpoint 0 Buffer Descriptors are used. All transfers utilize the Endpoint 0 Buffer Descriptor and Endpoint Control register (U1EP0). For received packets, the attached device's source endpoint is indicated by the value of ENDPT<3:0> in the USB status register (U1STAT<7:4>). For transmitted packets, the attached device's destination endpoint is indicated by the value written to the Token register (U1TOK).

FIGURE 19-7: BDT MAPPING FOR ENDPOINT BUFFERING MODES

PIC24FJ128GC010 FAMILY

BDs have a fixed relationship to a particular endpoint, depending on the buffering configuration. [Table 19-2](#) provides the mapping of BDs to endpoints. This relationship also means that gaps may occur in the BDT if endpoints are not enabled contiguously. This, theoretically, means that the BDs for disabled endpoints could be used as buffer space. In practice, users should avoid using such spaces in the BDT unless a method of validating BD addresses is implemented.

19.2.1 BUFFER OWNERSHIP

Because the buffers and their BDs are shared between the CPU and the USB module, a simple semaphore mechanism is used to distinguish which is allowed to update the BD and associated buffers in memory. This is done by using the UOWN bit as a semaphore to distinguish which is allowed to update the BD and associated buffers in memory. UOWN is the only bit that is shared between the two configurations of BDnSTAT.

When UOWN is clear, the BD entry is “owned” by the microcontroller core. When the UOWN bit is set, the BD entry and the buffer memory are “owned” by the USB peripheral. The core should not modify the BD or its

corresponding data buffer during this time. Note that the microcontroller core can still read BDnSTAT while the SIE owns the buffer and vice versa.

The Buffer Descriptors have a different meaning based on the source of the register update. [Register 19-1](#) and [Register 19-2](#) show the differences in BDnSTAT depending on its current “ownership”.

When UOWN is set, the user can no longer depend on the values that were written to the BDs. From this point, the USB module updates the BDs as necessary, overwriting the original BD values. The BDnSTAT register is updated by the SIE with the token PID and the transfer count is updated.

19.2.2 DMA INTERFACE

The USB OTG module uses a dedicated DMA to access both the BDT and the endpoint data buffers. Since part of the address space of the DMA is dedicated to the Buffer Descriptors, a portion of the memory connected to the DMA must comprise a contiguous address space, properly mapped for the access by the module.

TABLE 19-2: ASSIGNMENT OF BUFFER DESCRIPTORS FOR THE DIFFERENT BUFFERING MODES

| Endpoint | BDs Assigned to Endpoint | | | | | | | |
|----------|--------------------------|----|----------------------------------|----|----------------------------------|----------------|--|----------------|

- bit 15 **UOWN:** USB Own bit
 1 = The USB module owns the BD and its corresponding buffer; the CPU must not modify the BD or the buffer
- bit 14 **DTS:** Data Toggle Packet bit
 1 = Data 1 packet
 0 = Data 0 packet
- bit 13-10 **PID<3:0>:** Packet Identifier bits (written by the USB module)
In Device mode:
 Represents the PID of the received token during the last transfer.
In Host mode:
 Represents the last returned PID or the transfer status indicator.
- bit 9-0 **BC<9:0>:** Byte Count bits
 This represents the number of bytes to be transmitted or the maximum number of bytes to be received during a transfer. Upon completion, the byte count is updated by the USB module with the actual number of bytes transmitted or received.

1 = Data 1 packet
0 = Data 0 packet
- bit 13-12 **Reserved:** Maintain as '0'
- bit 11 **DTSEN:** Data Toggle Synchronization Enable bit
1 = Data toggle synchronization is enabled; data packets with incorrect Sync value will be ignored
0 = No data toggle synchronization is performed
- bit 10 **BSTALL:** Buffer STALL Enable bit
1 = Buffer STALL is enabled; STALL handshake issued if a token is received that would use the BD in the given location (UOWN bit remains set, BD value is unchanged); corresponding EPSTALL bit will get set on any STALL handshake
0 = Buffer STALL is disabled
- bit 9-0 **BC<9:0>:** Byte Count bits
This represents the number of bytes to be transmitted or the maximum number of bytes to be received during a transfer. Upon completion, the byte count is updated by the USB module with the actual number of bytes transmitted or received.

Note 1: This bit is ignored unless DTSEN = 1.

PIC24FJ128GC010 FAMILY

19.3 USB Interrupts

The USB OTG module has many conditions that can be configured to cause an interrupt. All interrupt sources use the same interrupt vector.

Figure 19-8 shows the interrupt logic for the USB module. There are two layers of interrupt registers in the USB module. The top level consists of overall USB status interrupts; these are enabled and flagged in the U1IE and U1IR registers, respectively. The second level consists of USB error conditions, which are enabled and flagged in the U1EIR and U1EIE registers.

An interrupt condition in any of these triggers a USB Error Interrupt Flag (UERRIF) in the top level. Unlike the device-level interrupt flags in the IFSx registers, USB interrupt flags in the U1IR registers can only be cleared by writing a '1' to the bit position.

Interrupts may be used to trap routine events in a USB transaction. Figure 19-9 provides some common events within a USB frame and their corresponding interrupts.

FIGURE 19-8: USB OTG INTERRUPT FUNNEL

PIC24FJ128GC010 FAMILY

19.3.1 CLEARING USB OTG INTERRUPTS

Unlike device level interrupts, the USB OTG interrupt status flags are not freely writable in software. All USB OTG flag bits are implemented as hardware set only bits. Additionally, these bits can only be cleared in software by writing a '1' to their locations (i.e., performing a MOV type instruction). Writing a '0' to a flag bit (i.e., a BCLR instruction) has no effect.

Note: Throughout this data sheet, a bit that can only be cleared by writing a '1' to its location is referred to as "Write 1 to clear". In register descriptions, this function is indicated by the descriptor, "K".

FIGURE 19-9: EXAMPLE OF A USB TRANSACTION AND INTERRUPT EVENTS

19.4 Device Mode Operation

The following section describes how to perform a common Device mode task. In Device mode, USB transfers are performed at the transfer level. The USB module automatically performs the status phase of the transfer.

19.4.1 ENABLING DEVICE MODE

1. Reset the Ping-Pong Buffer Pointers by setting, then clearing, the Ping-Pong Buffer Reset bit, PPBRST (U1CON<1>).
2. Disable all interrupts (U1IE and U1EIE = 00h).
3. Clear any existing interrupt flags by writing FFh to U1IR and U1EIR.
4. Verify that VBUS is present (non-OTG devices only).
5. Enable the USB module by setting the USBEN bit (U1CON<0>).
6. Set the OTGEN bit (U1OTGCON<2>) to enable OTG operation.
7. Enable the endpoint zero buffer to receive the first setup packet by setting the EPRXEN and EPHSHK bits for Endpoint 0 (U1EP0<3,0> = 1).
8. Power up the USB module by setting the USBPWR bit (U1PWRC<0>).
9. Enable the D+ pull-up resistor to signal an attach by setting the DPPULUP bit (U1OTGCON<7>).

PIC24FJ128GC010 FAMILY

19.4.2 RECEIVING AN IN TOKEN IN DEVICE MODE

1. Attach to a USB host and enumerate as described in Chapter 9 of the *“USB 2.0 Specification”*.
2. Create a data buffer and populate it with the data to send to the host.
3. In the appropriate (even or odd) TX BD for the desired endpoint:
 - a) Set up the status register (BDnSTAT) with the correct data toggle (DATA0/1) value and the byte count of the data buffer.
 - b) Set up the address register (BDnADR) with the starting address of the data buffer.
 - c) Set the UOWN bit of the status register to ‘1’.
4. When the USB module receives an IN token, it automatically transmits the data in the buffer. Upon completion, the module updates the status register (BDnSTAT) and sets the Token Complete Interrupt Flag, TRNIF (U1IR<3>).

19.4.3 RECEIVING AN OUT TOKEN IN DEVICE MODE

1. Attach to a USB host and enumerate as described in Chapter 9 of the *“USB 2.0 Specification”*.
2. Create a data buffer with the amount of data you are expecting from the host.
3. In the appropriate (even or odd) TX BD for the desired endpoint:
 - a) Set up the status register (BDnSTAT) with the correct data toggle (DATA0/1) value and the byte count of the data buffer.
 - b) Set up the address register (BDnADR) with the starting address of the data buffer.
 - c) Set the UOWN bit of the status register to ‘1’.
4. When the USB module receives an OUT token, it automatically receives the data sent by the host to the buffer. Upon completion, the module updates the status register (BDnSTAT) and sets the Token Complete Interrupt Flag, TRNIF (U1IR<3>).

19.5 Host Mode Operation

The following sections describe how to perform common Host mode tasks. In Host mode, USB transfers are invoked explicitly by the host software. The host software is responsible for the Acknowledge portion of the transfer. Also, all transfers are performed using the Endpoint 0 Control register (U1EP0) and Buffer Descriptors.

19.5.1 ENABLE HOST MODE AND DISCOVER A CONNECTED DEVICE

1. Enable Host mode by setting the HOSTEN bit (U1CON<3>). This causes the Host mode control bits in other USB OTG registers to become available.
2. Enable the D+ and D- pull-down resistors by setting the DPPULDWN and DMPULDWN bits (U1OTGCON<5:4>). Disable the D+ and D-pull-up resistors by clearing the DPPULUP and DMPULUP bits (U1OTGCON<7:6>).
3. At this point, SOF generation begins with the SOF counter loaded with 12,000. Eliminate noise on the USB by clearing the SOFEN bit (U1CON<0>) to disable Start-of-Frame (SOF) packet generation.
4. Enable the device attached interrupt by setting the ATTACHIE bit (U1IE<6>).
5. Wait for the device attached interrupt (U1IR<6> = 1). This is signaled by the USB device changing the state of D+ or D- from ‘0’ to ‘1’ (SE0 to J-state). After it occurs, wait 100 ms for the device power to stabilize.
6. Check the state of the JSTATE and SE0 bits in U1CON. If the JSTATE bit (U1CON<7>) is ‘0’, the connecting device is low speed. If the connecting device is low speed, set the low LSPDEN and LSPD bits (U1ADDR<7> and U1EP0<7>) to enable low-speed operation.
7. Reset the USB device by setting the USBRST bit (U1CON<4>) for at least 50 ms, sending Reset signaling on the bus. After 50 ms, terminate the Reset by clearing USBRST.
8. In order to keep the connected device from going into suspend, enable the SOF packet generation by setting the SOFEN bit.
9. Wait 10 ms for the device to recover from Reset.
10. Perform enumeration as described by Chapter 9 of the *“USB 2.0 Specification”*.

PIC24FJ128GC010 FAMILY

19.5.2 COMPLETE A CONTROL TRANSACTION TO A CONNECTED DEVICE

1. Follow the procedure described in [Section 19.5.1 “Enable Host Mode and Discover a Connected Device”](#) to discover a device.
2. Set up the Endpoint Control register for bidirectional control transfers by writing 0Dh to U1EP0 (this sets the EPCONDIS, EPTXEN and EPHSHK bits).
3. Place a copy of the device framework setup command in a memory buffer. See Chapter 9 of the *“USB 2.0 Specification”* for information on the device framework command set.
4. Initialize the Buffer Descriptor (BD) for the current (even or odd) TX EP0 to transfer the eight bytes of command data for a device framework command (i.e., GET_DEVICE_DESCRIPTOR):
 - a) Set the BD Data Buffer Address (BD0ADR) to the starting address of the 8-byte memory buffer containing the command.
 - b) Write 8008h to BD0STAT (this sets the UOWN bit and sets a byte count of 8).
5. Set the USB device address of the target device in the address register (U1ADDR<6:0>). After a USB bus Reset, the device USB address will be zero. After enumeration, it will be set to another value between 1 and 127.
6. Write D0h to U1TOK; this is a SETUP token to Endpoint 0, the target device’s default control pipe. This initiates a SETUP token on the bus, followed by a data packet. The device handshake is returned in the PID field of BD0STAT after the packets are complete. When the USB module updates BD0STAT, a Token Complete Interrupt Flag is asserted (the TRNIF flag is set). This completes the setup phase of the setup transaction, as referenced in Chapter 9 of the *“USB 2.0 Specification”*.
7. To initiate the data phase of the setup transaction (i.e., get the data for the GET_DEVICE_DESCRIPTOR command), set up a buffer in memory to store the received data.
8. Initialize the current (even or odd) RX or TX (RX for IN, TX for OUT) EP0 BD to transfer the data.
 - a) Write C040h to BD0STAT. This sets the UOWN, configures Data Toggle (DTS) to DATA1 and sets the byte count to the length of the data buffer (64 or 40h in this case).
 - b) Set BD0ADR to the starting address of the data buffer.
9. Write the Token register with the appropriate IN or OUT token to Endpoint 0, the target device’s default control pipe (e.g., write 90h to U1TOK for an IN token for a GET_DEVICE_DESCRIPTOR command). This initiates an IN token on the bus, followed by a data packet from the device to the host. When the data packet completes, the BD0STAT is written and a Token Complete Interrupt Flag is asserted (the TRNIF flag is set). For control transfers with a single packet data phase, this completes the data phase of the setup transaction, as referenced in Chapter 9 of the *“USB 2.0 Specification”*. If more data needs to be transferred, return to Step 8.
10. To initiate the status phase of the setup transaction, set up a buffer in memory to receive or send the zero length status phase data packet.
11. Initialize the current (even or odd) TX EP0 BD to transfer the status data:
 - a) Set the BDT buffer address field to the start address of the data buffer.
 - b) Write 8000h to BD0STAT (set UOWN bit, configure DTS to DATA0 and set byte count to 0).
12. Write the Token register with the appropriate IN or OUT token to Endpoint 0, the target device’s default control pipe (e.g., write 01h to U1TOK for an OUT token for a GET_DEVICE_DESCRIPTOR command). This initiates an OUT token on the bus, followed by a zero length data packet from the host to the device. When the data packet completes, the BD is updated with the handshake from the device and a Token Complete Interrupt Flag is asserted (the TRNIF flag is set). This completes the status phase of the setup transaction, as described in Chapter 9 of the *“USB 2.0 Specification”*.

Note: Only one control transaction can be performed per frame.

PIC24FJ128GC010 FAMILY

19.5.3 SEND A FULL-SPEED BULK DATA TRANSFER TO A TARGET DEVICE

1. Follow the procedure described in [Section 19.5.1 “Enable Host Mode and Discover a Connected Device”](#) and [Section 19.5.2 “Complete a Control Transaction to a Connected Device”](#) to discover and configure a device.
2. To enable transmit and receive transfers with handshaking enabled, write 1Dh to U1EP0. If the target device is a low-speed device, also set the LSPD (U1EP0<7>) bit. If you want the hardware to automatically retry indefinitely if the target device asserts a NAK on the transfer, clear the Retry Disable bit, RETRYDIS (U1EP0<6>).
3. Set up the BD for the current (even or odd) TX EP0 to transfer up to 64 bytes.
4. Set the USB device address of the target device in the address register (U1ADDR<6:0>).
5. Write an OUT token to the desired endpoint to U1TOK. This triggers the module's transmit state machines to begin transmitting the token and the data.
6. Wait for the Token Complete Interrupt Flag, TRNIF. This indicates that the BD has been released back to the microprocessor and the transfer has completed. If the Retry Disable bit (RETRYDIS) is set, the handshake (ACK, NAK, STALL or ERROR (0Fh)) is returned in the BD PID field. If a STALL interrupt occurs, the pending packet must be dequeued and the error condition in the target device cleared. If a detach interrupt occurs (SE0 for more than 2.5 μ s), then the target has detached (U1IR<0> is set).
7. Once the Token Complete Interrupt Flag occurs (TRNIF is set), the BD can be examined and the next data packet queued by returning to Step 2.

Note: USB speed, transceiver and pull-ups should only be configured during the module setup phase. It is not recommended to change these settings while the module is enabled.

19.6 OTG Operation

19.6.1 SESSION REQUEST PROTOCOL (SRP)

An OTG A-device may decide to power down the VBUS supply when it is not using the USB link through the Session Request Protocol (SRP). Software may do this by configuring a GPIO pin to disable an external power transistor, or voltage regulator enable signal, which controls the VBUS supply. When the VBUS supply is powered down, the A-device is said to have ended a USB session.

An OTG A-device or embedded host may repower the VBUS supply at any time (initiate a new session). An OTG B-device may also request that the OTG A-device repower the VBUS supply (initiate a new session). This is accomplished via Session Request Protocol (SRP).

Prior to requesting a new session, the B-device must first check that the previous session has definitely ended. To do this, the B-device must check for two conditions:

1. VBUS supply is below the session valid voltage.
2. Both D+ and D- have been low for at least 2 ms.

The B-device will be notified of Condition 1 by the SESENDIF (U1OTGIR<2>) interrupt. Software will have to manually check for Condition 2.

Note: When the A-device powers down the VBUS supply, the B-device must disconnect its pull-up resistor from power. If the device is self-powered, it can do this by clearing DPPULUP (U1OTGCON<7>) and DMPULUP (U1OTGCON<6>).

The B-device may aid in achieving Condition 1 by discharging the VBUS supply through a resistor. Software may do this by setting VBUSDIS (U1OTGCON<0>).

After these initial conditions are met, the B-device may begin requesting the new session. The B-device begins by pulsing the D+ data line. Software should do this by setting DPPULUP (U1OTGCON<7>). The data line should be held high for 5 to 10 ms.

The B-device then proceeds by pulsing the VBUS supply. Software should do this by setting PUVBUS (U1CNFG2<4>). When an A-device detects SRP signaling (either via the ATTACHIF (U1IR<6>) interrupt or via the SESVDIF (U1OTGIR<3>) interrupt), the A-device must restore the VBUS supply by properly configuring the general purpose I/O port pin controlling the external power source.

The B-device should not monitor the state of the VBUS supply while performing VBUS supply pulsing. When the B-device does detect that the VBUS supply has been restored (via the SESVDIF (U1OTGIR<3>) interrupt), the B-device must reconnect to the USB link by pulling up D+ or D- (via the DPPULUP or DMPULUP bit).

The A-device must complete the SRP by driving USB Reset signaling.

PIC24FJ128GC010 FAMILY

19.6.2 HOST NEGOTIATION PROTOCOL (HNP)

In USB OTG applications, a Dual Role Device (DRD) is a device that is capable of being either a host or a peripheral. Any OTG DRD must support Host Negotiation Protocol (HNP).

HNP allows an OTG B-device to temporarily become the USB host. The A-device must first enable the B-device to follow HNP. Refer to the “*On-The-Go Supplement*” to the “*USB 2.0 Specification*” for more information regarding HNP. HNP may only be initiated at full speed.

After being enabled for HNP by the A-device, the B-device requests being the host any time that the USB link is in suspend state, by simply indicating a disconnect. This can be done in software by clearing DPPULUP and DMPULUP. When the A-device detects the disconnect condition (via the URSTIF (U1IR<0>) interrupt), the A-device may allow the B-device to take over as host. The A-device does this by signaling connect as a full-speed function. Software may accomplish this by setting DPPULUP.

If the A-device responds instead with resume signaling, the A-device remains as host. When the B-device detects the connect condition (via ATTACHIF (U1IR<6>)), the B-device becomes host. The B-device drives Reset signaling prior to using the bus.

When the B-device has finished in its role as host, it stops all bus activity and turns on its D+ pull-up resistor by setting DPPULUP. When the A-device detects a suspend condition (Idle for 3 ms), the A-device turns off its D+ pull-up. The A-device may also power down the VBUS supply to end the session. When the A-device detects the connect condition (via ATTACHIF), the A-device resumes host operation and drives Reset signaling.

