

Full-Bridge PWM Controller with Integrated MOSFET Drivers

Check for Samples: [LM5045](#)

FEATURES

- Highest Integration Controller for Small Form Factor, High Density Power Converters
- High Voltage Start-up Regulator
- Intelligent Sync Rectifier Start-up Allows Linear Turn-on into Pre-biased Loads
- Synchronous Rectifiers Disabled in UVLO mode and Hiccup Mode
- Two Independent, Programmable Synchronous Rectifier dead-time Adjustments
- Four High Current 2A Bridge Gate Drivers
- Wide-Bandwidth Opto-coupler Interface
- Configurable for either Current Mode or Voltage Mode Control
- Dual-mode Over-Current Protection
- Resistor Programmed 2MHz Oscillator
- Programmable Line UVLO and OVP

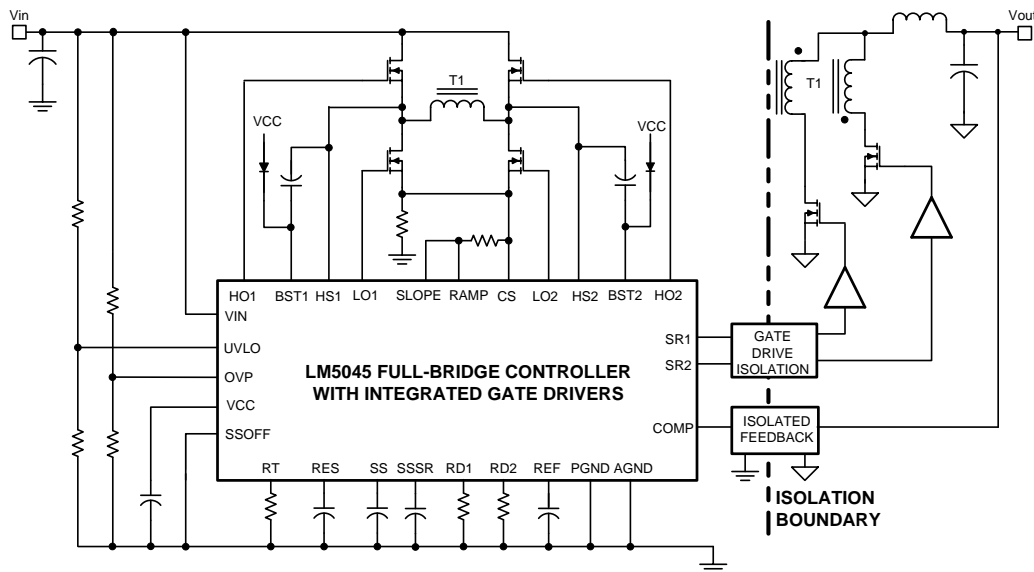

DESCRIPTION

The LM5045 PWM controller contains all of the features necessary to implement Full-Bridge topology power converters using either current mode or voltage mode control. This device is intended to operate on the primary side of an isolated dc-dc converter with input voltage up to 100V. This highly integrated controller-driver provides dual 2A high and low side gate drivers for the four external bridge MOSFETs plus control signals for the secondary side synchronous rectifier MOSFETs. External resistors program the leading and trailing edge dead-time between the main and synchronous rectifier control signals. Intelligent startup of the synchronous rectifiers allows monotonic turn-on of the power converter even with pre-bias load conditions. Additional features include cycle-by-cycle current limiting, hiccup mode restart, programmable soft-start, synchronous rectifier soft-start and a 2 MHz capable oscillator with synchronization capability and thermal shutdown.

PACKAGES

- HTSSOP 28 pin
- WQFN 28 pin (5mm x 5mm)

Simplified Full-Bridge Power Converter

PIN DESCRIPTIONS

HTSSOP Pin	WQFN Pin	Name	Description	Application Information
1	25	UVLO	Line Under-Voltage Lockout	An external voltage divider from the power source sets the shutdown and standby comparator levels. When UVLO reaches the 0.4V threshold the VCC and REF regulators are enabled. At the 1.25V threshold, the SS pin is released and the controller enters the active mode. Hysteresis is set by an internal current sink that pulls 20µA from the external resistor divider.
2	26	OVP/OTP	Over Voltage Protection	An external voltage divider from the input power supply sets the shutdown level during an over-voltage condition. Alternatively, an external NTC thermistor voltage divider can be used to set the shutdown temperature. The threshold is 1.25V. Hysteresis is set by an internal current that sources 20 µA of current into the external resistor divider.
3	27	RAMP	Input to PWM Comparator	Modulation ramp for the PWM comparator. This ramp can be a signal representative of the primary current (current mode) or proportional to the input voltage (feed-forward voltage mode). This pin is reset to GND at the end of every cycle.
4	28	CS	Current Sense Input	If CS exceeds 750mV the PWM output pulse will be terminated, entering cycle-by-cycle current limit. An internal switch holds CS low for 40nS after either output switches high to blank leading edge transients.
5	1	SLOPE	Slope Compensation Current	A ramping current source from 0 to 100µA is provided for slope compensation in current mode control. This pin can be connected through an appropriate resistor to the CS pin to provide slope compensation. If slope compensation is not required, SLOPE must be tied to ground.
6	2	COMP	Input to the Pulse Width Modulator	An external opto-coupler connected to the COMP pin sources current into an internal NPN current mirror. The PWM duty cycle is at maximum with zero input current, while 1mA reduces the duty cycle to zero. The current mirror improves the frequency response by reducing the AC voltage across the opto-coupler.
7	3	REF	Output of a 5V reference	Maximum output current is 15mA. Locally decouple with a 0.1µF capacitor.
8	4	RT/SYNC	Oscillator Frequency Control and Frequency Synchronization	The resistance connected between RT and AGND sets the oscillator frequency. Synchronization is achieved by AC coupling a pulse to the RT/SYNC pin that raises the voltage at least 1.5V above the 2V nominal bias level.
9	5	AGND	Analog Ground	Connect directly to the Power Ground.
10	6	RD1	Synchronous Rectifier Leading Edge Delay	The resistance connected between RD1 and AGND sets the delay from the falling edge of SR1 or SR2 and the rising edge of HO2/LO1 or HO1/LO2 respectively.
11	7	RD2	Synchronous Rectifier Trailing Edge Delay	The resistance connected between RD2 and AGND sets the delay from the falling edge of HO1/LO2 or HO2/LO1 and the rising edge of SR2 or SR1 respectively.
12	8	RES	Restart Timer	Whenever the CS pin exceeds the 750mV cycle-cycle current limit threshold, 30µA current is sourced into the RES capacitor for the remainder of the PWM cycle. If the RES capacitor voltage reaches 1.0V, the SS capacitor is discharged to disable the HO1, HO2, LO1, LO2 and SR1, SR2 outputs. The SS pin is held low until the voltage on the RES capacitor has been ramped between 2V and 4V eight times by 10µA charge and 5µA discharge currents. After the delay sequence, the SS capacitor is released to initiate a normal start-up sequence.
13	9	SS	Soft-Start Input	An internal 20µA current source charges the SS pin during start-up. The input to the PWM comparator gradually rises as the SS capacitor charges to steadily increase the PWM duty cycle. Pulling the SS pin to a voltage below 200mV stops PWM pulses at HO1,2 and LO1,2 and turns off the synchronous rectifier FETs to a low state.
14	10	SSSR	Secondary Side Soft-Start	An external capacitor and an internal 20µA current source set the soft-start ramp for the synchronous rectifiers. The SSSR capacitor charge-up is enabled after the first output pulse and SS>2V and Icomp <800µA

PIN DESCRIPTIONS (continued)

