# <span id="page-0-0"></span>**1. General description**

The TDA8922C is a high-efficiency Class D audio power amplifier. Typical output power is 2 × 75 W with a speaker load impedance of 6  $\Omega$ .

The TDA8922C is available in both HSOP24 and DBS23P power packages. The amplifier operates over a wide supply voltage range from  $\pm$ 12.5 V to  $\pm$ 32.5 V and features low quiescent current consumption.

### <span id="page-0-1"></span>**2. Features**

- Pin compatible with TDA8950/20C for both HSOP24 and DBS23P packages
- Symmetrical operating supply voltage range from  $±12.5$  V to  $±32.5$  V
- Stereo full differential inputs, can be used as stereo Single-Ended (SE) or mono Bridge-Tied Load (BTL) amplifier
- High output power in typical applications:
	- $\triangle$  SE 2 × 75 W, R<sub>L</sub> = 6 Ω (V<sub>DD</sub> = 30 V; V<sub>SS</sub> = -30 V)
	- $\triangle$  SE 2 × 60 W, R<sub>L</sub> = 8 Ω (V<sub>DD</sub> = 30 V; V<sub>SS</sub> = -30 V)
	- $\triangle$  BTL 1 × 155 W, R<sub>L</sub> = 8 Ω (V<sub>DD</sub> = 25 V; V<sub>SS</sub> = -25 V)
- Low noise
- Smooth pop noise-free start-up and switch off
- Zero dead time switching
- Fixed frequency
- Internal or external clock
- High efficiency
- Low quiescent current
- Advanced protection strategy: voltage protection and output current limiting
- Thermal FoldBack (TFB)
- Fixed gain of 30 dB in SE and 36 dB in BTL applications
- Fully short-circuit proof across load
- BD modulation in BTL configuration

### <span id="page-0-2"></span>**3. Applications**

- DVD
- Mini and micro receiver
- Home Theater In A Box (HTIAB) system
- High-power speaker system

### **8.1 General**

The TDA8922C is a two-channel audio power amplifier that uses Class D technology.

For each channel, the audio input signal is converted into a digital Pulse Width Modulation (PWM) signal using an analog input stage and a PWM modulator; see [Figure](#page-2-0) 1. To drive the output power transistors, the digital PWM signal is fed to a control and handshake block and to high- and low-side driver circuits. This level-shifts the low-power digital PWM signal from a logic level to a high-power PWM signal switching between the main supply lines.

A second order low-pass filter converts the PWM signal to an analog audio signal that can be used to drive a loudspeaker.

The TDA8922C single-chip Class D amplifier contains high-power switches, drivers, timing and handshaking between the power switches, along with some control logic. To ensure maximum system robustness, an advanced protection strategy has been implemented to provide overvoltage, overtemperature and overcurrent protection.

Each of the two audio channels contains a PWM modulator, an analog feedback loop and a differential input stage. The TDA8922C also contains circuits common to both channels such as the oscillator, all reference sources, the mode interface and a digital timing manager.

The two independent amplifier channels feature high output power, high efficiency, low distortion and low quiescent currents. They can be connected in the following configurations:

- **•** Stereo Single-Ended (SE)
- **•** Mono Bridge-Tied Load (BTL)

The amplifier system can be switched to one of three operating modes using pin MODE:

- **•** Standby mode: featuring very low quiescent current
- **•** Mute mode: the amplifier is operational but the audio signal at the output is suppressed by disabling the voltage-to-current (VI) converter input stages
- **•** Operating mode: the amplifier is fully operational, de-muted and can deliver an output signal

A slowly rising voltage should be applied (e.g. via an RC network) to pin MODE to ensure pop noise-free start-up. The bias-current setting of the (VI converter) input stages is related to the voltage on the MODE pin.

In Mute mode, the bias-current setting of the VI converters is zero (VI converters are disabled). In Operating mode, the bias current is at a maximum. The time constant required to apply the DC output offset voltage gradually between Mute and Operating mode levels can be generated using an RC network connected to pin MODE. An example of a circuit for driving the MODE pin, optimized for optimal pop noise performance, is shown in [Figure](#page-5-0) 4. If the capacitor was omitted, the very short switching time constant could result in audible pop noises being generated at start-up (depending on the DC output offset voltage and loudspeaker used).