19.6.3 EXTERNAL VBUS COMPARATORS

The external VBUS comparator option is enabled by setting the UVCMPDIS bit (U1CNFG2<1>). This disables the internal VBUS comparators, removing the need to attach VBUS to the microcontroller’s VBUS pin.

The external comparator interface uses either the VCOMPST1 and VCOMPST2 pins, or the VBUSVLD, SESSVLD and SESSEND pins, based upon the setting of the UVCMPSEL bit (U1CNFG2<5>). These pins are digital inputs and should be set in the following patterns (see Table 19-3), based on the current level of the VBUS voltage.

TABLE 19-3: EXTERNAL VBUS COMPARATOR STATES

| If UVCMPSEL = 0 | | | |
|-----------------|----------|----------------------------------|----------------------------------|
| VCOMPST1 | VCOMPST2 | Bus Condition | |
| 0 | 0 | VBUS < VB_SESS_END | |
| 1 | 0 | VB_SESS_END < VBUS < VA_SESS_VLD | |
| 0 | 1 | VA_SESS_VLD < VBUS < VA_VBUS_VLD | |
| 1 | 1 | VBUS > VBUS_VLD | |
| If UVCMPSEL = 1 | | | |
| VBUSVLD | SESSVLD | SESSEND | Bus Condition |
| 0 | 0 | 1 | VBUS < VB_SESS_END |
| 0 | 0 | 0 | VB_SESS_END < VBUS < VA_SESS_VLD |
| 0 | 1 | 0 | VA_SESS_VLD < VBUS < VA_VBUS_VLD |
| 1 | 1 | 0 | VBUS > VBUS_VLD |

PIC24FJ128GC010 FAMILY

19.7 USB OTG Module Registers

There are a total of 37 memory mapped registers associated with the USB OTG module. They can be divided into four general categories:

- USB OTG Module Control (12)
- USB Interrupt (7)
- USB Endpoint Management (16)
- USB VBus Power Control (2)

This total does not include the (up to) 128 BD registers in the BDT. Their prototypes, described in [Register 19-1](#) and [Register 19-2](#), are shown separately in [Section 19.2 “USB Buffer Descriptors and the BDT”](#).

All USB OTG registers are implemented in the Least Significant Byte (LSB) of the register. Bits in the upper byte are unimplemented and have no function. Note that some registers are instantiated only in Host mode, while other registers have different bit instantiations and functions in Device and Host modes.

The registers described in the following sections are those that have bits with specific control and configuration features. The following registers are used for data or address values only:

- U1BDTP1: Specifies the 256-word page in data RAM used for the BDT; 8-bit value with bit 0 fixed as '0' for boundary alignment.
- U1FRML and U1FRMH: Contain the 11-bit byte counter for the current data frame.

| | | x = Bit is unknown |

bit 15-8 **Unimplemented:** Read as '0'

bit 7 **UACTPND:** USB Activity Pending bit

- 1 = Module should not be suspended at the moment (requires the USLPGRD bit to be set)
- 0 = Module may be suspended or powered down

bit 6-5 **Unimplemented:** Read as '0'

bit 4 **USLPGRD:** USB Sleep/Suspend Guard bit

- 1 = Indicates to the USB module that it is about to be suspended or powered down
- 0 = No suspend

bit 3-2 **Unimplemented:** Read as '0'

bit 1 **USUSPND:** USB Suspend Mode Enable bit

- 1 = USB OTG module is in Suspend mode; USB clock is gated and the transceiver is placed in a low-power state
- 0 = Normal USB OTG operation

bit 0 **USBPWR:** USB Operation Enable bit

- 1 = USB OTG module is enabled
- 0 = USB OTG module is disabled⁽¹⁾

Note 1: Do not clear this bit unless the HOSTEN, USBEN and OTGEN bits (U1CON<3,0> and U1OTGCON<2>) are all cleared.

 - 0 = Processing of the current token is not complete; clear the U1STAT register or load the next token from U1STAT
- bit 2 **SOFIF:** Start-of-Frame Token Interrupt bit
 - 1 = A Start-of-Frame token is received by the peripheral or the Start-of-Frame threshold is reached by the host
 - 0 = No Start-of-Frame token is received or threshold reached
- bit 1 **UERRIF:** USB Error Condition Interrupt bit
 - 1 = An unmasked error condition has occurred; only error states enabled in the U1EIE register can set this bit
 - 0 = No unmasked error condition has occurred
- bit 0 **DETACHIF:** Detach Interrupt bit
 - 1 = A peripheral detachment has been detected by the module; Reset state must be cleared before this bit can be re-asserted
 - 0 = No peripheral detachment is detected. Individual bits can only be cleared by writing a '1' to the bit position as part of a word write operation on the entire register. Using Boolean instructions or bitwise operations to write to a single bit position will cause all set bits, at the moment of the write, to become cleared.

Note: Individual bits can only be cleared by writing a '1' to the bit position as part of a word write operation on the entire register. Using Boolean instructions or bitwise operations to write to a single bit position will cause all set bits, at the moment of the write, to become cleared.

- bit 0 **EPHSHK:** Endpoint Handshake Enable bit
 1 = Endpoint handshake is enabled
 0 = Endpoint handshake is disabled (typically used for isochronous endpoints)

Note 1: These bits are available only for U1EP0 and only in Host mode. For all other U1EPn registers, these bits are always unimplemented and read as '0'.

PIC24FJ128GC010 FAMILY

20.0 DATA SIGNAL MODULATOR

Note: This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “PIC24F Family Reference Manual”, “Data Signal Modulator (DSM)” (DS39744). The information in this data sheet supersedes the information in the FRM.

The modulated output signal is generated by performing a logical AND operation of both the carrier and modulator signals and then it is provided to the MDOUT pin. Using this method, the DSM can generate the following types of key modulation schemes:

- Frequency Shift Keying (FSK)
- Phase-Shift Keying (PSK)
- On-Off Keying (OOK)

Figure 20-1 shows a simplified block diagram of the Data Signal Modulator peripheral.

The Data Signal Modulator (DSM) allows the user to mix a digital data stream (the “modulator signal”) with a carrier signal (the “modulator signal”) with a carrier signal to produce a modulated output. Both the carrier and the modulator signals are supplied to the DSM module, either internally from the output of a peripheral, or externally through an input pin.

PIC24FJ128GC010 FAMILY

21.0 ENHANCED PARALLEL MASTER PORT (EPMP)

Note: This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “PIC24F Family Reference Manual”, “Enhanced Parallel Master Port (EPMP)” (DS39730). The information in this data sheet supersedes the information in the FRM.

The Enhanced Parallel Master Port (EPMP) module provides a parallel, 4-bit (Master mode only), 8-bit (Master and Slave modes) or 16-bit (Master mode only) data bus interface to communicate with off-chip modules, such as memories, FIFOs, LCD controllers and other microcontrollers. This module can serve as either the master or the slave on the communication bus.

For EPMP Master modes, all external addresses are mapped into the internal Extended Data Space (EDS). This is done by allocating a region of the EDS for each Chip Select (CS) and then assigning each Chip Select to a particular external resource, such as a memory or external controller. This region should not be assigned to another device resource, such as RAM or SFRs. To perform a write or read on an external resource, the CPU simply performs a write or read within the address range assigned for the EPMP.

Key features of the EPMP module are:

- Extended Data Space (EDS) Interface Allows Direct Access from the CPU
- Up to 23 Programmable Address Lines
- Up to 2 Chip Select Lines
- Up to 2 Acknowledgment Lines (one per Chip Select)
- 4-Bit, 8-Bit or 16-Bit Wide Data Bus

- Programmable Strobe Options (per Chip Select):
 - Individual Read and Write Strobes; or
 - Read/Write Strobe with Enable Strobe
- Programmable Address/Data Multiplexing
- Programmable Address Wait States
- Programmable Data Wait States (per Chip Select)
- Programmable Polarity on Control Signals (per Chip Select)
- Legacy Parallel Slave Port (PSP) Support
- Enhanced Parallel Slave Support:
 - Address Support
 - 4-Byte Deep Auto-Incrementing Buffer

21.1 Specific Package Variations

While all PIC24FJ128GC010 family devices implement the EPMP, I/O pin constraints place some limits on 16-Bit Master mode operations in some package types. This is reflected in the number of dedicated Chip Select pins implemented and the number of dedicated address lines that are available. The differences are summarized in [Table 21-1](#). All available EPMP pin functions are summarized in [Table 21-2](#).

For 64-pin devices, the dedicated Chip Select pins (PMCS1 and PMCS2) are not implemented. In addition, only 16 address lines (PMA<15:0>) are available. If required, PMA14 and PMA15 can be remapped to function as PMCS1 and PMCS2, respectively.

The memory space addressable by the device depends on the number of address lines available, as well as the number of Chip Select signals required for the application. Devices with lower pin counts are more affected by Chip Select requirements, as these take away address lines. [Table 21-1](#) shows the maximum addressable range for each pin count.

TABLE 21-1: EPMP FEATURE DIFFERENCES BY DEVICE PIN COUNT

| Device | Dedicated Chip Select | | Address Lines | Address Range (bytes) | | |
|-------------------------------|-----------------------|-----|---------------|-----------------------|------|------|
| | CS1 | CS2 | | No CS | 1 CS | 2 CS |
| PIC24FJXXXGC006 (64-pin) | — | — | 16 | 64K | 32K | 16K |
| PIC24FJXXXGC010 (100/121-pin) | X | X | 23 | 16M | | |

PIC24FJ128GC010 FAMILY

TABLE 21-2: ENHANCED PARALLEL MASTER PORT PIN DESCRIPTIONS

| Pin Name (Alternate Function) | Type | Description |

PIC24FJ128GC010 FAMILY

NOTES:

PIC24FJ128GC010 FAMILY

22.0 LIQUID CRYSTAL DISPLAY (LCD) CONTROLLER

Note: This data sheet summarizes the features of the PIC24FJ128GC010 family of devices. It is not intended to be a comprehensive reference source. To complement the information in this data sheet, refer to the "PIC24F Family Reference Manual", "Liquid Crystal Display (LCD)" (DS39740) which is available from the Microchip web site (www.microchip.com).

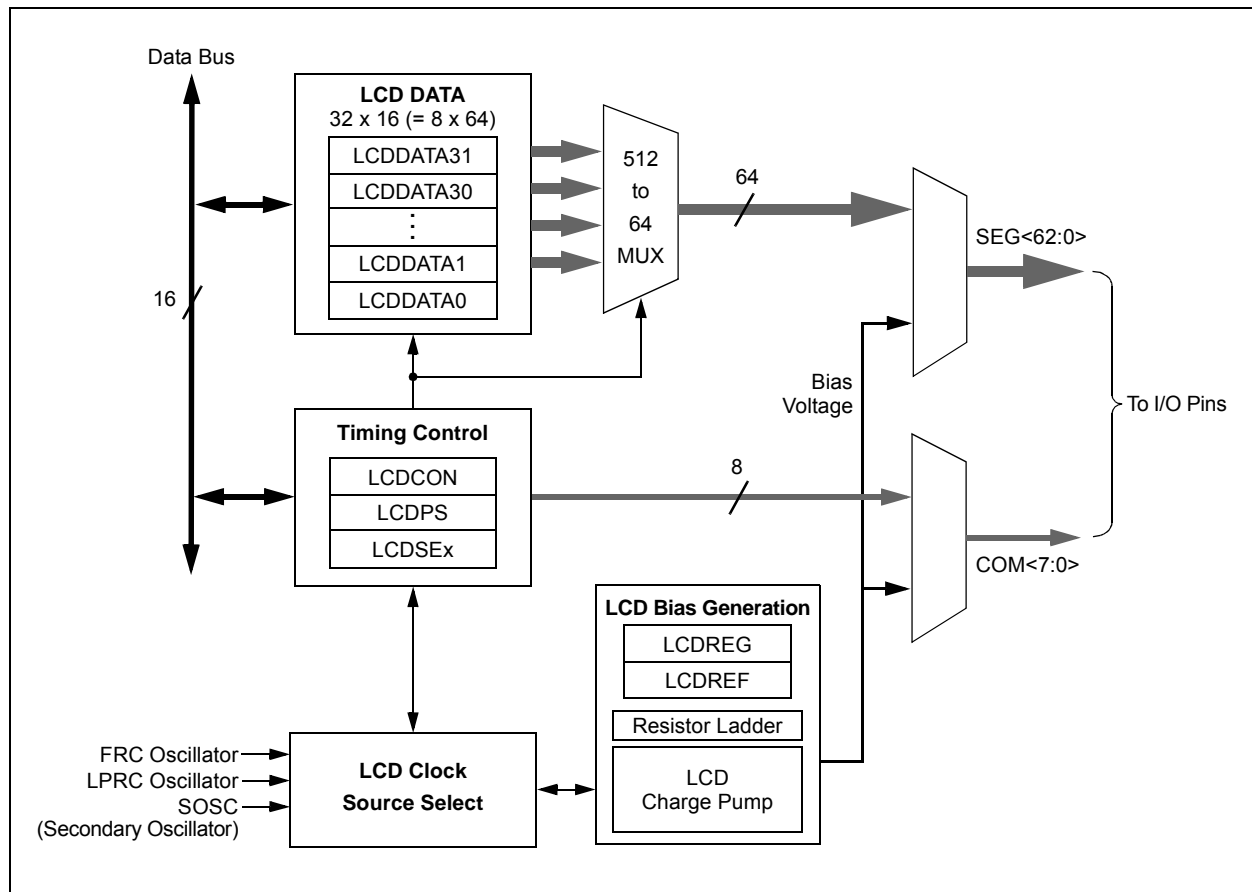

The Liquid Crystal Display (LCD) controller generates the data and timing control required to directly drive a static or multiplexed LCD panel. In 100-pin devices (PIC24FJXXXGC010), the module can drive panels of up to eight commons and up to 59 segments when 5 to 8 commons are used, or up to 63 segments when 1 to 4 commons are used.

The module has these features:

- Direct driving of LCD panel
- Three LCD clock sources with selectable prescaler
- Up to eight commons:
 - Static (one common)
 - 1/2 multiplex (two commons)
 - 1/3 multiplex (three commons)
 - 1/8 multiplex (eight commons)
- Ability to drive from 29 (in 64-pin devices) to 63 (100/121-pin) segments, depending on the Multiplexing mode selected
- Static, 1/2 or 1/3 LCD bias
- On-chip bias generator with dedicated charge pump to support a range of fixed and variable bias options
- Internal resistors for bias voltage generation
- Software contrast control for LCD using internal biasing

A simplified block diagram of the module is shown in Figure 22-1.

FIGURE 22-1: LCD CONTROLLER MODULE BLOCK DIAGRAM

PIC24FJ128GC010 FAMILY

22.1 Registers

The LCD controller has up to 40 registers:

- LCD Control Register (LCDCON)
- LCD Charge Pump Control Register (LCDREG)
- LCD Phase Register (LCDPS)
- LCD Voltage Ladder Control Register (LCDREF)
- Four LCD Segment Enable Registers (LCDSE3:LCDSE0)
- Up to 32 LCD Data Registers (LCDDATA31:LCD-DATA0)

000 = Internal LCD reference ladder is always in B Power mode

PIC24FJ128GC010 FAMILY

23.0 REAL-TIME CLOCK AND CALENDAR (RTCC)

Note: This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information on the Real-Time Clock and Calendar, refer to the “PIC24F Family Reference Manual”, “Real-Time Clock and Calendar (RTCC)” (DS39696).

The RTCC provides the user with a Real-Time Clock and Calendar (RTCC) function that can be calibrated.

Key features of the RTCC module are:

- Operates in Deep Sleep mode
- Selectable clock source
- Provides hours, minutes and seconds using 24-hour format
- Visibility of one half second period
- Provides calendar – weekday, date, month and year
- Alarm-configurable for half a second, one second, 10 seconds, one minute, 10 minutes, one hour, one day, one week, one month or one year
- Alarm repeat with decrementing counter
- Alarm with indefinite repeat chime
- Year 2000 to 2099 leap year correction

- BCD format for smaller software overhead
- Optimized for long-term battery operation
- User calibration of the 32.768 kHz clock crystal/32K INTRC frequency with periodic auto-adjust
- Optimized for long-term battery operation
- Fractional second synchronization
- Calibration to within ± 2.64 seconds error per month
- Calibrates up to 260 ppm of crystal error
- Ability to periodically wake up external devices without CPU intervention (external power control)
- Power control output for external circuit control
- Calibration takes effect every 15 seconds
- Runs from any one of the following:
 - External Real-Time Clock (RTC) of 32.768 kHz
 - Internal 31.25 kHz LPRC clock
 - 50 Hz or 60 Hz external input

23.1 RTCC Source Clock

The user can select between the SOSC crystal oscillator, LPRC internal oscillator or an external 50 Hz/60 Hz power line input as the clock reference for the RTCC module. This gives the user an option to trade off system cost, accuracy and power consumption, based on the overall system needs.

FIGURE 23-1: RTCC BLOCK DIAGRAM

PIC24FJ128GC010 FAMILY

23.2 RTCC Module Registers

The RTCC module registers are organized into three categories:

- RTCC Control Registers
- RTCC Value Registers
- Alarm Value Registers

23.2.1 REGISTER MAPPING

To limit the register interface, the RTCC Timer and Alarm Time registers are accessed through corresponding register pointers. The RTCC Value register window (RTCVALH and RTCVALL) uses the RTCPTR<1:0> bits (RCFGCAL<9:8>) to select the desired Timer register pair (see [Table 23-1](#)).

By writing the RTCVALH byte, the RTCC Pointer value, the RTCPTR<1:0> bits decrement by one until they reach '00'. Once they reach '00', the MINUTES and SECONDS value will be accessible through RTCVALH and RTCVALL until the pointer value is manually changed.

TABLE 23-1: RTCVAL REGISTER MAPPING

| RTCPTR<1:0> | RTCC Value Register Window | |
|-------------|----------------------------|-------------|
| | RTCVAL<15:8> | RTCVAL<7:0> |
| 00 | MINUTES | SECONDS |
| 01 | WEEKDAY | HOURS |
| 10 | MONTH | DAY |
| 11 | — | YEAR |

The Alarm Value register window (ALRMVALH and ALRMVALL) uses the ALRMPTR<1:0> bits (ALCFGRPT<9:8>) to select the desired Alarm register pair (see [Table 23-2](#)).

By writing the ALRMVALH byte, the Alarm Pointer value, ALRMPTR<1:0> bits, decrement by one until they reach '00'. Once they reach '00', the ALRMMIN and ALRMSEC value will be accessible through ALRMVALH and ALRMVALL until the pointer value is manually changed.

EXAMPLE 23-1: SETTING THE RTCWREN BIT

```
asm volatile ("push w7");
asm volatile ("push w8");
asm volatile ("disi #5");
asm volatile ("mov #0x55, w7");
asm volatile ("mov w7, _NVMKEY");
asm volatile ("mov #0xAA, w8");
asm volatile ("mov w8, _NVMKEY");
asm volatile ("bset _RCFGCAL, #13"); //set the RTCWREN bit
asm volatile ("pop w8");
asm volatile ("pop w7");
```

TABLE 23-2: ALRMVAL REGISTER MAPPING

| ALRMPTR <1:0> | Alarm Value Register Window | |
|------------------|-----------------------------|--------------|
| | ALRMVAL<15:8> | ALRMVAL<7:0> |
| 00 | ALRMMIN | ALRMSEC |
| 01 | ALRMWD | ALRMHR |
| 10 | ALRMMNTH | ALRMDAY |
| 11 | — | — |

Considering that the 16-bit core does not distinguish between 8-bit and 16-bit read operations, the user must be aware that when reading either the ALRMVALH or ALRMVALL bytes, the ALRMPTR<1:0> value will be decremented. The same applies to the RTCVALH or RTCVALL bytes with the RTCPTR<1:0> bits being decremented.