HTSSOP Pin	WQFN Pin	Name	Description	Application Information
15	11	SSOFF	Soft-Stop Disable	When SS OFF pin is connected to the AGND, the LM5045 soft-stops in the event of a VIN UVLO and Hiccup mode current limit condition. If the SSOFF pin is connected to REF pin, the controller hard-stops on any fault condition. Refer Table 1 for more details.
19	15	SR2	Synchronous Rectifier Driver	Control output for synchronous rectifier gate. Capable of peak sourcing 100mA and sinking 400mA.
21	17	VCC	Output of Start-Up Regulator	The output voltage of the start-up regulator is initially regulated to 9.5V. Once the secondary side soft-start (SSSR pin) reaches 1V, the VCC output is reduced to 7.7V. If an auxiliary winding raises the voltage on this pin above the regulation set-point, the internal start-up regulator will shutdown, thus reducing the IC power dissipation.
22	18	PGND	Power Ground	Connect directly to Analog Ground
23, 20	19, 16	LO1, LO2	Low Side Output Driver	Alternating output of the PWM gate driver. Capable of 1.5A peak source and 2A peak sink current.
24	20	SR1	Synchronous Rectifier Driver	Control output for synchronous rectifier gate. Capable of peak sourcing 100mA and sinking 400mA.
25, 18	21, 14	BST1,2	Gate Drive Bootstrap	Bootstrap capacitors connected between BST1,2 and SW1,2 provide bias supply for the high side HO1,2 gate drivers. External diodes are required between VCC and BST1,2 to charge the bootstrap capacitors when SW1,2 are low.
26, 17	22, 13	HO1,2	High Side Output Driver	High side PWM outputs capable of driving the upper MOSFET of the bridge with 1.5A peak source and 2A peak sink current.
27, 16	23, 12	HS1,2	Switch Node	Common connection of the high side FET source, low side FET drain and transformer primary winding.
28	24	VIN	Input Power Source	Input to the Start-up Regulator. Operating input range is 14V to 100V. For power sources outside of this range, the LM5045 can be biased directly at VCC by an external regulator.

These devices have limited built-in ESD protection. The leads should be shorted together or the device placed in conductive foam during storage or handling to prevent electrostatic damage to the MOS gates.

Absolute Maximum Ratings ⁽¹⁾

VIN to GND	-0.3V to 105V
HS to GND ⁽²⁾	-5V to 105V
BST1/BST2 to GND	-0.3V to 116V
BST1/BST2 to HS1/HS2	-0.3V to 16V
HO1/HO2 to HS1/HS2 ⁽³⁾	-0.3V to BST1/BST2+0.3V
LO1/LO2/SR1/SR2 ⁽³⁾	-0.3V to VCC+0.3V
VCC to GND	-0.3V to 16V
REF,SSOFF,RT,OVP,UVLO to GND	-0.3V to 7V
RAMP	-0.3V to 7V
COMP	-0.3V
COMP Input Current	+10mA
All other inputs to GND ⁽³⁾	-0.3 to REF+0.3V
ESD Rating HBM ⁽⁴⁾	2 kV
Storage Temperature Range	-55°C to 150°C
Junction Temperature	150°C

- (1) Absolute Maximum Ratings are limits beyond which damage to the device may occur. Operating Ratings are conditions under which operation of the device is intended to be functional. For ensured specifications and test conditions, see the Electrical Characteristics.
- (2) The negative HS voltage must never be more negative than VCC-16V. For example, if VCC=12V, the negative transients at HS must not exceed -4V.
- (3) These pins are output pins and as such should not be connected to an external voltage source. The voltage range listed is the limits the internal circuitry is designed to reliably tolerate in the application circuit.
- (4) The human body model is a 100pF capacitor discharged through a 1.5kΩ resistor into each pin.

Operating Ratings ⁽¹⁾

VIN Voltage	14V to 100V
External Voltage Applied to VCC	10V to 14V
Junction Temperature	-40°C to +125°C
SLOPE	-0.3V to 2V

- (1) Absolute Maximum Ratings are limits beyond which damage to the device may occur. Operating Ratings are conditions under which operation of the device is intended to be functional. For ensured specifications and test conditions, see the Electrical Characteristics.

Electrical Characteristics

Limits in standard typeface are for T_J = 25°C only; limits in **boldface** type apply the junction temperature range of **-40°C to +125°C**. Unless otherwise specified, the following conditions apply: VIN = 48V, RT = 25kΩ, RD1=RD2=20kΩ. No load on HO1, HO2, LO1, LO2, SR1, SR2, COMP=0V, UVLO=2.5V, OVP=0V, SSOFF=0V.

Symbol	Parameter	Conditions	Min	Typ	Max	Units
Startup Regulator (VCC pin)						
VCC1	VCC voltage	I _{CC} = 10mA (SSSR<1V)	9.3	9.6	9.9	V
VCC2	VCC voltage	I _{CC} = 10mA (SSSR>1V)	7.5	7.8	8.1	V
I _{CC(Lim)}	VCC current limit	VCC= 6V	60	80		mA
I _{CC(ext)}	VCC supply current	Supply current into VCC from an externally applied source. VCC = 10V		4.6		mA
	VCC load regulation	I _{CC} from 0 to 50 mA		35		mV
VCC(UV)	VCC under-voltage threshold	Positive going VCC	V_{CC1}-0.2	V _{CC1} -0.1		V
	VCC under-voltage threshold	Negative going VCC	5.9	6.3	6.7	V
I _{IN}	VIN operating current			4		mA
	VIN shutdown current	V _{IN} =20V, V _{UVLO} =0V		300	520	μA
		V _{IN} =100V, V _{UVLO} =0V		350	550	μA
	VIN start-up regulator leakage	VCC=10V		160		μA
Voltage Reference Regulator (REF pin)						

Electrical Characteristics (continued)

Limits in standard typeface are for $T_J = 25^\circ\text{C}$ only; limits in **boldface** type apply the junction temperature range of -40°C to $+125^\circ\text{C}$. Unless otherwise specified, the following conditions apply: $V_{IN} = 48\text{V}$, $R_T = 25\text{k}\Omega$, $RD1=RD2=20\text{k}\Omega$. No load on $HO1$, $HO2$, $LO1$, $LO2$, $SR1$, $SR2$, $COMP=0\text{V}$, $UVLO=2.5\text{V}$, $OVP=0\text{V}$, $SSOFF=0\text{V}$.

Symbol	Parameter	Conditions	Min	Typ	Max	Units
V_{REF}	REF Voltage	$I_{REF} = 0\text{mA}$	4.85	5	5.15	V
	REF voltage regulation	$I_{REF} = 0$ to 10mA		25	50	mV
$I_{REF(Lim)}$	REF current limit	$V_{REF} = 4.5\text{V}$	15	20		mA
V_{REFUV}	V_{REF} under-voltage threshold	Positive going V_{REF}	4.3	4.5	4.7	V

Block Diagram

FUNCTIONAL DESCRIPTION

The LM5045 PWM controller contains all of the features necessary to implement a Full-Bridge topology power converter using either current mode or voltage mode control. This device is intended to operate on the primary side of an isolated dc-dc converter with input voltage up to 100V. This highly integrated controller-driver provides dual 2A high and low side gate drivers for the four external bridge MOSFETs plus control signals for secondary side synchronous rectifiers. External resistors program the leading and trailing edge dead-time between the main and synchronous rectifier control signals. Intelligent startup of synchronous rectifier allows turn-on of the power converter into the pre-bias loads. Cycle-by-cycle current limit protects the power components from load transients while hiccup mode protection limits average power dissipation during extended overload conditions. Additional features include programmable soft-start, soft-start of the synchronous rectifiers, and a 2 MHz capable oscillator with synchronization capability and thermal shutdown.