<span id="page-5-0"></span>

**2** × **75 W class-D power amplifier**

To ensure the coupling capacitors at the inputs  $(C_{IN}$  in [Figure](#page-21-0) 10) are fully charged before the outputs start switching, a delay is inserted during the transition from Mute to Operating mode. An overview of the start-up timing is provided in [Figure](#page-6-0) 5.

<span id="page-6-0"></span>

### <span id="page-7-0"></span>**8.2 Pulse-width modulation frequency**

The amplifier output signal is a PWM signal with a typical carrier frequency of between 250 kHz and 450 kHz. A second order LC demodulation filter on the output converts the PWM signal into an analog audio signal. The carrier frequency is determined by an external resistor,  $R_{\text{OSC}}$ , connected between pins OSC and VSSA. The optimal carrier frequency setting is between 250 kHz and 450 kHz.

The carrier frequency is set to 345 kHz by connecting an external 30 kΩ resistor between pins OSC and VSSA. See [Table](#page-13-0) 9 for more details.

If two or more Class D amplifiers are used in the same audio application, it is recommended that an external clock circuit be used with all devices (see [Section](#page-17-0) 13.4). This will ensure that they operate at the same switching frequency, thus avoiding beat tones (if the switching frequencies are different, audible interference known as 'beat tones' can be generated).

### <span id="page-7-1"></span>**8.3 Protection**

The following protection circuits are incorporated into the TDA8922C:

- **•** Thermal protection:
	- **–** Thermal FoldBack (TFB)
	- **–** OverTemperature Protection (OTP)
- **•** OverCurrent Protection (OCP)
- **•** Window Protection (WP)
- **•** Supply voltage protection:
	- **–** UnderVoltage Protection (UVP)
	- **–** OverVoltage Protection (OVP)
	- **–** UnBalance Protection (UBP)

How the device reacts to a fault conditions depends on which protection circuit has been activated.

### <span id="page-7-2"></span>**8.3.1 Thermal protection**

The TDA8922C employes an advanced thermal protection strategy. A TFB function gradually reduces the output power within a defined temperature range. If the temperature continues to rise, OTP is activated to shut down the device completely.

### <span id="page-7-3"></span>**8.3.1.1 Thermal FoldBack (TFB)**

If the junction temperature  $(T_j)$  exceeds the thermal foldback activation threshold, the gain is gradually reduced. This reduces the output signal amplitude and the power dissipation, eventually stabilizing the temperature.

<span id="page-8-2"></span>TFB is specified at the thermal foldback activation temperature  $T_{\text{act(th fold)}}$  where the closed-loop voltage gain is reduced by 6 dB. The TFB range is:

 $T_{\text{act(th-fold}} - 5 \text{ °C} < T_{\text{act(th-fold}} < T_{\text{act(th prot}})$ 

The value of T<sub>act(th\_fold</sub>) for the TDA8922C is approximately 153 °C; see [Table](#page-12-0) 8 for more details.

#### <span id="page-8-3"></span>**8.3.1.2 OverTemperature Protection (OTP)**

If TFB fails to stabilize the temperature and the junction temperature continues to rise, the amplifier will shut down as soon as the temperature reaches the thermal protection activation threshold,  $T_{\text{act-th}}$  prot). The amplifier will resume switching approximately 100 ms after the temperature drops below  $T_{\text{act(th-prot)}}$ .

The thermal behavior is illustrated in [Figure](#page-8-0) 6.

### <span id="page-8-1"></span><span id="page-8-0"></span>**8.3.2 OverCurrent Protection (OCP)**

In order to guarantee the robustness of the TDA8922C, the maximum output current delivered at the output stages is limited. OCP is built in for each output power switch.

OCP is activated when the current in one of the power transistors exceeds the OCP threshold ( $I_{\text{ORM}}$  = 6 A) due, for example, to a short-circuit to a supply line or across the load.

The TDA8922C amplifier distinguishes between low-ohmic short-circuit conditions and other overcurrent conditions such as a dynamic impedance drop at the loudspeakers. The impedance threshold  $(Z<sub>th</sub>)$  depends on the supply voltage.

