Volume 1: Program Overview

1 Introduction and Product Offerings

Note: This document contains preliminary information and is highly subject to change.

1.1 Overview

The Intel Atom® Processor C3000 Product Family is the next generation System-On-Chip (SoC) built on the latest Intel 14-nanometer process technology. This highly-integrated SoC contains two to 16 next generation 64-bit Intel Atom® processor cores depending on the product SKU. The SoCs were created to address the growing needs for the emerging markets like Microserver, Cloud Storage and growing Communication Infrastructure market segments.

Note: Throughout this document, the Intel Atom® Processor C3000 Product Family SoC will be referred to as simply SoC.

Network and Enterprise Storage SKUs are targeted for long life supply and extended communications reliability. Four Extended Temperature SKUs provide operation over an extended temperature range.

The parameter T_{CASE} is mentioned in this chapter and is the temperature of the SoC package measured at the geometric center of the topside of the Integrated Heat Spreader (IHS).

Note: The product SKUs, feature lists, and values in the following tables are preliminary based on current expectations and are subject to change without notice:

- Table 1-1, “Features by product SKU - Server and Cloud Storage SKUs 0 through 4”,
- Table 1-2, “Features by Product SKU - Network and Enterprise Storage SKUs 5 through 10”,
- Table 1-3, “Features by Product SKU - Extended Temperature SKUs 11 through 14”

Table 1-1. Features by product SKU - Server and Cloud Storage SKUs 0 through 4 (Sheet 1 of 2)

Features	C3955 SKU 0	C3950 SKU 1	C3850 SKU 2	C3830 SKU 3	C3750 SKU 4
Number of 64-bit Intel Atom® Microarchitecture Goldmont Cores	16		12		8
Number of threads per Core	1				
Processor base frequency (GHz)	2.1	1.7	2.1	1.9	2.2
Intel® Turbo Boost Technology	Enabled	Enabled	Enabled	Enabled	Enabled
P0n Turbo frequency @ 70 °C (GHz)	2.4	2.2	2.4	2.3	2.4
Total SoC L2 Cache (MB)	16		12		16
L2 Cache for each Core (MB)	2 (shared by two cores)				2 (dedicated)
Maximum number of memory channels available	2				
Maximum DDR4 (1.2V) memory data rate supported (MT/s)	2400			2133	2400
Number of High-Speed I/O (HSIO) Lanes shared between PCIe*, SATA, and USB 3.0	20			12	
HSIO Lane Numbers (0 through 19) available	Lanes 0-19			Any 12 Lanes from Lanes 0-19	
Maximum number of PCI Express* (8.0 / 5.0 / 2.5 GT/s) Lanes	16 via HSIO Lanes			12 via HSIO Lanes	
Maximum number of SATA (6.0 / 3.0 / 1.5 Gbps) Lanes	16 via HSIO Lanes			12 via HSIO Lanes	
Maximum number of sets of USB 3.0 signals SSTX+/SSTX- SSRX+/SSRX-	4 via HSIO Lanes				
Number of sets of USB 2.0 signals (DATA+/DATA-)	4				

Table 1-1. Features by product SKU - Server and Cloud Storage SKUs 0 through 4 (Sheet 2 of 2)

Features	C3955 SKU 0	C3950 SKU 1	C3850 SKU 2	C3830 SKU 3	C3750 SKU 4
LAN Controller 0 (Gb/s) [1]	10 2.5 1				
LAN Controller 1 (Gb/s) [1]	10 2.5 1	1	not available		
Intel® Management Engine (Intel® ME)	Yes	Yes			
Innovation Engine (IE)	Yes	Yes			
Intel® QuickAssist Technology (Intel® QAT)	No				
Intel® QAT Speed (MHz)	n/a				
Intel® QAT Speed	n/a				
Intel® QAT Cryptographic Functions	n/a				
Relative temperature offset ($T_{CONTROL}$) from the Thermal Monitor Trip Temperature at which fans will be engaged (°C)	15				

Notes:
1. Each LAN controller must run the same LEK. See Chapter 13, "LAN Controllers" for details.

Table 1-2. Features by Product SKU - Network and Enterprise Storage SKUs 5 through 10 (Sheet 1 of 2)

Features	C3958 SKU 5	C3858 SKU 6	C3758 SKU 7	C3558 SKU 8	C3538 SKU 9	C3338 SKU 10
Number of 64-bit Intel Atom® Microarchitecture Goldmont Cores	16	12	8	4		2
Number of threads per Core	1					
Processor base frequency (GHz)	2	2	2.2	2.2	2.1	1.5
Intel® Turbo Boost Technology	No					Yes
P0n Turbo frequency @ 70°C (GHz)	N/A					2.2
Total SoC L2 Cache (MB)	16	12	16	8		4
L2 Cache for each Core (MB)	2 (shared by two cores)		2 (dedicated)			
Maximum number of memory channels available	2					1 [3]
Maximum DDR4 (1.2V) memory data rate supported (MT/s)	2400			2133		1866
Number of High-Speed I/O (HSIO) Lanes shared between PCIe*, SATA, and USB 3.0	20			12		10 [1]
HSIO Lane Numbers (0 through 19) available	Lanes 0-19			Any 12 Lanes from Lanes 0-19		Any 10 Lanes from Lanes 0-19
Maximum number of PCI Express* (8.0 / 5.0 / 2.5 GT/s) Lanes	16 via HSIO Lanes			12 via HSIO Lanes		10 via HSIO Lanes
Maximum number of SATA (6.0 / 3.0 / 1.5 Gbps) Lanes	16 via HSIO Lanes			12 via HSIO Lanes		10 via HSIO Lanes
Maximum number of sets of USB 3.0 signals SSTX+/SSTX- SSRX+/SSRX-	4 via HSIO Lanes					
Number of sets of USB 2.0 signals (DATA+/DATA-)	4					

Table 1-2. Features by Product SKU - Network and Enterprise Storage SKUs 5 through 10 (Sheet 2 of 2)

Features	C3958 SKU 5	C3858 SKU 6	C3758 SKU 7	C3558 SKU 8	C3538 SKU 9	C3338 SKU 10
LAN Controller 0 (Gb/s) [2]	10 2.5 1					2.5 1
LAN Controller 1 (Gb/s) [2]	10 2.5 1			2.5 1		
Intel® Management Engine (Intel® ME)	Yes					
Innovation Engine (IE)	Yes					
Intel® QuickAssist Technology (Intel® QAT)	Yes					No
Intel® QAT Speed	High	High	Medium	Low	Low	n/a
Intel® QAT Cryptographic Functions	Yes				No	n/a
Intel® QAT Compression/ Decompression	Yes					n/a
Relative temperature offset ($T_{CONTROL}$) from the Thermal Monitor Trip Temperature at which fans will be engaged (°C)	20					

Notes:
1. This product SKU has 10 total available HSIO Lanes. To meet the specified TDP, four of the 10 HSIO Lanes must be disabled with Soft Straps or BIOS. If more than six HSIO Lanes are enabled, the TDP will increase with a thermal resistance between the processor's case and the ambient air. An adequate thermal solution must be designed if more than 6 lanes are used.
2. Each LAN controller must run the same LEK. See Chapter 13, "LAN Controllers" for details.
3. Only one memory channel may be used with this SKU. It can be memory channel 0 or memory channel 1.

Table 1-3. Features by Product SKU - Extended Temperature SKUs 11 through 14 (Sheet 1 of 2)

Features	C3808 SKU 11	C3708 SKU 12	C3508 SKU 13	C3308 SKU 14
Number of 64-bit Intel Atom® Microarchitecture Goldmont Cores	12	8	4	2
Number of threads per Core	1			
Processor base frequency (GHz)	2	1.7	1.6	1.6
Intel® Turbo Boost Technology	No			Yes
P0n Turbo frequency @ 70°C (GHz)	N/A			2.1
Total SoC L2 Cache (MB)	12	16	8	4
L2 Cache for each Core (MB)	2 (shared by two cores)	2 (dedicated)		
Maximum number of memory channels available	2			1 [2]
Maximum DDR4 (1.2V) memory data rate supported (MT/s)	2133		1866	
Number of High-Speed I/O (HSIO) Lanes shared between PCIe*, SATA, and USB 3.0	20		8	6
HSIO Lane Numbers (0 through 19) available	Lanes 0-19		Any 8 Lanes from Lanes 0-19	Any 6 Lanes from Lanes 0-19
Maximum number of PCI Express* (8.0 / 5.0 / 2.5 GT/s) Lanes	16 via HSIO Lanes		8 via HSIO Lanes	6 via HSIO Lanes
Maximum number of SATA (6.0 / 3.0 / 1.5 Gbps) Lanes	16 via HSIO Lanes		8 via HSIO Lanes	6 via HSIO Lanes
Maximum number of sets of USB 3.0 signals SSTX+/SSTX- SSRX+/SSRX-	4 via HSIO Lanes			
Number of sets of USB 2.0 signals (DATA+/DATA-)	4			

Table 1-3. Features by Product SKU - Extended Temperature SKUs 11 through 14 (Sheet 2 of 2)