Note: This only applies to read operations and not write operations.

23.2.2 WRITE LOCK

In order to perform a write to any of the RTCC Timer registers, the RTCWREN bit (RCFGCAL<13>) must be set (see [Example 23-1](#)).

Note: To avoid accidental writes to the timer, it is recommended that the RTCWREN bit (RCFGCAL<13>) is kept clear at any other time. For the RTCWREN bit to be set, there is only one instruction cycle time window allowed between the 55h/AA sequence and the setting of RTCWREN; therefore, it is recommended that code follow the procedure in [Example 23-1](#).

23.2.3 SELECTING RTCC CLOCK SOURCE

The clock source for the RTCC module can be selected using the RTCLK<1:0> bits in the RTCPWC register. When the bits are set to '00', the Secondary Oscillator (SOSC) is used as the reference clock and when the bits are '01', LPRC is used as the reference clock. When RTCLK<1:0> = 10 and 11, the external power line (50 Hz and 60 Hz) is used as the clock source.

| -n = Value at POR | '1' = Bit is set |
| | U = Unimplemented bit, read as '0' |
| | '0' = Bit is cleared |
| | x = Bit is unknown |

- bit 15 **RTCEN:** RTCC Enable bit⁽²⁾
 1 = RTCC module is enabled
 0 = RTCC module is disabled
- bit 14 **Unimplemented:** Read as '0'
- bit 13 **RTCWREN:** RTCC Value Registers Write Enable bit
 1 = RTCVALH and RTCVALL registers can be written to by the user
 0 = RTCVALH and RTCVALL registers are locked out from being written to by the user
- bit 12 **RTCSYNC:** RTCC Value Registers Read Synchronization bit
 1 = RTCVALH, RTCVALL and ALCFGRPT registers can change while reading due to a rollover ripple resulting in an invalid data read. If the register is read twice and results in the same data, the data can be assumed to be valid.
 0 = RTCVALH, RTCVALL or ALCFGRPT registers can be read without concern over a rollover ripple
- bit 11 **HALFSEC:** Half Second Status bit⁽³⁾
 1 = Second half period of a second
 0 = First half period of a second
- bit 10 **RTCOE:** RTCC Output Enable bit
 1 = RTCC output is enabled
 0 = RTCC output is disabled
- bit 9-8 **RTCPTR<1:0>:** RTCC Value Register Window Pointer bits
 Points to the corresponding RTCC Value registers when reading the RTCVALH and RTCVALL registers. The RTCPTR<1:0> value decrements on every read or write of RTCVALH until it reaches '00'.
 RTCVAL<15:8>:
 11 = Reserved
 10 = MONTH
 01 = WEEKDAY
 00 = MINUTES
 RTCVAL<7:0>:
 11 = YEAR
 10 = DAY
 01 = HOURS
 00 = SECONDS

- Note 1:** The RCFGAL register is only affected by a POR.
2: A write to the RTCEN bit is only allowed when RTCWREN = 1.
3: This bit is read-only; it is cleared to '0' on a write to the lower half of the MINSEC register.

PIC24FJ128GC010 FAMILY

REGISTER 23-1: RCFGAL: RTCC CALIBRATION/CONFIGURATION REGISTER⁽¹⁾ (CONTINUED)

- Note 1:** The RTCPWC register is only affected by a POR.
Note 2: When a new value is written to these register bits, the lower half of the MINSEC register should also be written to properly reset the clock prescalers in the RTCC.

| -n = Value at POR | '1' = Bit is set | '0' = Bit is cleared |
| | | x = Bit is unknown |

- bit 15 **ALRMEN:** Alarm Enable bit
 1 = Alarm is enabled (cleared automatically after an alarm event whenever ARPT<7:0> = 00h and CHIME = 0)
 0 = Alarm is disabled
- bit 14 **CHIME:** Chime Enable bit
 1 = Chime is enabled; ARPT<7:0> bits are allowed to roll over from 00h to FFh
 0 = Chime is disabled; ARPT<7:0> bits stop once they reach 00h
- bit 13-10 **AMASK<3:0>:** Alarm Mask Configuration bits
 0000 = Every half second
 0001 = Every second
 0010 = Every 10 seconds
 0011 = Every minute
 0100 = Every 10 minutes
 0101 = Every hour
 0110 = Once a day
 0111 = Once a week
 1000 = Once a month
 1001 = Once a year (except when configured for February 29th, once every 4 years)
 101x = Reserved – do not use
 11xx = Reserved – do not use
- bit 9-8 **ALRMPTR<1:0>:** Alarm Value Register Window Pointer bits
 Points to the corresponding Alarm Value registers when reading the ALRMVALH and ALRMVALL registers. The ALRMPTR<1:0> value decrements on every read or write of ALRMVALH until it reaches '00'.
ALRMVAL<15:8>:
 00 = ALRMMIN
 01 = ALRMWD
 10 = ALRMMNTH
 11 = Unimplemented
ALRMVAL<7:0>:
 00 = ALRMSEC
 01 = ALRMHR
 10 = ALRMDAY
 11 = Unimplemented
- bit 7-0 **ARPT<7:0>:** Alarm Repeat Counter Value bits
 11111111 = Alarm will repeat 255 more times
 .
 .
 .
 00000000 = Alarm will not repeat
 The counter decrements on any alarm event; it is prevented from rolling over from 00h to FFh unless CHIME = 1.

23.4 Calibration

The real-time crystal input can be calibrated using the periodic auto-adjust feature. When properly calibrated, the RTCC can provide an error of less than 3 seconds per month. This is accomplished by finding the number of error clock pulses and storing the value into the lower half of the RCFGAL register. The 8-bit signed value loaded into the lower half of RCFGAL is multiplied by four and will either be added or subtracted from the RTCC timer, once every minute. Refer to the steps below for RTCC calibration:

1. Using another timer resource on the device, the user must find the error of the 32.768 kHz crystal.
2. Once the error is known, it must be converted to the number of error clock pulses per minute.
3.
 - a) If the oscillator is faster than ideal (negative result from Step 2), the RCFGAL register value must be negative. This causes the specified number of clock pulses to be subtracted from the timer counter, once every minute.
 - b) If the oscillator is slower than ideal (positive result from Step 2), the RCFGAL register value must be positive. This causes the specified number of clock pulses to be subtracted from the timer counter, once every minute.

EQUATION 23-1:

$$\frac{(\text{Ideal Frequency} \dagger - \text{Measured Frequency}) * 60}{\text{Clocks per Minute}} \\ \dagger \text{ Ideal Frequency} = 32,768 \text{ Hz}$$

Writes to the lower half of the RCFGAL register should only occur when the timer is turned off, or immediately after the rising edge of the seconds pulse, except when SECONDS = 00, 15, 30 or 45. This is due to the auto-adjust of the RTCC at 15 second intervals.

Note: It is up to the user to include, in the error value, the initial error of the crystal: drift due to temperature and drift due to crystal aging.

23.5 Alarm

- Configurable from half second to one year
- Enabled using the ALRMEN bit (ALCFGRPT<15>)
- One-time alarm and repeat alarm options available

23.5.1 CONFIGURING THE ALARM

The alarm feature is enabled using the ALRMEN bit. This bit is cleared when an alarm is issued. Writes to ALRMVAL should only take place when ALRMEN = 0.

As shown in [Figure 23-2](#), the interval selection of the alarm is configured through the AMASK<3:0> bits (ALCFGRPT<13:10>). These bits determine which, and how many, digits of the alarm must match the clock value for the alarm to occur.

The alarm can also be configured to repeat based on a preconfigured interval. The amount of times this occurs, once the alarm is enabled, is stored in the ARPT<7:0> bits (ALCFGRPT<7:0>). When the value of the ARPTx bits equals 00h, and the CHIME bit (ALCFGRPT<14>) is cleared, the repeat function is disabled and only a single alarm will occur. The alarm can be repeated, up to 255 times by loading ARPT<7:0> with FFh.

After each alarm is issued, the value of the ARPTx bits is decremented by one. Once the value has reached 00h, the alarm will be issued one last time, after which, the ALRMEN bit will be cleared automatically and the alarm will turn off.

Indefinite repetition of the alarm can occur if the CHIME bit = 1. Instead of the alarm being disabled when the value of the ARPTx bits reaches 00h, it rolls over to FFh and continues counting indefinitely while CHIME is set.

23.5.2 ALARM INTERRUPT

At every alarm event, an interrupt is generated. In addition, an alarm pulse output is provided that operates at half the frequency of the alarm. This output is completely synchronous to the RTCC clock and can be used as a trigger clock to other peripherals.

Note: Changing any of the registers, other than the RCFGAL and ALCFGRPT registers, and the CHIME bit, while the alarm is enabled (ALRMEN = 1), can result in a false alarm event leading to a false alarm interrupt. To avoid a false alarm event, the timer and alarm values should only be changed while the alarm is disabled (ALRMEN = 0). It is recommended that the ALCFGRPT register and CHIME bit be changed when RTCSYNC = 0.

Note 1: Annually, except when configured for February 29.

23.6 POWER CONTROL

The RTCC includes a power control feature that allows the device to periodically wake-up an external device, wait for the device to be stable before sampling wake-up events from that device, and then shut down the external device. This can be done completely autonomously by the RTCC, without the need to wake from the current lower power mode (Sleep, Deep Sleep, etc.).

To use this feature:

1. Enable the RTCC (RTCCEN = 1).
2. Set the PWCEN bit (RTCPWC<15>).
3. Configure the RTCC pin to drive the PWC control signal (RTCCOE = 1 and RTCCOUT<1:0> = 11).

The polarity of the PWC control signal may be chosen using the PWCPOL bit (RTCPWC<14>). An active-low or active-high signal may be used with the appropriate external switch to turn on or off the power to one or more external devices. The active-low setting may also be used in conjunction with an open-drain setting on the RTCC pin, in order to drive the ground pin(s) of the external device directly (with the appropriate external VDD pull-up device), without the need for external switches. Finally, the CHIME bit should be set to enable the PWC periodicity.

23.7 RTCC VBAT OPERATION

The RTCC can operate in VBAT mode when there is a power loss on the VDD pin. The RTCC will continue to operate if the VBAT pin is powered on (it is usually connected to the battery).

Note: It is recommended to connect the VBAT pin to VDD if the VBAT mode is not used (not connected to the battery).

The VBAT BOR can be enabled/disabled using the VBTBOR bit in the CW2 Configuration register (CW2<14>). If the VBTBOR enable bit is cleared, the VBAT BOR is always disabled and there will be no indication of a VBAT BOR. If the VBTBOR bit is set, the RTCC can receive a Reset and the RTCCEN bit will get cleared; it can happen anywhere between 1.95-1.4V (typical).

PIC24FJ128GC010 FAMILY

24.0 32-BIT PROGRAMMABLE CYCLIC REDUNDANCY CHECK (CRC) GENERATOR

Note: This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “PIC24F Family Reference Manual”, “32-Bit Programmable Cyclic Redundancy Check (CRC)” (DS39729). The information in this data sheet supersedes the information in the FRM.

The 32-bit programmable CRC generator provides a hardware implemented method of quickly generating checksums for various networking and security applications. It offers the following features:

- User-programmable CRC polynomial equation, up to 32 bits
- Programmable shift direction (little or big-endian)
- Independent data and polynomial lengths
- Configurable interrupt output
- Data FIFO

Figure 24-1 displays a simplified block diagram of the CRC generator. A simple version of the CRC shift engine is displayed in Figure 24-2.

FIGURE 24-1: CRC BLOCK DIAGRAM

FIGURE 24-2: CRC SHIFT ENGINE DETAIL

PIC24FJ128GC010 FAMILY

24.1 User Interface

24.1.1 POLYNOMIAL INTERFACE

The CRC module can be programmed for CRC polynomials of up to the 32nd order, using up to 32 bits.

Polynomial length, which reflects the highest exponent in the equation, is selected by the PLEN<4:0> bits (CRCCON2<4:0>).

The CRCXORL and CRCXORH registers control which exponent terms are included in the equation. Setting a particular bit includes that exponent term in the equation. Functionally, this includes an XOR operation on the corresponding bit in the CRC engine. Clearing the bit disables the XOR.

For example, consider two CRC polynomials, one a 16-bit and the other a 32-bit equation.

EQUATION 24-1: 16-BIT, 32-BIT CRC POLYNOMIALS

| |
|--|
| $X^{16} + X^{12} + X^5 + 1$ <p>and</p> $X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$ |
|--|

To program these polynomials into the CRC generator, set the register bits, as shown in [Table 24-1](#).

Note that the appropriate positions are set to '1' to indicate that they are used in the equation (for example, X26 and X23). The '0' bit required by the equation is always XORed; thus, X0 is a don't care. For a polynomial of length 32, it is assumed that the 32nd bit will be used. Therefore, the X<31:1> bits do not have the 32nd bit.

24.1.2 DATA INTERFACE

The module incorporates a FIFO that works with a variable data width. Input data width can be configured to any value, between 1 and 32 bits, using the DWIDTH<4:0> bits (CRCCON2<12:8>). When the data width is greater than 15, the FIFO is 4 words deep. When the DWIDTHx bits are between 15 and 8, the FIFO is 8 words deep. When the DWIDTHx bits are less than 8, the FIFO is 16 words deep.

The data for which the CRC is to be calculated must first be written into the FIFO. Even if the data width is less than 8, the smallest data element that can be written into the FIFO is 1 byte. For example, if the DWIDTHx bits are 5, then the size of the data is DWIDTH<4:0> + 1 or 6. The data is written as a whole byte; the two unused upper bits are ignored by the module.

Once data is written into the MSb of the CRCDAT registers (that is, the MSb as defined by the data width), the value of the VWORD<4:0> bits (CRCCON1<12:8>) increments by one. For example, if the DWIDTHx bits are 24, the VWORDx bits will increment when bit 7 of CRCDATH is written. Therefore, CRCDATL must always be written to before CRCDATH.

The CRC engine starts shifting data when the CRCGO bit is set and the value of the VWORDx bits is greater than zero.

Each word is copied out of the FIFO into a buffer register, which decrements the VWORDx bits. The data is then shifted out of the buffer. The CRC engine continues shifting at a rate of two bits per instruction cycle, until the VWORDx bits reach zero. This means that for a given data width, it takes half that number of instructions for each word to complete the calculation. For example, it takes 16 cycles to calculate the CRC for a single word of 32-bit data.

When the VWORDx bits reach the maximum value for the configured value of the DWIDTHx bits (4, 8 or 16), the CRCFUL bit becomes set. When the VWORDx bits reach zero, the CRCMPT bit becomes set. The FIFO is emptied and the VWORD<4:0> bits are set to '00000' whenever CRCEN is '0'.

At least one instruction cycle must pass after a write to CRCWDAT before a read of the VWORDx bits is done.

TABLE 24-1: CRC SETUP EXAMPLES FOR 16 AND 32-BIT POLYNOMIALS

| CRC Control Bits | Bit Values | |
|------------------|---------------------|---------------------|
| | 16-Bit Polynomial | 32-Bit Polynomial |
| PLEN<4:0> | 01111 | 11111 |
| X<31:16> | 0000 0000 0000 0001 | 0000 0100 1100 0001 |
| X<15:0> | 0001 0000 0010 000X | 0001 1101 1011 011x |

PIC24FJ128GC010 FAMILY

24.1.3 DATA SHIFT DIRECTION

The LENDIAN bit (CRCCON1<3>) is used to control the shift direction. By default, the CRC will shift data through the engine, MSb first. Setting LENDIAN (= 1) causes the CRC to shift data, LSb first. This setting allows better integration with various communication schemes and removes the overhead of reversing the bit order in software. Note that this only changes the direction the data is shifted into the engine. The result of the CRC calculation will still be a normal CRC result, not a reverse CRC result.

24.1.4 INTERRUPT OPERATION

The module generates an interrupt that is configurable by the user for either of two conditions.

If CRCISEL is '0', an interrupt is generated when the VWORD<4:0> bits make a transition from a value of '1' to '0'. If CRCISEL is '1', an interrupt will be generated after the CRC operation finishes and the module sets the CRCGO bit to '0'. Manually setting CRCGO to '0' will not generate an interrupt. Note that when an interrupt occurs, the CRC calculation would not yet be complete. The module will still need (PLENx + 1)/2 clock cycles after the interrupt is generated until the CRC calculation is finished.

24.1.5 TYPICAL OPERATION

To use the module for a typical CRC calculation:

1. Set the CRCEN bit to enable the module.
2. Configure the module for desired operation:
 - a) Program the desired polynomial using the CRCXORL and CRCXORH registers, and the PLEN<4:0> bits.
 - b) Configure the data width and shift direction using the DWIDTHx and LENDIAN bits.
 - c) Select the desired Interrupt mode using the CRCISEL bit.

3. Preload the FIFO by writing to the CRCDATL and CRCDATH registers until the CRCFUL bit is set or no data is left.
4. Clear old results by writing 00h to CRCWDATL and CRCWDATH. The CRCWDAT registers can also be left unchanged to resume a previously halted calculation.
5. Set the CRCGO bit to start calculation.
6. Write remaining data into the FIFO as space becomes available.
7. When the calculation completes, CRCGO is automatically cleared. An interrupt will be generated if CRCISEL = 1.
8. Read CRCWDATL and CRCWDATH for the result of the calculation.

There are eight registers used to control programmable CRC operation:

- CRCCON1
- CRCCON2
- CRCXORL
- CRCXORH
- CRCDATL
- CRCDATH
- CRCWDATL
- CRCWDATH

The CRCCON1 and CRCCON2 registers ([Register 24-1](#) and [Register 24-2](#)) control the operation of the module and configure the various settings.

The CRCXOR registers ([Register 24-3](#) and [Register 24-4](#)) select the polynomial terms to be used in the CRC equation. The CRCDAT and CRCWDAT registers are each register pairs that serve as buffers for the double-word input data, and CRC processed output, respectively.

25.0 OVERVIEW OF ADVANCED ANALOG FEATURES

The defining feature of PIC24FJ128GC010 family devices is the collection of analog peripherals, designed to extend the range of PIC24F microcontrollers into high-performance analog and mixed-signal applications. All devices include a set of new advanced modules and several existing analog peripherals, plus a common voltage reference for ease of use.

The analog block includes four new modules:

- 12-Bit High-Speed, Pipeline A/D Converter (described in [Section 26.0 “12-Bit High-Speed, Pipeline A/D Converter”](#))
- 16-Bit Sigma-Delta A/D (described in [Section 27.0, 16-Bit Sigma-Delta Analog-to-Digital \(A/D\) Converter](#))
- Dual 10-Bit Digital-to-Analog Converters (described in [Section 28.0, 10-Bit Digital-to-Analog Converter \(DAC\)](#))
- Dual Operational Amplifiers (described in [Section 29.0, Dual Operational Amplifier Module](#))

It also includes these legacy PIC24F analog modules:

- Triple Comparator module (described in [Section 30.0, Triple Comparator Module](#)) with independent voltage reference (described in [Section 31.0, Comparator Voltage Reference](#))
- CTMU (described in [Section 32.0, Charge Time Measurement Unit \(CTMU\)](#))

A high-level overview of the analog block and its integrating features is shown in [Figure 25-1](#). For a more detailed diagram of each module and an explanation of its operation, please refer to the appropriate chapter.

