## Data Sheet

## FEATURES

Power supply rejection ratio (PSRR): 98 dB minimum Common-mode rejection ratio (CMRR): 95 dB minimum
Offset voltage: $\mathbf{1 2 0 \mu V}$ maximum
Single-supply operation: 2.7 V to 5.5 V
Dual-supply operation: $\pm 1.35 \mathrm{~V}$ to $\pm 2.75 \mathrm{~V}$
Wide bandwidth: $10 \mathbf{~ M H z}$
Rail-to-rail input and output Low noise
$2 \mu \mathrm{~V}$ p-p from 0.1 Hz to 10 Hz
$14.5 \mathrm{nV} / \sqrt{ } \mathrm{Hz}$ at 1 kHz
Very low input bias current: 2 pA maximum

## APPLICATIONS

## Pressure and position sensors

Remote security
Medical monitors
Process controls
Hazard detectors
Photodiode applications

## PIN CONFIGURATION

Figure 1. 8-Lead MSOP Pin Configuration
For more information on the pin connections, see the Pin Configurations and Function Descriptions section

Figure 2. The ADA4500-2 Eliminates Crossover Distortion Across its Full Supply Range

This combination of features makes the ADA4500-2 an ideal choice for precision sensor applications because it minimizes errors due to power supply variation and maintains high CMRR over the full input voltage range. The ADA4500-2 is also an excellent amplifier for driving analog-to-digital converters (ADCs) because the output does not distort with the common-mode voltage, which enables the ADC to use its full input voltage range, maximizing the dynamic range of the conversion subsystem.
Many applications such as sensors, handheld instrumentation, precision signal conditioning, and patient monitors can benefit from the features of the ADA4500-2.

The ADA4500-2 is specified for the extended industrial temperature range $\left(-40^{\circ} \mathrm{C}\right.$ to $\left.+125^{\circ} \mathrm{C}\right)$ and available in the standard 8 -lead MSOP and 8-lead LFCSP packages.

## ABSOLUTE MAXIMUM RATINGS

Table 3.

| Parameter | Rating |
| :--- | :--- |
| Supply Voltage | 6 V |
| Input Voltage | $(\mathrm{V}-)-0.2 \mathrm{~V}$ to $(\mathrm{V}+)+0.2 \mathrm{~V}$ |
| Differential Input Voltage ${ }^{1}$ | $(\mathrm{~V}-)-0.2 \mathrm{~V}$ to $(\mathrm{V}+)+0.2 \mathrm{~V}$ |
| Output Short-Circuit Duration | Indefinite |
| Storage Temperature Range | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| Operating Temperature Range | $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |
| Junction Temperature Range | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| Lead Temperature (Soldering, 60 sec$)$ | $300^{\circ} \mathrm{C}$ |

${ }^{1}$ Differential input voltage is limited to 5.6 V or the supply voltage +0.6 V , whichever is less.

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## THERMAL RESISTANCE

$\theta_{\mathrm{IA}}$ is specified for the worst-case conditions, that is, a device soldered in a circuit board for surface-mount packages.

Table 4. Thermal Resistance

| Package Type | $\boldsymbol{\theta}_{\text {JA }}$ | $\boldsymbol{\theta}_{\text {JC }}$ | Unit |
| :--- | :--- | :--- | :--- |
| 8-Lead MSOP (RM-8) |  |  |  |
| 8-Lead LFCSP $(\mathrm{CP}-8-12)^{2,3}$ | 142 | 45 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |

${ }^{1}$ Thermal numbers were simulated on a 4-layer JEDEC printed circuit board (PCB).
${ }^{2}$ Thermals numbers were simulated on a 4 layer JEDEC PCB with the exposed pad soldered to the PCB.
${ }^{3} \theta_{\mathrm{JC}}$ was simulated at the exposed pad on the bottom of the package.