How the amplifier reacts to a short circuit depends on the short-circuit impedance:

• Short-circuit impedance  $> Z_{th}$ : the amplifier limits the maximum output current to  $I_{\rm ORM}$ but the amplifier does not shut down the PWM outputs. Effectively, this results in a clipped output signal across the load (behavior very similar to voltage clipping).

• Short-circuit impedance  $Z_{th}$ : the amplifier limits the maximum output current to  $I_{\text{ORM}}$ and at the same time discharges the capacitor on pin PROT. When  $C_{PROT}$  is fully discharged, the amplifier shuts down completely and an internal timer is started.

The value of the protection capacitor  $(C_{PROT})$  connected to pin PROT can be between 10 pF and 220 pF (typically 47 pF). While OCP is activated, an internal current source is enabled that will discharge  $C_{PROT}$ .

When OCP is activated, the active power transistor is turned off and the other power transistor is turned on to reduce the current  $(C_{PROT}$  is partially discharged). Normal operation is resumed at the next switching cycle ( $C_{\text{PROT}}$  is recharged).  $C_{\text{PROT}}$  is partially discharge each time OCP is activated during a switching cycle. If the fault condition that caused OCP to be activated persists long enough to fully discharge  $C_{PROT}$ , the amplifier will switch off completely and a restart sequence will be initiated.

After a fixed period of 100 ms, the amplifier will attempt to switch on again, but will fail if the output current still exceeds the OCP threshold. The amplifier will continue trying to switch on every 100 ms. The average power dissipation will be low in this situation because the duty cycle is short.

Switching the amplifier on and off in this way will generate unwanted 'audio holes'. This can be avoided by increasing the value of  $C_{PROT}$  (up to 220 pF) to delay amplifier switch-off.  $C_{PROT}$  will also prevent the amplifier switching off due to transient frequency-dependent impedance drops at the speakers.

The amplifier will switch on, and remain in Operating mode, once the overcurrent condition has been removed. OCP ensures the TDA8922C amplifier is fully protected against short-circuit conditions while avoiding audio holes.

#### **Table 4. Current limiting behavior during low output impedance conditions at different values of CPROT**<sup>[1]</sup>

<span id="page-9-0"></span>[1] Tested using three samples and an external clock.

### <span id="page-9-1"></span>**8.3.3 Window Protection (WP)**

Window Protection (WP) checks the conditions at the output terminals of the power stage and is activated:

**•** During the start-up sequence, when the TDA8922C is switching from Standby to Mute.

Start-up will be interrupted If a short-circuit is detected between one of the output terminals and pin VDDP1/VDDP2 or VSSP1/VSSP2. The TDA8922C will wait until the short-circuit to the supply lines has been removed before resuming start-up. The short circuit will not generate large currents because the short-circuit check is carried out before the power stages are enabled.

**•** When the amplifier is shut down completely because the OCP circuit has detected a short circuit to one of the supply lines.

 WP will be activated when the amplifier attempts to restart after 100 ms (see [Section](#page-8-1) 8.3.2). The amplifier will not start-up again until the short circuit to the supply lines has been removed.

### <span id="page-10-5"></span>**8.3.4 Supply voltage protection**

If the supply voltage drops below the minimum supply voltage threshold,  $V_{th(uvp)}$ , the UVP circuit will be activated and the system will shut down. Once the supply voltage rises above  $V_{th(uvo)}$  again, the system will restart after a delay of 100 ms.

If the supply voltage exceeds the maximum supply voltage threshold,  $V_{th(ovp)}$ , the OVP circuit will be activated and the power stages will be shut down. When the supply voltage drops below  $V_{th(ovp)}$  again, the system will restart after a delay of 100 ms.

An additional UnBalance Protection (UBP) circuit compares the positive analog supply voltage (on pin VDDA) with the negative analog supply voltage (on pin VSSA) and is triggered if the voltage difference exceeds a factor of two ( $V_{DDA} > 2 \times |V_{SSA}|$  OR  $|V_{SSA}| >$  $2 \times V_{\text{DNA}}$ ). When the supply voltage difference drops below the unbalance threshold,  $V_{th (ubp)}$ , the system restarts after 100 ms.

An overview of all protection circuits and their respective effects on the output signal is provided in [Table](#page-10-3) 5.

#### <span id="page-10-3"></span>**Table 5. Overview of TDA8922C protection circuits**

<span id="page-10-0"></span>[1] Amplifier gain depends on the junction temperature and heatsink size.