High-Voltage Start-Up Regulator

The LM5045 contains an internal high voltage start-up regulator that allows the input pin (VIN) to be connected directly to the supply voltage over a wide range from 14V to 100V. The input can withstand transients up to 105V. When the UVLO pin potential is greater than 0.4V, the VCC regulator is enabled to charge an external capacitor connected to the VCC pin. The VCC regulator provides power to the voltage reference (REF) and the gate drivers (HO1/HO2 and LO1/LO2). When the voltage on the VCC pin exceeds its Under Voltage (UV) threshold, the internal voltage reference (REF) reaches its regulation set point of 5V and the UVLO voltage is greater than 1.25V, the soft-start capacitor is released and normal operation begins. The regulator output at VCC is internally current limited. The value of the VCC capacitor depends on the total system design, and its start-up characteristics. The recommended range of values for the VCC capacitor is 0.47μF to 10μF.

The internal power dissipation of the LM5045 can be reduced by powering VCC from an external supply. The output voltage of the VCC regulator is initially regulated to 9.5V. After the synchronous rectifiers are engaged (which is approximately when the output voltage is within regulation), the VCC voltage is reduced to 7.7V. In typical applications, an auxiliary transformer winding is connected through a diode to the VCC pin. This winding must raise the VCC voltage above 8V to shut off the internal start-up regulator. Powering VCC from an auxiliary winding improves efficiency while reducing the controller's power dissipation. The VCC UV circuit will still function in this mode, requiring that VCC never falls below its UV threshold during the start-up sequence. The VCC regulator series pass transistor includes a diode between VCC and VIN that should not be forward biased in normal operation. Therefore, the auxiliary VCC voltage should never exceed the VIN voltage.

An external DC bias voltage can be used instead of the internal regulator by connecting the external bias voltage to both the VCC and the VIN pins. This implementation is shown in the [APPLICATIONS INFORMATION](#) section. The external bias must be greater than 10V and less than the VCC maximum voltage rating of 14V.

Line Under-Voltage Detector

The LM5045 contains a dual level Under-Voltage Lockout (UVLO) circuit. When the UVLO pin voltage is below 0.4V, the controller is in a low current shutdown mode. When the UVLO pin voltage is greater than 0.4V but less than 1.25V, the controller is in standby mode. In standby mode the VCC and REF bias regulators are active while the controller outputs are disabled. When the VCC and REF outputs exceed their respective under-voltage thresholds and the UVLO pin voltage is greater than 1.25V, the soft-start capacitor is released and the normal operation begins. An external set-point voltage divider from VIN to GND can be used to set the minimum operating voltage of the converter. The divider must be designed such that the voltage at the UVLO pin will be greater than 1.25V when VIN enters the desired operating range. UVLO hysteresis is accomplished with an internal 20μA current sink that is switched on or off into the impedance of the set-point divider. When the UVLO threshold is exceeded, the current sink is deactivated to quickly raise the voltage at the UVLO pin. When the UVLO pin voltage falls below the 1.25V threshold, the current sink is enabled causing the voltage at the UVLO pin to quickly fall. The hysteresis of the 0.4V shutdown comparator is internally fixed at 50mV.

The UVLO pin can also be used to implement various remote enable / disable functions. Turning off the converter by forcing the UVLO pin to standby condition ($0.4V < UVLO < 1.25V$) provides a controlled soft-stop. Refer to the [Soft-Stop](#) section for more details.

Over Voltage Protection

An external voltage divider can be used to set either an over voltage or an over temperature protection. During an OVP condition, the SS and SSSR capacitors are discharged and all the outputs are disabled. The divider must be designed such that the voltage at the OVP pin is greater than 1.25V when over voltage/temperature condition exists. Hysteresis is accomplished with an internal 20µA current source. When the OVP pin voltage exceeds 1.25V, the 20µA current source is activated to quickly raise the voltage at the OVP pin. When the OVP pin voltage falls below the 1.25V threshold, the current source is deactivated causing the voltage at the OVP to quickly fall. Refer to the [APPLICATIONS INFORMATION](#) section for more details.

Reference

The REF pin is the output of a 5V linear regulator that can be used to bias an opto-coupler transistor and external housekeeping circuits. The regulator output is internally current limited to 15mA. The REF pin needs to be locally decoupled with a ceramic capacitor, the recommended range of values are from 0.1µF to 10µF

Oscillator, Sync Input

The LM5045 oscillator frequency is set by a resistor connected between the RT pin and AGND. The RT resistor should be located very close to the device. To set a desired oscillator frequency (F_{OSC}), the necessary value of RT resistor can be calculated from the following equation:

$$R_T = \frac{1}{F_{OSC} \times 1 \times 10^{-10}} \quad (1)$$

For example, if the desired oscillator frequency is 400 kHz i.e. each phase (LO1 or LO2) at 200 kHz, the value of R_T will be 25kΩ. If the LM5045 is to be synchronized to an external clock, that signal must be coupled into the RT pin through a 100pF capacitor. The RT pin voltage is nominally regulated at 2.0V and the external pulse amplitude should lift the pin to between 3.5V and 5.0V on the low-to-high transition. The synchronization pulse width should be between 15 and 200ns. The RT resistor is always required, whether the oscillator is free running or externally synchronized and the SYNC frequency must be equal to, or greater than the frequency set by the RT resistor. When syncing to an external clock, it is recommended to add slope compensation by connecting an appropriate resistor from the VCC pin to the CS pin. Also disable the SLOPE pin by grounding it.

Cycle-by-Cycle Current Limit

The CS pin is to be driven by a signal representative of the transformer's primary current. If the voltage on the CS pin exceeds 0.75V, the current sense comparator immediately terminates the PWM cycle. A small RC filter connected to the CS pin and located near the controller is recommended to suppress noise. An internal 18Ω MOSFET discharges the external current sense filter capacitor at the conclusion of every cycle. The discharge MOSFET remains on for an additional 40ns after the start of a new PWM cycle to blank leading edge spikes. The current sense comparator is very fast and may respond to short duration noise pulses. Layout is critical for the current sense filter and the sense resistor. The capacitor associated with CS filter must be placed very close to the device and connected directly to the CS and AGND pins. If a current sense transformer is used, both the leads of the transformer secondary should be routed to the filter network, which should be located close to the IC. When designing with a current sense resistor, all of the noise sensitive low power ground connections should be connected together near the AGND pin, and a single connection should be made to the power ground (sense resistor ground point).

Hiccup Mode

The LM5045 provides a current limit restart timer to disable the controller outputs and force a delayed restart (i.e. Hiccup mode) if a current limit condition is repeatedly sensed. The number of cycle-by-cycle current limit events required to trigger the restart is programmed by the external capacitor at the RES pin. During each PWM cycle, the LM5045 either sources or sinks current from the RES capacitor. If current limit is detected, the 5µA current sink is disabled and a 30µA current source is enabled. If the RES voltage reaches the 1.0V threshold, the following restart sequence occurs, as shown in [Figure 12](#):

- The SS and SSSR capacitors are fully discharged
- The 30µA current source is turned-off and the 10µA current source is turned-on.
- Once the voltage at the RES pin reaches 4.0V the 10µA current source is turned-off and a 5µA current sink is turned-on, ramping the voltage on the RES capacitor down to 2.0V.

- Once RES capacitor reaches 2.0V, threshold, the 10 μ A current source is turned-on again. The RES capacitor voltage is ramped between 4.0V and 2.0V eight times.
- When the counter reaches eight, the RES pin voltage is pulled low and the soft-start capacitor is released to begin a soft-start sequence. The SS capacitor voltage slowly increases. When the SS voltage reaches 1.0V, the PWM comparator will produce the first narrow pulse.
- If the overload condition persists after restart, cycle-by-cycle current limiting will begin to increase the voltage on the RES capacitor again, repeating the hiccup mode sequence.
- If the overload condition no longer exists after restart, the RES pin will be held at ground by the 5 μ A current sink and the normal operation resumes.

