

2D, Dual-Channel, Ultrasensitive Hall-Effect Latch

FEATURES AND BENEFITS

- 2D magnetic sensing via planar and vertical Hall elements
- Phase separation between the two channels is inherently 90°
- Dual-channel output allows independent use of Z-axis planar Hall in conjunction with vertical Hall:
 - Y-axis (default option)
 - X-axis (with -X option)
- High sensitivity, B_{OP} typically 17 G
- Automotive grade
 - AEC-Q100 qualified for use in automotive applications
 - Output short-circuit protection
 - Resistant to physical stress
 - Reverse-battery protection
 - Solid-state reliability
 - Superior temperature stability
 - Supply voltage Zener clamp
- Small size

PACKAGES:

5-Pin SOT23W (Suffix LH)

Not to scale

DESCRIPTION

The A1262 integrated circuit is an ultrasensitive Hall-effect latch. It features operation with traditional planar magnetic field direction as well as vertical. The dual operation of the planar and vertical Hall elements allows the end user to achieve 90° of phase separation that is inherently independent of magnetic pole spacing. The quadrature outputs of the A1262 allow rotation direction to be determined, such as when sensing a rotating ring-magnet target.

The A1262 is available in two options that allow flexibility in end-system magnetic design. Both options feature a planar Hall plate that is sensitive to magnetic fields perpendicular to the face of the package (Z). The primary option features a vertical Hall plate that is sensitive to magnetic fields parallel with the face of the package across the leaded edges of the package (Y). The -X option features a vertical Hall plate that is sensitive to magnetic fields parallel with the face of the package across the leadless edges of the package (X), resulting in lower total effective air gap.

On a single silicon chip, the device includes: two Hall plates (one planar and one vertical), a multiplexer, a small-signal amplifier, chopper stabilization, a Schmitt trigger, and two short-circuit protected NMOS output transistors to sink up to 20 mA. The A1262 features circuitry that provides automotive ruggedness and allows operation from 4 to 24 V over a temperature range

2D, Dual-Channel, Ultrasensitive Hall-Effect Latch

Description (continued)

of –40°C to 85°C (E temperature range option) or –40°C to 150°C (K temperature range option).

The small geometries of the BiCMOS process allow these devices to be offered in an ultrasmall package suitable for most applications.

The A1262 is available in a 5-pin SOT23W surface-mount package, magnetically optimized for a variety of orientations. The package is RoHS compliant and lead (Pb) free, with 100% matte-tin leadframe plating.

FUNCTIONAL DESCRIPTION

Operation

The outputs of the A1262 switch low (turn on) when the corresponding Hall element is presented with a perpendicular south magnetic field of sufficient strength. OUTPUTA switches low if the Z-axis direction exceeds the operate point (B_{OP}), and OUTPUTB switches low if the Y-axis direction (A1262 with default option) or X-axis direction (A1262 with -X option) exceeds B_{OP} . After turn-on, the output voltage is $V_{OUT(SAT)}$. The device outputs switch high (turn off) when the strength of a perpendicular north magnetic field exceeds the release point (B_{RP}). The difference in the magnetic operate and release points is the hysteresis (B_{HYS}) of the device. See Figure 1.

Removal of the magnetic field will leave the device output latched on if the last crossed switchpoint is B_{OP} , or latched off if the last crossed switchpoint is B_{RP} .

This built-in hysteresis allows clean switching of the output even in the presence of external mechanical vibration and electrical noise. The device will power-on in the low output state, even when powering-on in the hysteresis region, between B_{OP} and B_{RP} .

Unlike dual-planar Hall-effect sensors, which have two planar Hall-effect sensing elements spaced apart across the width of the package, both the vertical and planar sensing elements on the A1262 are located in essentially the same location on the IC.

Figure 1: Switching Behavior of Latches

On the horizontal axis, the B+ direction indicates increasing south polarity magnetic field strength, and the B- direction indicates decreasing south polarity field strength (including the case of increasing north polarity)

With dual-planar Hall sensors, the ring magnet must be properly designed and optimized for the physical Hall spacing (distance) in order to have the outputs of the two latches to be in quadrature, or 90 degrees out of phase. With the A1262, which uses one planar and one vertical Hall-effect sensing element, no target optimization is required. When the face of the IC is facing the ring magnet, the planar Hall senses the magnet poles and the vertical Hall senses the transition between poles, therefore the

Figure 2: Ring magnet optimized for a dual-planar Hall-effect sensor resulting in output quadrature also results in quadrature for the A1262.

two channels will inherently be in quadrature, irrespective of the ring-magnet pole spacing.

Figure 2 above shows a ring magnet optimized for the E1-to-E2 spacing of a dual-planar sensor, resulting in quadrature, or 90 degrees phase separation between channels. This same target also results in quadrature for the 2D sensing A1262. However when a different ring magnet is used which is not optimized for

the E1-to-E2 spacing, the dual-planar sensor exhibits diminished phase separation, making signal processing the outputs into speed and direction less robust. Using a different ring-magnet geometry has no effect on the A1262, and the two channels remain in quadrature (see Figure 3 below).