- <span id="page-10-1"></span>[2] The amplifier shuts down completely only if the short-circuit impedance is below the impedance threshold  $(Z<sub>th</sub>; see Section 8.3.2)$  $(Z<sub>th</sub>; see Section 8.3.2)$  $(Z<sub>th</sub>; see Section 8.3.2)$ . In all other cases, current limiting results in a clipped output signal.
- <span id="page-10-2"></span>[3] Fault condition detected during any Standby-to-Mute transition or during a restart after OCP has been activated (short-circuit to one of the supply lines).

### <span id="page-10-4"></span>**8.4 Differential audio inputs**

The audio inputs are fully differential ensuring a high common mode rejection ratio and maximum flexibility in the application.

- **•** Stereo operation: to avoid acoustical phase differences, the inputs should be in anti-phase and the speakers should be connected in anti-phase. This configuration:
	- **–** minimizes power supply peak current
	- **–** minimizes supply pumping effects, especially at low audio frequencies
- **•** Mono BTL operation: the inputs must be connected in anti-parallel. The output of one channel is inverted and the speaker load is connected between the two outputs of the TDA8922C. In practice (because of the OCP threshold) the output power can be boosted to twice the output power that can be achieved with the single-ended configuration.

The input configuration for a mono BTL application is illustrated in [Figure](#page-11-0) 7.

**2** × **75 W class-D power amplifier**

### <span id="page-16-2"></span><span id="page-16-1"></span>**13. Application information**

### **13.1 Mono BTL application**

When using the power amplifier in a mono BTL application, the inputs of the two channels must be connected in anti-parallel and the phase of one of the inputs must be inverted; (see [Figure](#page-11-0) 7). In principle, the loudspeaker can be connected between the outputs of the two single-ended demodulation filters.

### <span id="page-16-3"></span>**13.2 Pin MODE**

To ensure a pop noise-free start-up, an RC time-constant must be applied to pin MODE. The bias-current setting of the VI converter input is directly related to the voltage on pin MODE. In turn the bias-current setting of the VI converters is directly related to the DC output offset voltage. A slow dV/dt on pin MODE results in a slow dV/dt for the DC output offset voltage, ensuring a pop noise-free transition between Mute and Operating modes. A time-constant of 500 ms is sufficient to guarantee pop noise-free start-up; see [Figure](#page-5-0) 4, [Figure](#page-13-6) 5 and Figure 8 for more information.

### **13.3 Estimating the output power**

### <span id="page-16-4"></span><span id="page-16-0"></span>**13.3.1 Single-Ended (SE)**

Maximum output power:

$$
P_{o(0.5\%)} = \frac{\left[\frac{R_L}{R_L + R_{DSon(hs)} + R_{s(L)}} \times 0.5(V_{DD} - V_{SS}) \times (1 - t_{w(min)} \times 0.5f_{osc})\right]^2}{2R_L}
$$
(1)

Maximum output current is internally limited to 6 A:

$$
I_{o (peak)} = \frac{0.5(V_{DD} - V_{SS}) \times (1 - t_{w(min)} \times 0.5 f_{osc})}{R_L + R_{DSon(hs)} + R_{s(L)}}
$$
(2)

Where:

- P<sub>o(0.5 %</sub>): output power at the onset of clipping
- R<sub>L</sub>: load impedance
- R<sub>DSon(hs)</sub>: high-side R<sub>DSon</sub> of power stage output DMOS (temperature dependent)
- R<sub>s(L)</sub>: series impedance of the filter coil
- t<sub>w(min)</sub>: minimum pulse width (typical 100 ns, temperature dependent)
- f<sub>osc</sub>: oscillator frequency

**Remark:** Note that  $I_{o(pek)}$  should be less than 6 A ([Section](#page-8-1) 8.3.2).  $I_{o(pek)}$  is the sum of the current through the load and the ripple current. The value of the ripple current is dependent on the coil inductance and the voltage drop across the coil.