## ESD CAUTION

|  | ESD (electrostatic discharge) sensitive device. <br> Charged devices and circuit boards can discharge <br> without detection. Although this product features <br> patented or proprietary protection circuitry, damage <br> may occur on devices subjected to high energy ESD. <br> Therefore, proper ESD precautions should be taken to <br> avoid performance degradation or loss of functionality. |
| :--- | :--- |

## PIN CONFIGURATIONS AND FUNCTION DESCRIPTIONS

Figure 3. 8-Lead MSOP Pin Configuration

Table 5. 8-Lead MSOP and 8-Lead LFCSP Pin Function Descriptions

| Pin No. | Mnemonic | Description |
| :--- | :--- | :--- |
| 1 | OUT A | Output, Channel A. |
| 2 | - IN A | Inverting Input, Channel A. |
| 3 | + IN A | Noninverting Input, Channel A. |
| 4 | V- | Negative Supply Voltage. |
| 5 | + IN B | Noninverting Input, Channel B. |
| 6 | - IN B | Inverting Input, Channel B. |
| 7 | OUT B | Output, Channel B. |
| 8 | V+ | Positive Supply Voltage. |
|  | EPAD | For the LFCSP package only, connect the exposed pad to V- or leave it unconnected. |

## THEORY OF OPERATION

## RAIL-TO-RAIL OUTPUT

When processing a signal through an op amp to a load, it is often desirable to have the output of the op amp swing as close to the voltage supply rails as possible. For example, when an op amp is driving an ADC and both the op amp and ADC are using the same supply rail voltages, the op amp must drive as close to the $\mathrm{V}+$ and V - rails as possible so that all codes in the ADC are usable. A non-rail-to-rail output can require as much as 1.5 V or more between the output and the rails, thus limiting the input dynamic range to the ADC , resulting in less precision (number of codes) in the converted signal.

The ADA4500-2 can drive its output to within a few millivolts of the supply rails (see the output voltage high and output voltage low specifications in Table 1 and Table 2). The rail-to-rail output maximizes the dynamic range of the output, increasing the range and precision, and often saving the cost, board space, and added error of the additional gain stages.

## RAIL-TO-RAIL INPUT (RRI)

Using a CMOS nonrail-to-rail input stage (that is, a single differential pair) limits the input voltage to approximately one gatesource voltage ( $\mathrm{V}_{\mathrm{GS}}$ ) away from one of the supply lines. Because $\mathrm{V}_{\mathrm{GS}}$ for normal operation is commonly more than 1 V , a single differential pair, input stage op amp greatly restricts the allowable input voltage. This can be quite limiting with low supply voltages supplies. To solve this problem, RRI stages are designed to allow the input signal to range to the supply voltages (see the input voltage range specifications in Table 1 and Table 2). In the case of the ADA4500-2, the inputs continue to operate 200 mV beyond the supply rails (see Figure 7 and Figure 10).

## ZERO CROSS-OVER DISTORTION

A typical rail-to-rail input stage uses two differential pairs (see Figure 59). One differential pair amplifies the input signal when the common-mode voltage is on the high end, and the other pair amplifies the input signal when the common-mode voltage is on the low end. This classic dual-differential pair topology does have a potential drawback. If the signal level moves through the range where one input stage turns off and the other input stage turns on, noticeable distortion occurs. Figure 60 shows the distortion in a typical plot of $\mathrm{V}_{\mathrm{OS}}$ (voltage difference between the inverting and the noninverting input) vs. $\mathrm{V}_{\mathrm{CM}}$ (input voltage).

Figure 59. Typical PMOS-NMOS Rail-to-Rail Input Structure

Figure 60. Typical Input Offset Voltage ( $V_{O S}$ ) vs. Common-Mode Voltage ( $V_{C M}$ ) Response in a Dual Differential Pair Input Stage Op Amp (Powered by a 5 V Supply; Results of Approximately 100 Units per Graph Are Displayed)

This distortion in the offset error forces the designer to live with the bump in the common-mode error or devise impractical ways to avoid the crossover distortion areas, thereby narrowing the common-mode dynamic range of the op amp.