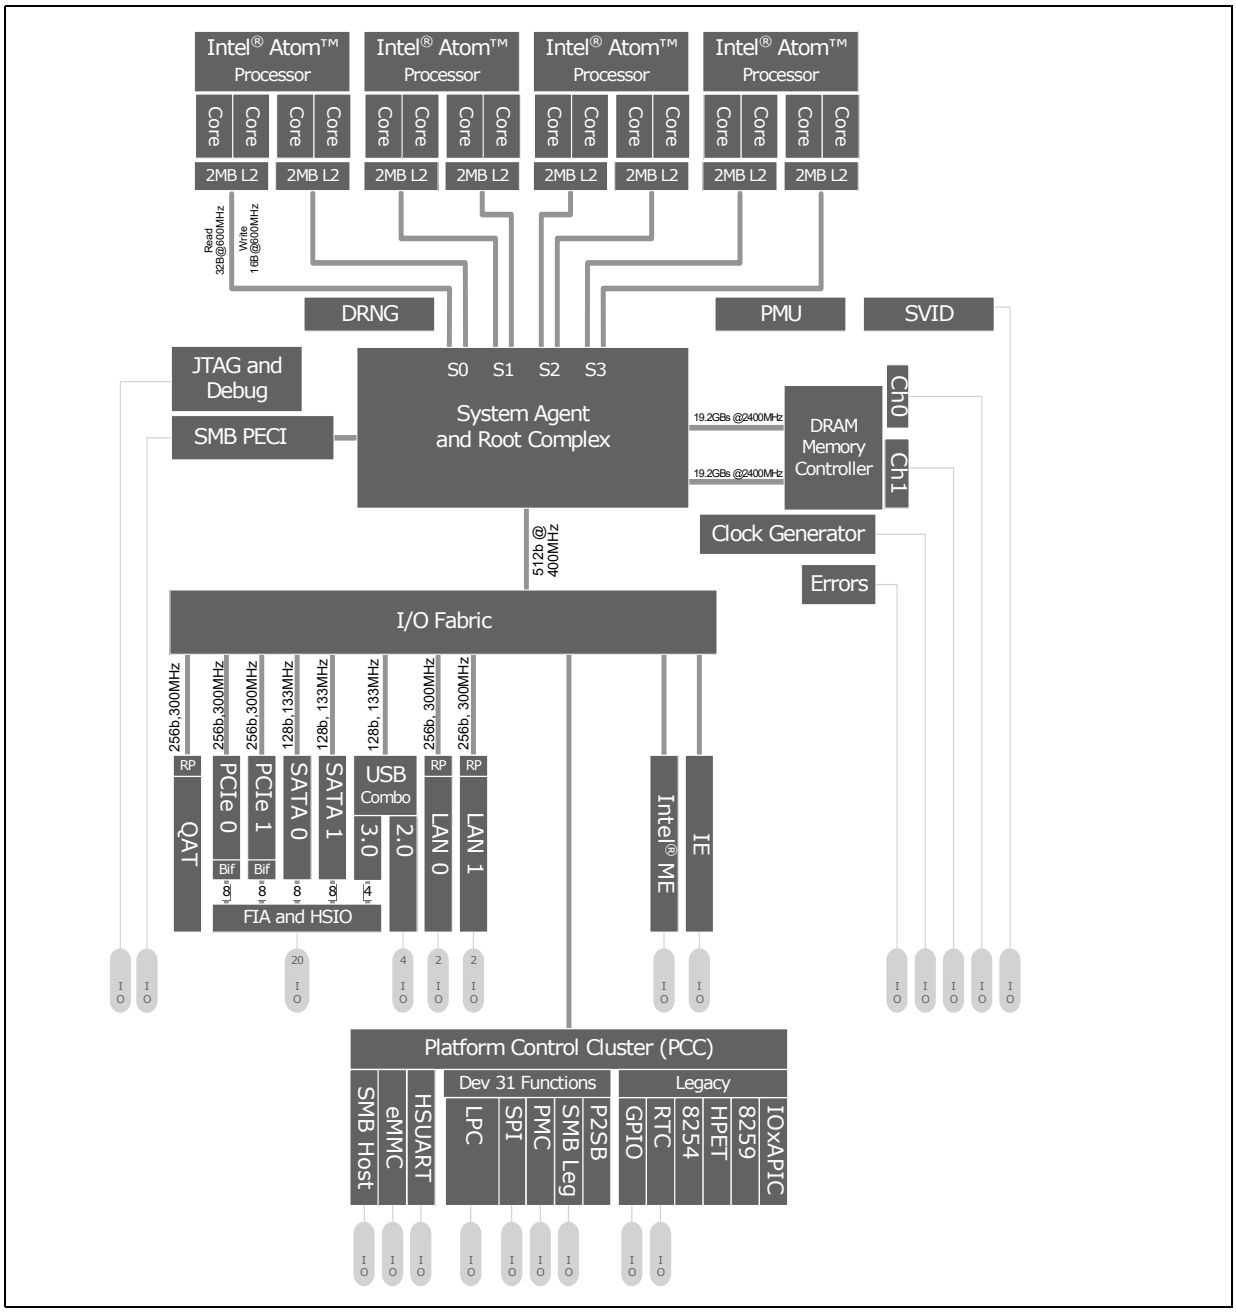
Features	C3808 SKU 11	C3708 SKU 12	C3508 SKU 13	C3308 SKU 14
LAN Controller 0 (Gb/s) [1]	10 2.5 1		2.5 1	
LAN Controller 1 (Gb/s) [1]	10 2.5 1		2.5 1	
Intel® Management Engine (Intel® ME)	Yes		Yes	
Innovation Engine (IE)	Yes		Yes	
Intel® QuickAssist Technology (Intel® QAT)	Yes			
Intel® QAT Speed	High	Medium	Low	
Intel® QAT Cryptographic Functions	Yes			
Intel® QAT Compression/ Decompression	Yes			
Relative temperature offset ($T_{CONTROL}$) from the Thermal Monitor Trip Temperature at which fans will be engaged (°C)	20			

Notes:
1. Each LAN controller must run the same LEK. See Chapter 13, "LAN Controllers" for details.
2. Only one memory channel may be used with this SKU. It can be memory channel 0 or memory channel 1.

1.2 SoC Key Features

This section describes the features offered in the SoC.

Figure 1-1. High-Level Block Diagram



1.2.1 Processor Details

The SoC has up to sixteen 64-bit Intel Atom® processor cores:

- Each core has an L1 (first-level) cache consisting of:
  - 24-KB data, parity protected.
  - 32-KB instruction, parity protected.
- L2 (second-level) instruction/data cache, ECC protected:
  - SoC with 2, 4 or 8 cores have a 2-MB L2 cache per core.
  - SoC with 12 or 16 cores share a 2-MB L2 cache per 2 cores.

1.2.2 Supported Technologies

- Intel® Virtualization Technology (Intel® VT) for Intel® 64 and IA-32 Intel® Architecture (Intel® VT-x).
- Intel® Virtualization Technology (Intel® VT-x) for Directed I/O (Intel® VT-d).
- Advanced Encryption Standard New Instructions (AES-NI).
- Secure Hash Algorithm New Instruction (SHA-NI).
- Intel® 64 Architecture.
- Intel® Streaming SIMD Extensions 4.1 (Intel® SSE4.1).
- Intel® Streaming SIMD Extensions 4.2 (Intel® SSE4.2).
- Execute Disable Bit.
- Intel® Turbo Boost Technology.
- Enhanced Intel SpeedStep® Technology.

1.2.3 System Memory Support

- Up to two 32/40 bit [1] or 64/72 bit wide memory channels. Up to two DIMMs per channel.
- Single-rank or dual-rank per DIMM module.
- ECC [4] and non-ECC support.
- DDR4 (1.2V):
  - 1600, 1866 [2], 2133, and 2400 MT/s.
  - x8 or x16 width for unbuffered memory (UDIMM, SO-DIMM and memory down).
  - x4 or x8 width devices for RDIMM
  - Minimum memory is:
    32 bit [1] wide memory channel: 1GB (4 Gb, 1 rank, x16 width)
    64-bit wide memory channel: 2GB (4 Gb, 1 rank, x16 width).
  - Maximum memory single channel is 128 GB (16 Gb, x4 width, 4 ranks, 64-bit).
  - Both memory channels maximum is 256 GB (128GB with two 64-bit channels).
- SoC memory population rules:
  - Both channels must be 32 bit [1] or 64 bits wide
  - At least 1 memory channel must be populated.
    Either channel 0 or channel 1 maybe disabled.
  - Both channels require either unbuffered memory (UDIMM, SO-DIMM or memory down), or registered memory (RDIMM and/or NVRDIMM). Technology mixing is not supported.
  - Rank mixing is allowed but can result in a speed bin loss.
  - Each populated channel must be x4 or x8 or x16 only (no width mixing within a channel) 4 Gb, 8 Gb, and 16 Gb technology device mixing between channels is allowed (i.e., Channel 0 can be x4 while Channel 1 is x8).

Notes:

1. A0 and A1 step silicon only support 64/72-bit wide memory channels.
2. The silicon design supports 1866 MT/s but is not validated on Intel platforms. Customers are responsible for validation.
3. With a standard DIMM and NVDIMM in the same channel, the NVDIMM must be in the second slot or be the same size or smaller than the standard DIMM.
4. The ECC SDRAM device must be of the same type and width as the SDRAM devices used for the data bits. This limitation is driven by the DDR4 spec.
   - It is NOT alright to use x16 SDRAM devices for data and a x8 device for ECC.
   - It is NOT alright to use x8 SDRAM devices for data and a x4 device for ECC.
5. Memory based on 16 Gb dual rank technology (including maximum memory configuration of 256GB) is supported by silicon but not validated on Intel platforms.

1.2.4 Integrated Clock Generator

The integrated clock generator requires two external crystals (32.768-kHz and 25-MHz) and eliminates the need for an external clock chip.

- Generates all required internal clocks.
- Two flex clock outputs for platform use.
- Five PCIe output clocks.
- Optional Spread-Spectrum Clocking support.

1.2.5 Intel® QuickAssist Technology (Intel® QAT)

Intel® QuickAssist Technology is only available on Network and Enterprise Storage SKUs and provides hardware acceleration for:

Symmetric cryptographic functions:

- Cipher operations.
- Hash/authenticate operation.
- Cipher-hash combined operation.

Public key functions:

- RSA operation, encryption/decryption and digital signature generation/verification.
- Modular exponentiation for Diffie-Hellman (DH).
- DSA parameter generation and digital signature generation/verification.
- Key derivation operation.
- Elliptic curve cryptography: ECDSA and ECDH.

Compression/Decompression:

- Deflate.

1.2.6 Intel® Management Engine (Intel® ME)

The Intel® ME provides the services that are released and documented in Intel® Server Platform Services Firmware (SPS 4.0) release.

1.2.7 Innovation Engine (IE)

The Innovation Engine (IE) is a complete, embedded, Intel Architecture system intended for Intel customers (system builders) to create innovative or differentiating firmware of their choosing. The IE is available on all SoC product SKUs bit is not required for normal system operation.