#### <span id="page-17-1"></span>**13.3.2 Bridge-Tied Load (BTL)**

Maximum output power:

$$
P_{o(0.5\%)} = \frac{\left[\frac{R_L}{R_L + R_{DSon(hs)} + R_{DSon(ls)}} \times (V_{DD} - V_{SS}) \times (1 - t_{w(min)} \times 0.5 f_{osc})\right]^2}{2R_L}
$$
(3)

Maximum output current internally limited to 6 A:

$$
I_{o (peak)} = \frac{(V_{DD} - V_{SS}) \times (1 - t_{w(min)} \times 0.5f_{osc})}{R_L + (R_{DSon(hs)} + R_{DSon(ls)}) + 2R_{s(L)}}\tag{4}
$$

Where:

- P<sub>o(0.5 %)</sub>: output power at the onset of clipping
- R<sub>L</sub>: load impedance
- R<sub>DSon(hs)</sub>: high-side R<sub>DSon</sub> of power stage output DMOS (temperature dependent)
- R<sub>DSon(ls)</sub>: low-side R<sub>DSon</sub> of power stage output DMOS (temperature dependent)
- R<sub>s(L)</sub>: series impedance of the filter coil
- $V_P$ : single-sided supply voltage or  $0.5 \times (V_{DD} + |V_{SS}|)$
- t<sub>w(min)</sub>: minimum pulse width (typical 100 ns, temperature dependent)
- f<sub>osc</sub>: oscillator frequency

**Remark:** Note that I<sub>o(peak)</sub> should be less than 6 A; see [Section](#page-8-1) 8.3.2. I<sub>o(peak)</sub> is the sum of the current through the load and the ripple current. The value of the ripple current is dependent on the coil inductance and the voltage drop across the coil.

### <span id="page-17-0"></span>**13.4 External clock**

To ensure duty cycle-independent operation, the external clock frequency is divided by two internally. The external clock frequency is therefore twice the internal clock frequency (typically  $2 \times 350$  kHz = 700 kHz).

If several Class D amplifiers are used in a single application, it is recommended that all the devices run at the same switching frequency. This can be achieved by connecting the OSC pins together and feeding them from an external oscillator. When using an external oscillator, it is necessary to force pin OSC to a DC level above SGND. This disables the internal oscillator and causes the PWM to switch at half the external clock frequency.

The internal oscillator requires an external resistor  $R_{\rm OSC}$ , connected between pin OSC and pin VSSA.  $R_{\text{OSC}}$  must be removed when using an external oscillator.

The noise generated by the internal oscillator is supply voltage dependent. An external low-noise oscillator is recommended for low-noise applications running at high supply voltages.

### <span id="page-17-2"></span>**13.5 Heatsink requirements**

An external heatsink must be connected to the TDA8922C.

### **2** × **75 W class-D power amplifier**

<span id="page-18-0"></span>[Equation](#page-18-0) 5 defines the relationship between maximum power dissipation before activation of TFB and total thermal resistance from junction to ambient.

(5)

$$
R_{th(j-a)} = \frac{T_j - T_{amb}}{P}
$$

Power dissipation (P) is determined by the efficiency of the TDA8922C. Efficiency measured as a function of output power is given in [Figure](#page-26-0) 20. Power dissipation can be derived as a function of output power as shown in [Figure](#page-26-1) 19.

<span id="page-18-1"></span>![](_page_18_Figure_7.jpeg)

In the following example, a heatsink calculation is made for an  $8 \Omega$  BTL application with a  $±30$  V supply:

The audio signal has a crest factor of 10 (the ratio between peak power and average power (20 dB)); this means that the average output power is  $\frac{1}{10}$  of the peak power.

Thus, the peak RMS output power level is the 0.5 % THD level, i.e. 110 W.

The average power is then  $\frac{1}{10} \times 110$  W = 11 W.

The dissipated power at an output power of 11 W is approximately 5 W.

When the maximum expected ambient temperature is 50 °C, the total  $R_{th(i-a)}$  becomes

$$
\frac{(150-50)}{5} = 20
$$
 K/W

 $R_{th(i-a)} = R_{th(i-c)} + R_{th(c-h)} + R_{th(h-a)}$ 

 $R_{th(i-c)}$  (thermal resistance from junction to case) = 1.5 K/W

 $R_{th(c-h)}$  (thermal resistance from case to heatsink) = 0.5 K/W to 1 K/W (dependent on mounting)

So the thermal resistance between heatsink and ambient temperature is:

 $R_{th(h-a)}$  (thermal resistance from heatsink to ambient) = 20 – (1.5 + 1) = 17.5 K/W

The derating curves for power dissipation (for several  $R<sub>th(i-a)</sub>$  values) are illustrated in [Figure](#page-18-1) 9. A maximum junction temperature  $T_i = 150 \degree C$  is taken into account. The maximum allowable power dissipation for a given heatsink size can be derived, or the required heatsink size can be determined, at a required power dissipation level; see [Figure](#page-18-1) 9.