25.1 Shared Analog Pins

Apart from the reserved differential inputs for the Sigma-Delta A/D Converter, PIC24FJ128GC010 family devices may have up to 50 analog input channels (in 100-pin devices). Because of the number of analog features available on the microcontroller, many of the inputs and outputs of the other advanced analog modules share pins with these channels.

[Table 25-1](#) describes how features are multiplexed. Note that not all of these analog channels and their shared analog peripherals are available on all devices.

25.2 Internal Band Gap References

As an integrating feature, the analog block of PIC24FJ128GC010 family devices includes a common internal voltage reference source. This band gap provides several functions:

- A single, configurable internal reference source (BGBUF0) for all on-chip analog consumers
- Two additional and independently programmable band gap sources that can provide buffered internal references (BGBUF1 and BGBUF2) to external pins
- Independent configurability of all sources in Idle, Sleep and other low-power modes, allowing for flexibility in power consumption

The reference sources are controlled by three registers: BUFCON0 for the internal reference ([Register 25-1](#)), and BUFCON1 and BUFCON2 ([Register 25-2](#)) for the buffered references.

PIC24FJ128GC010 FAMILY

NOTES:

26.0 12-BIT HIGH-SPEED, PIPELINE A/D CONVERTER

Note: This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information on the Pipeline A/D Converter, refer to the “PIC24F Family Reference Manual”, “12-Bit, High-Speed Pipeline A/D Converter” (DS30686).

The 12-Bit Pipeline A/D Converter has the following key features:

- Conversion Speeds of up to 10 Msps
- Up to 50 Analog Single-Ended Input Channels or up to 15 Unique Differential Input Channel Pairs
- 12-Bit Conversion Resolution
- Multiple Internal Reference Input Channels
- External Voltage Reference Input Pins
- Automated Threshold Scan and Compare Operation to Pre-Evaluate Conversion Results
- Extended Automated and Fully Programmable Sampling Sequences from up to Four Different Lists
- Conversion Result Accumulation
- Selectable Conversion Trigger Source
- Internal 32-Word, Configurable Conversion Result Buffer
- Eight Options for Results Alignment
- Configurable Interrupt Generation
- Operation During CPU Sleep and Idle modes

The A/D Converter module is a pipelined 12-bit A/D Converter, capable of sampling up to once per A/D clock cycle. Its operation is enhanced with a wide range of automatic sampling options, tighter integration with other analog modules, result accumulation across many samples and a configurable results buffer.

A simplified block diagram for the module is shown in [Figure 26-1](#).

26.1 Basic Operation

To perform a standard A/D conversion:

1. Configure the module:
 - a) Configure port pins as analog inputs by setting the appropriate bits in the ANSx registers (see [Section 11.2 “Configuring Analog Port Pins \(ANSx\)”](#) for more information).
 - b) Configure “global” ADCON1, ADCON2 and ADCON3 control settings, but do not set the ADON bit until all global settings are configured:
 - Configure A/D clock source/rate
 - Select A/D reference sources
 - Configure data formatting
 - Configure other settings
 - c) Enable the A/D module by setting the ADON bit (ADCON1<15>).
 - d) Wait until the ADREADY bit (ADSTATH<1>) becomes set, indicating the module is finished with internal calibration and initialization.
 - e) Configure Sample List 0 settings, controlled by the ADL0CONH and ADL0CONL registers, but do not enable the sample list yet (SLEN):
 - Select the desired sample list interrupt generation settings
 - Select a Data Write mode (ex: write all results to buffer)
 - Configure analog sampling time (SAMC<4:0>)
 - Select a trigger source
 - Specify how many entries are in the sample list (SLSIZE<4:0>)
 - Configure other Sample List 0 specific settings
 - f) Initialize the ADTBL0 register (and higher if SLSIZEx > 0) to select the analog channel(s) to be included in Sample List 0.
 - g) Configure and enable A/D interrupts (if desired):
 - Clear the AD1IF and SL0IF bits
 - Select an interrupt priority
 - Enable AD1IE
 - h) Enable Sample List 0 by setting the SLEN bit (in ADL0CONL<15>).
 - i) Generate a trigger event for Sample List 0 (as configured in Step e).
 - j) Wait for the SL0IF or top level AD1IF interrupt flag to assert, indicating that the A/D result(s) are now ready.
 - k) Read the respective result(s) from the appropriate ADRESn register(s) (as configured based on the BUFORG setting).

PIC24FJ128GC010 FAMILY

26.2 Registers

The Pipeline A/D Converter uses a total of 116 registers. Of these, 75 registers control the module's operations; the remainder are data and result buffers.

Five "global" registers control overall module operation and provide module status:

- ADCON1 through ADCON3 ([Register 26-1](#) through [Register 26-3](#))
- ADSTATH and ADSTATL ([Register 26-4](#) and [Register 26-5](#))

Twelve registers control accumulator and threshold detect operations:

- ACCONH and ACCONL ([Register 26-11](#) and [Register 26-12](#))
- ADCHITH and ADCHITL ([Register 26-13](#) and [Register 26-14](#))
- ADTHnH and ADTHnL (0 through 3) (prototypes, [Register 26-15](#) and [Register 26-16](#))

Sixty-four registers control sample list selection, configuration and execution:

- ADLnCONH and ADLnCONL (0 through 3) (prototypes, [Register 26-6](#) and [Register 26-7](#))
- ADLnSTAT (0 through 3) (prototype, [Register 26-8](#))
- ADLnPTR (0 through 3) (prototype, [Register 26-9](#))
- ADLTLBn (0 through 31) (prototype, [Register 26-10](#))
- ADLnMSEL0 through ADLnMSEL3 (0 through 3) (prototypes, [Register 26-17](#) through [Register 26-20](#))

 0001 = Signed Integer (ssss sddd dddd dddd)
 0000 = Integer, Raw Data (0000 dddd dddd dddd)
- bit 7 **PUMPEN:** Analog Channel Switch Charge Pump Enable bit
 1 = Charge pump for switches is enabled, reducing switch impedance⁽¹⁾
 0 = Charge pump for switches is disabled
- bit 6 **ADCAL:** A/D Internal Analog Calibration bit⁽²⁾
 1 = Initiates internal analog calibration
 0 = No operation
- bit 5-1 **Unimplemented:** Read as '0'
- bit 0 **PWRLVL:** Power Level Select bit
 1 = Full-Power mode; A/D clock rates from 1 MHz to 10 MHz are allowed
 0 = Low-Power mode; A/D clock rates from 1 MHz to 2.5 MHz are allowed

Note 1: Use of the channel switch charge pump is recommended when AVDD < 2.5V.

Note 2: When set, ADCAL remains set for at least one TAD and is then automatically cleared by hardware. Manually clearing the bit does not necessarily cancel the calibration routine. Calibration is complete when ADSTATH<1> = 1.

Note 1: Not all external analog channels are available on all devices. See [Table 1-3](#) for more information. For 64-pin devices, do not use values of ADCH<6:0> associated with unimplemented channels.

2: Single-ended conversion returns 000h + offset; differential conversions return 8000h + offset.

3: Single-ended conversion returns 000h; differential conversion returns 000h + offset and gain error.

4: Single-ended conversion returns FFFh + offset and gain error; differential conversion returns FFFh + offset and gain error.

27.0 16-BIT SIGMA-DELTA ANALOG-TO-DIGITAL (A/D) CONVERTER

Note: This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “PIC24F Family Reference Manual”, “16-Bit Sigma-Delta A/D Converter” (DS30687). The information in this data sheet supersedes the information in the FRM.

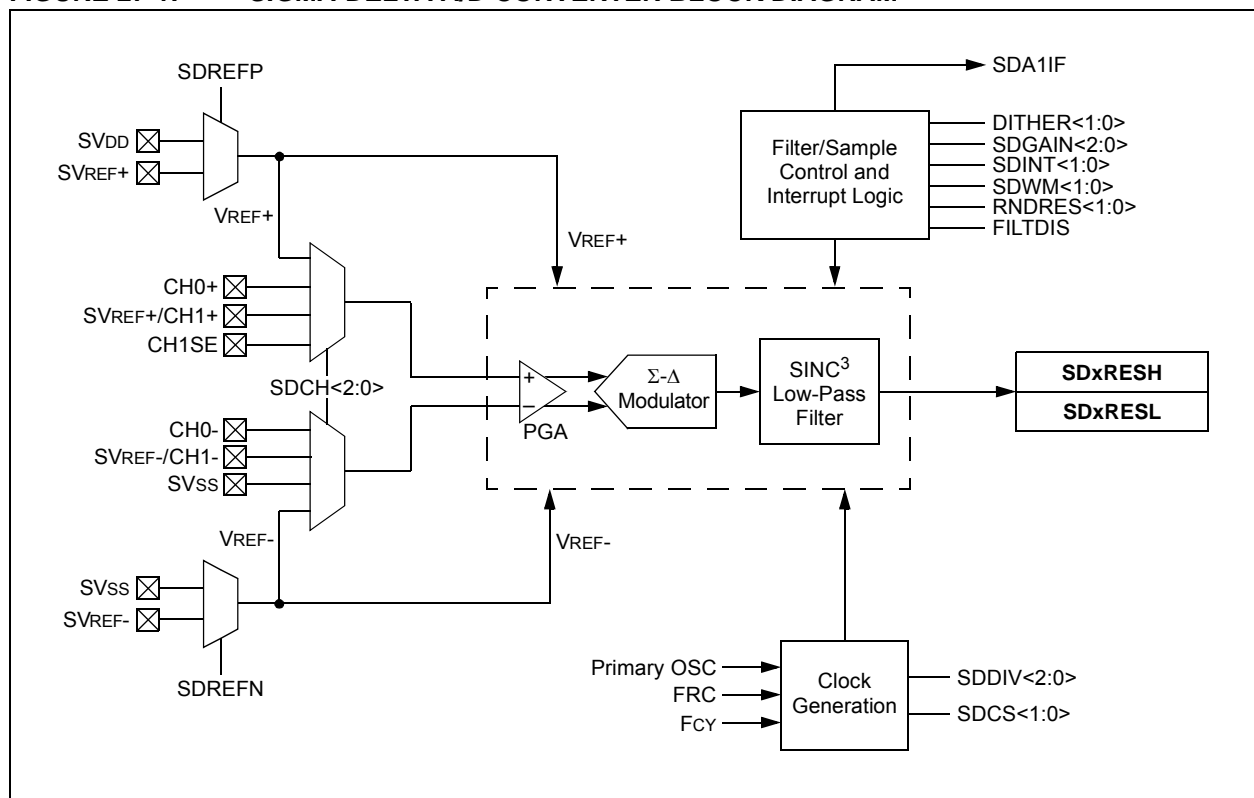

The Sigma-Delta A/D Converter employs sigma-delta modulation techniques to convert analog signals to a digital equivalent. This method achieves exceptional resolution and output code stability, which can significantly

exceed that of conventional 10-bit or 12-bit SAR-based A/Ds. A block diagram of the 16-bit Sigma-Delta A/D is shown in Figure 27-1.

Key features include:

- Adjustable sampling rates
- Configurable A/D data rates between 976 samples per second (highest quality) and 62.5 ksp/s (highest speed)
- Two differential input channels
- Programmable gain amplifier input
- User-selectable clock sources
- User-selectable oversampling, dithering and data rounding
- Self-measurement of internal offset and gain error
- Operation in Idle and Sleep modes
- Independent module Reset option

FIGURE 27-1: SIGMA-DELTA A/D CONVERTER BLOCK DIAGRAM

PIC24FJ128GC010 FAMILY

27.1 Important Differences Compared to Conventional A/Ds

In principle, the Sigma-Delta A/D Converter does what most other A/Ds do: it samples an analog input voltage and generates a digital output code representing the analog voltage. There are, however, a number of differences when comparing a Sigma-Delta Converter to conventional A/D Converters, such as the Successive Approximation Register (SAR) design that is popular on many of today's microcontrollers.

The most important differences that are noticeable at the application level include:

- Readily achieved resolution/quality of result
- Analog channel sampling methodology
- Uncorrected offset error
- Uncorrected gain error

27.1.1 RESULT QUALITY AND OVERSAMPLING

In a typical application, involving switching digital circuitry, oscillators, clocks and other noise sources common in a microcontroller-based circuit, it is often difficult to reduce the high-frequency noise floor below some arbitrary value. For A/Ds, which perform instantaneous "snapshot" based sampling (e.g., charging a Sample-and-Hold capacitor in a conventional SAR-based A/D), this noise floor ultimately restricts the maximum achievable stable result resolution.

To achieve higher effective stable resolution and to minimize the effects of high-frequency noise, the Sigma-Delta A/D Converter implements inherent oversampling in the design. This oversampling has an effect similar to low-pass filtering the analog signal and voltage references to the A/D. Therefore, when the converter generates a result, the output code represents the average voltage of the signal or reference being measured over a specific time window, rather than an instantaneous snapshot in time (like that of the SAR-based A/D). This sampling method enables the Sigma-Delta A/D Converter to generate stable results at significantly higher resolution than is typically achievable with conventional A/D designs.

The design of this Sigma-Delta A/D Converter allows user-configurable Oversampling Ratios (OSRs), between 16 and 1024. The lowest settings provide the fastest results, but they sacrifice result code accuracy. The highest OSR settings provide the best quality and most stable results, but generate results at a much slower rate.

27.1.2 UNCORRECTED OFFSET ERROR

When uncorrected, the Sigma-Delta A/D Converter typically has more LSBs worth of offset error than conventional SAR-based A/Ds. This is partly due to the high resolution and small size of each LSB. Additionally, internal or external input circuitry, such as the internal input gain stage, can also introduce some offset error.

Fortunately, the Sigma-Delta A/D Converter implements a feature that allows it to measure its own internal offset error. This feature is controlled by the VOSCAL bit (SD1CON1<4>). Once the application firmware has measured the internal offset error, the digital output code can be saved in the firmware, and subsequently subtracted from all future A/D measurements on the regular input channel(s). This procedure significantly improves the absolute accuracy of the A/D and is recommended for most applications.

27.1.3 UNCORRECTED GAIN ERROR

When uncorrected, Sigma-Delta A/D Converters typically exhibit high gain error compared to other A/D designs. To obtain high absolute accuracy from the Sigma-Delta A/D Converter, it is necessary to compensate for both offset error and gain error. Gain error can be corrected by first removing the offset error, then multiplying the resulting code with a suitable gain error correction factor.

One of the input channel settings, selectable in the SD1CON3 register, allows the A/D to measure its own references. When a measurement (with a gain of 1) is performed on this channel, the result code can be corrected for offset error (using the method described in [Section 27.1.2 "Uncorrected Offset Error"](#)) and then used to calculate the gain error correction factor. Once the gain error correction factor is known, it can be saved and stored in the firmware, so that it may be used later to correct for gain error when performing measurements on the other A/D input channels.

2: 8 MHz FRC output is used directly, prior to the FRCDIV postscaler.

PIC24FJ128GC010 FAMILY

NOTES:

PIC24FJ128GC010 FAMILY

28.0 10-BIT DIGITAL-TO-ANALOG CONVERTER (DAC)

Note: This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “PIC24F Family Reference Manual”, “10-Bit Digital-to-Analog Converter (DAC)” (DS39615). The information in this data sheet supersedes the information in the FRM.

PIC24FJ128GC010 family devices include two 10-bit Digital-to-Analog Converters (DACs) for generating analog outputs from digital data. A simplified block diagram for a single DAC is shown in Figure 28-1. Both of the DACs are identical.

The DAC generates an analog output voltage based on the digital input code, according to the formula:

$$V_{DAC} = \frac{V_{DACREF} \times DACxDAT}{1024}$$

where V_{DAC} is the analog output voltage and V_{DACREF} is the reference voltage selected by $DACREF<1:0>$.

Each DAC includes these features:

- Precision 10-bit resistor ladder for high accuracy
- Fast settling time, supporting 1 Msps effective sampling rates
- Buffered output voltage
- Three user-selectable voltage reference options
- Multiple conversion trigger options, plus a manual convert-on-write option
- Left and right justified input data options
- User-selectable Sleep and Idle mode operation

When using the DAC, it is required to set the $ANSx$ and $TRISx$ bits for the $DACx$ output pin to configure it as an analog output. See Section 11.2 “Configuring Analog Port Pins ($ANSx$)” for more information.

PIC24FJ128GC010 FAMILY

29.0 DUAL OPERATIONAL AMPLIFIER MODULE

Note: This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “PIC24F Family Reference Manual”, “Operational Amplifier (Op Amp)” (DS30505). Device-specific information in this data sheet supersedes the information in the “PIC24F Family Reference Manual”.

PIC24FJ128GC010 family devices include two operational amplifiers to complement the microcontroller’s other analog features. They may be used to provide analog signal conditioning, either as stand-alone devices or in addition to other analog peripherals. They may also be configured to operate as digital comparators in addition to the triple comparator module (see Section 30.0 “Triple Comparator Module” for more information).

The two op amps are functionally identical; the block diagram for a single amplifier is shown in Figure 29-1. Each op amp has these features:

- Configurable as either an operational amplifier or a comparator
- Internal unity-gain buffer option
- Six input options each on the inverting and non-inverting amplifier inputs
- Rail-to-rail input and output capabilities
- User-configurable interrupt with comparator operation, including four interrupt options
- User-selectable option for regular or low-power operation
- User-selectable operation in Idle and Sleep modes

When using the op amps, it is recommended to set the ANSx and TRISx bits of both the input and output pins to configure them as analog pins. See Section 11.2 “Configuring Analog Port Pins (ANSx)” for more information.

PIC24FJ128GC010 FAMILY

NOTES:

PIC24FJ128GC010 FAMILY

30.0 TRIPLE COMPARATOR MODULE

Note: This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “PIC24F Family Reference Manual”, “Scalable Comparator Module” (DS39734). The information in this data sheet supersedes the information in the FRM.

The triple comparator module provides three dual input comparators. The inputs to the comparator can be configured to use any one of five external analog inputs (CxINA, CxINB, CxINC, CxIND and VREF+) and a

voltage reference input from one of the internal band gap references or the comparator voltage reference generator (V_{BG}, V_{BG}/2, V_{BG}/6 and CVREF).

The comparator outputs may be directly connected to the CxOUT pins. When the respective COE equals ‘1’, the I/O pad logic makes the unsynchronized output of the comparator available on the pin.

A simplified block diagram of the module is shown in Figure 30-1. Diagrams of the possible individual comparator configurations are shown in Figure 30-2.

Each comparator has its own control register, CMxCON (Register 30-1), for enabling and configuring its operation. The output and event status of all three comparators is provided in the CMSTAT register (Register 30-2).

31.0 COMPARATOR VOLTAGE REFERENCE

Note: This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the "PIC24F Family Reference Manual", "Dual Comparator Module" (DS39710). The information in this data sheet supersedes the information in the FRM.

31.1 Configuring the Comparator Voltage Reference

The voltage reference module is controlled through the CVRCON register (Register 31-1). The comparator voltage reference provides a range of output voltages, with 32 distinct levels. The comparator reference supply voltage can come from either VDD and VSS, or the external CVREF+ and CVREF- pins. The voltage source is selected by the CVRSS bit (CVRCON<5>).

The settling time of the comparator voltage reference must be considered when changing the CVREF output.