The IE is based on Intel® Quark™ technology:

- 32-bit Intel Architecture processor core
- Suite of connections to a number of platform resources

For security, the IE software is cryptographically bound to the owner, the system builder, using a digital-signing technique.

For the IE, the system builder can install an embedded operating system, drivers and application they develop on their own, or purchase them from a third-party vendor. Intel does not provide operating systems, drivers or applications for the IE.

The IE usage is only limited by its technical capabilities. Sample uses include using the IE as a replacement for a low-end Baseboard Management Controller (BMC), or offloading fast-loop sensor monitoring from the BMC.

1.2.8 Interface Features

1.2.8.1 High Speed I/O Lanes

Depending on the SoC product SKU, there are up to 20 High-Speed I/O (HSIO) lanes that are shared between the PCI Express*, Serial ATA (SATA) and Universal Serial Bus (USB) 3.0 ports. See the Chapter 10, "Flexible I/O Adapter (FIA) Overview" for more information on the sharing. The maximum number of available lanes is shown in Table 1-1 on page 107, Table 1-2 on page 109, and Table 1-3 on page 111.

1.2.8.1.1 PCIe Root Port Clusters

- Up to two PCIe Root Port Clusters 0 and 1.
- Fully-compliant to the *PCI Express Base Specification Revision 3.0*.
- Each 1x8 PCIe Root Port Cluster maybe bifurcated by BIOS to:
  - 1x8
  - 2x4
  - 2x2 and 1x4
  - 4x2
  - 4x1
- Minimum Root Port width is 1-lane.
- Maximum Root Port width is 8-lanes with degrades to x4, x2 or x1.
- Lane Reversal supported.
- Polarity Inversion supported.
- No support for peer-to-peer transfers between PCIe Root Ports.

1.2.8.1.2 Serial ATA (SATA)

The SATA ports are 3.1 or 2.0 capable:

- Up to 16 SATA ports:
  - Implemented with up to two controllers.
  - Up to eight ports per controller.
  - One SGPIO per controller.
- No support for IDE mode.

1.2.8.1.3 Universal Serial Bus (USB)

There is a single combo USB 3.0 and USB 2.0 controller with support for:

- Up to four USB 3.0 compliant ports.
- USB 2.0 ports have dedicated SoC I/O pins.
- USB 3.0 ports share HSIO lanes as described above.

1.2.8.2 LAN Ports

Depending on the SoC product SKU, there is either one or two, dual-port, Enterprise-Class, LAN controllers. The controllers support 10GbE or 2500BASE-X depending on the product SKU.

- Based on Intel® Ethernet Controller X55x
- 10GbE LAN ports support SFI, KR, 2500BASE-X, SGMII and 1000BASE-KX
- 2500BASE-X LAN ports support 2500BASE-X, SGMII and 1000BASE-KX
- SGMII is supported for Full Duplex 10Mb, 100Mb and 1Gb
- No support for Half Duplex at 10Mb, 100Mb, 1Gb, 2.5Gb or 10Gb
- Management Interface via NC-SI or SMBus

1.2.8.3 SMBus Controllers

Note: There are seven sets of SMBus pins. And so a maximum of seven SMBus controllers may be configured to be active.

The SoC has the following 10 SMBus controllers:

- Legacy and Host SMBus controllers used by the IA cores
- PECI over SMBus controller
- LAN Management SMBus controller for BMC use
- Three Management Engine SMBus controllers
- Three Innovation Engine SMBus controllers

1.2.8.4 Embedded Multi Media Card (eMMC)

The Embedded Multi-Media Controller (eMMC) is a high speed Flash memory controller that provides low cost, small form factor storage.

- Support for eMMC v5.0
- Eight-bit interface maximum frequency of 200 MHz for transfer rates up to 400 MB/s

1.2.8.5 High-Speed Universal Asynchronous Receiver/Transmitter

Note: At most, three of the SoC four High Speed Universal Asynchronous Receiver/Transmitter (HSUART) controllers can be active. One set of the SoC HSUART pins is configurable to be either the Host Root HSUART or else the Innovation Engine (IE) HSUART.

There are 4 HSUART each supporting Clear-To-Send (CTS) and Request-To-Send (RTS) depending on MUXing. Three (3) of the HSUARTs are in the IA Host space and 1 is in the Innovation Engine Root space.

- Baud rate from 300 bps to 3.6864 Mbps

1.2.8.6 Low Pin Count (LPC)

- LPC
  - Interface is described in the *Intel® Low Pin Count (LPC) Interface Specification*
  - Support for Security Device Trusted Platform Module (TPM)

1.2.8.7 Serial Peripheral Interface (SPI)

- Supports up to two SPI NOR Flash devices and a SPI NOR TPM device
- Supports 17 MHz, 30 MHz, and 48 MHz SPI Devices
- Supports Serial Flash Discovery Parameters (SFDP)
- Supports Quad I/O Fast Read, Quad Output Fast Read, Dual IO Fast Read

1.2.9 Package

The SoC is available in one package size:

- A 34 x 28 mm 1310-ball FCBGA package (FCBGA15)
- Integrated Heat Spreader (IHS)
- 0.65 mm minimum outer pin pitch, maintaining 0.7mm pitch for breakout direction to keep 0.7 mm pitch board routing rules.

1.2.10 Testability

- Includes boundary-scan for board and system level testability.

1.3 Terminology

Table 1-4. Terminology (Sheet 1 of 6)

Term	Description
1000BASE-KX	1000BASE-KX is the IEEE 802.3ap electrical specification for transmission of 1 Gb/s Ethernet over the backplane.
2500BASE-X	Refer to 2.5 GbE in this table. Note this is not an IEEE Standard.
1000BASE-T	1000BASE-T is the specification for 1 Gb/s Ethernet over category 5e twisted pair cables as defined in IEEE 802.3 clause 40.
2.5 GbE	The 2.5-GbE link mode is a special enhanced-speed mode of the 1000BASE-X link mode. This mode should not be confused with third-party solutions being offered in the marketplace today. Contact your local Intel representative for further information on the scope of this feature.
ACPI	Advanced Configuration and Power Interface
ADR	Asynchronous DRAM Refresh
AEN	Asynchronous Event Notification
AFE	Analog Front End
Aggressor	A network that transmits a coupled signal to another network.
AH	IP Authentication Header - An IPsec header providing authentication capabilities defined in RFC 4302.
Anti-Etch	Any plane-split, void, or cutout in a VCC or GND plane is referred to as an anti-etch.
ARP	Address Resolution Protocol
ASF	Alert Standard Format
b/w	Bandwidth
BER	Bit Error Rate
BGA	Ball Grid Array
BIOS	Basic Input/Output System. BIOS is the same as what is called UEFI IA Firmware in this document. Both terms are used and refer to the same thing.
BIST FIS	Built-In Self-Test Frame Information Structure
BMC	Baseboard Management Controller (often used interchangeably with MC)
BT	Bit Time
Bus Agent	A component which represents a load on a bus.
CDV	Cell Delay Variation
CMC	Common Mode Choke
CMCI	Corrected Machine Check error Interrupt
CMP	Chip-Level Multi Processing (CMP)
CRC	Cyclic Redundancy Check
CSR	Configuration and Status Register
DCA	Direct Cache Access
DDR3	Third generation Double Data Rate SDRAM memory technology that is the successor to DDR2 SDRAM.
DDR4	Forth generation Double Data Rate SDRAM memory technology that is the successor to DDR3 SDRAM.
DFT	Design for Testability
DMA	Direct Memory Access
DMTF	Distributed Management Task Force standard body
DP	Display Port

Table 1-4. Terminology (Sheet 2 of 6)

Term	Description
DQ	Descriptor Queue
DUT	Device Under Test
DW	Double Word (4 bytes)
ECC	Error Correction Code
EEE	Energy Efficient Ethernet - IEEE 802.3az standard
EEPROM	Electrically Erasable Programmable Memory. A non-volatile memory directly accessible from the host.
EHCI	Enhanced Host Controller Interface
EMI	Electromagnetic Interference
Enhanced Intel SpeedStep® Technology	Allows the operating system to reduce power consumption when performance is not needed.
EOP	End of Packet
EPT	Extended Page Tables
ESD	Electrostatic Discharge
Execute Disable Bit	The Execute Disable bit allows memory to be marked as executable or non-executable, when combined with a supporting operating system. If code attempts to run in non-executable memory the processor raises an error to the operating system. This feature prevents some classes of viruses or worms that exploit buffer overrun vulnerabilities and improves the overall system security. See the Intel® 64 and IA-32 architectures software developer manuals for more detailed information.
FC	Flow Control
FCS	Frame Check Sequence
Firmware (FW)	Embedded code on the LAN controller that implements the NC-SI protocol and pass-through functionality.
Flight Time	A term in the timing equation that includes the signal propagation delay, any effects the system has on the driver TCO, plus any adjustments to the signal at the receiver needed to guarantee the receiver setup time. More precisely, flight time is defined as the following: • The time difference between a signal at the input pin of a receiving agent crossing the switching voltage (adjusted to meet the receiver manufacturer conditions required for AC timing specifications; i.e., ringback, etc.) and the output pin of the driving agent crossing the switching voltage when the driver is driving a test load used to specify the driver AC timings. Maximum and Minimum Flight Time – Flight time variations are caused by many different parameters. The more obvious causes include the board dielectric constant variation, changes in load condition, crosstalk, power noise, variation in termination resistance, and differences in I/O buffer performance as a function of temperature, voltage, and manufacturing process. Some less obvious causes include effects of Simultaneous Switching Output (SSO) and packaging effects. Maximum flight time is the largest acceptable flight time a network experiences under all conditions. Minimum flight time is the smallest acceptable flight time a network experiences under all conditions.
FS	Full-speed. Refers to USB.
Host Interface	RAM on the LAN controller shared between the firmware and the host, and used to pass commands from the host to the firmware and responses from the firmware to the host.
HPC	High Performance Computing
HS	High-speed. Refers to USB.
IIO	The Integrated I/O Controller. An I/O controller that is integrated in the processor die.
IOMMU	Input/Output Memory Management Unit
iMC	The Integrated Memory Controller. A Memory Controller that is integrated in the processor die.
IE	Innovation Engine
Intel® 64 Technology	64-bit memory extensions to the IA-32 architecture. Further details on the Intel 64 architecture and the programming model are found at: http://developer.intel.com/technology/intel64/.
Intel® ME	Intel® Management Engine