The hiccup mode function can be completely disabled by connecting the RES pin to the AGND pin. In this configuration the cycle-by-cycle protection will limit the maximum output current indefinitely, no hiccup restart sequences will occur.

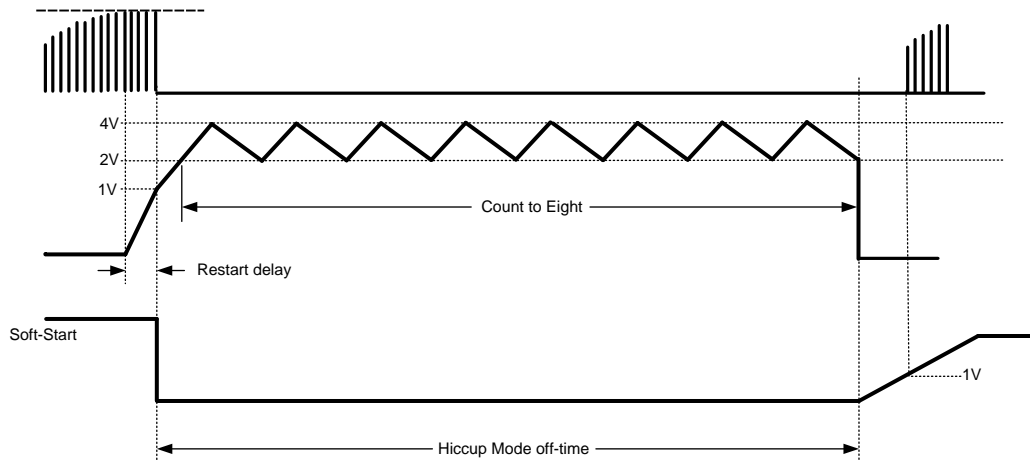

Figure 12. Hiccup Mode Delay and Soft-Start Timing Diagram

PWM Comparator

The LM5045 pulse width modulator (PWM) comparator is a three input device, it compares the signal at the RAMP pin to the loop error signal or the soft-start, whichever is lower, to control the duty cycle. This comparator is optimized for speed in order to achieve minimum controllable duty cycles. The loop error signal is received from the external feedback and isolation circuit in the form of a control current into the COMP pin. The COMP pin current is internally mirrored by a matching pair of NPN transistors which sink current through a 5k Ω resistor connected to the 5V reference. The resulting control voltage passes through a 1V offset, followed by a 2:1 resistor divider before being applied to the PWM comparator.

An opto-coupler detector can be connected between the REF pin and the COMP pin. Because the COMP pin is controlled by a current input, the potential difference across the opto-coupler detector is nearly constant. The bandwidth limiting phase delay which is normally introduced by the significant capacitance of the opto-coupler is thereby greatly reduced. Higher loop bandwidths can be realized since the bandwidth limiting pole associated with the opto-coupler is now at a much higher frequency. The PWM comparator polarity is configured such that with no current flowing into the COMP pin, the controller produces maximum duty cycle.

Ramp Pin

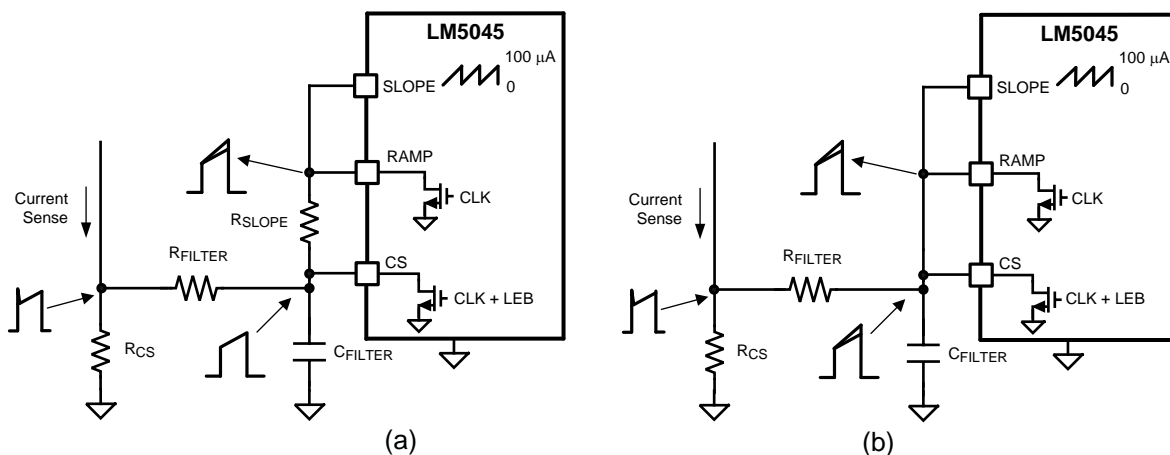

The voltage at the RAMP pin provides the modulation ramp for the PWM comparator. The PWM comparator compares the modulation ramp signal at the RAMP pin to the loop error signal to control the duty cycle. The modulation ramp signal can be implemented either as a ramp proportional to the input voltage, known as feed-forward voltage mode control, or as a ramp proportional to the primary current, known as current mode control. The RAMP pin is reset by an internal MOSFET with an $R_{DS(ON)}$ of 5.5Ω at the conclusion of each PWM cycle. The ability to configure the RAMP pin for either voltage mode or current mode allows the controller to be implemented for the optimum control method depending upon the design constraints. Refer to the [APPLICATIONS INFORMATION](#) section for more details on configuring the RAMP pin for feed-forward voltage mode control and peak current mode control.

Slope Pin

For duty cycles greater than 50% (25% for each phase), peak current mode control is subject to sub-harmonic oscillation. Sub-harmonic oscillation is normally characterized by observing alternating wide and narrow duty cycles. This can be eliminated by adding an artificial ramp, known as slope compensation, to the modulating signal at the RAMP pin. The SLOPE pin provides a current source ramping from 0 to $100\mu A$, at the frequency set by the RT resistor, for slope compensation. The ramping current source at the SLOPE pin can be utilized in a couple of different ways to add slope compensation to the RAMP signal:

1. As shown in [Figure 13\(a\)](#), the SLOPE and RAMP pins can be connected together through an appropriate resistor to the CS pin. This configuration will inject current sense signal plus slope compensation to the RAMP pin but CS pin will not see any slope compensation. Therefore, in this scheme slope compensation will not affect the current limit.
2. In a second configuration, as shown in [Figure 13\(b\)](#), the SLOPE, RAMP and CS pins can be tied together. In this configuration the ramping current source from the SLOPE pin will flow through the filter resistor and filter capacitor, therefore both the CS pin and the RAMP pin will see the current sense signal plus the slope compensation ramp. In this scheme, the current limit is compensated by the slope compensation and the current limit onset point will vary.

If the slope compensation is not required for e.g. in feed-forward voltage mode control, the SLOPE pin must be connected to the AGND pin. When the RT pin is synched to an external clock, it is recommended to disable the SLOPE pin and add slope compensation externally by connecting an appropriate resistor from the VCC pin to the CS pin. Please refer to the [APPLICATIONS INFORMATION](#) section for more details.