32.0 CHARGE TIME MEASUREMENT UNIT (CTMU)

Note: This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information on the Charge Measurement Unit, refer to the “PIC24F Family Reference Manual”, “**Charge Time Measurement Unit (CTMU) with Threshold Detect**” (DS39743).

The Charge Time Measurement Unit (CTMU) is a flexible analog module that provides charge measurement, accurate differential time measurement between pulse sources and asynchronous pulse generation. Its key features include:

- Thirteen external edge input trigger sources
- Polarity control for each edge source
- Control of edge sequence
- Control of response to edge levels or edge transitions
- Time measurement resolution of one nanosecond
- Accurate current source suitable for capacitive measurement

Together with other on-chip analog modules, the CTMU can be used to precisely measure time, measure capacitance, measure relative changes in capacitance or generate output pulses that are independent of the system clock. The CTMU module is ideal for interfacing with capacitive-based touch sensors.

The CTMU is controlled through three registers: CTMUCON1, CTMUCON2 and CTMUICON. CTMUCON1 enables the module and controls the mode of operation of the CTMU, as well as controlling edge sequencing. CTMUCON2 controls edge source selection and edge source polarity selection. The CTMUICON register selects the current range of current source and trims the current.

32.1 Measuring Capacitance

The CTMU module measures capacitance by generating an output pulse with a width equal to the time between edge events on two separate input channels. The pulse edge events to both input channels can be selected from four sources: two internal peripheral modules (OC1 and Timer1) and up to 13 external pins (CTEDG1 through CTEDG13). This pulse is used with the module's precision current source to calculate capacitance according to the relationship:

EQUATION 32-1:

$$I = C \cdot \frac{dV}{dT}$$

For capacitance measurements, the A/D Converter samples an external capacitor (CAPP) on one of its input channels, after the CTMU output's pulse. A precision resistor (RPR) provides current source calibration on a second A/D channel. After the pulse ends, the converter determines the voltage on the capacitor. The actual calculation of capacitance is performed in software by the application.

Figure 32-1 illustrates the external connections used for capacitance measurements, and how the CTMU and A/D modules are related in this application. This example also shows the edge events coming from Timer1, but other configurations using external edge sources are possible. A detailed discussion on measuring capacitance and time with the CTMU module is provided in the “PIC24F Family Reference Manual”, “**Charge Time Measurement Unit (CTMU)**”.

PIC24FJ128GC010 FAMILY

FIGURE 32-1: TYPICAL CONNECTIONS AND INTERNAL CONFIGURATION FOR CAPACITANCE MEASUREMENT

32.2 Measuring Time

Time measurements on the pulse width can be similarly performed using the A/D module's Internal Capacitor (CAD) and a precision resistor for current calibration. [Figure 32-2](#) displays the external connections used for time measurements, and how the CTMU and A/D modules are related in this application. This example also shows both edge events coming from the external CTEDGx pins, but other configurations using internal edge sources are possible.

32.3 Pulse Generation and Delay

The CTMU module can also generate an output pulse with edges that are not synchronous with the device's system clock. More specifically, it can generate a pulse with a programmable delay from an edge event input to the module.

When the module is configured for pulse generation delay by setting the TGEN bit (CTMUCON1<12>), the internal current source is connected to the B input of Comparator 2. A capacitor (CDELAY) is connected to the Comparator 2 pin, C2INB, and the Comparator Voltage Reference, CVREF, is connected to C2INA. CVREF is then configured for a specific trip point. The module begins to charge CDELAY when an edge event is detected. When CDELAY charges above the CVREF trip point, a pulse is output on CTPLS. The length of the pulse delay is determined by the value of CDELAY and the CVREF trip point.

[Figure 32-3](#) illustrates the external connections for pulse generation, as well as the relationship of the different analog modules required. While CTED1 is shown as the input pulse source, other options are available. A detailed discussion on pulse generation with the CTMU module is provided in the "[PIC24F Family Reference Manual](#)".

PIC24FJ128GC010 FAMILY

NOTES:

PIC24FJ128GC010 FAMILY

33.0 HIGH/LOW-VOLTAGE DETECT (HLVD)

Note: This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information on the High/Low-Voltage Detect, refer to the "PIC24F Family Reference Manual", "High-Level Integration with Programmable High/Low-Voltage Detect (HLVD)" (DS39725).

The High/Low-Voltage Detect (HLVD) module is a programmable circuit that allows the user to specify both the device voltage trip point and the direction of change.

An interrupt flag is set if the device experiences an excursion past the trip point in the direction of change. If the interrupt is enabled, the program execution will branch to the interrupt vector address and the software can then respond to the interrupt.

The HLVD Control register (see [Register 33-1](#)) completely controls the operation of the HLVD module. This allows the circuitry to be "turned off" by the user under software control, which minimizes the current consumption for the device.

34.0 SPECIAL FEATURES

Note: This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the following sections of the “*PIC24F Family Reference Manual*”. The information in this data sheet supersedes the information in the FRMs.

- “**Watchdog Timer (WDT)**” (DS39697)
- “**High-Level Device Integration**” (DS39719)
- “**Programming and Diagnostics**” (DS39716)

PIC24FJ128GC010 family devices include several features intended to maximize application flexibility and reliability, and minimize cost through elimination of external components. These are:

- Flexible Configuration
- Watchdog Timer (WDT)
- Code Protection
- JTAG Boundary Scan Interface
- In-Circuit Serial Programming™
- In-Circuit Emulation

34.1 Configuration Bits

The Configuration bits can be programmed (read as ‘0’), or left unprogrammed (read as ‘1’), to select various device configurations. These bits are mapped, starting at program memory location, F80000h. A detailed explanation of the various bit functions is provided in [Register 34-1](#) through [Register 34-6](#).

Note that address, F80000h, is beyond the user program memory space. In fact, it belongs to the configuration memory space (800000h-FFFFFFh), which can only be accessed using table reads and table writes.

34.1.1 CONSIDERATIONS FOR CONFIGURING PIC24FJ128GC010 FAMILY DEVICES

In PIC24FJ128GC010 family devices, the configuration bytes are implemented as volatile memory. This means that configuration data must be programmed each time the device is powered up. Configuration data is stored in the four words at the top of the on-chip program memory space, known as the Flash Configuration Words. Their specific locations are shown in [Table 34-1](#). These are packed representations of the actual device Configuration bits, whose actual locations are distributed among several locations in configuration space. The configuration data is automatically loaded from the Flash Configuration Words to the proper Configuration registers during device Resets.

Note: Configuration data is reloaded on all types of device Resets.

When creating applications for these devices, users should always specifically allocate the location of the Flash Configuration Word for configuration data. This is to make certain that program code is not stored in this address when the code is compiled.

The upper byte of all Flash Configuration Words in program memory should always be ‘0000 0000’. This makes them appear to be NOP instructions in the remote event that their locations are ever executed by accident. Since Configuration bits are not implemented in the corresponding locations, writing ‘0’s to these locations has no effect on device operation.

Note: Performing a page erase operation on the last page of program memory clears the Flash Configuration Words, enabling code protection as a result. Therefore, users should avoid performing page erase operations on the last page of program memory.

TABLE 34-1: FLASH CONFIGURATION WORD LOCATIONS FOR PIC24FJ128GC010 FAMILY DEVICES

 10 = Either the 31 kHz FRC source or LPRC, depending on device configuration⁽²⁾
 01 = SOSC input
 00 = System clock when active, LPRC while in Sleep mode
 When WDTCMX = 0:
 LPRC is always the WDT clock source.
- bit 2 **Reserved:** Configure as '0'
- bit 1-0 **POSCMD<1:0>:** Primary Oscillator Configuration bits
 11 = Primary Oscillator mode is disabled
 10 = HS Oscillator mode is selected (HS mode is used if crystal \geq 10 MHz)
 01 = XT Oscillator mode is selected (XT mode is used if crystal < 10 MHz)
 00 = EC Oscillator mode is selected

Note 1: These bits should be treated as reserved on the 64-pin devices (PIC24FJ64GC006 and PIC24FJ128GC006) and should always be programmed to '0'. The AVREF+/CVREF+ and AVREF-/CVREF- functions are located on RB0 and RB1 on these devices.

2: The 31 kHz FRC source is used when a Windowed WDT mode is selected and the LPRC is not being used as the system clock. The LPRC is used when the device is in Sleep mode and in all other cases.

PIC24FJ128GC010 FAMILY

34.2 On-Chip Voltage Regulator

All PIC24FJ128GC010 family devices power their core digital logic at a nominal 1.8V. This may create an issue for designs that are required to operate at a higher typical voltage, such as 3.3V. To simplify system design, all devices in the PIC24FJ128GC010 family incorporate an on-chip regulator that allows the device to run its core logic from VDD.

This regulator is always enabled. It provides a constant voltage (1.8V nominal) to the digital core logic, from a VDD of 2.0V all the way up to the device's VDDMAX. It does not have the capability to boost VDD levels. In order to prevent "brown-out" conditions when the voltage drops too low for the regulator, the Brown-out Reset occurs. Then the regulator output follows VDD with a typical voltage drop of 300 mV.

A low-ESR capacitor (such as ceramic) must be connected to the VCAP pin (Figure 34-1). This helps to maintain the stability of the regulator. The recommended value for the filter capacitor (CEFC) is provided in Section 37.1 "DC Characteristics".

FIGURE 34-1: CONNECTIONS FOR THE ON-CHIP REGULATOR

34.2.1 ON-CHIP REGULATOR AND POR

The voltage regulator requires a small amount of time to transition from a disabled or standby state into normal operating mode. During this time, designated as TVREG, code execution is disabled. TVREG is applied every time the device resumes operation after any power-down, including Sleep mode. TVREG is determined by the status of the PMSLP bit (RCON<8>). Refer to Section 37.0 "Electrical Characteristics" for more information on TVREG.

Note: For more information, see Section 37.0 "Electrical Characteristics". The information in this data sheet supersedes the information in the "PIC24F Family Reference Manual".

34.2.2 VOLTAGE REGULATOR STANDBY MODE

The on-chip regulator always consumes a small incremental amount of current over IDD/IPD, including when the device is in Sleep mode, even though the core digital logic does not require power. To provide additional savings in applications where power resources are critical, the regulator can be made to enter Standby mode on its own whenever the device goes into Sleep mode. This feature is controlled by the PMSLP bit (RCON<8>). Clearing the PMSLP bit enables the Standby mode. When waking up from Standby mode, the regulator needs to wait for TVREG to expire before wake-up.

34.2.3 LOW-VOLTAGE/RETENTION REGULATOR

When power-saving modes, such as Sleep and Deep Sleep are used, PIC24FJ128GC010 family devices may use a separate low-power, low-voltage/retention regulator to power critical circuits. This regulator, which operates at 1.2V nominal, maintains power to data RAM and the RTCC while all other core digital logic is powered down. It operates only in Sleep, Deep Sleep and VBAT modes.

The low-voltage/retention regulator is described in more detail in Section 10.1.3 "Low-Voltage/Retention Regulator".

PIC24FJ128GC010 FAMILY

34.3 Watchdog Timer (WDT)

For PIC24FJ128GC010 family devices, the WDT is driven by the LPRC oscillator. When the WDT is enabled, the clock source is also enabled.

The nominal WDT clock source from LPRC is 31 kHz. This feeds a prescaler that can be configured for either 5-bit (divide-by-32) or 7-bit (divide-by-128) operation. The prescaler is set by the FWPSA Configuration bit. With a 31 kHz input, the prescaler yields a nominal WDT Time-out period (TWDT) of 1 ms in 5-bit mode or 4 ms in 7-bit mode.

A variable postscaler divides down the WDT prescaler output and allows for a wide range of time-out periods. The postscaler is controlled by the WDTPS<3:0> Configuration bits (CW1<3:0>), which allows the selection of a total of 16 settings, from 1:1 to 1:32,768. Using the prescaler and postscaler time-out periods, ranges from 1 ms to 131 seconds can be achieved.

The WDT, prescaler and postscaler are reset:

- On any device Reset
- On the completion of a clock switch, whether invoked by software (i.e., setting the OSWEN bit after changing the NOSCx bits) or by hardware (i.e., Fail-Safe Clock Monitor)
- When a PWRSAV instruction is executed (i.e., Sleep or Idle mode is entered)
- When the device exits Sleep or Idle mode to resume normal operation
- By a CLRWDT instruction during normal execution

If the WDT is enabled, it will continue to run during Sleep or Idle modes. When the WDT time-out occurs, the device will wake the device and code execution will continue from where the PWRSAV instruction was executed. The corresponding SLEEP or IDLE (RCON<3:2>) bit will need to be cleared in software after the device wakes up.

The WDT Flag bit, WDTO (RCON<4>), is not automatically cleared following a WDT time-out. To detect subsequent WDT events, the flag must be cleared in software.

Note: The CLRWDT and PWRSAV instructions clear the prescaler and postscaler counts when executed.

34.3.1 WINDOWED OPERATION

The Watchdog Timer has an optional Fixed Window mode of operation. In this Windowed mode, CLRWDT instructions can only reset the WDT during the last 1/4 of the programmed WDT period. A CLRWDT instruction executed before that window causes a WDT Reset, similar to a WDT time-out.

Windowed WDT mode is enabled by programming the WINDIS Configuration bit (CW1<5>) to '0'.

34.3.2 CONTROL REGISTER

The WDT is enabled or disabled by the FWDTEN<1:0> Configuration bits. When the Configuration bits, FWDTEN<1:0> = 11, the WDT is always enabled.

The WDT can be optionally controlled in software when the Configuration bits, FWDTEN<1:0> = 10. When FWDTEN<1:0> = 00, the Watchdog Timer is always disabled. The WDT is enabled in software by setting the SWDTEN control bit (RCON<5>). The SWDTEN control bit is cleared on any device Reset. The software WDT option allows the user to enable the WDT for critical code segments and disable the WDT during non-critical segments for maximum power savings.

FIGURE 34-2: WDT BLOCK DIAGRAM

PIC24FJ128GC010 FAMILY

34.4 Program Verification and Code Protection

PIC24FJ128GC010 family devices provide two complimentary methods to protect application code from overwrites and erasures. These also help to protect the device from inadvertent configuration changes during run time.

34.4.1 GENERAL SEGMENT PROTECTION

For all devices in the PIC24FJ128GC010 family, the on-chip program memory space is treated as a single block, known as the General Segment (GS). Code protection for this block is controlled by one Configuration bit, GCP. This bit inhibits external reads and writes to the program memory space. It has no direct effect in normal execution mode.

Write protection is controlled by the GWRP bit in the Configuration Word. When GWRP is programmed to '0', internal write and erase operations to program memory are blocked.

34.4.2 CODE SEGMENT PROTECTION

In addition to global General Segment protection, a separate subrange of the program memory space can be individually protected against writes and erases. This area can be used for many purposes where a separate block of write and erase-protected code is needed, such as bootloader applications. Unlike common boot block implementations, the specially protected segment in the PIC24FJ128GC010 family devices can be located by the user anywhere in the program space and configured in a wide range of sizes.

Code segment protection provides an added level of protection to a designated area of program memory by disabling the NVM safety interlock whenever a write or erase address falls within a specified range. It does not override General Segment protection controlled by the GCP or GWRP bit. For example, if GCP and GWRP are enabled, enabling segmented code protection for the bottom half of program memory does not undo General Segment protection for the top half.

The size and type of protection for the segmented code range are configured by the WFPFx, WPEND, WPCFG and WPDIS bits in Configuration Word 3. Code segment protection is enabled by programming the WPDIS bit (= 0). The WFPFx bits specify the size of the segment to be protected by specifying the 512-word code page that is the start or end of the protected segment. The specified region is inclusive, therefore, this page will also be protected.

The WPEND bit determines if the protected segment uses the top or bottom of the program space as a boundary. Programming WPEND (= 0) sets the bottom of program memory (000000h) as the lower boundary of the protected segment. Leaving WPEND unprogrammed (= 1) protects the specified page through the last page of implemented program memory, including the Configuration Word locations.

A separate bit, WPCFG, is used to protect the last page of program space, including the Flash Configuration Words. Programming WPCFG (= 0) protects the last page in addition to the pages selected by the WPEND and WFPF<6:0> bits' setting. This is useful in circumstances where write protection is needed for both the code segment in the bottom of the memory and the Flash Configuration Words.

The various options for segment code protection are shown in [Table 34-2](#).

TABLE 34-2: CODE SEGMENT PROTECTION CONFIGURATION OPTIONS

| Segment Configuration Bits | | | Write/Erase Protection of Code Segment |
|----------------------------|-------|-------|---|
| WPDIS | WPEND | WPCFG | |
| 1 | x | x | No additional protection is enabled; all program memory protection is configured by GCP and GWRP. |
| 0 | 1 | x | Addresses from the first address of the code page are defined by WFPF<6:0> through the end of implemented program memory (inclusive); erase/write-protected, including Flash Configuration Words. |
| 0 | 0 | 1 | Address, 000000h through the last address of the code page, is defined by WFPF<6:0> (inclusive); write/erase protected. |
| 0 | 0 | 0 | Address, 000000h through the last address of code page, is defined by WFPF<6:0> (inclusive); erase/write-protected and the last page, including Flash Configuration Words, are erase/write-protected. |

PIC24FJ128GC010 FAMILY

34.4.3 CONFIGURATION REGISTER PROTECTION

The Configuration registers are protected against inadvertent or unwanted changes or reads in two ways. The primary protection method is the same as that of the RP registers – shadow registers contain a complimentary value which is constantly compared with the actual value.

To safeguard against unpredictable events, Configuration bit changes resulting from individual cell level disruptions (such as ESD events) will cause a parity error and trigger a device Reset.

The data for the Configuration registers is derived from the Flash Configuration Words in program memory. When the GCP bit is set, the source data for device configuration is also protected as a consequence. Even if General Segment protection is not enabled, the device configuration can be protected by using the appropriate code segment protection setting.

34.5 JTAG Interface

PIC24FJ128GC010 family devices implement a JTAG interface, which supports boundary scan device testing.

34.6 In-Circuit Serial Programming

PIC24FJ128GC010 family microcontrollers can be serially programmed while in the end application circuit. This is simply done with two lines for clock (PGECx) and data (PGEDx), and three other lines for power (VDD), ground (VSS) and MCLR. This allows customers to manufacture boards with unprogrammed devices and then program the microcontroller just before shipping the product. This also allows the most recent firmware or a custom firmware to be programmed.

34.7 In-Circuit Debugger

When MPLAB® ICD 3 is selected as a debugger, the in-circuit debugging functionality is enabled. This function allows simple debugging functions when used with MPLAB IDE. Debugging functionality is controlled through the PGECx (Emulation/Debug Clock) and PGEDx (Emulation/Debug Data) pins.

To use the in-circuit debugger function of the device, the design must implement ICSP connections to MCLR, VDD, VSS and the PGECx/PGEDx pin pair, designated by the ICSx Configuration bits. In addition, when the feature is enabled, some of the resources are not available for general use. These resources include the first 80 bytes of data RAM and two I/O pins.