Table 1-4. Terminology (Sheet 3 of 6)

Term	Description
IPC	Inter-Processor Communication
IPDC	Internet Portal Data Center
IPI	Inter-Processor Interrupt
IPG	Inter-Packet Gap
IPMI	Intelligent Platform Management Interface specification
Intel® QuickAssist Technology	Intel® QuickAssist Technology consists of a family of interrelated Intel and industry-standard technologies that simplify the use and deployment of accelerators on the Intel platforms.
Intel® Virtualization Technology (Intel® VT)	Processor virtualization which when used in conjunction with the Virtual Machine Monitor software enables multiple, robust independent software environments inside a single platform.
Integrated Heat Spreader (IHS)	A component of the processor package used to enhance the thermal performance of the package. Component thermal solutions interface with the processor at the IHS surface.
ISA	Instruction Set Architecture
ISI	The effect of a previous signal (or transition) on the interconnect delay. For example, when a signal is transmitted down a line and the reflections due to the transition have not completely dissipated, the following data transition launched onto the bus is affected. Interconnect Symbolic Interference (ISI) is dependent upon frequency, time delay of the line, and the reflection coefficient at the driver and receiver. ISI impacts both timing and signal integrity.
Jitter	Any timing variation of a transition edge or edges from the defined Unit Interval (UI).
LAN (Auxiliary Power-Up)	If connecting the LAN controller to a power source (occurs even before system power-up).
Land	The contact point of the SoC FCBGA package.
LCD	Name for the external LAN Connected Device, sometimes also called a PHY device. The LCD name distinguishes between the whole device and the PHY portion within the LCD.
LCI	LAN Connect Interface
LLC	Last Level Cache
LLDP	Link Layer Discovery Protocol defined in IEEE 802.1AB and used by IEEE 802.3az (EEE) for system wake time negotiation.
LOM	LAN on Motherboard
LPC	Low Pin Count
LPI	Low-Power Idle is the low-power state of Ethernet link as defined in IEEE 802.3az.
LRU	Least Recently Used. A term used in conjunction with cache hierarchy.
LS	Low-speed. Refers to USB.
LSO	Large Send Offload
LTR	Latency Tolerance Reporting (PCI Express* (PCIe*) protocol)
LVR	Linear Voltage Regulator
M0	Intel® Management Engine (Intel® ME) power state where all HW power planes are activated. Host power state is S0.
M3	Intel® Management Engine (Intel® ME) power state where all HW power planes are activated, however the host power state is different than S0 (some host power planes are not activated). Host PCI-E* interface are unavailable to the host SW. Main memory is not available for Intel® Management Engine use.
MAC	Media Access Control
MC	Management Controller
MCA	Machine Check Abort
MCTP	DMTF Management Component Transport Protocol (MCTP) specification. A transport protocol to allow communication between a management controller and controlled device over various transports.
MDIO	Management Data Input/Output Interface over MDC/MDIO lines

Table 1-4. Terminology (Sheet 4 of 6)

Term	Description
ME	See Intel® Management Engine (Intel® ME)
MIFS/MIPG	Minimum Inter-Frame Spacing/Minimum Inter-Packet Gap
MLC	Mid-Level Cache
MMC	Multi-Node Management Controller
MMW	Maximum Memory Window
MPS	Maximum Payload Size in PCIe specification
MSS	Maximum Segment Size. Largest amount of data, in a packet (without headers) that can be transmitted. Specified in bytes.
MTU	Maximum Transmit Unit. Largest packet size (headers and data) that can be transmitted. Specified in bytes.
NC	Network Controller
NC-SI	Network Controller Sideband Interface DMTF Specification
Network	The trace of a Printed Circuit Board (PCB) that completes an electrical connection between two or more components.
NIC	Network Interface Controller
NVDIMM	Nonvolatile DIMM is a DIMM technology that will save its DRAM content to flash on power loss and allow recover of the data on the next system boot.
OOB	Out of Band
Overshoot	The maximum voltage observed for a signal at the device pad, measured with respect to V_{CC}.
Pad	The electrical contact point of a semiconductor die to the package substrate. A pad is only observable in simulations.
PCI, PCIe*	Peripheral Component Interconnect (Express). In this document, this interconnect refers to the PCI logical layer used by the SoC I/O fabric protocol.
PCI Express*	PCI Express
Pcode	Power Management Unit Micro-code
PCS	Physical Coding Sub layer
PEC	Packet Error Code
PECI	Platform Environmental Control Interface
PHY	Physical Layer Device
Pin	The contact point of a component package to the traces on a substrate, such as the motherboard. Signal quality and timings are measured at the pin.
PLC	Platform LAN Connect
PMA	Physical Medium Attachment
PMC	Power Management Controller
PMD	Physical Medium Dependent
PMU	Power Management Unit
Power-Good	Power-Good, or PWRGOOD (an active high signal) indicates that all the system power supplies and clocks are stable. PWRGOOD does go active a predetermined time after system voltages are stable and does go inactive as soon as any of these voltages fail their specifications.
Processor	The 64-bit, single-core or multi-core component (package)
Processor Core	The term Processor Core refers to the silicon die itself which contains multiple execution cores. Each execution core has an instruction cache, data cache, and shares its 1-MB L2 cache with a sibling execution core.
PXE	Preboot Execution Environment
Rank	A unit of DRAM corresponding 4 to 16 devices in parallel, ignoring ECC. These devices are usually, but not always, mounted on a DIMM Raw Card.

Table 1-4. Terminology (Sheet 5 of 6)

Term	Description
Ringback	The voltage to which a signal changes after reaching its maximum absolute value. Ringback is caused by reflections, driver oscillations, or other transmission line phenomena.
RP	Root Port
RTC	Real Time Clock
SA	System Agent
SATA	Serial ATA
SDP	Software Defined Pins
SerDes	Serializer/Deserializer: A transceiver that converts parallel data to serial data and vice-versa.
SFD	Start Frame Delimiter
SFI	SerDes Frame Interface
SFP	Small Form-factor Pluggable
SFP+	enhanced Small Form-factor Pluggable
SGMII	Serialized Gigabit Media Independent Interface ***Note:*** SoC SGMII is supported for Full Duplex 10mb, 100mb and 1Gb only (No Half Duplex support).
SIMD	Single Instruction Multiple Data
SMBus	System Management Bus. A two-wire interface through which simple system and power management related devices communicate with the rest of the system. A bus carrying various manageability components, including the LAN controller, BIOS, sensors, and remote-control devices. SMBus is based on the operational principles of the I^2C two-wire serial bus from Philips Semiconductor.
So-DIMM	Small outline Dual In-line Memory Module
SPD	Serial Presence Detect
SPI	Serial Peripheral Interface
SSE	Intel® Streaming SIMD Extensions (Intel® SSE)
SSO	Simultaneous Switching Output (SSO) effects are differences in electrical timing parameters and degradation in signal quality caused by multiple signal outputs simultaneously switching voltage levels in the opposite direction from a single signal or in the same direction. These are called odd mode and even mode switching, respectively. This simultaneous switching of multiple outputs creates higher current swings that may cause additional propagation delay (“push-out”) or a decrease in propagation delay (“pull-in”). These SSO effects may impact the setup and/or hold times and are not always taken into account by simulations. System timing budgets include margin for SSO effects.
STR	Suspend To RAM
Stub	The branch from the bus trunk terminating at the pad of an agent.
SVR	Switched Voltage Regulator
TAC	Thermal Averaging Constant
TCO	Total Cost of Ownership (TCO) System Management
TDP	Thermal Design Power
TDR	Time Domain Reflectometry
TLB	Translation Lookaside Buffer
TLP	Transaction Layer Packet in the PCI Express specification
Trunk	The main connection, excluding interconnect branches, from one end-agent pad to the other end-agent pad.
TSO	Transmit Segmentation Offload. A mode in which a large TCP/UDP I/O is handed to the device which the device then segments into L2 packets according to the requested MSS.
TSOD	Temperature Sensor On DIMM

Table 1-4. Terminology (Sheet 6 of 6)

Term	Description
UDIMM	Unbuffered Dual In-line Memory Module
UEFI IA Firmware	This is another term used for BIOS. Both terms are used and refer to the same thing.
UHCI	Universal Host Controller Interface
Undershoot	The minimum voltage extending below V_{SS} observed for a signal at the device pad.
Unit Interval (UI)	Binary signaling convention that is measure of time representing the transmission of a single data bit in a serial data stream. One bit is sent for every forwarded clock edge, whether it be a rising edge or a falling edge. If a number of edges are collected at instances t1, t2, tn,...., tk, then the UI at instance "n" is defined as the following: UI n = t n - t n-1.
USB	Universal Serial Bus
VCC	Processor core-power supply
Vcc_core	The core-power rail for the processor.
Victim	A network that receives a coupled crosstalk signal from another network is called the victim network.
VLAN	Virtual LAN
VPD	Vital Product Data (PCI protocol)
VRD	The Voltage Regulator Down (a down on the board solution) for the processor. The VRD is a DC-DC converter module that supplies the required voltage and current to a single processor.
VSS	Processor ground
Intel® VT-d	Intel® Virtualization Technology (Intel® VT-x) for Directed I/O (Intel® VT-d)
Intel® VT-x	Intel® Virtualization Technology (Intel® VT) for Intel® 64 and IA-32 Intel® Architecture (Intel® VT-x)
x1	Refers to a link or port with one physical lane.
x2	Refers to a link or port with two physical lanes.
x4	Refers to a link or port with four physical lanes.
x8	Refers to a link or port with eight physical lanes.
XDP	eXtended Debug Port

2 Multi-Core Intel Atom® Processors

Warning: This document contains preliminary information and is highly subject to change.

2.1 Introduction

The SoC is a highly-integrated System-on-Chip (SoC). The SoC core is a 3-way superscalar, out-of-order, IA core. It is designed using the cutting edge 14 nm process. The SoC core provides roughly 40% Instructions-Per-Cycle (IPC) increase over the previous Intel Atom® processor core.