### <span id="page-19-0"></span>**13.6 Pumping effects**

In a typical stereo single-ended configuration, the TDA8922C is supplied by a symmetrical supply voltage (e.g.  $V_{DD} = 30$  V and  $V_{SS} = -30$  V). When the amplifier is used in an SE configuration, a 'pumping effect' can occur. During one switching interval, energy is taken from one supply (e.g.  $V_{DD}$ ), while a part of that energy is returned to the other supply line (e.g.  $V_{SS}$ ) and vice versa. When the voltage supply source cannot sink energy, the voltage across the output capacitors of that voltage supply source increases and the supply voltage is pumped to higher levels. The voltage increase caused by the pumping effect depends on:

- **•** Speaker impedance
- **•** Supply voltage
- **•** Audio signal frequency
- **•** Value of supply line decoupling capacitors
- **•** Source and sink currents of other channels

Pumping effects should be minimized to prevent the malfunctioning of the audio amplifier and/or the voltage supply source. Amplifier malfunction due to the pumping effect can trigger UVP, OVP or UBP.

The most effective way to avoid pumping effects is to connect the TDA8922C in a mono full-bridge configuration. In the case of stereo single-ended applications, it is advised to connect the inputs in anti-phase (see [Section](#page-10-4) 8.4 on page 11). The power supply can also be adapted; for example, by increasing the values of the supply line decoupling capacitors.

### <span id="page-20-0"></span>**13.7 Application schematic**

Notes on the application schematic:

- **•** Connect a solid ground plane around the switching amplifier to avoid emissions
- **•** Place 100 nF capacitors as close as possible to the TDA8922C power supply pins
- **•** Connect the heatsink to the ground plane or to VSSPn using a 100 nF capacitor
- **•** Use a thermally conductive, electrically non-conductive, Sil-Pad between the TDA8922C heat spreader and the external heatsink
- **•** The heat spreader of the TDA8922C is internally connected to VSSD
- **•** Use differential inputs for the most effective system level audio performance with unbalanced signal sources. In case of hum due to floating inputs, connect the shielding or source ground to the amplifier ground.

### <span id="page-34-0"></span>**15. Soldering of SMD packages**

This text provides a very brief insight into a complex technology. A more in-depth account of soldering ICs can be found in Application Note AN10365 "Surface mount reflow soldering description".

### <span id="page-34-1"></span>**15.1 Introduction to soldering**

Soldering is one of the most common methods through which packages are attached to Printed Circuit Boards (PCBs), to form electrical circuits. The soldered joint provides both the mechanical and the electrical connection. There is no single soldering method that is ideal for all IC packages. Wave soldering is often preferred when through-hole and Surface Mount Devices (SMDs) are mixed on one printed wiring board; however, it is not suitable for fine pitch SMDs. Reflow soldering is ideal for the small pitches and high densities that come with increased miniaturization.

### <span id="page-34-2"></span>**15.2 Wave and reflow soldering**

Wave soldering is a joining technology in which the joints are made by solder coming from a standing wave of liquid solder. The wave soldering process is suitable for the following:

- **•** Through-hole components
- **•** Leaded or leadless SMDs, which are glued to the surface of the printed circuit board

Not all SMDs can be wave soldered. Packages with solder balls, and some leadless packages which have solder lands underneath the body, cannot be wave soldered. Also, leaded SMDs with leads having a pitch smaller than ~0.6 mm cannot be wave soldered, due to an increased probability of bridging.

The reflow soldering process involves applying solder paste to a board, followed by component placement and exposure to a temperature profile. Leaded packages, packages with solder balls, and leadless packages are all reflow solderable.