PIC24FJ128GC010 FAMILY

35.0 DEVELOPMENT SUPPORT

The PIC® microcontrollers (MCU) and dsPIC® digital signal controllers (DSC) are supported with a full range of software and hardware development tools:

- Integrated Development Environment
 - MPLAB® X IDE Software
- Compilers/Assemblers/Linkers
 - MPLAB XC Compiler
 - MPASM™ Assembler
 - MPLINK™ Object Linker/
MPLIB™ Object Librarian
 - MPLAB Assembler/Linker/Librarian for
Various Device Families
- Simulators
 - MPLAB X SIM Software Simulator
- Emulators
 - MPLAB REAL ICE™ In-Circuit Emulator
- In-Circuit Debuggers/Programmers
 - MPLAB ICD 3
 - PICKit™ 3
- Device Programmers
 - MPLAB PM3 Device Programmer
- Low-Cost Demonstration/Development Boards,
Evaluation Kits and Starter Kits
- Third-party development tools

35.1 MPLAB X Integrated Development Environment Software

The MPLAB X IDE is a single, unified graphical user interface for Microchip and third-party software, and hardware development tool that runs on Windows®, Linux and Mac OS® X. Based on the NetBeans IDE, MPLAB X IDE is an entirely new IDE with a host of free software components and plug-ins for high-performance application development and debugging. Moving between tools and upgrading from software simulators to hardware debugging and programming tools is simple with the seamless user interface.

With complete project management, visual call graphs, a configurable watch window and a feature-rich editor that includes code completion and context menus, MPLAB X IDE is flexible and friendly enough for new users. With the ability to support multiple tools on multiple projects with simultaneous debugging, MPLAB X IDE is also suitable for the needs of experienced users.

Feature-Rich Editor:

- Color syntax highlighting
- Smart code completion makes suggestions and provides hints as you type
- Automatic code formatting based on user-defined rules
- Live parsing

User-Friendly, Customizable Interface:

- Fully customizable interface: toolbars, toolbar buttons, windows, window placement, etc.
- Call graph window

Project-Based Workspaces:

- Multiple projects
- Multiple tools
- Multiple configurations
- Simultaneous debugging sessions

File History and Bug Tracking:

- Local file history feature
- Built-in support for Bugzilla issue tracker

PIC24FJ128GC010 FAMILY

35.2 MPLAB XC Compilers

The MPLAB XC Compilers are complete ANSI C compilers for all of Microchip's 8, 16, and 32-bit MCU and DSC devices. These compilers provide powerful integration capabilities, superior code optimization and ease of use. MPLAB XC Compilers run on Windows, Linux or MAC OS X.

For easy source level debugging, the compilers provide debug information that is optimized to the MPLAB X IDE.

The free MPLAB XC Compiler editions support all devices and commands, with no time or memory restrictions, and offer sufficient code optimization for most applications.

MPLAB XC Compilers include an assembler, linker and utilities. The assembler generates relocatable object files that can then be archived or linked with other relocatable object files and archives to create an executable file. MPLAB XC Compiler uses the assembler to produce its object file. Notable features of the assembler include:

- Support for the entire device instruction set
- Support for fixed-point and floating-point data
- Command-line interface
- Rich directive set
- Flexible macro language
- MPLAB X IDE compatibility

35.3 MPASM Assembler

The MPASM Assembler is a full-featured, universal macro assembler for PIC10/12/16/18 MCUs.

The MPASM Assembler generates relocatable object files for the MPLINK Object Linker, Intel® standard HEX files, MAP files to detail memory usage and symbol reference, absolute LST files that contain source lines and generated machine code, and COFF files for debugging.

The MPASM Assembler features include:

- Integration into MPLAB X IDE projects
- User-defined macros to streamline assembly code
- Conditional assembly for multipurpose source files
- Directives that allow complete control over the assembly process

35.4 MPLINK Object Linker/ MPLIB Object Librarian

The MPLINK Object Linker combines relocatable objects created by the MPASM Assembler. It can link relocatable objects from precompiled libraries, using directives from a linker script.

The MPLIB Object Librarian manages the creation and modification of library files of precompiled code. When a routine from a library is called from a source file, only the modules that contain that routine will be linked in with the application. This allows large libraries to be used efficiently in many different applications.

The object linker/library features include:

- Efficient linking of single libraries instead of many smaller files
- Enhanced code maintainability by grouping related modules together
- Flexible creation of libraries with easy module listing, replacement, deletion and extraction

35.5 MPLAB Assembler, Linker and Librarian for Various Device Families

MPLAB Assembler produces relocatable machine code from symbolic assembly language for PIC24, PIC32 and dsPIC DSC devices. MPLAB XC Compiler uses the assembler to produce its object file. The assembler generates relocatable object files that can then be archived or linked with other relocatable object files and archives to create an executable file. Notable features of the assembler include:

- Support for the entire device instruction set
- Support for fixed-point and floating-point data
- Command-line interface
- Rich directive set
- Flexible macro language
- MPLAB X IDE compatibility

35.6 MPLAB X SIM Software Simulator

The MPLAB X SIM Software Simulator allows code development in a PC-hosted environment by simulating the PIC MCUs and dsPIC DSCs on an instruction level. On any given instruction, the data areas can be examined or modified and stimuli can be applied from a comprehensive stimulus controller. Registers can be logged to files for further run-time analysis. The trace buffer and logic analyzer display extend the power of the simulator to record and track program execution, actions on I/O, most peripherals and internal registers.

The MPLAB X SIM Software Simulator fully supports symbolic debugging using the MPLAB XC Compilers, and the MPASM and MPLAB Assemblers. The software simulator offers the flexibility to develop and debug code outside of the hardware laboratory environment, making it an excellent, economical software development tool.

35.7 MPLAB REAL ICE In-Circuit Emulator System

The MPLAB REAL ICE In-Circuit Emulator System is Microchip's next generation high-speed emulator for Microchip Flash DSC and MCU devices. It debugs and programs all 8, 16 and 32-bit MCU, and DSC devices with the easy-to-use, powerful graphical user interface of the MPLAB X IDE.

The emulator is connected to the design engineer's PC using a high-speed USB 2.0 interface and is connected to the target with either a connector compatible with in-circuit debugger systems (RJ-11) or with the new high-speed, noise tolerant, Low-Voltage Differential Signal (LVDS) interconnection (CAT5).

The emulator is field upgradable through future firmware downloads in MPLAB X IDE. MPLAB REAL ICE offers significant advantages over competitive emulators including full-speed emulation, run-time variable watches, trace analysis, complex breakpoints, logic probes, a ruggedized probe interface and long (up to three meters) interconnection cables.

35.8 MPLAB ICD 3 In-Circuit Debugger System

The MPLAB ICD 3 In-Circuit Debugger System is Microchip's most cost-effective, high-speed hardware debugger/programmer for Microchip Flash DSC and MCU devices. It debugs and programs PIC Flash microcontrollers and dsPIC DSCs with the powerful, yet easy-to-use graphical user interface of the MPLAB IDE.

The MPLAB ICD 3 In-Circuit Debugger probe is connected to the design engineer's PC using a high-speed USB 2.0 interface and is connected to the target with a connector compatible with the MPLAB ICD 2 or MPLAB REAL ICE systems (RJ-11). MPLAB ICD 3 supports all MPLAB ICD 2 headers.

35.9 PICkit 3 In-Circuit Debugger/Programmer

The MPLAB PICkit 3 allows debugging and programming of PIC and dsPIC Flash microcontrollers at a most affordable price point using the powerful graphical user interface of the MPLAB IDE. The MPLAB PICkit 3 is connected to the design engineer's PC using a full-speed USB interface and can be connected to the target via a Microchip debug (RJ-11) connector (compatible with MPLAB ICD 3 and MPLAB REAL ICE). The connector uses two device I/O pins and the Reset line to implement in-circuit debugging and In-Circuit Serial Programming™ (ICSP™).

35.10 MPLAB PM3 Device Programmer

The MPLAB PM3 Device Programmer is a universal, CE compliant device programmer with programmable voltage verification at VDDMIN and VDDMAX for maximum reliability. It features a large LCD display (128 x 64) for menus and error messages, and a modular, detachable socket assembly to support various package types. The ICSP cable assembly is included as a standard item. In Stand-Alone mode, the MPLAB PM3 Device Programmer can read, verify and program PIC devices without a PC connection. It can also set code protection in this mode. The MPLAB PM3 connects to the host PC via an RS-232 or USB cable. The MPLAB PM3 has high-speed communications and optimized algorithms for quick programming of large memory devices, and incorporates an MMC card for file storage and data applications.

PIC24FJ128GC010 FAMILY

35.11 Demonstration/Development Boards, Evaluation Kits, and Starter Kits

A wide variety of demonstration, development and evaluation boards for various PIC MCUs and dsPIC DSCs allows quick application development on fully functional systems. Most boards include prototyping areas for adding custom circuitry and provide application firmware and source code for examination and modification.

The boards support a variety of features, including LEDs, temperature sensors, switches, speakers, RS-232 interfaces, LCD displays, potentiometers and additional EEPROM memory.

The demonstration and development boards can be used in teaching environments, for prototyping custom circuits and for learning about various microcontroller applications.

In addition to the PICDEM™ and dsPICDEM™ demonstration/development board series of circuits, Microchip has a line of evaluation kits and demonstration software for analog filter design, KEELOQ® security ICs, CAN, IrDA®, PowerSmart battery management, SEEVAL® evaluation system, Sigma-Delta ADC, flow rate sensing, plus many more.

Also available are starter kits that contain everything needed to experience the specified device. This usually includes a single application and debug capability, all on one board.

Check the Microchip web page (www.microchip.com) for the complete list of demonstration, development and evaluation kits.

35.12 Third-Party Development Tools

Microchip also offers a great collection of tools from third-party vendors. These tools are carefully selected to offer good value and unique functionality.

- Device Programmers and Gang Programmers from companies, such as SoftLog and CCS
- Software Tools from companies, such as Gimpel and Trace Systems
- Protocol Analyzers from companies, such as Saleae and Total Phase
- Demonstration Boards from companies, such as MikroElektronika, Digilent® and Olimex
- Embedded Ethernet Solutions from companies, such as EZ Web Lynx, WIZnet and IPLogika®

36.0 INSTRUCTION SET SUMMARY

Note: This chapter is a brief summary of the PIC24F Instruction Set Architecture (ISA) and is not intended to be a comprehensive reference source.

The PIC24F instruction set adds many enhancements to the previous PIC[®] MCU instruction sets, while maintaining an easy migration from previous PIC MCU instruction sets. Most instructions are a single program memory word. Only three instructions require two program memory locations.

Each single-word instruction is a 24-bit word divided into an 8-bit opcode, which specifies the instruction type and one or more operands, which further specify the operation of the instruction. The instruction set is highly orthogonal and is grouped into four basic categories:

- Word or byte-oriented operations
- Bit-oriented operations
- Literal operations
- Control operations

Table 36-1 shows the general symbols used in describing the instructions. The PIC24F instruction set summary in Table 36-2 lists all the instructions, along with the status flags affected by each instruction.

Most word or byte-oriented W register instructions (including barrel shift instructions) have three operands:

- The first source operand, which is typically a register, 'Wb', without any address modifier
- The second source operand, which is typically a register, 'Ws', with or without an address modifier
- The destination of the result, which is typically a register, 'Wd', with or without an address modifier

However, word or byte-oriented file register instructions have two operands:

- The file register specified by the value, 'f'
- The destination, which could either be the file register, 'f', or the W0 register, which is denoted as 'WREG'

Most bit-oriented instructions (including simple rotate/shift instructions) have two operands:

- The W register (with or without an address modifier) or file register (specified by the value of 'Ws' or 'f')
- The bit in the W register or file register (specified by a literal value or indirectly by the contents of register, 'Wb')

The literal instructions that involve data movement may use some of the following operands:

- A literal value to be loaded into a W register or file register (specified by the value of 'k')
- The W register or file register where the literal value is to be loaded (specified by 'Wb' or 'f')

However, literal instructions that involve arithmetic or logical operations use some of the following operands:

- The first source operand, which is a register, 'Wb', without any address modifier
- The second source operand, which is a literal value
- The destination of the result (only if not the same as the first source operand), which is typically a register, 'Wd', with or without an address modifier

The control instructions may use some of the following operands:

- A program memory address
- The mode of the table read and table write instructions

All instructions are a single word, except for certain double-word instructions, which were made double-word instructions so that all the required information is available in these 48 bits. In the second word, the 8 MSBs are '0's. If this second word is executed as an instruction (by itself), it will execute as a NOP.

Most single-word instructions are executed in a single instruction cycle, unless a conditional test is true or the Program Counter is changed as a result of the instruction. In these cases, the execution takes two instruction cycles, with the additional instruction cycle(s) executed as a NOP. Notable exceptions are the BRA (unconditional/computed branch), indirect CALL/GOTO, all table reads and writes, and RETURN/RETFIE instructions, which are single-word instructions but take two or three cycles.

Certain instructions that involve skipping over the subsequent instruction require either two or three cycles if the skip is performed, depending on whether the instruction being skipped is a single-word or two-word instruction. Moreover, double-word moves require two cycles. The double-word instructions execute in two instruction cycles.

PIC24FJ128GC010 FAMILY

TABLE 36-1: SYMBOLS USED IN OPCODE DESCRIPTIONS

| Field | Description |
|-----------------|---|
| #text | Means literal defined by "text" |
| (text) | Means "content of text" |
| [text] | Means "the location addressed by text" |
| { } | Optional field or operation |
| <n:m> | Register bit field |
| .b | Byte mode selection |
| .d | Double-Word mode selection |
| .S | Shadow register select |
| .w | Word mode selection (default) |
| bit4 | 4-bit Bit Selection field (used in word addressed instructions) $\in \{0..15\}$ |
| C, DC, N, OV, Z | MCU Status bits: Carry, Digit Carry, Negative, Overflow, Sticky Zero |
| Expr | Absolute address, label or expression (resolved by the linker) |
| f | File register address $\in \{0000h..1FFFh\}$ |
| lit1 | 1-bit unsigned literal $\in \{0,1\}$ |
| lit4 | 4-bit unsigned literal $\in \{0..15\}$ |
| lit5 | 5-bit unsigned literal $\in \{0..31\}$ |
| lit8 | 8-bit unsigned literal $\in \{0..255\}$ |
| lit10 | 10-bit unsigned literal $\in \{0..255\}$ for Byte mode, $\{0:1023\}$ for Word mode |
| lit14 | 14-bit unsigned literal $\in \{0..16383\}$ |
| lit16 | 16-bit unsigned literal $\in \{0..65535\}$ |
| lit23 | 23-bit unsigned literal $\in \{0..8388607\}$; LSB must be '0' |
| None | Field does not require an entry, may be blank |
| PC | Program Counter |
| Slit10 | 10-bit signed literal $\in \{-512..511\}$ |
| Slit16 | 16-bit signed literal $\in \{-32768..32767\}$ |
| Slit6 | 6-bit signed literal $\in \{-16..16\}$ |
| Wb | Base W register $\in \{W0..W15\}$ |
| Wd | Destination W register $\in \{Wd, [Wd], [Wd++] , [Wd--], [++Wd], [--Wd] \}$ |
| Wdo | Destination W register $\in \{Wnd, [Wnd], [Wnd++] , [Wnd--], [++Wnd], [--Wnd], [Wnd+Wb] \}$ |
| Wm,Wn | Dividend, Divisor working register pair (direct addressing) |
| Wn | One of 16 working registers $\in \{W0..W15\}$ |
| Wnd | One of 16 destination working registers $\in \{W0..W15\}$ |
| Wns | One of 16 source working registers $\in \{W0..W15\}$ |
| WREG | W0 (working register used in file register instructions) |
| Ws | Source W register $\in \{Ws, [Ws], [Ws++] , [Ws--], [++Ws], [--Ws] \}$ |
| Wso | Source W register $\in \{Wns, [Wns], [Wns++] , [Wns--], [++Wns], [--Wns], [Wns+Wb] \}$ |

PIC24FJ128GC010 FAMILY

NOTES:

PIC24FJ128GC010 FAMILY

37.0 ELECTRICAL CHARACTERISTICS

This section provides an overview of the PIC24FJ128GC010 family electrical characteristics. Additional information will be provided in future revisions of this document as it becomes available.

Absolute maximum ratings for the PIC24FJ128GC010 family are listed below. Exposure to these maximum rating conditions for extended periods may affect device reliability. Functional operation of the device at these, or any other conditions above the parameters indicated in the operation listings of this specification, is not implied.

Absolute Maximum Ratings^(†)

| | |
|---|---|
| Ambient temperature under bias | -40°C to +100°C |
| Storage temperature | -65°C to +150°C |
| Voltage on VDD with respect to VSS | -0.3V to +4.0V |
| Voltage on any general purpose digital or analog pin (not 5.5V tolerant) with respect to VSS | -0.3V to (VDD + 0.3V) |
| Voltage on any general purpose digital or analog pin (5.5V tolerant, including MCLR) with respect to VSS: | |
| When VDD = 0V: | -0.3V to +4.0V |
| When VDD ≥ 2.0V: | -0.3V to +6.0V |
| Voltage on AVDD and SVDD with respect to VSS | (VDD - 0.3V) to (lesser of: 4.0V or (VDD + 0.3V)) |
| Voltage on AVSS and SVSS with respect to VSS | -0.3V to +0.3V |
| Voltage on CH0+, CH0-, CH1+ and CH1- with respect to SVSS | -0.3V to (SVDD + 0.3V) |
| Voltage on VBAT with respect to VSS | -0.3V to +4.0V |
| Voltage on VUSB3V3 with respect to VSS | (VCAP - 0.3V) to +4.0V |
| Voltage on VBUS with respect to VSS | -0.3V to +6.0V |
| Voltage on D+ or D- with respect to VSS: | |
| (0Ω source impedance) (Note 1) | -0.5V to (VUSB3V3 + 0.5V) |
| (source impedance ≥ 28Ω, VUSB3V3 ≥ 3.0V) | -1.0V to +4.6V |
| Maximum current out of VSS pin | 300 mA |
| Maximum current into VDD pin (Note 2) | 250 mA |
| Maximum output current sunk by any I/O pin | 25 mA |
| Maximum output current sourced by any I/O pin | 25 mA |
| Maximum current sunk by all ports | 200 mA |
| Maximum current sourced by all ports (Note 2) | 200 mA |

Note 1: The original “USB 2.0 Specification” indicated that USB devices should withstand 24-hour short circuits of D+ or D- to VBUS voltages. This requirement was later removed in an Engineering Change Notice (ECN) supplement to the USB specifications, which supersedes the original specifications. PIC24FJ128GC010 family devices will typically be able to survive this short-circuit test, but it is recommended to adhere to the absolute maximum specified here to avoid damaging the device.

2: Maximum allowable current is a function of device maximum power dissipation (see [Table 37-1](#)).

† **NOTICE:** Stresses above those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. This is a stress rating only and functional operation of the device at those or any other conditions above those indicated in the operation listings of this specification is not implied. Exposure to maximum rating conditions for extended periods may affect device reliability.

PIC24FJ128GC010 FAMILY

37.1 DC Characteristics

FIGURE 37-1: PIC24FJ128GC010 FAMILY VOLTAGE-FREQUENCY GRAPH (INDUSTRIAL)

TABLE 37-1: THERMAL OPERATING CONDITIONS

| Rating | Symbol | Min | Typ | Max | Unit |
|---|--------------------|--|-----|------|------|
| PIC24FJ128GC010 Family: | | | | | |
| Operating Junction Temperature Range | T _J | -40 | — | +100 | °C |
| Operating Ambient Temperature Range | T _A | -40 | — | +85 | °C |
| Power Dissipation: Internal Chip Power Dissipation: P _{INT} = V _{DD} x (I _{DD} - Σ I _{OH}) I/O Pin Power Dissipation: P _{I/O} = Σ ({V _{DD} - V _{OH} } x I _{OH}) + Σ (V _{OL} x I _{OL}) | P _D | P _{INT} + P _{I/O} | | | W |
| Maximum Allowed Power Dissipation | P _D MAX | (T _J MAX - T _A)/θ _{JA} | | | W |

TABLE 37-2: THERMAL PACKAGING CHARACTERISTICS

| Characteristic | Symbol | Typ | Max | Unit | Note |
|--|-----------------|------|-----|------|----------|
| Package Thermal Resistance, 12x12x1 mm 100-pin TQFP | θ _{JA} | 45.0 | — | °C/W | (Note 1) |
| Package Thermal Resistance, 10x10x1 mm 64-pin TQFP | θ _{JA} | 48.3 | — | °C/W | (Note 1) |
| Package Thermal Resistance, 9x9x0.9 mm 64-pin QFN | θ _{JA} | 28.0 | — | °C/W | (Note 1) |
| Package Thermal Resistance, 10x10x1.1 mm 121-pin BGA | θ _{JA} | 40.2 | — | °C/W | (Note 1) |

Note 1: Junction to ambient thermal resistance, Theta-JA (θ_{JA}) numbers are achieved by package simulations.