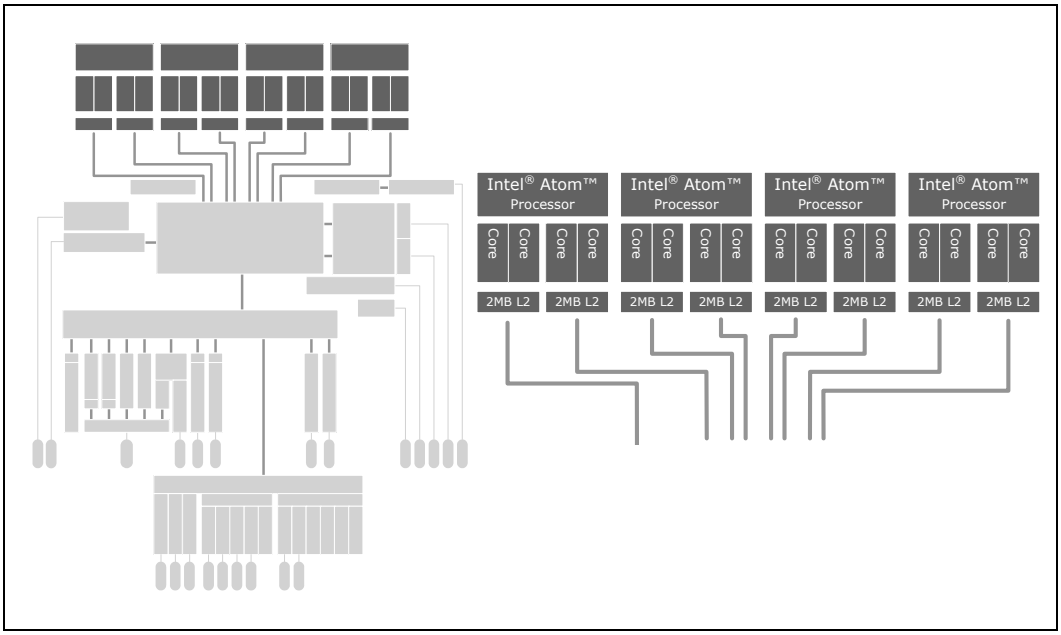
Also see Table 1-5, "Reference Documents" for newest version of the *Intel® 64 and IA-32 Architectures Software Developer's Manual*.

The SoC supports a variety of SKUs: up to 16 cores (with SKUs containing 2, 4, 8, 12 or 16 cores). Refer to the following:

- Table 1-1, "Features by product SKU - Server and Cloud Storage SKUs 0 through 4"
- Table 1-2, "Features by Product SKU - Network and Enterprise Storage SKUs 5 through 10"
- Table 1-3, "Features by Product SKU - Extended Temperature SKUs 11 through 14".

The cores and the rest of the SoC are shown in a general block diagram in Figure 2-1. Most of the chapters in this document refer to this diagram to convey the portion of the SoC pertaining to the chapter.

Figure 2-1. What is Covered in This Chapter



2.2 Features

The main architectural features are:

- Intel® Xeon® series processor Instruction Set Architecture (ISA) compatibility
- Intel® Virtualization Technology (Intel® VT-x, Intel® VT-d):
  - Intel® VT-x for Intel® IA-32 Architecture
  - Intel® VT and Intel® VT-d for Directed I/O
- Each core supports 1 hardware thread
- Each core has an L1 cache consisting of:
  - 24-KB data, parity protected
  - 32-KB instruction, parity protected
- L2 (second-level) instruction/data cache, ECC protected:
  - SoC with 2, 4 or 8 cores have 2-MB L2 per core
  - SoC with 12 or 16 cores share a 2-MB L2 per 2 cores
- 3-wide Out-of-Order (OOO) scheduler
- Improved instruction fetch and decode functions
- Improved branch prediction
- Improvements to TLB and caching hierarchy
- Hybrid OOO scheduling and OOO cache miss processing
- Per core power gating support
- Intel® Streaming SIMD Extensions 4.1 and 4.2 (SSE4.1 and SSE4.2)
- Intel® 64 bit architecture
- Support for IA-32 instruction set
- Support for Intel® Advanced Encryption Standard New Instructions (Intel® AES-NI)
- Secure Hash Algorithm New Instruction (SHA-NI)
- Support for rd_rand and rd_seed instructions
- Intel® Turbo Boost Technology (SKU dependent)
- Supported CPU Power States (C-States): C0, C1, C1e, and C6.

2.2.1 Goldmont New Technologies and ISA Extensions

Goldmont is the codename for the next generation 64-bit Intel® Atom™ processor cores in the SoC.

- EPT - Extended Page Tables (hardware virtualization of page tables).
- Hybrid Out-of Order (OOO) scheduling and OOO cache miss processing.
- Intel® Secure Hash Algorithm Extensions - instruction extensions that target the acceleration of the Secure Hash Algorithm (SHA).
- DRNG - Digital Random Number Generator Instructions:
  - RDRAND
  - RDSEED
- SMM Range Register - Full SMM range protection.
- Energy Efficient Turbo - Improved performance headroom.
- SMM external call trap execute disable - Security feature detects SMM code accesses outside SMRR and causes a machine check.
- APIC Virtualization; x2 APIC - Better APIC handling in Intel® VT mode.
- Pause Loop Exiting - Better spin-lock handling in Intel® VT mode.
- VMCS shadowing - Better performance of VMREAD,VMWRTE under nested virtual machine scenarios.
- CPUID Faulting - Better CPUID handling in VT mode.
- RTIT 2.0 - Improvements to make RTIT architectural.
- Memory Protection Extensions (MPX) + XSAVE - Security technology to detect buffer overflow attacks.
- "Light" Machine Check Abort (MCA) - Corrected Machine Check error Interrupt (CMCI), additional parity.
- Cache QOS - L2 cache partitioning for better real-time performance.
- Parity on IDI (Intra-Die Interconnect).
- 40-bit memory address (1,024 GB).

2.2.2 Intel® Virtualization Technology

Intel® Virtualization Technology (Intel® VT) makes a single system appear as multiple independent systems to the software. This allows multiple, independent operating systems to run simultaneously on a single system. Intel VT comprises technology components to support virtualization of platforms based on Intel® architecture microprocessors and chipsets. Intel® Virtualization Technology for IA-32, Intel® 64 and Intel® Architecture (Intel® VT-x) added hardware support in the processor to improve the virtualization performance and robustness. Intel® VT-x specifications and functional descriptions are included in the *Intel® 64 and IA-32 Architectures Software Developer's Manual*.

The first revision of this technology (Intel® VT-x) added hardware support in the processor to improve the virtualization performance and robustness. The latest revisions of this specification (Intel® VT-d), now called "Intel Virtualization Technology for Directed I/O, v1.3" adds direct chipset hardware hooks to improve I/O performance and robustness through DMA remapping. The SoC incorporates the Input/Output Memory Management Unit (IOMMU) (Intel® VT-d) block inside the System Agent to facilitate the translation.

2.2.3 Intel® VT-x Objectives

- Intel® Xeon® series processor Instruction Set Architecture (ISA) compatibility
- Robust - Virtual Machine Monitors (VMMs) no longer need to use paravirtualization or binary translation. This means that they run off-the-shelf operating systems and applications without any special steps.
- Enhanced - Intel® VT enables VMMs to run 64-bit guest operating systems on IA x86 processors.
- More Reliable - Due to the hardware support, VMMs are now smaller, less complex, and more efficient. This improves reliability and availability and reduces the potential for software conflicts.
- More Secure - Use of hardware transitions in the VMM strengthens the isolation of VMs and further prevents corruption of one VM from affecting others on the same system. Intel VT-x provides hardware acceleration for virtualization of IA platforms. VMMs use Intel VT-x features to provide improved reliable virtualized platform.

2.2.4 Intel® VT-x Features

- Extended Page Tables (EPT):
  - An EPT is hardware-assisted page table physical memory virtualization
  - EPT supports guest VM execution in unpaged protected / real address mode
  - EPT eliminates VM exits from guest OS to the VMM for shadow page-table Maintenance
- Virtual Processor IDs (VPID):
  - The ability to use an assigned VM Virtual Processor ID to tag processor core
- Hardware structures (such as TLBs) allowing a logic processor to cache information (such as TLBs) for multiple-linear address spaces:
  - This avoids flushes on VM transitions to give a lower-cost VM transition time
- Overall reduction in virtualization overhead
- Guest Preemption Timer:
  - A mechanism for a VMM to preempt the execution of a guest OS VM after an amount of time specified by the VMM. The VMM sets a timer value before entering a guest.
  - The feature aids VMM developers in flexibility and Quality of Service (QoS) guarantees flexibility in guest VM scheduling and building QoS schemes.
- Descriptor-Table Exiting:
  - Descriptor-table exiting allows a VMM to protect a guest OS from internal (malicious software based) attack by preventing relocation of key system data structures like Interrupt Descriptor Table (IDT), Global Descriptor Table (GDT)
- Local Descriptor Table (LDT), and Task Segment Selector (TSS):
  - A VMM using this feature intercepts (by a VM exit) attempts to relocate these data structures and prevent them from being tampered by malicious software
- VM Functions:
  - A VM function is an operation provided by the processor that is invoked using the VMFUNC instruction from guest VM without a VM exit
  - A VM function to perform EPTP switching is supported and allows guest VM to load a new value for the EPT pointer, thereby establishing a different EPT

2.2.5 Security and Cryptography Technologies

2.2.5.1 Intel® Advanced Encryption Standard New Instructions (Intel® AES-NI)

The processor supports Advanced Encryption Standard New Instructions (Intel®AES-NI) that are a set of Single Instruction Multiple Data (SIMD) instructions that enable fast and secure data encryption and decryption based on the Advanced Encryption Standard (AES). Intel® AES-NI are valuable for a wide range of cryptographic applications, for example:

- applications that perform bulk encryption/decryption
- authentication, random number generation
- authenticated encryption

AES is broadly accepted as the standard for both government and industry applications, and is widely deployed in various protocols. Intel® AES-NI consists of six Intel® SSE instructions.