The ADA4500-2 solves the crossover distortion problem by using an on-chip charge pump in its input structure to power the input differential pair (see Figure 61). The charge pump creates a supply voltage higher than the voltage of the supply, allowing the input stage to handle a wide range of input signal voltages without using a second differential pair. With this solution, the input voltage can vary from one supply voltage to the other with no distortion, thereby restoring the full common-mode dynamic range of the op amp.

Figure 61. ADA4500-2 Input Structure
Some charge pumps are designed to run in an open-loop configuration. Disadvantages of this design include: a large ripple voltage on the output, no output regulation, slow start-up, and a large power-supply current ripple. The charge pump in this op amp uses a feedback network that includes a controllable clock driver and a differential amplifier. This topology results in a low ripple voltage; a regulated output that is robust to line, load, and process variations; a fast power-on startup; and lower ripple on the power supply current. ${ }^{1}$ The charge pump ripple does not show up on an oscilloscope; however, it can be seen at a high frequency on a spectrum analyzer. The charge pump clock speed adjusts between 3.5 MHz (when the supply voltage is 2.7 V ) to $5 \mathrm{MHz}\left(\right.$ at $\left.\mathrm{V}_{\mathrm{SY}}=5 \mathrm{~V}\right)$. The noise and distortion are limited only by the input signal and the thermal or flicker noise.

Figure 62 shows the elimination of the crossover distortion in the ADA4500-2. This solution improves the CMRR performance tremendously. For example, if the input varies from rail to rail on a 5 V supply rail, using a part with a CMRR of 70 dB minimum, an input-referred error of $1581 \mu \mathrm{~V}$ is introduced. The ADA4500-2, with its high CMRR of 90 dB minimum (over its full operating temperature) reduces distortion to a maximum error of $158 \mu \mathrm{~V}$ with a 5 V supply. The ADA4500-2 eliminates crossover distortion without unnecessary circuitry complexity and increased cost.

Figure 62. Charge Pump Design Eliminates Crossover Distortion

## OVERLOAD RECOVERY

When the output is driven to one of the supply rails, the ADA4500-2 is in an overload condition. The ADA4500-2 recovers quickly from the overload condition. Typical op amp recovery times can be in the tens of microseconds. The ADA4500-2 typically recovers from an overload condition in $1 \mu$ from the time the overload condition is removed until the output is active again. This is important in, for example, a feedback control system. The fast overload recovery of the ADA4500-2 greatly reduces loop delay and increases the response time of the control loop (see Figure 41 to Figure 44).

[^0]
## POWER-ON CURRENT PROFILE

The ADA4500-2 powers up with a smooth current profile, with no supply current overshoot (see Figure 63). When powering up a system, spikes in the power-up current are undesirable (see Figure 64). The overshoot requires a designer to source a large enough power supply (such as a voltage regulator) to supply the peak current, even though a heavier supply is not necessary once the system is powered up. If multiple amplifiers are pulling a spike in current, the system can go into a current limit state and not power up. This is all avoided with the smooth power up of the ADA4500-2.

Figure 63. $I_{S Y}$ and $V_{S Y}$ vs. Time for ADA4500-2 with No Spike

Figure 64. $I_{S Y}$ and $V_{S Y}$ vs. Time with a Power-Up Spike
For systems that are frequently switching off and on, the powerup overshoot results in excess power use. As the amplifier switches off and on, the power consumed by the large spike is repeated on each power-up, increasing the total power consumption by magnitudes. As an example, if a battery-powered sensor system periodically powers up the sensor and signal path, takes a reading, and shuts down until the next reading, the ADA4500-2 enables much longer battery life because there is no excess charge being consumed at each power-up.