The relationship of the various signals and the typical system timing is shown in Figure 4.

Figure 3: Ring magnet not optimized for a dual-planar Hall-effect sensor resulting in significantly reduced output phase separation, however still results in quadrature for the A1262.

Figure 4: Typical System Timing

The Planar (P) and Vertical (V) signals represent the magnetic input signal, which is converted to the device outputs, OUTPUTA and OUTPUTB, respectively. While the A1262 does not process the signals into Speed and Direction, these could be determined by the user based on the individual output signals.

A1262 Sensor and Relationship to Target

The A1262 is available in two sensing options: with Z-axis planar Hall and the Y-axis vertical Hall active (default option), or with the Z-axis planar Hall and the X-axis vertical Hall active (-X option). This offers incredible flexibility for positioning the IC within various applications.

The Z-Y option supports the traditional configuration with the face of the package facing the ring magnet (Figure 5a), with the axis of rotation going cross the leads, or with the either of the leaded sides of the package facing the ring magnet (Figure 5b).

Figure 5a

Figure 5b

The Z-X option supports having the IC positioned with the face of the package facing the ring magnet, and the axis of rotation lengthwise along the package body (Figure 6a) lengthwise along the package body, or with either of the non-leaded sides of the package facing the ring magnet (Figure 6b). This latter configuration has the advantage of being able to be mounted extremely close to the ring magnet, since there are no leads or solder pads to accommodate for in that dimension.

Figure 6a

Figure 6b

Power-On Sequence and Timing

The states of OUTPUTA and OUTPUT B are only valid when the supply voltage is within the specified operating range ($V_{DD(MIN)} \leq V_{DD} \leq V_{DD(MAX)}$) and the power-on time has elapsed ($t > t_{ON}$). Refer to Figure 7: Power-On Sequence and Timing for an illustration of the power-on sequence.

Figure 7: Power-On Sequence and Timing

Once the supply voltage is within the operational range, the outputs will be in the low state (power-on state), irrespective of the magnetic field. The outputs will remain low until the sensor is fully powered on ($t > t_{ON}$), at which point, both outputs will respond to the corresponding magnetic field presented to the sensor (the vertical Hall channel typically responds before the planar Hall channel).

Applications

It is strongly recommended that an external capacitor be connected (in close proximity to the Hall sensor) between the supply and ground of the device to reduce both external noise and noise generated by the chopper stabilization technique. As shown in Figure 8, a 0.1 μF capacitor is typical.

Figure 8: Typical Application Circuit

Extensive applications information on magnets and Hall-effect sensors is available in:

Chopper Stabilization Technique

When using Hall-effect technology, a limiting factor for switch-point accuracy is the small signal voltage developed across the Hall element. This voltage is disproportionately small relative to the offset that can be produced at the output of the Hall sensor. This makes it difficult to process the signal while maintaining an accurate, reliable output over the specified operating temperature and voltage ranges.

Chopper stabilization is a proven approach used to minimize Hall offset on the chip. The patented Allegro technique, namely Dynamic Quadrature Offset Cancellation, removes key sources of output drift induced by thermal and mechanical stresses. This technique is based on a signal modulation-demodulation process. The undesired offset signal is separated from the magnetic field-induced signal in the frequency domain, through modulation. The subsequent demodulation acts as a modulation process for the offset, causing the magnetic field induced signal to recover its original spectrum at baseband, while the dc offset becomes a high-frequency signal. The magnetic sourced signal then can pass through a low-pass filter, while the modulated DC offset is suppressed. This configuration is illustrated in Figure 3.

The chopper stabilization technique uses a 400 kHz high-frequency clock. For demodulation process, a sample, hold, and averaging technique is used, where the sampling is performed at twice the chopper frequency (800 kHz). This high-frequency operation allows a greater sampling rate, which results in higher accuracy and faster signal-processing capability. This approach desensitizes the chip to the effects of thermal and mechanical stresses, and produces devices that have extremely stable quiescent Hall output voltages and precise recoverability after temperature cycling. This technique is made possible through the use of a BiCMOS process, which allows the use of low-offset, low-noise amplifiers in combination with high-density logic and sample-and-hold circuits.

The repeatability of magnetic field-induced switching is affected slightly by a chopper technique. However, the Allegro high-frequency chopping approach minimizes the effect of jitter and makes it imperceptible in most applications. Applications that are more likely to be sensitive to such degradation are those requiring precise sensing of alternating magnetic fields—for example, speed sensing of ring-magnet targets. For such applications, Allegro recommends its digital sensor families with lower sensitivity to jitter. For more information on those devices, contact your Allegro sales representative.

Figure 9: Model of Chopper Stabilization Technique

POWER DERATING

The device must be operated below the maximum junction temperature of the device, $T_{J(max)}$. Under certain combinations of peak conditions, reliable operation may require derating supplied power or improving the heat dissipation properties of the application. This section presents a procedure for correlating factors affecting operating T_J . (Thermal data is also available on the Allegro MicroSystems website.)