PIC24FJ128GC010 FAMILY

TABLE 37-3: DC CHARACTERISTICS: TEMPERATURE AND VOLTAGE SPECIFICATIONS

| DC CHARACTERISTICS | | | Standard Operating Conditions: 2.0V to 3.6V (unless otherwise stated) Operating temperature -40°C ≤ TA ≤ +85°C for Industrial | | | | |
|--------------------------|---------|--|--|------|------|-------|---|
| Param No. | Symbol | Characteristic | Min | Typ | Max | Units | Conditions |
| Operating Voltage | | | | | | | |
| DC10 | VDD | Supply Voltage | 2.0 | — | 3.6 | V | BOR disabled |
| | | | VBOR | — | 3.6 | | BOR enabled |
| DC12 | VDR | RAM Data Retention Voltage⁽¹⁾ | Greater of: VPORREL or VBOR | — | — | V | VBOR used only if BOR is enabled (BOREN = 1) |
| DC16 | VPOR | VDD Start Voltage to Ensure Internal Power-on Reset Signal | VSS | — | — | V | (Note 2) |
| DC16A | VPORREL | VDD Power-on Reset Release Voltage | 1.80 | 1.88 | 1.95 | V | (Note 3) |
| DC17A | SRVDD | Recommended VDD Rise Skew Rate to Ensure Internal Power-on Reset Signal | 0.05 | — | — | V/ms | 0-3.3V in 66 ms 0-2.5V in 50 ms (Note 2) |
| DC17B | VBOR | Brown-out Reset Voltage on VDD Transition, High-to-Low | 2.0 | 2.1 | 2.2 | V | (Note 3) |
| DC17C | VBATBOR | VBAT BOR Threshold on VBAT High-to-Low | — | 1.68 | — | V | Applies when VBTBOR = 1 |

Note 1: This is the limit to which VDD may be lowered and the RAM contents will always be retained.

2: If the VPOR or SRVDD parameters are not met, or the application experiences slow power-down VDD ramp rates, it is recommended to enable and use the BOR.

3: On a rising VDD power-up sequence, application firmware execution begins at the higher of the VPORREL or VBOR level (when BOREN = 1).

PIC24FJ128GC010 FAMILY

TABLE 37-4: DC CHARACTERISTICS: OPERATING CURRENT (IDD)

| DC CHARACTERISTICS | | | Standard Operating Conditions: 2.0V to 3.6V (unless otherwise stated) Operating temperature -40°C ≤ TA ≤ +85°C for Industrial | | | |
|--|------------------------|------|--|-----------------------|------|------------------------------------|
| Parameter No. | Typical ⁽¹⁾ | Max | Units | Operating Temperature | VDD | Conditions |
| Operating Current (IDD)⁽²⁾ | | | | | | |
| DC19 | 0.20 | 0.28 | mA | -40°C to +85°C | 2.0V | 0.5 MIPS, Fosc = 1 MHz |
| | 0.21 | 0.28 | mA | -40°C to +85°C | 3.3V | |
| DC20 | 0.38 | 0.52 | mA | -40°C to +85°C | 2.0V | 1 MIPS, Fosc = 2 MHz |
| | 0.39 | 0.52 | mA | -40°C to +85°C | 3.3V | |
| DC23 | 1.5 | 2.0 | mA | -40°C to +85°C | 2.0V | 4 MIPS, Fosc = 8 MHz |
| | 1.5 | 2.0 | mA | -40°C to +85°C | 3.3V | |
| DC24 | 5.6 | 7.6 | mA | -40°C to +85°C | 2.0V | 16 MIPS, Fosc = 32 MHz |
| | 5.7 | 7.6 | mA | -40°C to +85°C | 3.3V | |
| DC31 | 23 | 78 | μA | -40°C to +85°C | 2.0V | LPRC (15.5 KIPS), Fosc = 31 kHz |
| | 25 | 80 | μA | -40°C to +85°C | 3.3V | |

Note 1: Data in the "Typical" column is at 3.3V, +25°C unless otherwise stated. Typical parameters are for design guidance only and are not tested.

- 2:** The supply current is mainly a function of the operating voltage and frequency. Other factors, such as I/O pin loading and switching rate, oscillator type, internal code execution pattern and temperature, also have an impact on the current consumption. No peripheral modules are operating and all of the Peripheral Module Disable (PMD) bits are set.

TABLE 37-5: DC CHARACTERISTICS: IDLE CURRENT (IDLE)

| DC CHARACTERISTICS | | | Standard Operating Conditions: 2.0V to 3.6V (unless otherwise stated) Operating temperature -40°C ≤ TA ≤ +85°C for Industrial | | | |
|----------------------------|------------------------|------|--|-----------------------|------|------------------------------------|
| Parameter No. | Typical ⁽¹⁾ | Max | Units | Operating Temperature | VDD | Conditions |
| Idle Current (IDLE) | | | | | | |
| DC40 | 116 | 150 | μA | -40°C to +85°C | 2.0V | 1 MIPS, Fosc = 2 MHz |
| | 123 | 160 | μA | -40°C to +85°C | 3.3V | |
| DC43 | 0.39 | 0.50 | mA | -40°C to +85°C | 2.0V | 4 MIPS, Fosc = 8 MHz |
| | 0.41 | 0.54 | mA | -40°C to +85°C | 3.3V | |
| DC47 | 1.5 | 1.9 | mA | -40°C to +85°C | 2.0V | 16 MIPS, Fosc = 32 MHz |
| | 1.6 | 2.0 | mA | -40°C to +85°C | 3.3V | |
| DC50 | 0.54 | 0.61 | mA | -40°C to +85°C | 2.0V | 4 MIPS (FRC), Fosc = 8 MHz |
| | 0.54 | 0.64 | mA | -40°C to +85°C | 3.3V | |
| DC51 | 17 | 78 | μA | -40°C to +85°C | 2.0V | LPRC (15.5 KIPS), Fosc = 31 kHz |
| | 18 | 80 | μA | -40°C to +85°C | 3.3V | |

Note 1: Data in the "Typical" column is at 3.3V, +25°C unless otherwise stated. Parameters are for design guidance only and are not tested.

PIC24FJ128GC010 FAMILY

TABLE 37-6: DC CHARACTERISTICS: POWER-DOWN CURRENT (IPD)

| DC CHARACTERISTICS | | | Standard Operating Conditions: 2.0V to 3.6V (unless otherwise stated) Operating temperature $-40^{\circ}\text{C} \leq T_A \leq +85^{\circ}\text{C}$ for Industrial | | | |
|---------------------------------|------------------------|------|---|--|------|---|
| Parameter No. | Typical ⁽¹⁾ | Max | Units | Operating Temperature | VDD | Conditions |
| Power-Down Current (IPD) | | | | | | |
| DC60 | 2.9 | — | μA | -40°C | 2.0V | Sleep ⁽²⁾ |
| | 4.3 | 17 | μA | $+25^{\circ}\text{C}$ | | |
| | 8.3 | — | μA | $+60^{\circ}\text{C}$ | | |
| | 20 | 27.5 | μA | $+85^{\circ}\text{C}$ | | |
| | 2.9 | — | μA | -40°C | 3.3V | |
| | 4.3 | 18 | μA | $+25^{\circ}\text{C}$ | | |
| | 8.4 | — | μA | $+60^{\circ}\text{C}$ | | |
| | 20.5 | 28 | μA | $+85^{\circ}\text{C}$ | | |
| DC61 | 0.07 | — | μA | -40°C | 2.0V | Low-Voltage Sleep ⁽³⁾ |
| | 0.38 | — | μA | $+25^{\circ}\text{C}$ | | |
| | 2.6 | — | μA | $+60^{\circ}\text{C}$ | | |
| | 9.0 | — | μA | $+85^{\circ}\text{C}$ | | |
| | 0.09 | — | μA | -40°C | 3.3V | |
| | 0.42 | — | μA | $+25^{\circ}\text{C}$ | | |
| | 2.75 | — | μA | $+60^{\circ}\text{C}$ | | |
| | 9.0 | — | μA | $+85^{\circ}\text{C}$ | | |
| DC70 | 0.1 | — | nA | -40°C | 2.0V | Deep Sleep, capacitor on VCAP is fully discharged |
| | 18 | 700 | nA | $+25^{\circ}\text{C}$ | | |
| | 230 | — | nA | $+60^{\circ}\text{C}$ | | |
| | 1.8 | 3 | μA | $+85^{\circ}\text{C}$ | | |
| | 5 | — | nA | -40°C | 3.3V | |
| | 75 | 900 | nA | $+25^{\circ}\text{C}$ | | |
| | 540 | — | nA | $+60^{\circ}\text{C}$ | | |
| | 1.5 | 6.0 | μA | $+85^{\circ}\text{C}$ | | |
| DC74 | 0.4 | 2.0 | μA | -40°C to $+85^{\circ}\text{C}$ | 0V | RTCC with VBAT mode (LPRC/SOSC) ⁽⁴⁾ |

Note 1: Data in the Typical column is at 3.3V, $+25^{\circ}\text{C}$ unless otherwise stated. Parameters are for design guidance only and are not tested.

2: The retention low-voltage regulator is disabled; RETEN (RCON<12>) = 0, $\overline{\text{LPCFG}}$ (CW1<10>) = 1.

3: The retention low-voltage regulator is enabled; RETEN (RCON<12>) = 1, $\overline{\text{LPCFG}}$ (CW1<10>) = 0.

4: The VBAT pin is connected to the battery and RTCC is running with VDD = 0.

| Incremental Current Deep Sleep BOR (ΔDSBOR)⁽²⁾ | | | | | | |
| DC81 | 0.11 | 0.40 | μA | -40°C to $+85^{\circ}\text{C}$ | 2.0V | Δ Deep Sleep BOR ⁽²⁾ |
| | 0.12 | 0.40 | μA | -40°C to $+85^{\circ}\text{C}$ | 3.3V | |
| Incremental Current Deep Sleep Watchdog Timer Reset (ΔDSWDT)⁽²⁾ | | | | | | |
| DC80 | 0.24 | 0.40 | μA | -40°C to $+85^{\circ}\text{C}$ | 2.0V | Δ Deep Sleep WDT ⁽²⁾ |
| | 0.24 | 0.40 | μA | -40°C to $+85^{\circ}\text{C}$ | 3.3V | |
| Incremental Current LCD (ΔLCD)⁽²⁾ | | | | | | |
| DC82 | 0.8 | 3.0 | μA | -40°C to $+85^{\circ}\text{C}$ | 3.3V | Δ LCD External/Internal; ^(2,3) 1/8 MUX, 1/3 Bias |
| DC90 | 20 | — | μA | -40°C to $+85^{\circ}\text{C}$ | 2.0V | Δ LCD Charge Pump; ^(2,4) 1/8 MUX, 1/3 Bias |
| | 24 | — | μA | -40°C to $+85^{\circ}\text{C}$ | 3.3V | |
| VBAT A/D Monitor⁽⁵⁾ | | | | | | |
| DC91 | 1.5 | — | μA | -40°C to $+85^{\circ}\text{C}$ | 3.3V | VBAT = 2V |
| | 4.0 | — | μA | -40°C to $+85^{\circ}\text{C}$ | 3.3V | VBAT = 3.3V |

Note 1: Data in the Typical column is at 3.3V, $+25^{\circ}\text{C}$ unless otherwise stated. Parameters are for design guidance only and are not tested.

2: Incremental current while the module is enabled and running.

3: LCD is enabled and running, no glass is connected; the resistor ladder current is not included.

4: LCD is enabled and running, no glass is connected.

5: The A/D channel is connected to the VBAT pin internally; this is the current during A/D VBAT operation.

| DBG11 | | Module Start-up Time from Disabled State | — | 5 | — | ms | Time from BUFEN and BUFOE = 1 to output stable, CLOAD = 20 μF |
| DBG12 | | Module Start-up Time from Standby Mode | — | 100 | — | μs | Time from BUFSTBY = 0 to output stable |
| DBG14 | | AVDD Active Current | — | 100 | — | μA | Module enabled, BUFOE = 1 |

- Note 1:** No DC loading on module unless otherwise stated.
Note 2: For BUFREF<1:0> \neq 00, (Reference Output Max + 100 mV) $< AV_{DD} < 3.6\text{V}$.
Note 3: To minimize voltage error, the DC loading on the BGBUF output pins should be $< 100\ \mu\text{A}$.

PIC24FJ128GC010 FAMILY

TABLE 37-13: VBAT OPERATING VOLTAGE SPECIFICATIONS

| Param No. | Symbol | Characteristic | Min | Typ | Max | Units | Comments |
|-----------|--------|--|--------|-----|-----|-------|--|
| DVB01 | VBT | Operating Voltage | 1.6 | — | 3.6 | V | Battery connected to the VBAT pin, VBTBOR = 0 |
| DVB02 | | | VBTBOR | — | 3.6 | V | Battery connected to the VBAT pin, VBTBOR = 1 |
| DVB10 | VBTADC | VBAT A/D Monitoring Voltage Specification ⁽¹⁾ | 1.6 | — | 3.6 | V | A/D monitoring the VBAT pin using the internal A/D channel |

Note 1: Measuring the A/D value using the A/D is represented by the equation:
 Measured Voltage = ((VBAT/2)/VDD) * 4096 for 12-bit A/D.

TABLE 37-14: CTMU CURRENT SOURCE SPECIFICATIONS

| DC CHARACTERISTICS | | | Standard Operating Conditions: 2.0V to 3.6V (unless otherwise stated) Operating temperature -40°C ≤ TA ≤ +85°C for Industrial | | | | | |
|--------------------|-------|---|--|--------------------|-----|-------|-----------------------------------|---------------------|
| Param No. | Sym | Characteristic | Min | Typ ⁽¹⁾ | Max | Units | Comments | Conditions |
| DCT10 | IOUT1 | CTMU Current Source, Base Range | — | 550 | — | nA | CTMUICON<1:0> = 00 | 2.5V < VDD < VDDMAX |
| DCT11 | IOUT2 | CTMU Current Source, 10x Range | — | 5.5 | — | μA | CTMUICON<1:0> = 01 | |
| DCT12 | IOUT3 | CTMU Current Source, 100x Range | — | 55 | — | μA | CTMUICON<1:0> = 10 | |
| DCT13 | IOUT4 | CTMU Current Source, 1000x Range | — | 550 | — | μA | CTMUICON<1:0> = 11 ⁽²⁾ | |
| DCT21 | VΔ | Temperature Diode Voltage Change per Degree Celsius | — | -3 | — | mV/°C | | |

Note 1: Nominal value at center point of current trim range (CTMUICON<7:2> = 000000).

2: Do not use this current range with temperature sensing diode.

TABLE 37-15: USB ON-THE-GO MODULE SPECIFICATIONS

| DC CHARACTERISTICS | | | Standard Operating Conditions: 2.0V to 3.6V (unless otherwise stated) Operating temperature -40°C ≤ TA ≤ +85°C for Industrial | | | | |
|--------------------------|---------|--------------------|--|-----|-----|-------|--|
| Param No. | Symbol | Characteristic | Min | Typ | Max | Units | Conditions |
| Operating Voltage | | | | | | | |
| DUS01 | VUSB3V3 | USB Supply Voltage | Greater of: 3.0 or (VDD – 0.3V) | 3.3 | 3.6 | V | USB module enabled |
| | | | (VDD – 0.3V) ⁽¹⁾ | — | 3.6 | V | USB disabled, RG2/RG3 are unused and externally pulled low or left in a high-impedance state |
| | | | (VDD – 0.3V) | VDD | 3.6 | V | USB disabled, RG2/RG3 are used as general purpose I/O |

Note 1: The VUSB pin may also be left in a high-impedance state under these conditions. However, if the voltage floats below (VDD – 0.3V), this may result in higher IPD currents than specified. The preferred method is to tie the VUSB pin to VDD, even if the USB module is not used.

| CM54b | | | — | 40 | — | μA | Module enabled, SPDSEL = 0, no output load |
| Comparator Mode Specifications | | | | | | | |
| CM10a | TRESPL | Large Signal Comparator Response Time | — | 500 | — | ns | SPDSEL = 1, 3V step with 1.5V input overdrive |
| | | | — | 2.6 | — | μs | SPDSEL = 0, 3V step with 1.5V input overdrive |
| CM10B | TRESPL | Small Signal Comparator Response Time | — | 1.6 | — | μs | SPDSEL = 1, 50 mV step with 15 mV input overdrive |
| | | | — | 4.6 | — | μs | SPDSEL = 0, 50 mV step with 15 mV input overdrive |
| CM15 | VCMCR | Common-Mode Input Voltage Range | AVSS | — | AVDD | V | |

Note 1: The op amps use CMOS input circuitry with negligible input bias current. The maximum “effective bias current” is the I/O pin leakage specified by electrical Parameter [DI51](#).

PIC24FJ128GC010 FAMILY

37.2 AC Characteristics and Timing Parameters

The information contained in this section defines the PIC24FJ128GC010 family AC characteristics and timing parameters.

TABLE 37-20: TEMPERATURE AND VOLTAGE SPECIFICATIONS – AC

| | | |
|--------------------|--|---|
| AC CHARACTERISTICS | Standard Operating Conditions: 2.0V to 3.6V (unless otherwise stated) | |
| | Operating temperature | -40°C ≤ TA ≤ +85°C for Industrial |
| | Operating voltage VDD range as described in | Section 37.1 “DC Characteristics” . |

FIGURE 37-2: LOAD CONDITIONS FOR DEVICE TIMING SPECIFICATIONS

TABLE 37-21: CAPACITIVE LOADING REQUIREMENTS ON OUTPUT PINS

| Param No. | Symbol | Characteristic | Min | Typ ⁽¹⁾ | Max | Units | Conditions |
|-----------|--------|-----------------------|-----|--------------------|-----|-------|--|
| DO50 | Cosco | OSCO/CLKO Pin | — | — | 15 | pF | In XT and HS modes when external clock is used to drive OSC1 |
| DO56 | Cio | All I/O Pins and OSCO | — | — | 50 | pF | EC mode |
| DO58 | CB | SCLx, SDAx | — | — | 400 | pF | In I ² C™ mode |

Note 1: Data in the “Typ” column is at 3.3V, +25°C unless otherwise stated.