- A. Slope Compensation Configured for PWM Only (No Current Limit Slope)
- B. Slope Compensation Configured for PWM and Current Limit

Figure 13. Slope Compensation Configuration

Soft-Start

The soft-start circuit allows the power converter to gradually reach a steady state operating point, thereby reducing the start-up stresses and current surges. When bias is supplied to the LM5045, the SS capacitor is discharged by an internal MOSFET. When the UVLO, VCC and REF pins reach their operating thresholds, the SS capacitor is released and is charged with a 20µA current source. Once the SS pin voltage crosses the 1V offset, SS controls the duty cycle. The PWM comparator is a three input device; it compares the RAMP signal against the lower of the signals between the soft-start and the loop error signal. In a typical isolated application, as the secondary bias is established, the error amplifier on the secondary side soft-starts and establishes closed-loop control, steering the control away from the SS pin.

One method to shutdown the regulator is to ground the SS pin. This forces the internal PWM control signal to ground, reducing the output duty cycle quickly to zero. Releasing the SS pin begins a soft-start cycle and normal operation resumes. A second shutdown method is presented in the [UVLO](#) section.

Gate Driver Outputs

The LM5045 provides four gate drivers: two floating high side gate drivers HO1 and HO2 and two ground referenced low side gate drivers LO1 and LO2. Each internal driver is capable of source 1.5A peak and sinking 2A peak. Initially, the diagonal HO1 and LO2 are turned-on together, followed by an off-time when all the four gate driver outputs are off. In the subsequent phase the diagonal HO2 and LO1 are turned on together followed by an off-time. The low-side gate drivers are powered directly by the VCC regulator. The HO1 and HO2 gate drivers are powered from a bootstrap capacitor connected between BST1/BST2 and HS1/HS2 respectively. An external diode connected between VCC (anode pin) and BST (cathode pin) provides the high side gate driver power by charging the bootstrap capacitor from VCC when the corresponding switch node (HS1/HS2 pin) is low. When the high side MOSFET is turned on, BST1 rises to a peak voltage equal to $V_{CC} + V_{HS1}$ where V_{HS1} is the switch node voltage.

The BST and VCC capacitors should be placed close to the pins of the LM5045 to minimize voltage transients due to parasitic inductances since the peak current sourced to the MOSFET gates can exceed 1.5A. The recommended value of the BST capacitor is 0.1µF or greater. A low ESR / ESL capacitor, such as a surface mount ceramic, should be used to prevent voltage droop during the HO transitions.

If the COMP pin is open circuit, the outputs will operate at maximum duty cycle. The maximum duty cycle for each phase is limited by the dead-time set by the RD1 resistor. If the RD1 resistor is set to zero then the maximum duty cycle is slightly less than 50% due to the internally fixed dead-time. The internally fixed dead-time is 30ns which does not vary with the operating frequency. The maximum duty cycle for each output can be calculated from the following equation:

$$D_{MAX} = \frac{\left(\frac{1}{F_{OSC}}\right) - (T1)}{\left(\frac{2}{F_{OSC}}\right)}$$

where

- T1 is the time set by the RD1 resistor
 - F_{OSC} is the frequency of the oscillator
- (2)

For example, if the oscillator frequency is set at 400 kHz and the T1 time set by the RD1 resistor is 60ns, the resulting D_{MAX} will be equal to 0.488.

Figure 14. Timing Diagram Illustrating the Maximum Duty Cycle and Dead-Time Set by RD1

Synchronous Rectifier Control Outputs (SR1 & SR2)

Synchronous rectification (SR) of the transformer secondary provides higher efficiency, especially for low output voltage converters, compared to the diode rectification. The reduction of rectifier forward voltage drop (0.5V - 1.5V) to 10mV - 200mV VDS voltage for a MOSFET significantly reduces rectification losses. In a typical application, the transformer secondary winding is center tapped, with the output power inductor in series with the center tap. The SR MOSFETs provide the ground path for the energized secondary winding and the inductor current. From [Figure 15](#) it can be seen that when the HO1/LO2 diagonal is turned ON, power transfer is enabled from the primary. During this period, the SR1 MOSFET is enabled and the SR2 MOSFET is turned-off. The secondary winding connected to the SR2 MOSFET drain is twice the voltage of the center tap at this time. At the conclusion of the HO1/LO2 pulse, the inductor current continues to flow through the SR2 MOSFET body diode. Since the body diode causes more loss than the SR MOSFET, efficiency can be improved by minimizing the T2 period while maintaining sufficient timing margin over all conditions (component tolerances, etc.) to prevent the shoot-through current. When HO2/LO1 enables power transfer from the primary, the SR2 MOSFET is enabled and the SR1 MOSFET is off.

During the freewheeling period, the inductor current is almost equally shared between both the SR1 and SR2 MOSFETs which effectively shorts the transformer secondary. The SR2 MOSFET is disabled before HO1/LO2 is turned-on. The SR2 MOSFET body diode continues to carry about the half inductor current until the primary power raises the SR2 MOSFET drain voltage and reverse biases the body diode. Ideally, dead-time T1 would be set to the minimum time that allows the SR MOSFET to turn off before the SR MOSFET body diode starts conducting.

The SR drivers are powered by the REF regulator and each SR output is capable of sourcing 0.1A and sinking 0.4A peak. The amplitude of the SR drivers is limited to 5V. The 5V SR signals enable the LM5045 to transfer SR control across the isolation barrier either through a solid-state isolator or a pulse transformer. The actual gate sourcing and sinking currents for the synchronous MOSFETs are provided by the secondary-side bias and gate drivers.

T1 and T2 can be programmed by connecting a resistor between RD1 and RD2 pins and AGND. It should be noted that while RD1 effects the maximum duty cycle, RD2 does not. The RD1 and RD2 resistors should be located very close to the device. The formula for RD1 and RD2 resistors are given below:

$$RD(1,2) = \frac{T(1,2)}{3 \text{ pF}}; \text{ For } 20k < (1,2) < 100k \quad (3)$$

If the desired dead-time for T1 is 60ns, then the RD1 will be 20 kΩ.

Figure 15. Synchronous Rectifier Timing Diagram

Soft-Start of the Synchronous Rectifiers

In addition to the basic soft-start already described, the LM5045 contains a second soft-start function that gradually turns on the synchronous rectifiers to their steady-state duty cycle. This function keeps the synchronous rectifiers off during the basic soft-start allowing a linear start-up of the output voltage even into pre-biased loads. Then the SR output duty cycle is gradually increased to prevent output voltage disturbances due to the difference in the voltage drop between the body diode and the channel resistance of the synchronous MOSFETs. Initially, when bias is supplied to the LM5045, the SSSR capacitor is discharged by an internal MOSFET. When the SS capacitor reaches a 2V threshold and once it is established that COMP is in control of the duty cycle i.e. $I_{COMP} < 800\mu A$, the SSSR discharge is released and SSSR capacitor begins charging with a 20 μA current source. Once the SSSR cap crosses the internal 1V threshold, the LM5045 begins the soft-start of the synchronous FETs. The SR soft-start follows a leading edge modulation technique i.e. the leading edge of the SR pulse is soft-started as opposed trailing edge modulation of the primary FETs. As shown in the [Figure 16\(a\)](#), SR1 and SR2 are turned-on simultaneously with a narrow pulse-width during the freewheeling cycle. At the end of the freewheel cycle i.e. at the rising edge of the internal CLK, the SR FET in-phase with the next power transfer cycle is kept on while the SR FET out of phase with it is turned-off. The in-phase SR FET is kept on throughout the power transfer cycle and at the end of it, both the primary FETs and the in-phase SR FETs are turned-off together. The synchronous rectifier outputs can be disabled by grounding the SSSR pin.

Figure 16.