## APPLICATIONS INFORMATION

## RESISTANCE AND CAPACITANCE SENSOR CIRCUIT

The application shown in Figure 65 generates a square-wave output in which the period is proportional to the value of $\mathrm{R}_{\mathrm{x}}$ and $C_{x}$ by Equation 1 . By fixing the $C_{x}$ and measuring the period of the output signal, $\mathrm{R}_{\mathrm{x}}$ can be determined. Fixing $\mathrm{R}_{\mathrm{X}}$ allows for the measurement of $\mathrm{C}_{\mathrm{x}}$.

$$
\begin{equation*}
\text { Period }=4.80 \times \mathrm{R}_{\mathrm{x}} \times \mathrm{C}_{\mathrm{x}} \tag{1}
\end{equation*}
$$

U1A takes advantage of the high input impedance and large rail-to-rail input dynamic range of the ADA4500-2 to measure a wide range of resistances $\left(\mathrm{R}_{\mathrm{X}}\right)$.
U1B is used as a comparator; with the noninverting input swinging between $(1 / 12) \times V_{\text {POS }}$ and $(11 / 12) \times V_{\text {POS }}$, and the output swinging from rail to rail. Because the accuracy of the circuit depends on the propagation time through the amplifers, the fast recovery of U1B from the output overload conditions makes it ideal for this application.

Figure 65. A Resistance/Capacitance Sensor

## ADAPTIVE SINGLE-ENDED-TO-DIFFERENTIAL SIGNAL CONVERTER

## The Challenge

When designing a signal path in systems that have a single voltage supply, the biggest challenge is how to represent the full range of an input signal that may have positive, zero, and negative values. By including zero in the output, the output signal must go completely to ground, which single-supply amplifiers cannot do. Converting the single-ended input signal to a differential signal (through a single-ended-to-differential signal converter circuit) allows zero to be represented as the positive and negative outputs being equal, requiring neither amplifier to go to ground.
There are other benefits of the single-ended-to-differential signal conversion, such as doubling the amplitude of the signal for better signal-to-noise ratio, rejecting common-mode noise, and driving the input of a high precision differential ADC.
In addition to converting to a differential signal, the circuit must set the common-mode dc level of its output to a level that gives the ac signal maximum swing at the load (like the input to an ADC).

Three key challenges are encountered often when designing a single-ended-to-differential signal converter circuit with a single supply:

- When the supply is limited to a single voltage, the input signal level to the circuit is generally limited to operate from ground to the supply voltage $\left(\mathrm{V}_{\mathrm{SY}}\right)$. This limitation on the input dynamic range can require attenuation and/or level-shifting of the source signal before it even gets to the single-ended-to-differential signal converter. This results in reduced signal-to-noise ratio (SNR) and additional error.
- The dc part of the input signal, on which the ac signal rides, is generally not known during system operation. For example, if multiple input signals from varying sources are multiplexed into the single-ended-to-differential signal converter circuit, each one could have a different dc level. Accommodating multiple dc input levels means that the system design must compromise the maximum allowed peak voltage of the ac part of the input so that it does not clip against the rails.
- The system processor does not know what the dc level is of the original signal so it cannot make adjustments accordingly.