PIC24FJ128GC010 FAMILY

FIGURE 37-3: EXTERNAL CLOCK TIMING

TABLE 37-22: EXTERNAL CLOCK TIMING REQUIREMENTS

| AC CHARACTERISTICS | | | Standard Operating Conditions: 2.0V to 3.6V (unless otherwise stated) Operating temperature -40°C ≤ TA ≤ +85°C for Industrial | | | | | |
|--------------------|---------------|---|--|-----------------------|---------------------------|---------------------------------|------------------------------------|-----------------------------------|
| Param No. | Symbol | Characteristic | Min | Typ ⁽¹⁾ | Max | Units | Conditions | |
| OS10 | Fosc | External CLKI Frequency (External clocks allowed only in EC mode) | DC 1.97 | — — | 32 48 | MHz MHz | EC ECPLL (Note 2) | |
| | | Oscillator Frequency | 3.5 4 10 12 31 | — — — — — | 10 8 32 32 33 | MHz MHz MHz MHz kHz | XT XTPLL HS HSPLL SOSC | |
| | | Tosc = 1/Fosc | — | — | — | — | — | See Parameter OS10 for Fosc value |
| | | Tcy | Instruction Cycle Time ⁽³⁾ | 62.5 | — | DC | ns | |
| | | TosL, TosH | External Clock in (OSCI) High or Low Time | 0.45 x Tosc | — | — | ns | EC |
| OS31 | TosR, TosF | External Clock in (OSCI) Rise or Fall Time | — | — | 20 | ns | EC | |
| OS40 | TckR | CLKO Rise Time ⁽⁴⁾ | — | 6 | 10 | ns | | |
| OS41 | TckF | CLKO Fall Time ⁽⁴⁾ | — | 6 | 10 | ns | | |

Note 1: Data in the “Typ” column is at 3.3V, +25°C unless otherwise stated.

2: Represents input to the system clock prescaler. PLL dividers and postscalers must still be configured so that the system clock frequency does not exceed the maximum frequency shown in Figure 37-1.

3: Instruction cycle period (Tcy) equals two times the input oscillator time base period. All specified values are based on characterization data for that particular oscillator type, under standard operating conditions, with the device executing code. Exceeding these specified limits may result in an unstable oscillator operation and/or higher than expected current consumption. All devices are tested to operate at “Min.” values with an external clock applied to the OSCI/CLKI pin. When an external clock input is used, the “Max.” cycle time limit is “DC” (no clock) for all devices.

4: Measurements are taken in EC mode. The CLKO signal is measured on the OSCO pin. CLKO is low for the Q1-Q2 period (1/2 Tcy) and high for the Q3-Q4 period (1/2 Tcy).

| Param No. | Symbol | Characteristic | Min | Typ | Max | Units | Conditions |
| OS50 | FPLLI | PLL Input Frequency Range ⁽¹⁾ | 1.97 | 4 | 4.04 | MHz | ECPLL, XTPLL, HSPLL or FRCPLL modes |
| OS52 | TLOCK | PLL Start-up Time (Lock Time) | — | — | 128 | μs | |
| OS53 | DCLK | CLKO Stability (Jitter) | -0.25 | — | 0.25 | % | |

Note 1: The PLL accepts a 1.97 MHz to 4.04 MHz input frequency. Higher input frequencies, up to 48 MHz, may be supplied to the PLL if they are prescaled down by the PLLDIVx Configuration bits into the 1.97 MHz to 4.04 MHz range.

TABLE 37-24: INTERNAL RC ACCURACY

| AC CHARACTERISTICS | | Standard Operating Conditions: 2.0V to 3.6V (unless otherwise stated) Operating temperature -40°C ≤ TA ≤ +85°C for Industrial | | | | |
|--------------------|-------------------------------------|--|-------|------|-------|---|
| Param No. | Characteristic | Min | Typ | Max | Units | Conditions |
| F20 | FRC Accuracy @ 8 MHz ⁽⁴⁾ | -1 | ±0.15 | 1 | % | 2.0V ≤ VDD ≤ 3.6V, 0°C ≤ TA ≤ +85°C (Note 1) |
| | | -1.5 | — | 1.5 | % | 2.0V ≤ VDD ≤ 3.6V, -40°C ≤ TA < 0°C |
| | | -0.20 | ±0.05 | 0.20 | % | 2.0V ≤ VDD ≤ 3.6V, -40°C ≤ TA ≤ +85°C, self-tune is enabled and locked (Note 2) |
| F21 | LPRC @ 31 kHz | -20 | — | 20 | % | |
| F22 | OSCTUN Step-Size | — | 0.05 | — | %/bit | |
| F23 | FRC Self-Tune Lock Time | — | <5 | 8 | ms | (Note 3) |

Note 1: To achieve this accuracy, physical stress applied to the microcontroller package (ex., by flexing the PCB) must be kept to a minimum.

2: Accuracy measured with respect to reference source accuracy.

3: Time from reference clock is stable and in range until the FRC is tuned within the range specified by F20 (with self-tune).

4: Other frequencies that are derived from the FRC (either through digital division by prescalers or multiplication through a PLL) will also have the same accuracy tolerance specifications as provided here.

TABLE 37-25: RC OSCILLATOR START-UP TIME

| AC CHARACTERISTICS | | | Standard Operating Conditions: 2.0V to 3.6V (unless otherwise stated) Operating temperature -40°C ≤ TA ≤ +85°C for Industrial | | | | |
|--------------------|--------|---------------------------------------|--|-----|-----|-------|------------|
| Param No. | Symbol | Characteristic | Min | Typ | Max | Units | Conditions |
| FR0 | TFRC | FRC Oscillator Start-up Time | — | 15 | — | μs | |
| FR1 | TLPRC | Low-Power RC Oscillator Start-up Time | — | 50 | — | μs | |

TABLE 37-28: 12-BIT PIPELINE A/D MODULE SPECIFICATIONS

| AC CHARACTERISTICS | | | Standard Operating Conditions: 2.0V to 3.6V (unless otherwise stated) Operating temperature $-40^{\circ}\text{C} \leq T_A \leq +85^{\circ}\text{C}$ for Industrial | | | | |
|-------------------------|------------------|-----------------------------|---|-----------|-------------------------------------|-------|--|
| Param No. | Symbol | Characteristic | Min. | Typ | Max. | Units | Conditions |
| Device Supply | | | | | | | |
| AD01 | AVDD | Module VDD Supply | Greater of: (VDD – 0.3) or 2.0 | — | Lesser of: (VDD + 0.3) or 3.6 | V | |
| AD02 | AVSS | Module VSS Supply | VSS – 0.3 | — | VSS + 0.3 | V | |
| AD03 | IQADC1 | AVDD Current | — | 0.4 | — | mA | VDD = AVDD = 3.3V, 1 MHz A/D clock, PWRLVL = 0, A/D active and not halted |
| | IQADC8 | | — | 2 | — | mA | VDD = AVDD = 3.3V, 8 MHz A/D clock, PWRLVL = 1, A/D active and not halted |
| Reference Inputs | | | | | | | |
| AD05 | VREFH | Reference Voltage High | AVSS + 1.8 | — | AVDD | V | |
| AD06 | VREFL | Reference Voltage Low | AVSS | — | VREFH – 1.2 | V | |
| AD07 | VREF | Absolute Reference Voltage | AVSS – 0.3 | — | AVDD + 0.3 | V | |
| | | | AVSS + 1.8 | — | AVDD + 0.3 | V | REFPUMP = 0 |
| | | | AVSS + 1.2 | — | 2.0 | V | REFPUMP = 1 |
| Analog Input | | | | | | | |
| AD10 | VINH-VINL | Full-Scale Input Span | VREFL | — | VREFH | V | (Note 2) |
| AD11 | VIN | Absolute Input Voltage | AVSS – 0.3 | — | AVDD + 0.3 | V | |
| AD12 | VINL | Absolute VINL Input Voltage | AVSS – 0.3 | — | AVDD/3 | V | |
| AD13 | ILKG | Leakage Current | — | ± 1.0 | 610 | nA | VINL = AVSS = VREFL = 0V, AVDD = VREFH = 3V, Source Impedance = 2.5 k Ω |
| A/D Accuracy | | | | | | | |
| AD20B | Nr | Resolution | — | 12 | — | bits | |
| AD21B | INL | Integral Nonlinearity | -6 | — | +6 | LSb | VINL = AVSS = VREFL = 0V, AVDD = VREFH = 3V |
| AD22B | DNL | Differential Nonlinearity | -3 | — | +3 | LSb | VINL = AVSS = VREFL = 0V, AVDD = VREFH = 3V (Note 3) |
| AD23B | GERR | Gain Error | -8 | — | +8 | LSb | VINL = AVSS = VREFL = 0V, AVDD = VREFH = 3V |
| AD24B | E _{OFF} | Offset Error | -12 | — | +12 | LSb | VINL = AVSS = VREFL = 0V, AVDD = VREFH = 3V |
| AD25B | | Monotonicity | — | — | — | — | (Note 1) |

Note 1: The A/D conversion result never decreases with an increase in the input voltage.

Note 2: Measurements are taken with the external AVREF+ and AVREF- used as the A/D voltage reference.

Note 3: Overall accuracy can be improved if 4 or more consecutive measurements are averaged. For details, see the “PIC24F Family Reference Manual”, “12-Bit, High-Speed Pipeline A/D Converter” (DS30686).

38.0 PACKAGING INFORMATION

38.1 Package Marking Information

64-Lead QFN (9x9x0.9 mm)

Example

64-Lead TQFP (10x10x1 mm)

Example

100-Lead TQFP (12x12x1 mm)

Example

| | | |
|----------------|-----------------|---|
| Legend: | XX...X | Customer-specific information |
| | Y | Year code (last digit of calendar year) |
| | YY | Year code (last 2 digits of calendar year) |
| | WW | Week code (week of January 1 is week '01') |
| | NNN | Alphanumeric traceability code |
| | ^(e3) | Pb-free JEDEC designator for Matte Tin (Sn) |
| | * | This package is Pb-free. The Pb-free JEDEC designator ^(e3) can be found on the outer packaging for this package. |

Note: In the event the full Microchip part number cannot be marked on one line, it will be carried over to the next line, thus limiting the number of available characters for customer-specific information.

| Overall Length | D | 10.00 BSC | | |
| Array Length | D1 | 8.00 BSC | | |
| Contact Diameter | b | 0.40 TYP | | |

Notes:

- Pin 1 visual index feature may vary, but must be located within the hatched area.
- Dimensioning and tolerancing per ASME Y14.5M.
 - BSC: Basic Dimension. Theoretically exact value shown without tolerances.
 - REF: Reference Dimension, usually without tolerance, for information purposes only.
- The outer rows and columns of balls are located with respect to datums A and B.

Microchip Technology Drawing C04-148 Rev D Sheet 2 of 2

PIC24FJ128GC010 FAMILY

121-Lead Plastic Thin Profile Ball Grid Array (BG) - 10x10x1.10 mm Body [TFBGA--Formerly XBGA]

Note: For the most current package drawings, please see the Microchip Packaging Specification located at <http://www.microchip.com/packaging>

RECOMMENDED LAND PATTERN

| Dimension Limits | Units | MILLIMETERS | | |
|-----------------------------|-------|-------------|------|------|
| | | MIN | NOM | MAX |
| Contact Pitch | E1 | 0.80 BSC | | |
| Contact Pitch | E2 | 0.80 BSC | | |
| Contact Pad Spacing | C1 | | 8.00 | |
| Contact Pad Spacing | C2 | | 8.00 | |
| Contact Pad Diameter (X121) | X | | | 0.32 |

Notes:

1. Dimensioning and tolerancing per ASME Y14.5M

BSC: Basic Dimension. Theoretically exact value shown without tolerances.

Microchip Technology Drawing No. C04-2148 Rev D

APPENDIX A: REVISION HISTORY

Revision A (July 2012)

Original data sheet for the PIC24FJ128GC010 family of devices.

Revision B (May 2013)

Changes descriptive title on Page 1 to “16-Bit Flash Microcontrollers with 12-Bit Pipeline A/D, Sigma-Delta A/D, USB On-The-Go and XLP Technology”.

Adds CoreMark[®] rating to the “**High-Performance CPU**” section on Page 2.

Removes all references to JTAG device programming throughout the document.

Corrects the default Doze mode ratio as 1:8 (previously described as 1:1) throughout the document.

Corrects the default FRC postscaler setting to 1:2.

Corrects references in **Section 10.4.6 “Deep Sleep WDT”** regarding the Configuration register for the DSWDTOSC and DSWDPS<4:0> bits.

Changes the description of the behavior of the UERRIF bit in the U1IR register, from “Read-Only” to “Read, Write 1 to Clear”, in both contexts of the register.

Corrects the low end of the operating range of the voltage regulator, described in **Section 34.2 “On-Chip Voltage Regulator”**, to 2.0V.

Updates **Section 37.0 “Electrical Characteristics”**:

- Adds maximum specifications to most DC Specifications
- Adds systematic parameter numbers to existing DC and AC Specifications that were previously not numbered
- Moves DC Specification for USB module from **Table 37-4** to a new **Table 37-15**; all subsequent tables are renumbered accordingly
- Updates most typical and maximum specifications in the following tables:
 - **Table 37-12** (Band Gap Reference (BGBUFn) Specifications)
 - **Table 37-19** (Operational Amplifier Specifications)
 - **Table 37-28** (12-bit Pipeline A/D Module Specifications)
 - **Table 37-30** (10-Bit DAC Specifications)
 - **Table 37-31** (16-Bit Sigma-Delta A/D Converter Specifications)

Other minor typographic changes and updates throughout.

PIC24FJ128GC010 FAMILY

THE MICROCHIP WEB SITE

Microchip provides online support via our WWW site at www.microchip.com. This web site is used as a means to make files and information easily available to customers. Accessible by using your favorite Internet browser, the web site contains the following information:

- **Product Support** – Data sheets and errata, application notes and sample programs, design resources, user's guides and hardware support documents, latest software releases and archived software
- **General Technical Support** – Frequently Asked Questions (FAQ), technical support requests, online discussion groups, Microchip consultant program member listing
- **Business of Microchip** – Product selector and ordering guides, latest Microchip press releases, listing of seminars and events, listings of Microchip sales offices, distributors and factory representatives

CUSTOMER CHANGE NOTIFICATION SERVICE

Microchip's customer notification service helps keep customers current on Microchip products. Subscribers will receive e-mail notification whenever there are changes, updates, revisions or errata related to a specified product family or development tool of interest.

To register, access the Microchip web site at www.microchip.com. Under "Support", click on "Customer Change Notification" and follow the registration instructions.

CUSTOMER SUPPORT

Users of Microchip products can receive assistance through several channels:

- Distributor or Representative
- Local Sales Office
- Field Application Engineer (FAE)
- Technical Support
- Development Systems Information Line

Customers should contact their distributor, representative or field application engineer (FAE) for support. Local sales offices are also available to help customers. A listing of sales offices and locations is included in the back of this document.

Technical support is available through the web site at: <http://microchip.com/support>

READER RESPONSE

It is our intention to provide you with the best documentation possible to ensure successful use of your Microchip product. If you wish to provide your comments on organization, clarity, subject matter, and ways in which our documentation can better serve you, please FAX your comments to the Technical Publications Manager at (480) 792-4150.

Please list the following information, and use this outline to provide us with your comments about this document.

TO: Technical Publications Manager Total Pages Sent _____

RE: Reader Response

From: Name _____

Company _____

Address _____

City / State / ZIP / Country _____

Telephone: (_____) _____ - _____ FAX: (_____) _____ - _____

Application (optional):

Would you like a reply? Y N

Device: PIC24FJ128GC010 Family

Literature Number: DS30009312B

Questions:

1. What are the best features of this document?

2. How does this document meet your hardware and software development needs?

3. Do you find the organization of this document easy to follow? If not, why?

4. What additions to the document do you think would enhance the structure and subject?

5. What deletions from the document could be made without affecting the overall usefulness?

6. Is there any incorrect or misleading information (what and where)?

7. How would you improve this document?

Examples:

- PIC24FJ64GC006-I/MR:
PIC24F device with Advanced Analog, LCD Controller and XLP Technology, 64-Kbyte Program Memory, 64-pin, Industrial temp., QFN package.
- PIC24FJ128GC010-I/PT:
PIC24F device with Advanced Analog, LCD Controller and XLP Technology, 128-Kbyte Program Memory, 100-pin, Industrial temp., TQFP package.
- PIC24FJ128GC010-I/BG:
PIC24F device with Advanced Analog, LCD Controller and XLP Technology, 128-Kbyte Program Memory, 121-pin, Industrial temp., BGA package.

PIC24FJ128GC010 FAMILY

NOTES:

Note the following details of the code protection feature on Microchip devices:

- Microchip products meet the specification contained in their particular Microchip Data Sheet.
- Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip's Data Sheets. Most likely, the person doing so is engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.
- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as "unbreakable."

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break Microchip's code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.

Information contained in this publication regarding device applications and the like is provided only for your convenience and may be superseded by updates. It is your responsibility to ensure that your application meets with your specifications. MICROCHIP MAKES NO REPRESENTATIONS OR WARRANTIES OF ANY KIND WHETHER EXPRESS OR IMPLIED, WRITTEN OR ORAL, STATUTORY OR OTHERWISE, RELATED TO THE INFORMATION, INCLUDING BUT NOT LIMITED TO ITS CONDITION, QUALITY, PERFORMANCE, MERCHANTABILITY OR FITNESS FOR PURPOSE. Microchip disclaims all liability arising from this information and its use. Use of Microchip devices in life support and/or safety applications is entirely at the buyer's risk, and the buyer agrees to defend, indemnify and hold harmless Microchip from any and all damages, claims, suits, or expenses resulting from such use. No licenses are conveyed, implicitly or otherwise, under any Microchip intellectual property rights.

Trademarks

QUALITY MANAGEMENT SYSTEM
CERTIFIED BY DNV
== ISO/TS 16949 ==

Microchip received ISO/TS-16949:2009 certification for its worldwide headquarters, design and wafer fabrication facilities in Chandler and Tempe, Arizona; Gresham, Oregon and design centers in California and India. The Company's quality system processes and procedures are for its PIC[®] MCUs and dsPIC[®] DSCs, KEELOQ[®] code hopping devices, Serial EEPROMs, microperipherals, nonvolatile memory and analog products. In addition, Microchip's quality system for the design and manufacture of development systems is ISO 9001:2000 certified.

Компания «ЭлектроПласт» предлагает заключение долгосрочных отношений при поставках импортных электронных компонентов на взаимовыгодных условиях!

Наши преимущества:

- Оперативные поставки широкого спектра электронных компонентов отечественного и импортного производства напрямую от производителей и с крупнейших мировых складов;
- Поставка более 17-ти миллионов наименований электронных компонентов;
- Поставка сложных, дефицитных, либо снятых с производства позиций;
- Оперативные сроки поставки под заказ (от 5 рабочих дней);
- Экспресс доставка в любую точку России;
- Техническая поддержка проекта, помощь в подборе аналогов, поставка прототипов;
- Система менеджмента качества сертифицирована по Международному стандарту ISO 9001;
- Лицензия ФСБ на осуществление работ с использованием сведений, составляющих государственную тайну;
- Поставка специализированных компонентов (Xilinx, Altera, Analog Devices, Intersil, Interpoint, Microsemi, Aeroflex, Peregrine, Syfer, Eurofarad, Texas Instrument, Miteq, Cobham, E2V, MA-COM, Hittite, Mini-Circuits, General Dynamics и др.);

Помимо этого, одним из направлений компании «ЭлектроПласт» является направление «Источники питания». Мы предлагаем Вам помощь Конструкторского отдела:

- Подбор оптимального решения, техническое обоснование при выборе компонента;
- Подбор аналогов;
- Консультации по применению компонента;
- Поставка образцов и прототипов;
- Техническая поддержка проекта;
- Защита от снятия компонента с производства.