Pre-Bias Startup

A common requirement for power converters is to have a monotonic output voltage start-up into a pre-biased load i.e. a pre-charged output capacitor. In a pre-biased load condition, if the synchronous rectifiers are engaged prematurely they will sink current from the pre-charged output capacitors resulting in an undesired output voltage dip. This condition is undesirable and could potentially damage the power converter. The LM5045 utilizes unique control circuitry to ensure intelligent turn-on of the synchronous rectifiers such that the output has a monotonic startup. Initially, the SSSR capacitor is held at ground to disable the synchronous MOSFETs allowing the body diode to conduct. The synchronous rectifier soft-start is initiated once it is established the duty cycle is controlled by the COMP instead of the soft-start capacitor i.e. $I_{COMP} < 800\mu A$ and the voltage at the SS pin $> 2V$. The SSSR capacitor is then released and is charged by a $20\mu A$ current source. Further, as shown in Figure 17, a 1V offset on the SSSR pin is used to provide additional delay. This delay ensures the output voltage is in regulation avoiding any reverse current when the synchronous MOSFETs are engaged.

Soft-Stop

As shown in Figure 18, if the UVLO pin voltage falls below the 1.25V standby threshold, but above the 0.4V shutdown threshold, the SSSR capacitor is soft-stopped with a $60\mu A$ current source (3 times the charging current). Once the SSSR pin reaches the 1.0V threshold, both the SS and SSSR pins are immediately discharged to GND. Soft-stopping the power converter gradually winds down the energy in the output capacitors and results in a monotonic decay of the output voltage. During the hiccup mode, the same sequence is executed except that the SSSR is discharged with a $120\mu A$ current source (6 times the charging current). In case of an OVP, VCC UV, thermal limit or a VREF UV condition, the power converter hard-stops, whereby all of the control outputs are driven to a low state immediately.

Figure 17. Pre-Bias Voltage Startup Waveforms

Soft-Stop Off

The Soft-Start Off (SSOFF) pin gives additional flexibility by allowing the power converter to be configured for hard-stop during line UVLO and hiccup mode condition. If the SS OFF pin is pulled up to the 5V REF pin, the power converter hard-stops in any fault condition. Hard-stop drives each control output to a low state immediately. Refer to [Table 1](#) for more details.

Figure 18. Stop-Stop Waveforms during a UVLO Event

Table 1. Soft-Stop in Fault Conditions⁽¹⁾

Fault Condition	SSSR
UVLO (UVLO<1.25V)	Soft-Stop 3x the charging rate
OVP (OVP>1.25V)	Hard-Stop
Hiccup (CS>0.75 and RES>1V)	Soft-Stop 6x the charging rate
VCC/VREF UV	Hard-Stop
Internal Thermal Limit	Hard-Stop

(1) Note: All the above conditions are valid with SSOFF pin tied to GND. If SSOFF=5V, the LM5045 hard-stops in all the conditions. The SS pin remains high in all the conditions until the SSSR pin reaches 1V.

Thermal Protection

Internal thermal shutdown circuitry is provided to protect the integrated circuit in the event the maximum rated junction temperature is exceeded. When activated, typically at 160°C, the controller is forced into a shutdown state with the output drivers, the bias regulators (VCC and REF) disabled. This helps to prevent catastrophic failures from accidental device overheating. During thermal shutdown, the SS and SSSR capacitors are fully discharged and the controller follows a normal start-up sequence after the junction temperature falls to the operating level (140 °C).

APPLICATIONS INFORMATION

Control Method Selection

The LM5045 is a versatile PWM control IC that can be configured for either current mode control or voltage mode control. The choice of the control method usually depends upon the designer preference. The following must be taken into consideration while selecting the control method. Current mode control can inherently balance flux in both phases of the full-bridge topology. The full-bridge topology, like other double ended topologies, is susceptible to the transformer core saturation. Any asymmetry in the volt-second product applied between the two alternating phases results in flux imbalance that causes a dc buildup in the transformer. This continual dc buildup may eventually push the transformer into saturation. The volt-second asymmetry can be corrected by employing current mode control. In current mode control, a signal representative of the primary current is compared against an error signal to control the duty cycle. In steady-state, this results in each phase being terminated at the same peak current by adjusting the pulse-width and thus applying equal volt-seconds to both the phases.

Current mode control can be susceptible to noise and sub-harmonic oscillation, while voltage mode control employs a larger ramp for PWM and is usually less susceptible. Voltage-mode control with input line feed-forward also has excellent line transient response. When configuring for voltage mode control, a dc blocking capacitor can be placed in series with the primary winding of the power transformer to avoid any flux imbalance that may cause transformer core saturation.

Voltage Mode Control Using the LM5045

To configure the LM5045 for voltage mode control, an external resistor (R_{FF}) and capacitor (C_{FF}) connected to VIN, AGND, and the RAMP pins is required to create a saw-tooth modulation ramp signal shown in [Figure 19](#). The slope of the signal at RAMP will vary in proportion to the input line voltage. The varying slope provides line feed-forward information necessary to improve line transient response with voltage mode control. With a constant error signal, the on-time (T_{ON}) varies inversely with the input voltage (VIN) to stabilize the Volt- Second product of the transformer primary. Using a line feed-forward ramp for PWM control requires very little change in the voltage regulation loop to compensate for changes in input voltage, as compared to a fixed slope oscillator ramp. Furthermore, voltage mode control is less susceptible to noise and does not require leading edge filtering. Therefore, it is a good choice for wide input range power converters. Voltage mode control requires a Type-III compensation network, due to the complex-conjugate poles of the L-C output filter.

Figure 19. Feed-Forward Voltage Mode Configuration

The recommended capacitor value range for C_{FF} is from 100pF to 1800pF. Referring to [Figure 19](#), it can be seen that C_{FF} value must be small enough to be discharged with in the clock pulse-width which is typically within 50ns. The $R_{DS(ON)}$ of the internal discharge FET is 5.5 Ω .

The value of R_{FF} required can be calculated from

$$R_{FF} = \frac{-1}{F_{OSC} \times C_{FF} \times \ln \left(1 - \frac{V_{RAMP}}{V_{IN_{MIN}}} \right)} \quad (4)$$

For example, assuming a V_{RAMP} of 1.5V (a good compromise of signal range and noise immunity), at $V_{\text{IN_MIN}}$ of 36V (oscillator frequency of 400 kHz and $C_{\text{FF}} = 470\text{pF}$ results in a value for R_{FF} of 125 k Ω).

Current Mode Control Using the LM5045

The LM5045 can be configured for current mode control by applying a signal proportional to the primary current to the RAMP pin. One way to achieve this is shown in [Figure 20](#). The primary current can be sensed using a current transformer or sense resistor, the resulting signal is filtered and applied to the RAMP pin through a resistor used for slope compensation. It can be seen that the signal applied to the RAMP pin consists of the primary current information from the CS pin plus an additional ramp for slope compensation, added by the resistor R_{SLOPE} .

The current sense resistor is selected such that during over current condition, the voltage across the current sense resistor is above the minimum CS threshold of 728mV.

In general, the amount of slope compensation required to avoid sub-harmonic oscillation is equal to at least one-half the down-slope of the output inductor current, transformed to the primary. To mitigate sub-harmonic oscillation after one switching period, the slope compensation has to be equal to one times the down slope of the filter inductor current transposed to primary. This is known as deadbeat control. The slope compensation resistor required to implement dead-beat control can be calculated as follows:

$$R_{\text{SLOPE}} = \frac{V_{\text{OUT}} \times R_{\text{CS}}}{L_{\text{FILTER}} \times F_{\text{OSC}} \times I_{\text{SLOPE}} \times N_{\text{TR}}}$$

where

- N_{TR} is the turns-ratio with respect to the secondary (5)

For example, for a 3.3V output converter with a turns-ratio between primary and secondary of 9:1, an output filter inductance (L_{FILTER}) of 800nH and a current sense resistor (R_{SENSE}) of 150m Ω , R_{SLOPE} of 1.67k Ω will suffice.