## The Solution

These challenges are solved with the adaptive single-ended to differential converter shown in Figure 66. This circuit operates off a single supply from 2.7 V to 5.5 V , it automatically adjusts the dc common mode of the output to a desired level, and it provides the ability to measure the dc component of the input signal. This circuit uses two voltage sources: a positive supply rail $\left(\mathrm{V}_{\mathrm{SY}}\right)$ and a reference voltage ( $\mathrm{V}_{\text {REF }}$ ). U1A buffers the input signal, while U1B integrates that signal and feeds the integrated (dc) voltage back to U1A to center the output signal on $\mathrm{V}_{\text {REF }}$. Resistors R10 and R11 are set to equal the impedance of the resistors R8 and R9 for a matched ac response and for balancing the effects of the bias current.
The input frequency can range from 10 Hz to 1 MHz . Peak-to-peak amplitude of the input signal can be as large as $\mathrm{V}_{\mathrm{SY}}-100 \mathrm{mV}$. The dc common mode $\left(\mathrm{V}_{\mathrm{CM}}\right)$ of the input signal can be as high as $+1.5 \times \mathrm{V}_{\mathrm{SY}}$ and $-0.5 \times \mathrm{V}_{\mathrm{SY}}$; therefore, a system with a +5 V supply voltage can take a common mode from as high as +7.5 V and as low as -2.5 V with a signal amplitude of 5 V p-p. The wide range of $\mathrm{V}_{\mathrm{CM}}$ above and below ground, along with a signal amplitude as large as the supply, eliminates the need to reduce the amplitude of the input signal and sacrifice SNR. When measuring both the ac and the dc parts of the signal, a capacitor cannot be in the signal path. Figure 66 shows examples of the voltage ranges of the single-ended-to-differential signal converter circuit.

Besides converting the ac signal from single-ended to differential, this circuit separates the ac and dc part of the input signal and automatically adjusts the common-mode dc level of the output signal to the same voltage as $\mathrm{V}_{\text {REF }}$. The output signal is then a differential version of the input signal with its common-mode voltage set to an optimal value (such as, $1 / 2$ the full-scale input range to the ADC). The noninverted ac part of the signal is output at OUTP, and the inverted ac signal is output at OUTN. The differential output signal (OUTP to OUTN) is centered on the voltage applied to REF. In this design, R3 and R4 set REF to $1 / 2 \mathrm{~V}_{\text {Pos }}$ for maximum signal peak-to-peak swing; however, these resistors can be eliminated, and the REF input can be driven from an external source, such as a reference or the output of a digital-to-analog converter (DAC).

The dc common-mode part of the input signal $\left(\mathrm{V}_{\mathrm{DC}}\right)$ was measured using the voltage applied at REF and the voltage measured at the feedback (FB) output using Equation 2. With $\mathrm{V}_{\mathrm{CM}}$ of the input signal known to the system, it can respond appropriately to, for example, a situation when the common mode is getting too close to the rails.

$$
\begin{equation*}
V_{D C}=(2 \times F B)-(R E F) \tag{2}
\end{equation*}
$$

EXAMPLES $\left(\mathrm{V}_{\mathrm{SY}}=5 \mathrm{~V}\right)$

Компания «ЭлектроПласт» предлагает заключение долгосрочных отношений при поставках импортных электронных компонентов на взаимовыгодных условиях!

Наши преимущества:

- Оперативные поставки широкого спектра электронных компонентов отечественного и импортного производства напрямую от производителей и с крупнейших мировых складов;
- Поставка более 17-ти миллионов наименований электронных компонентов;
- Поставка сложных, дефицитных, либо снятых с производства позиций;
- Оперативные сроки поставки под заказ (от 5 рабочих дней);
- Экспресс доставка в любую точку России;
- Техническая поддержка проекта, помощь в подборе аналогов, поставка прототипов;
- Система менеджмента качества сертифицирована по Международному стандарту ISO 9001;
- Лицензия ФСБ на осуществление работ с использованием сведений, составляющих государственную тайну;
- Поставка специализированных компонентов (Xilinx, Altera, Analog Devices, Intersil, Interpoint, Microsemi, Aeroflex, Peregrine, Syfer, Eurofarad, Texas Instrument, Miteq, Cobham, E2V, MA-COM, Hittite, Mini-Circuits,General Dynamics и др.);

Помимо этого, одним из направлений компании «ЭлектроПласт» является направление «Источники питания». Мы предлагаем Вам помощь Конструкторского отдела:

- Подбор оптимального решения, техническое обоснование при выборе компонента;
- Подбор аналогов;
- Консультации по применению компонента;
- Поставка образцов и прототипов;
- Техническая поддержка проекта;
- Защита от снятия компонента с производства.