Key characteristics in both wave and reflow soldering are:

- **•** Board specifications, including the board finish, solder masks and vias
- **•** Package footprints, including solder thieves and orientation
- **•** The moisture sensitivity level of the packages
- **•** Package placement
- **•** Inspection and repair
- **•** Lead-free soldering versus SnPb soldering

### <span id="page-34-3"></span>**15.3 Wave soldering**

Key characteristics in wave soldering are:

- **•** Process issues, such as application of adhesive and flux, clinching of leads, board transport, the solder wave parameters, and the time during which components are exposed to the wave
- **•** Solder bath specifications, including temperature and impurities

### <span id="page-35-0"></span>**15.4 Reflow soldering**

Key characteristics in reflow soldering are:

- **•** Lead-free versus SnPb soldering; note that a lead-free reflow process usually leads to higher minimum peak temperatures (see Figure 32) than a SnPb process, thus reducing the process window
- **•** Solder paste printing issues including smearing, release, and adjusting the process window for a mix of large and small components on one board
- **•** Reflow temperature profile; this profile includes preheat, reflow (in which the board is heated to the peak temperature) and cooling down. It is imperative that the peak temperature is high enough for the solder to make reliable solder joints (a solder paste characteristic). In addition, the peak temperature must be low enough that the packages and/or boards are not damaged. The peak temperature of the package depends on package thickness and volume and is classified in accordance with Table 12 and 13

#### **Table 12. SnPb eutectic process (from J-STD-020C)**

![](_page_35_Picture_170.jpeg)

#### **Table 13. Lead-free process (from J-STD-020C)**

![](_page_35_Picture_171.jpeg)

Moisture sensitivity precautions, as indicated on the packing, must be respected at all times.

Studies have shown that small packages reach higher temperatures during reflow soldering, see Figure 32.

**2** × **75 W class-D power amplifier**

![](_page_36_Figure_3.jpeg)

For further information on temperature profiles, refer to Application Note AN10365 "Surface mount reflow soldering description".

# <span id="page-36-1"></span><span id="page-36-0"></span>**16. Soldering of through-hole mount packages**

### **16.1 Introduction to soldering through-hole mount packages**

This text gives a very brief insight into wave, dip and manual soldering.

Wave soldering is the preferred method for mounting of through-hole mount IC packages on a printed-circuit board.

### <span id="page-36-2"></span>**16.2 Soldering by dipping or by solder wave**

Driven by legislation and environmental forces the worldwide use of lead-free solder pastes is increasing. Typical dwell time of the leads in the wave ranges from 3 seconds to 4 seconds at 250 °C or 265 °C, depending on solder material applied, SnPb or Pb-free respectively.

The total contact time of successive solder waves must not exceed 5 seconds.

The device may be mounted up to the seating plane, but the temperature of the plastic body must not exceed the specified maximum storage temperature  $(T_{\text{sta(max)}})$ . If the printed-circuit board has been pre-heated, forced cooling may be necessary immediately after soldering to keep the temperature within the permissible limit.

### <span id="page-36-3"></span>**16.3 Manual soldering**

Apply the soldering iron (24 V or less) to the lead(s) of the package, either below the seating plane or not more than 2 mm above it. If the temperature of the soldering iron bit is less than 300  $\degree$ C it may remain in contact for up to 10 seconds. If the bit temperature is between 300 °C and 400 °C, contact may be up to 5 seconds.

### <span id="page-37-0"></span>**16.4 Package related soldering information**

### **Table 14. Suitability of through-hole mount IC packages for dipping and wave soldering**

![](_page_37_Picture_90.jpeg)

[1] For SDIP packages, the longitudinal axis must be parallel to the transport direction of the printed-circuit board.

[2] For PMFP packages hot bar soldering or manual soldering is suitable.

![](_page_38_Picture_320.jpeg)

[1] Please consult the most recently issued document before initiating or completing a design.

[2] The term 'short data sheet' is explained in section "Definitions".

[3] The product status of device(s) described in this document may have changed since this document was published and may differ in case of multiple devices. The latest product status information is available on the Internet at URL http://www.nxp.com.

### <span id="page-38-2"></span>**18.2 Definitions**

**Draft —** The document is a draft version only. The content is still under internal review and subject to formal approval, which may result in modifications or additions. NXP Semiconductors does not give any representations or warranties as to the accuracy or completeness of information included herein and shall have no liability for the consequences of use of such information.