Four instructions facilitate high performance AES encryption and decryption:

- AESENC
- AESENCLAST
- AESDEC
- AESDELAST

The other two, support the AES key expansion procedure.

- AESIMC
- AESKEYGENASSIST

Together, these instructions provide a full hardware AES support, offering security, high performance, and a great deal of flexibility.

2.2.5.2 Intel® Secure Hash Algorithm Extensions (Intel® SHA Extensions)

The Secure Hash Algorithm (SHA) is one of the most commonly employed cryptographic algorithms. Primary usages of SHA include data integrity, message authentication, digital signatures, and data de-duplication. As the pervasive use of security solutions continues to grow, SHA can be seen in more applications now than ever. The Intel® SHA Extensions are designed to improve the performance of these compute-intensive algorithms on Intel® architecture-based processors.

The Intel® SHA Extensions are a family of seven instructions based on the Intel® Streaming SIMD Extensions (Intel® SSE) that are used together to accelerate the performance of processing SHA-1 and SHA-256 on Intel architecture-based processors.

- **SHA1RNDS4**—Perform Four Rounds of SHA1 Operation
- **SHA1NEXTE**—Calculate SHA1 State Variable E after Four Rounds
- **SHA1MSG1**—Perform an Intermediate Calculation for the Next Four SHA1 Message Dwords
- **SHA1MSG2**—Perform a Final Calculation for the Next Four SHA1 Message Dwords
- **SHA256RNDS2**—Perform Two Rounds of SHA256 Operation
- **SHA256MSG1**—Perform an Intermediate Calculation for the Next Four SHA256 Message Dwords
- **SHA256MSG2**—Perform a Final Calculation for the Next Four SHA256 Message Dwords

A processor supports Intel® SHA Extensions if CPUID.(EAX=07H, ECX=0):EBX.SHA [bit 29] = 1. The Intel® SHA Extensions require only Intel® XMM™ Technology state support on operating systems, similar to SSE2 instructions.

Details of the seven instructions are in a PDF file *Intel® Architecture Instruction Set Extensions Programming Reference* available here: https://software.intel.com/en-us/isa-extensions.

2.2.5.3 PCLMULQDQ Instruction

The processor supports the carry-less multiplication instruction, PCLMULQDQ. PCLMULQDQ is a Single Instruction Multiple Data (SIMD) instruction that computes:

- The 128-bit carry-less multiplication of two 64-bit operands without generating Propagating carries

Carry-less multiplication is an essential processing component of several cryptographic systems and standards. Accelerating carry-less multiplication significantly contributes to achieving high-speed secure computing and communication.

2.2.5.4 Digital Random Number Generator

The processor introduces a software visible digital random number generation mechanism supported by a high-quality entropy source. This capability is available to programmers through the RDRAND and RDSEED instructions. The instruction is described as RDRAND—Read Random Number in Volume 2 of the *Intel® 64 and IA-32 Architectures Software Developer's Manual*.

Some uses of the RDRAND instruction include cryptographic key generation as used in a variety of applications including communication, digital signatures, secure storage, etc.

2.2.6 Intel® Turbo Boost Technology

Intel® Turbo Boost Technology is available on some of the SoC product SKUs. Refer to the following:

- Table 1-1, "Features by product SKU - Server and Cloud Storage SKUs 0 through 4"
- Table 1-2, "Features by Product SKU - Network and Enterprise Storage SKUs 5 through 10"
- Table 1-3, "Features by Product SKU - Extended Temperature SKUs 11 through 14".

Intel® Turbo Boost Technology is a feature that allows the processor to opportunistically and automatically run faster than its rated operating core and/or render clock frequency when there is sufficient power headroom, and the product is within specified temperature and current limits.

The Intel® Turbo Boost Technology feature increases performance of both multi-threaded and single-threaded workloads. The processor supports a turbo mode where the processor uses the thermal capacity associated with the package and core current being drawn to determine the higher core frequencies/power levels resulting in exceeding the SoCs TDP power for short durations.

For the processor to operate with maximum performance, the turbo feature needs to be properly enabled by the BIOS and the platform must have the correct implementation of SVID IMON. Since the turbo feature is configurable and dependent on many platform design limits outside of the processor control, the maximum performance cannot be guaranteed.

Turbo mode availability is independent of the number of active cores; however, the turbo mode frequency is dynamic and dependent on the instantaneous application power load, the number of active cores, user configurable settings, operating environment, and system design.

2.2.6.1 Intel® Turbo Boost Technology Frequency

The processor-rated frequency assumes that all execution cores are active and are at the sustained Thermal Design Power (TDP). However, under a typical operation not all cores are active or executing a high-power workload. Most applications are consuming less than the TDP at the rated frequency. Intel Turbo Boost Technology takes advantage of the available TDP headroom and active cores are able to increase their operating frequency. To determine the highest performance frequency amongst active cores, the processor takes the following into consideration to recalculate turbo frequency during runtime:

- Number of cores operating in the C0 state
- Estimated core current consumption
- Estimated package prior and present power consumption
- Package temperature

Any of these factors affect the maximum frequency for a given workload. If the power, current, or thermal limit is reached, the processor automatically reduces the frequency to stay within its TDP limit. Turbo processor frequencies are only active if the operating system is requesting the P0 state Section 34.10, "Performance States".

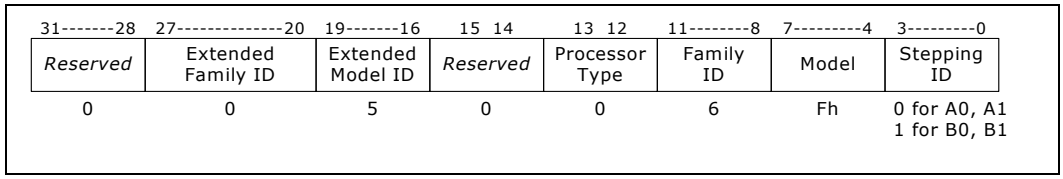
2.2.7 CPUID Instruction

The CPU Identification (CPUID) instruction returns processor identification and feature information to the EAX, EBX, ECX, and EDX registers, as determined by input entered in EAX (and in some cases, ECX as well).

Details of the instruction can be found in the Instruction Set Reference portion of the *Intel® 64 and IA-32 Architectures Software Developer's Manual*.

When CPUID executes with EAX set to 01h, the SoC version information is returned in EAX. See Figure 2-2, "Version Information Returned by CPUID in EAX".

Figure 2-2. Version Information Returned by CPUID in EAX



Note: Once the SoC product is launched, the *Intel® 64 and IA-32 Architectures Software Developer's Manual* will refer to the SoC as having "DisplayFamily_DisplayModel" as 06_5FH.

Leaves 0 through 15h provides Basic CPUID Information.

Leaves 80000000h through 80000008h provide Extended CPUID Information.

Table 2-1, "CPUID Leaf 0h" through Table 2-21, "Extended CPUID Leaf 80000008h" contain descriptions of the leaves and sub-leaves.

2.2.7.1 CPUID Leaf 0 — Basic CPUID Information

Table 2-1. CPUID Leaf 0h

Leaf [EAX] (Hex)	Sub-leaf [ECX] (Hex)	CPUID Results	Bits	Meaning	Returned Value	What Value Indicates
0	n/a	EAX	[31:0]	Maximum CPUID input value in EAX that is recognized by the SoC for its Basic CPUID Information.	Normally 0x15. *See bit 22 (BOOT_NT4) of MSR 1A0h, IA32_MISC_ENABLE.*	Leaf 15h is the final leaf for SoC Basic CPUID Features
		EBX	[31:0]	Intel identification, ASCII encoded "uneG"	0x756E6547	"Genu"
		ECX	[31:0]	Intel identification, ASCII encoded "letn"	0x6C65746E	"ntel"
		EDX	[31:0]	Intel identification, ASCII encoded "Ieni"	0x49656E69	"ineI"

2.2.7.2 CPUID Leaf 1 — Version and Feature Information

Table 2-2. CPUID Leaf 1h, Output EAX and EBX

Leaf [EAX] (Hex)	Sub-leaf [ECX] (Hex)	CPUID Results	Bits	Meaning	Returned Value	What Value Indicates
1	n/a	EAX	[3:0]	Stepping ID	Varies by product release	A0 Stepping = 0 A1 Stepping = 0 B0 Stepping = 1
			[7:4]	Model	0xF	0xF
			[11:8]	Family ID	6	6
			[13:12]	Processor Type	0	Original OEM Processor
			[15:14]	(Reserved)	0	
			[19:16]	Extended Model ID	5	5
			[27:20]	Extended Family ID	0	
		EBX	[7:0]	Brand Index	0	Brand String Method used rather than Brand Index Method
			[15:8]	CLFLUSH line size	8	64 bytes
			[23:16]	Maximum number of addressable IDs for logical processors in this package	0x20	32 IDs Max
			[31:24]	APIC ID assigned during power up	Varies	

Table 2-3. CPUID Leaf 1h, Output ECX (Sheet 1 of 2)