VIN and VCC

The voltage applied to the VIN pin, which may be the same as the system voltage applied to the power transformer's primary (V_{PWR}), can vary in the range of the 14 to 100V. It is recommended that the filter shown in [Figure 21](#) be used to suppress the transients that may occur at the input supply. This is particularly important when VIN is operated close to the maximum operating rating of the LM5045. The current into VIN depends primarily on the LM5045's operating current, the switching frequency, and any external loads on the VCC pin, that typically include the gate capacitances of the power MOSFETs. In typical applications, an auxiliary transformer winding is connected through a diode to the VCC pin. This pin must raise VCC voltage above 8V to shut off the internal start-up regulator.

After the outputs are enabled and the external VCC supply voltage has begun supplying power to the IC, the current into the VIN pin drops below 1mA. VIN should remain at a voltage equal to or above the VCC voltage to avoid reverse current through the internal body diode of the internal VCC regulator.

For Applications with > 100V Input

For applications where the system input voltage exceeds 100V, VIN can be powered from an external start-up regulator as shown in [Figure 22](#). In this configuration, the VIN and VCC pins should be connected together. The voltage at the VCC and VIN pins must be greater than 10V (>Max VCC reference voltage) yet not exceed 16V. To enable operation the VCC voltage must be raised above 10V. The voltage at the VCC pin must not exceed 16V. The voltage source at the right side of [Figure 22](#) is typically derived from the power stage, and becomes active once the LM5045's outputs are active.

Figure 20. Current Mode Configuration

Figure 21. Input Transient Protection

Figure 22. Start-up Regulator for $V_{PWR} > 100V$

UVLO and OVP Voltage Divider Selection

Two dedicated comparators connected to the UVLO and OVP pins are used to detect under voltage and over voltage conditions. The threshold values of both these comparators are set at 1.25V. The two functions can be programmed independently with two separate voltage dividers from VIN to AGND as shown in Figure 23 and Figure 24, or with a three-resistor divider as shown in Figure 25. Independent UVLO and OVP pins provide greater flexibility for the user to select the operational voltage range of the system. When the UVLO pin voltage is below 0.4V, the controller is in a low current shutdown mode. For a UVLO pin voltage greater than 0.4V but less than 1.25V the controller is in standby mode. Once the UVLO pin voltage is greater than 1.25V, the controller is fully enabled. Two external resistors can be used to program the minimum operational voltage for the power converter as shown in Figure 23. When the UVLO pin voltage falls below the 1.25V threshold, an internal 20μA current sink is enabled to lower the voltage at the UVLO pin, thus providing threshold hysteresis. Resistance values for R_1 and R_2 can be determined from the following equations:

$$R_1 = \frac{V_{HYS}}{20 \mu A}$$

$$R_2 = \frac{1.25V \times R_1}{V_{PWR-OFF} - 1.25V - (20 \mu A \times R_1)}$$

where

- V_{PWR} is the desired turn-on voltage
 - V_{HYS} is the desired UVLO hysteresis at V_{PWR}
- (6)

For example, if the LM5045 is to be enabled when V_{PWR} reaches 33V, and disabled when V_{PWR} is decreased to 31V, R_1 should be 100kΩ, and R_2 should be 4.2kΩ. The voltage at the UVLO pin should not exceed 7V at any time.

Two external resistors can be used to program the maximum operational voltage for the power converter as shown in Figure 24. When the OVP pin voltage rises above the 1.25V threshold, an internal 20μA current source is enabled to raise the voltage at the OVP pin, thus providing threshold hysteresis. Resistance values for R_1 and R_2 can be determined from the following equations:

$$R_1 = \frac{V_{HYS}}{20 \mu A}$$

$$R_2 = \frac{1.25V \times R_1}{V_{PWR} - 1.25V + (20 \mu A \times R_1)}$$
(7)

If the LM5045 is to be disabled when $V_{PWR-OFF}$ reaches 80V and enabled when it is decreased to 78V. R_1 should be 100kΩ, and R_2 should be 1.5 kΩ. The voltage at the OVP pin should not exceed 7V at any time.

Figure 23. Basic UVLO Configuration

Figure 24. Basic OVP Configuration

Figure 25. UVLO/OVP Divider

The UVLO and OVP can also be set together using a 3 resistor divider ladder as shown in Figure 25. R_1 is calculated as explained in the basic UVLO divider selection. Using the same values, as in the above two examples, for the UVLO and OVP set points, R_1 and R_3 remain the same at 100k Ω and 1.5k Ω . The R_2 is 2.7k Ω obtained by subtracting R_3 from 4.2k Ω .

Remote configuration of the controller's operational modes can be accomplished with open drain device(s) connected to the UVLO pin as shown in Figure 26.

Figure 27 shows an application of the OVP comparator for Remote Thermal Protection using a thermistor (or multiple thermistors) which may be located near the main heat sources of the power converter. The negative temperature coefficient (NTC) thermistor is nearly logarithmic, and in this example a 100k Ω thermistor with the β material constant of 4500 Kelvin changes to approximately 2k Ω at 130°C. Setting R_1 to one-third of this resistance (665 Ω) establishes 130°C as the desired trip point (for $V_{REF} = 5V$). In a temperature band from 20°C below to 20°C above the OVP threshold, the voltage divider is nearly linear with 25mV per °C sensitivity.

R_2 provides temperature hysteresis by raising the OVP comparator input by $R_2 \times 20\mu A$. For example, if a 22k Ω resistor is selected for R_2 , then the OVP pin voltage will increase by $22k \times 20\mu A = 506mV$. The NTC temperature must therefore fall by $506mV / 25mV \text{ per } ^\circ C = 20^\circ C$ before the LM5045 switches from standby mode to the normal mode.

Figure 26. Remote Standby and Disable Control

Figure 27. Remote Thermal Protection

Current Sense

The CS pin receives an input signal representative of its transformer's primary current, either from a current sense transformer or from a resistor located at the junction of source pin of the primary switches, as shown in Figure 28 and Figure 29 respectively. In both the cases, the filter components R_F and C_F should be located as close to the IC as possible, and the ground connection from the current sense transformer, or R_{SENSE} should be a dedicated trace to the appropriate GND pin. Please refer to the [Printed Circuit Board Layout](#) section for more layout tips.

The current sense components must provide a signal $> 710mV$ at the CS pin during an over-load event. Once the voltage on the CS pin crosses the current limit threshold, the current sense comparator terminates the PWM pulse and starts to charge the RES pin. Depending on the configuration of the RES pin, the LM5045 will eventually initiate a hiccup mode restart or be in continuous current limit.

Figure 28. Transformer Current Sense

Figure 29. Resistor Current Sense

Hiccup Mode Current Limit Restart

The operation of the hiccup mode restart circuit is explained in the [FUNCTIONAL DESCRIPTION](#) section. During a continuous current limit condition, the RES pin is charged with 30µA current source. The restart delay time required to reach the 1.0V threshold is given by:

$$T_{CS} = \frac{C_{RES} \times 1.0V}{30 \mu A} \quad (8)$$

This establishes the time allowed before the IC initiates a hiccup restart sequence. For example, if the $C_{RES}=0.01\mu F$, the time T_{CS} as noted in [Figure 30](#) below is 334µs. Once the RES pin reaches 1.0V, the 30µA current source is turned-off and a 10µA current source is turned-on during the ramp up to 4V and a 5µA is turned on during the ramp down to 2V. The hiccup mode off-time is given by:

$$T_{HICUP} = \frac{C_{RES} \times (2.0V \times 8)}{5 \mu A} + \frac{C_{RES} \times ((2.0V \times 8) + 1.0V)}{10 \mu A} \quad (9)$$

With a $C_{RES}=0.01\mu F$, the hiccup time is 49ms. Once the hiccup time is finished, the RES pin is pulled-low and the SS pin is released allowing a soft-start sequence to commence. Once the SS pin reaches 1V, the PWM pulses will commence. The hiccup mode provides a cool-down period for the power converter in the event of a sustained overload condition thereby lowering the average input current and temperature of the power components during such an event.