The Package Thermal Resistance ($R_{\theta JA}$) is a figure of merit summarizing the ability of the application and the device to dissipate heat from the junction (die), through all paths to the ambient air. Its primary component is the Effective Thermal Conductivity (K) of the printed circuit board, including adjacent devices and traces. Radiation from the die through the device case ($R_{\theta JC}$) is relatively small component of $R_{\theta JA}$. Ambient air temperature (T_A) and air motion are significant external factors, damped by overmolding.

The effect of varying power levels (Power Dissipation, P_D), can be estimated. The following formulas represent the fundamental relationships used to estimate T_J at P_D .

$$P_D = V_{IN} \times I_{IN} \quad (1)$$

$$\Delta T = P_D \times R_{\theta JA} \quad (2)$$

$$T_J = T_A + \Delta T \quad (3)$$

For example, given common conditions such as: $T_A = 25^\circ\text{C}$, $V_{DD} = 12\text{ V}$, $I_{DD} = 3\text{ mA}$, and $R_{\theta JA} = 124^\circ\text{C/W}$ for the LH5 package, then:

$$P_D = V_{DD} \times I_{DD} = 12\text{ V} \times 3.0\text{ mA} = 36.0\text{ mW}$$

$$\Delta T = P_D \times R_{\theta JA} = 36.0\text{ mW} \times 124^\circ\text{C/W} = 4.5^\circ\text{C}$$

$$T_J = T_A + \Delta T = 25^\circ\text{C} + 4.5^\circ\text{C} = 29.5^\circ\text{C}$$

A worst-case estimate ($P_{D(max)}$) represents the maximum allowable power level ($V_{DD(max)}$, $I_{DD(max)}$), without exceeding $T_{J(max)}$, at a selected $R_{\theta JA}$ and T_A .

Example: Reliability for V_{DD} at $T_A = 150^\circ\text{C}$, package LH5, using low-K PCB.

Observe the worst-case ratings for the device, specifically:

$R_{\theta JA} = 124^\circ\text{C/W}$, $T_{J(max)} = 165^\circ\text{C}$, $V_{DD(max)} = 24\text{ V}$, and $I_{DD(max)} = 7.5\text{ mA}$.

Calculate the maximum allowable power level ($P_{D(max)}$). First, invert equation 3:

$$\Delta T_{max} = T_{J(max)} - T_A = 165^\circ\text{C} - 150^\circ\text{C} = 15^\circ\text{C}$$

This provides the allowable increase to T_J resulting from internal power dissipation. Then, invert equation 2:

$$P_{D(max)} = \Delta T_{max} \div R_{\theta JA} = 15^\circ\text{C} \div 124^\circ\text{C/W} = 121\text{ mW}$$

Finally, invert equation 1 with respect to voltage:

$$V_{DD(est)} = P_{D(max)} \div I_{DD(max)}$$

$$V_{DD(est)} = 121\text{ mW} \div 7.5\text{ mA}$$

$$V_{DD(est)} = 16.1\text{ V}$$

The result indicates that, at T_A , the application and device can dissipate adequate amounts of heat at voltages $\leq V_{DD(est)}$.

Compare $V_{DD(est)}$ to $V_{DD(max)}$. If $V_{DD(est)} \leq V_{DD(max)}$, then reliable operation between $V_{DD(est)}$ and $V_{DD(max)}$ requires enhanced $R_{\theta JA}$. If $V_{DD(est)} \geq V_{DD(max)}$, then operation between $V_{DD(est)}$ and $V_{DD(max)}$ is reliable under these conditions.

Компания «ЭлектроПласт» предлагает заключение долгосрочных отношений при поставках импортных электронных компонентов на взаимовыгодных условиях!

Наши преимущества:

- Оперативные поставки широкого спектра электронных компонентов отечественного и импортного производства напрямую от производителей и с крупнейших мировых складов;
- Поставка более 17-ти миллионов наименований электронных компонентов;
- Поставка сложных, дефицитных, либо снятых с производства позиций;
- Оперативные сроки поставки под заказ (от 5 рабочих дней);
- Экспресс доставка в любую точку России;
- Техническая поддержка проекта, помощь в подборе аналогов, поставка прототипов;
- Система менеджмента качества сертифицирована по Международному стандарту ISO 9001;
- Лицензия ФСБ на осуществление работ с использованием сведений, составляющих государственную тайну;
- Поставка специализированных компонентов (Xilinx, Altera, Analog Devices, Intersil, Interpoint, Microsemi, Aeroflex, Peregrine, Syfer, Eurofarad, Texas Instrument, Miteq, Cobham, E2V, MA-COM, Hittite, Mini-Circuits, General Dynamics и др.);

Помимо этого, одним из направлений компании «ЭлектроПласт» является направление «Источники питания». Мы предлагаем Вам помощь Конструкторского отдела:

- Подбор оптимального решения, техническое обоснование при выборе компонента;
- Подбор аналогов;
- Консультации по применению компонента;
- Поставка образцов и прототипов;
- Техническая поддержка проекта;
- Защита от снятия компонента с производства.