Leaf [EAX] (Hex)	Sub-leaf [ECX] (Hex)	CPUID Results	Bits	Meaning	Returned Value	What Value Indicates
1	n/a	ECX	0	**SSE3** - Intel® Streaming SIMD Extensions 3 (Intel® SSE3)	1	Supported
			1	**PCLMULDQ** - PCLMULDQ instruction	1	Supported
			2	**DTES64** - 64-bit DS Area	1	Supported
			3	**MONITOR/MWAIT** feature supported	Varies	Depends on value of bit 18 in IA_MISC_ENABLE (MSR 1A0h)
			4	**DS_CPL** - CPL Qualified Debug Store	1	Supported
			5	**VMX** - Virtual Machine Extensions	1	Supported
			6	**SMX** - Safer Mode Extensions	0	Not Supported
			7	**EIST** - Intel Enhanced SpeedStep® Technology	1	Supported
			8	**TM2** - Intel® Thermal Monitor 2	1	Supported
			9	**SSSE3** - Supplemental Streaming SIMD Extensions 3	1	Supported
			10	**CNXT-ID** - L1 Context ID	0	Not Supported
			11	**Privacy MSR**	1	Supported
			12	**FMA** - **Intel®** Fast Memory Access (**Intel®** FMA) extensions using YMM state	0	Not Supported
			13	**CMPXCHG16B/CX16** - Compare and Exchange Bytes features	1	Supported
			14	**xTPR Update Control** - Allow changing bit 23 of IA32_MISC_ENABLE (MSR 1A0h)	1	Supported
			15	**PDCM** - PerfMon and Debug Capability, altering IA32_PERF_CAPABILITIES (MSR 345h)	1	Supported
			16	(Reserved)	0	
			17	**PCID** - Process-Context Identifiers	0	Not Supported
			18	**DCA** - Ability to prefetch data from memory-mapped device	0	Not Supported
			19	**SSE4.1** - Intel® Streaming SIMD Extensions 4.1	1	Supported
			20	**SSE4.2** - Intel® Streaming SIMD Extensions 4.2	1	Supported
			21	**x2APIC** - Extended Interrupt Mode	1	Supported
			22	**MOVBE** - MOVBE instruction	1	Supported
			23	**POPCNT** - POPCNT instruction	1	Supported
			24	**TSC-Deadline**	1	Supported
			25	**AESNI** - AESNI instruction	1	Supported
			26	**XSAVE** - XSAVE/XRSTOR extended states, XSETBV/XGETBV instructions, and XCRO	1	Supported

Table 2-3. CPUID Leaf 1h, Output ECX (Sheet 2 of 2)

1	n/a	ECX	27	**OSXSAVE** - A value of 1 indicates the OS has set CR4.OSXSAVE	Varies	
			28	**AVX** - AVX instruction extensions.	0	Not Supported
			29	**F16C/IVBNI** - 16-bit floating-point conversion instructions	0	Not Supported
			30	**RDRAND** - RDRAND instruction	1	Supported
			31	(Reserved)	0	

Table 2-4. CPUID Leaf 1h, Output EDX (Sheet 1 of 2)

Leaf [EAX] (Hex)	Sub-leaf [ECX] (Hex)	CPUID Results	Bits	Meaning	Returned Value	What Value Indicates
1	n/a	EDX	0	**FPU** - Floating Point Unit on Chip	1	Supported
			1	**VME** - Virtual 8086 Mode Enhancements	1	Supported
			2	**DE** - Debugging Extensions	1	Supported
			3	**PSE** - Page Size Extension	1	Supported
			4	**TSC** - Time Stamp Counter	1	Supported
			5	**MSR** - Model Specific Registers RDMSR & WRMSR Instructions	1	Supported
			6	**PAE** - Physical Address Extension	1	Supported
			7	**MCE** - Machine Check Exception	1	Supported
			8	**CX8** - CMPXCHG8B Instruction	1	Supported
			9	**APIC** - APIC On-Chip	Varies	1 if bit 11 of IA32_APIC_BASE (MSR 1Bh) is set
			10	(Reserved)	0	
			11	**SEP** - SYSTENTER & SYSEXIT Instructions	1	Supported
			12	**MTRR** - Memory Type Range Registers	1	Supported
			13	**PGE** - Page Global Bit	1	Supported
			14	**MCA** - Machine Check Architecture	1	Supported
			15	**CMOV** - Conditional Move Instruction	1	Supported
			16	**PAT** - Page Attribute Table	1	Supported
			17	**PSE-36** - 36-bit Page Size Extension	1	Supported. Physical addresses may be up to 39 bits
			18	**PSN** - Processor Serial Number	0	Not Supported
			19	**CLFSH** - CLFLUSH Instruction	1	Supported
			20	(Reserved)	0	
			21	**DS** - Debug Store	1	Supported
			22	**ACPI** - Software Controlled Clock Facilities	1	Supported
			23	**MMX** - Intel MMX™ technology	1	Supported

Table 2-4. CPUID Leaf 1h, Output EDX (Sheet 2 of 2)

1	n/a	EDX	24	**FXSR** - FXSAVE and FXRSTOR Instructions	1	Supported
			25	**SSE** - Intel® Streaming SIMD Extensions	1	Supported
			26	**SSE2** - Intel® Streaming SIMD Extensions 2	1	Supported
			27	**SS** - Self Snoop	1	Supported
			28	**HTT** - Max APIC IDs reserved field is Valid. See CPUID, Leaf 1, EBX[23:16]	1	Supported
			29	**TM** - Intel® Thermal Monitor	1	Supported
			30	(Reserved)	0	
			31	**PBE** - Pending Break-Enable	1	Supported

2.2.7.3 CPUID Leaf 2 — Cache and TLB Information

Table 2-5. CPUID Leaf 2h

Leaf [EAX] (Hex)	Sub-leaf [ECX] (Hex)	CPUID Results	Bits	Meaning	Returned Value	What Value Indicates
2	n/a	EAX	[7:0]	Loop value - Number of times CPUID leaf 2 must be executed to retrieve complete information about caches and TLBs.	0x01	One time
			[15:8]	Micro Translation Lookaside Buffer (uTLB) Descriptor	0xA0	4K pages, fully associative, 32 entries
			[23:16]	Data Translation Lookaside Buffer (DTLB) Descriptor	0x64	4K pages, 4-way, 512 entries
			[30:24]	Instruction Translation Lookaside Buffer (ITLB) Descriptor	0x61	4K pages, fully associative, 48 entries
			[31]	Valid bit	0	Bits [30:0] are valid
		EBX	[7:0]	Large-Page DTLB Descriptor	0xC2	2M and 4M pages, 4-way, 16 entries
			[15:8]	General	0xFF	CPUID leaf 2 does not report cache descriptor information. Use CPUID leaf 4 instead
			[31:16]	(Reserved)	0	
		ECX	[31:0]	(Reserved)	0	
		EDX	[31:0]	(Reserved)	0	

2.2.7.4 CPUID Leaf 3— Reserved

The 96-bit processor serial number is not supported. For CPUID with EAX = 3, the results in EAX, EBX, ECX and EDS are reserved and zeros are returned.

2.2.7.5 CPUID Leaf 4— Deterministic Cache Parameters

CPUID leaf 4 has three sub-leaves.

Table 2-6. CPUID Leaf 4h (Sheet 1 of 2)

Leaf [EAX] (Hex)	Sub-leaf [ECX] (Hex)	CPUID Results	Bits	Meaning	Returned Value	What Value Indicates
4	0	EAX	[4:0]	Cache Type	0x1	Data Cache
			[7:5]	Cache Level	0x1	Level 1 (L1)
			8	Self Initializing Cache?	1	Yes
			9	Fully Associative?	0	No
			[13:10]	(Reserved)	0	
			[25:14]	Max number of addressable IDs for logical processors sharing this cache	0	Max number is 1
			[31:26]	Max number of addressable IDs for processor cores in the SoC physical package (minus 1)	0xF	Max number is 16
		EBX	[11:0]	System Coherency Line Size (minus 1)	0x3F	64
			[21:12]	Physical Line Partitions	0	1 partition
			[31:22]	Ways (minus 1)	5	6 Ways
		ECX	[31:0]	Sets (minus 1)	0x3F	64 Sets
		EDX	0	Write-back Invalidate/Invalidate	1	WBINVD/INVD is not guaranteed to act upon lower level caches of non-originating threads sharing this cache.
			1	Cache Inclusiveness	0	Cache is not inclusive of lower cache levels
			2	Complex Cache Indexing	1	Complex Cache Indexing supported
			[31:3]	(Reserved)	0	
	1	EAX	[4:0]	Cache Type	0x2	Instruction Cache
			[7:5]	Cache Level	0x1	Level 1 (L1)
			8	Self Initializing Cache?	1	Yes
			9	Fully Associative?	0	No
			[13:10]	(Reserved)	0	
			[25:14]	Max number of addressable IDs for logical processors sharing this cache	0	Max number is 1
			[31:26]	Max number of addressable IDs for processor cores in the SoC physical package (minus 1)	0xF	Max number is 16
		EBX	[11:0]	System Coherency Line Size (minus 1)	0x3F	64
			[21:12]	Physical Line Partitions	0	1 partition
			[31:22]	Ways (minus 1)	7	8 Ways
		ECX	[31:0]	Sets (minus 1)	0x3F	64 Sets

Table 2-6. CPUID Leaf 4h (Sheet 2 of 2)

4	1	EDX	0	Write-back Invalidate/Invalidate	1	WBINVD/INVD is not guaranteed to act upon lower level caches of non-originating threads sharing this cache.
			1	Cache Inclusiveness	0	Cache is not inclusive of lower cache levels
			2	Complex Cache Indexing	1	Complex Cache Indexing supported
			[31:3]	(Reserved)	0	
	2	EAX	[4:0]	Cache Type	0x3	Unified Cache
			[7:5]	Cache Level	0x2	Level 2 (L2)
			8	Self Initializing Cache?	1	Yes
			9	Fully Associative?	0	No
			[13:10]	(Reserved)	0	
			[25:14]	Maximum number of addressable IDs for logical processors sharing this cache (minus 1)	0x3	Max number is 4
			[31:26]	Maximum number of addressable IDs for processor cores in the SoC physical package (minus 1)	0xF	Max number is 16
		EBX	[11:0]	System Coherency Line Size (minus 1)	0x3F	64
			[21:12]	Physical Line Partitions	0	1 partition
			[31:22]	Ways	0xF	16 Ways
		ECX	[31:0]	Sets (minus 1)	0x7FF	2048 Sets
		EDX	0	Write-back Invalidate/Invalidate	1	WBINVD/INVD is not guaranteed to act upon lower level caches of non-originating threads sharing this cache.
			1	Cache Inclusiveness	0	Cache is not inclusive of lower cache levels
			2	Complex Cache Indexing	0	Direct mapped cache
			[31:3]	(Reserved)	0	
	3+	EAX	[31:0]	(Reserved)	0	
		EBX	[31:0]	(Reserved)	0	
		ECX	[31:0]	(Reserved)	0	
		EDX	[31:0]	(Reserved)	0	

2.2.7.6 CPUID Leaf 5— MONITOR/MWAIT

Except for EDX[31:0], values shown in Table 2-7, "CPUID Leaf 5h" are valid only when MONITOR/MWAIT instructions are enabled.