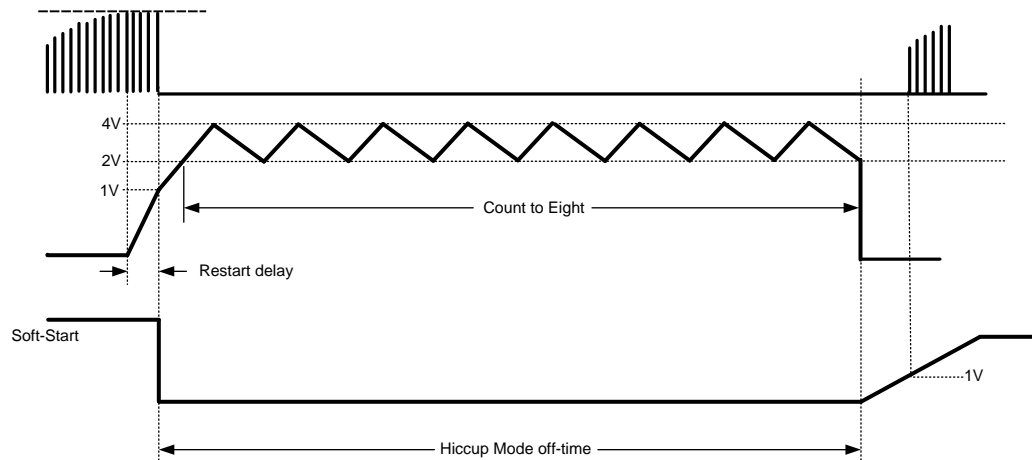

Figure 30. Hiccup Mode Delay and Soft-Start Timing Diagram

Augmenting the Gate Drive Strength

The LM5045 includes powerful 2A integrated gate drivers. However, in certain high power applications (>500W), it might be necessary to augment the strength of the internal gate driver to achieve higher efficiency and better thermal performance. In high power applications, typically, the I^2t loss in the primary MOSFETs is significantly higher than the switching loss. In order to minimize the I^2t loss, either the primary MOSFETs are paralleled or MOSFETs with low $R_{DS(on)}$ are employed. Both these scenarios increase the total gate charge to be driven by the controller IC. An increase in the gate charge increases the FET transition time and hence increases the switching losses. Therefore, to keep the total losses within a manageable limit the transition time needs to be reduced.

Generally, during the miller capacitance charge/discharge the total available driver current is lower during the turn-off process than during the turn-on process and often it is enough to speed-up the turn-off time to achieve the efficiency and thermal goals. This can be achieved simply by employing a PNP device, as shown in [Figure 31](#), from gate to source of the power FET. During the turn-on process, when the LO1 goes high, the current is sourced through the diode D1 and the BJT Q1 provides the path for the turn-off current. Q1 should be located as close to the power FET as possible so that the turn-off current has the shortest possible path to the ground and does not have to pass through the controller.

Figure 31. Circuit to Speed-up the Turn-off Process

Depending on the gate charge characteristics of the primary FET, if it is required to speed up both the turn-on and the turn-off time, a bipolar totem pole structure as shown in [Figure 32](#) can be used. When LO1 goes high, the gate to source current is sourced through the NPN transistor Q1 and similar to the circuit shown in [Figure 31](#) when LO1 goes low, the PNP transistor Q2 expedites the turn-off process.

Figure 32. Bipolar Totem Pole Arrangement

Alternatively, a low side gate driver such as LM5112 can be utilized instead of the discrete totem pole. The LM5112 comes in a small package with a 3A source and a 7A sink capability. While driving the high-side FET, the HS1 acts as a local ground and the boot capacitor between the BST and HS pins acts as VCC.

Figure 33. Using a Low Side Gate Driver to Augment Gate Drive Strength

Printed Circuit Board Layout

The LM5045 current sense and PWM comparators are very fast and respond to short duration noise pulses. The components at the CS, COMP, SLOPE, RAMP, SS, SSSR, RES, UVLO, OVP, RD1, RD2, and RT pins should be physically close as possible to the IC, thereby minimizing noise pickup on the PC board trace inductance. Eliminating or minimizing via's in these critical connections are essential. Layout consideration is critical for the current sense filter. If a current sense transformer is used, both leads of the transformer secondary should be routed to the sense filter components and to the IC pins. The ground side of the transformer should be connected via a dedicated PC board trace to the AGND pin, rather than through the ground plane. If the current sense circuit employs a sense resistor in the drive transistor source, low inductance resistors should be used. In this case, all the noise sensitive, low-current ground trace should be connected in common near the IC, and then a single connection made to the power ground (sense resistor ground point).

The gate drive outputs of the LM5045 should have short, direct paths to the power MOSFETs in order to minimize inductance in the PC board. The boot-strap capacitors required for the high side gate drivers should be located very close to the IC and connected directly to the BST and HS pins. The VCC and REF capacitors should also be placed close to their respective pins with short trace inductance. Low ESR and ESL ceramic capacitors are recommended for the boot-strap, VCC and the REF capacitors. The two ground pins (AGND, PGND) must be connected together directly underneath the IC with a short, direct connection, to avoid jitter due to relative ground bounce.

Application Circuit Example

The following schematic shows an example of a 100W full-bridge converter controlled by LM5045. The operating input voltage range is 36V to 75V, and the output voltage is 3.3V. The output current capability is 30 Amps. The converter is configured for current mode control with external slope compensation. An auxiliary winding is used to raise the VCC voltage to reduce the controller power dissipation.

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.

TBD: The Pb-Free/Green conversion plan has not been defined.

Pb-Free (RoHS): TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

Pb-Free (RoHS Exempt): This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

Green (RoHS & no Sb/Br): TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

(3) MSL, Peak Temp. -- The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) Only one of markings shown within the brackets will appear on the physical device.

Important Information and Disclaimer: The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as "components") are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI's terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers' products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers' products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI's goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or "enhanced plastic" are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have **not** been so designated is solely at the Buyer's risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.

Компания «ЭлектроПласт» предлагает заключение долгосрочных отношений при поставках импортных электронных компонентов на взаимовыгодных условиях!

Наши преимущества:

- Оперативные поставки широкого спектра электронных компонентов отечественного и импортного производства напрямую от производителей и с крупнейших мировых складов;
- Поставка более 17-ти миллионов наименований электронных компонентов;
- Поставка сложных, дефицитных, либо снятых с производства позиций;
- Оперативные сроки поставки под заказ (от 5 рабочих дней);
- Экспресс доставка в любую точку России;
- Техническая поддержка проекта, помощь в подборе аналогов, поставка прототипов;
- Система менеджмента качества сертифицирована по Международному стандарту ISO 9001;
- Лицензия ФСБ на осуществление работ с использованием сведений, составляющих государственную тайну;
- Поставка специализированных компонентов (Xilinx, Altera, Analog Devices, Intersil, Interpoint, Microsemi, Aeroflex, Peregrine, Syfer, Eurofarad, Texas Instrument, Miteq, Cobham, E2V, MA-COM, Hittite, Mini-Circuits, General Dynamics и др.);

Помимо этого, одним из направлений компании «ЭлектроПласт» является направление «Источники питания». Мы предлагаем Вам помощь Конструкторского отдела:

- Подбор оптимального решения, техническое обоснование при выборе компонента;
- Подбор аналогов;
- Консультации по применению компонента;
- Поставка образцов и прототипов;
- Техническая поддержка проекта;
- Защита от снятия компонента с производства.