**Short data sheet —** A short data sheet is an extract from a full data sheet with the same product type number(s) and title. A short data sheet is intended for quick reference only and should not be relied upon to contain detailed and full information. For detailed and full information see the relevant full data sheet, which is available on request via the local NXP Semiconductors sales office. In case of any inconsistency or conflict with the short data sheet, the full data sheet shall prevail.

### <span id="page-38-3"></span>**18.3 Disclaimers**

**General —** Information in this document is believed to be accurate and reliable. However, NXP Semiconductors does not give any representations or warranties, expressed or implied, as to the accuracy or completeness of such information and shall have no liability for the consequences of use of such information.

**Right to make changes —** NXP Semiconductors reserves the right to make changes to information published in this document, including without limitation specifications and product descriptions, at any time and without notice. This document supersedes and replaces all information supplied prior to the publication hereof.

**Suitability for use - NXP** Semiconductors products are not designed, authorized or warranted to be suitable for use in medical, military, aircraft, space or life support equipment, nor in applications where failure or malfunction of an NXP Semiconductors product can reasonably be expected to result in personal injury, death or severe property or environmental

damage. NXP Semiconductors accepts no liability for inclusion and/or use of NXP Semiconductors products in such equipment or applications and therefore such inclusion and/or use is at the customer's own risk.

**Applications —** Applications that are described herein for any of these products are for illustrative purposes only. NXP Semiconductors makes no representation or warranty that such applications will be suitable for the specified use without further testing or modification.

**Limiting values —** Stress above one or more limiting values (as defined in the Absolute Maximum Ratings System of IEC 60134) may cause permanent damage to the device. Limiting values are stress ratings only and operation of the device at these or any other conditions above those given in the Characteristics sections of this document is not implied. Exposure to limiting values for extended periods may affect device reliability.

**Terms and conditions of sale —** NXP Semiconductors products are sold subject to the general terms and conditions of commercial sale, as published at http://www.nxp.com/profile/terms, including those pertaining to warranty, intellectual property rights infringement and limitation of liability, unless explicitly otherwise agreed to in writing by NXP Semiconductors. In case of any inconsistency or conflict between information in this document and such terms and conditions, the latter will prevail.

**No offer to sell or license —** Nothing in this document may be interpreted or construed as an offer to sell products that is open for acceptance or the grant, conveyance or implication of any license under any copyrights, patents or other industrial or intellectual property rights.

**Quick reference data —** The Quick reference data is an extract of the product data given in the Limiting values and Characteristics sections of this document, and as such is not complete, exhaustive or legally binding.

**Export control —** This document as well as the item(s) described herein may be subject to export control regulations. Export might require a prior authorization from national authorities.

Компания «ЭлектроПласт» предлагает заключение долгосрочных отношений при поставках импортных электронных компонентов на взаимовыгодных условиях!

Наши преимущества:

- Оперативные поставки широкого спектра электронных компонентов отечественного и импортного производства напрямую от производителей и с крупнейших мировых складов;
- Поставка более 17-ти миллионов наименований электронных компонентов;
- Поставка сложных, дефицитных, либо снятых с производства позиций;
- Оперативные сроки поставки под заказ (от 5 рабочих дней);
- Экспресс доставка в любую точку России;
- Техническая поддержка проекта, помощь в подборе аналогов, поставка прототипов;
- Система менеджмента качества сертифицирована по Международному стандарту ISO 9001;
- Лицензия ФСБ на осуществление работ с использованием сведений, составляющих государственную тайну;
- Поставка специализированных компонентов (Xilinx, Altera, Analog Devices, Intersil, Interpoint, Microsemi, Aeroflex, Peregrine, Syfer, Eurofarad, Texas Instrument, Miteq, Cobham, E2V, MA-COM, Hittite, Mini-Circuits,General Dynamics и др.);

Помимо этого, одним из направлений компании «ЭлектроПласт» является направление «Источники питания». Мы предлагаем Вам помощь Конструкторского отдела:

- Подбор оптимального решения, техническое обоснование при выборе компонента;
- Подбор аналогов;
- Консультации по применению компонента;
- Поставка образцов и прототипов;
- Техническая поддержка проекта;
- Защита от снятия компонента с производства.