Table 2-7. CPUID Leaf 5h

Leaf [EAX] (Hex)	Sub-leaf [ECX] (Hex)	CPUID Results	Bits	Meaning	Returned Value	What Value Indicates
5	n/a	EAX	[15:0]	Smallest monitor-line size in bytes	0x40 this can vary depending on filter size	64 bytes or the filter size, whichever is smaller
			[31:16]	(Reserved)	0	
		EBX	[15:0]	Largest monitor-line size in bytes	0x40 this can vary depending on filter size	64 bytes or the filter size, whichever is smaller
			[31:16]	(Reserved)	0	
		ECX	0	Enumeration of MONITOR-WAIT extensions	1	Supported
			1	Supports treating interrupts as break-event for MWAIT, even when interrupts disabled	1	Supported
			[31:2]	(Reserved)	0	
		EDX	[3:0]	Number of MWAIT C0 sub-states supported	0	0
			[7:4]	Number of MWAIT C1 sub-states supported	2	2
			[11:8]	Number of MWAIT C2 sub-states supported	0	0
			[15:12]	Number of MWAIT C3 sub-states supported	2	2
			[19:16]	Number of MWAIT C4 sub-states supported	4	4
			[23:20]	Number of MWAIT C5 sub-states supported	2	2
			[27:24]	Number of MWAIT C6 sub-states supported	0	0
			[31:28]	Number of MWAIT C7 sub-states supported	0	0

2.2.7.7 CPUID Leaf 6— Digital Thermometer and Power Management

Table 2-8. CPUID Leaf 6h

Leaf [EAX] (Hex)	Sub-leaf [ECX] (Hex)	CPUID Results	Bits	Meaning	Returned Value	What Value Indicates
6	n/a	EAX	0	Digital Thermal Sensor (DTS) support	1	Supported
			1	Intel® Turbo Boost Technology	0 or 1	Support varies by product SKU. BIOS can also disable this technology
			2	**ARAT -** APIC-Timer-always-running feature	1	Supported
			3	(Reserved)	0	
			4	**PLN** - Power limit notification controls support	0	Not Supported
			5	**ECMD** - Clock modulation duty cycle extension support	0	Not Supported
			6	**PTM** - Package thermal management support	0	Not Supported
			[31:7]	(Reserved)	0	
		EBX	[3:0]	Number of Interrupt Thresholds in Digital Thermal Sensor (DTS)	2	2 thresholds
			[31:4]	(Reserved)	0	
		ECX	0	Hardware Coordination Feedback Capability	1	Supported. IA32_MPERF (MSR E7h) and IA32_APERF (MSR E8h) are present
			[2:1]	(Reserved)	0	
			3	Performance-Energy BIAS Preference support	0	Not Supported IA32_ENERGY_PERFORMANCE_BIAS (MSR 1B0h) is not available
			[31:4]	(Reserved)	0	
		EDX	[31:0]	(Reserved)	0	

2.2.7.8 CPUID Leaf 7— Extended feature Flags

The output shown in Table 2-9, "CPUID Leaf 7h" depends on the ECX input value.

Table 2-9. CPUID Leaf 7h (Sheet 1 of 2)

Leaf [EAX] (Hex)	Sub-leaf [ECX] (Hex)	CPUID Results	Bits	Meaning	Returned Value	What Value Indicates
7	0	EAX	[31:0]	Maximum supported sub-leaf for CPUID leaf 7	0	Only sub-leaf 0
		EBX	0	**FSGSBASE** - Support for RDFSBASE/RDGSBASE/WRFSBASE /WRGSBASE	1	Supported
			1	Support for IA32_TSC_ADJUST (MSR 3Bh)	1	Supported
			2	**SGX** - Support for Secure Enclaves (SE) and Intel® Software Guard Extensions (Intel® SGX)	0	Not Supported
			3	**BMI1** - Bit Manipulation Set 1	0	Not Supported
			4	**HLE**	0	Not Supported
			5	**AVX2** - Intel® Advanced Vector Extensions 2 (Intel® AVX2)	0	Not Supported
			6	(Reserved)	0	
			7	**SMEP** - Supervisor-Mode Execution Prevention	1	Supported
			8	**BMI2** - Bit Manipulation Set 2	0	Not Supported
			9	**ERMS** - Support for Enhanced REP MOV/STOSB	1	Supported
			10	**INVPCID** - Support for INVPCID instruction	0	Not Supported
			11	**RTM** - HLE+/RTM	0	Not Supported
			12	Support for Platform Quality of Service Monitoring (PQM) capability	0	Not Supported
			13	FPU CS and FPU DS Deprecation	1	The processor depreciates FPU CS and FPU DS values and these fields are 0000h
			14	Intel® Memory Protection Extensions (Intel® MPX)	1	Supported
			15	Support for Platform Quality of Service Enforcement (PQE)	1	Supported
			16	**AVX512F** - Intel® Advanced Vector Extensions 512 (Intel® AVX-512) Foundation instructions)	0	Not Supported
			17	**AVX512DQ** - Intel® Advanced Vector Extensions 512 (Intel® AVX-512)	0	Not Supported
			18	**RDSEED** - Read Random SEED instruction	1	Supported
			19	(Reserved)	0	
			20	**SMAP** - Supervisory Mode Access Protection and the LAC/STAC instructions	1	Supported

Table 2-9. CPUID Leaf 7h (Sheet 2 of 2)

7	0	EBX	21	**AVX512IFMA** - Intel® Advanced Vector Extensions 512 (Intel® AVX-512)	0	Not Supported
			22	**PCOMMIT** - Persistent Commit instruction	0	Not Supported
			23	**CLFLUSHOPT** - Flush a Cache Line Optimized instruction	1	Supported
			24	(Reserved)	0	
			25	Intel® Processor Trace (Intel® PT)	1	Supported
			26	**AVX512PF** - Intel® Advanced Vector Extensions 512 (Intel® AVX-512)	0	Not Supported
			27	**AVX512ER** - Intel® Advanced Vector Extensions 512 (Intel® AVX-512)	0	Not Supported
			28	**AVX512CD** - Intel® Advanced Vector Extensions 512 (Intel® AVX-512)	0	Not Supported
			29	**SHA** - Intel® Secure Hash Algorithm Extensions (Intel® SHA Extensions)	1	Supported
			30	**AVX512BW** - Intel® Advanced Vector Extensions 512 (Intel® AVX-512)	0	Not Supported
			31	**AVX512VL** - Intel® Advanced Vector Extensions 512 (Intel® AVX-512)	0	Not Supported
		ECX	0	**PREFETCHWT1** - PREFETCHWT1 instruction	0	Not Supported
			1	**AVX512VBMI** - Intel® Advanced Vector Extensions 512 (Intel® AVX-512)	0	Not Supported
			[31:2]	(Reserved)	0	
		EDX	[31:0]	(Reserved)	0	
7	1+	EAX	[31:0]	(Reserved)	0	
		EBX	[31:0]	(Reserved)	0	
		ECX	[31:0]	(Reserved)	0	
		EDX	[31:0]	(Reserved)	0	

2.2.7.9 CPUID Leaf 8 — Reserved

CPUID leaf 8 is not supported and is reserved. Zeros are returned.

2.2.7.10 CPUID Leaf 9 — Direct Cache Access (DCA) Information

CPUID leaf 9 is not supported and is reserved. Zeros are returned.

2.2.7.11 CPUID Leaf Ah — Architectural Performance Monitoring

Table 2-10. CPUID Leaf Ah

Leaf [EAX] (Hex)	Sub-leaf [ECX] (Hex)	CPUID Results	Bits	Meaning	Returned Value	What Value Indicates
A	n/a	EAX	[7:0]	Version ID of architectural performance monitoring	4	Version 4
			[15:8]	Number of general-purpose, performance monitoring counters per logical processor	4	4 counters
			[23:16]	Bit width of general-purpose, performance monitoring counter	0x30	48 bits
			[31:24]	Length of EBX bit vector to enumerate architectural events	7	7
		EBX	0	Core Cycle event unavailable	0	Core Cycle event is available
			1	Instruction Retired event unavailable	0	Instruction Retired event is available
			2	Reference Cycles event unavailable	0	Reference Cycles event is available
			3	Last-level cache (L2 Cache) reference event unavailable	0	Last-level cache (L2 Cache) reference event is available
			4	Last-level cache (L2 Cache) misses event unavailable	0	Last-level cache (L2 Cache) misses event is available
			5	Branch instruction retired event unavailable	0	Branch instruction retired event is available
			6	Branch mispredict retired event unavailable	0	Branch mispredict retired event is available
		ECX	[31:0]	(Reserved)	0	
		EDX	[4:0]	Number of fixed-function performance counters (if Version ID > 1)	3	3 counters
			[12:5]	Bit width of fixed-function performance counters (if Version ID > 1)	0x30	48 bits
			[31:13]	(Reserved)	0	

2.2.7.12 CPUID Leaf Bh — Extended Topology Enumeration

CPUID leaf Bh has two sub-leaves.

Table 2-11. CPUID Leaf Bh

Leaf [EAX] (Hex)	Sub-leaf [ECX] (Hex)	CPUID Results	Bits	Meaning	Returned Value	What Value Indicates
B	0	EAX	[4:0]	Number of bits to shift right on x2APIC ID (EDX[31:0]) to get a unique topology ID of the next level type	1	Shift right 1 bit
			[31:5]	(Reserved)	0	
		EBX	[15:0]	Number of logical processors at this level type. The number reflects configuration as shipped by Intel	1	1 logical processor
			[31:16]	(Reserved)	0	
		ECX	[7:0]	Level Number - Same value as ECX input	0	Level 0
			[15:8]	Level Type	1	SMT level
			[31:16]	(Reserved)	0	
		EDX	[31:0]	x2APIC ID the current logical processor	Varies	
	1	EAX	[4:0]	Number of bits to shift right on x2APIC ID (EDX[31:0]) to get a unique topology ID of the next level type	5	Shift right 5 bits
			[31:5]	(Reserved)	0	
		EBX	[15:0]	Number of logical processors at this level type. The number reflects configuration as shipped by Intel	2, 4, 8, 0xB, or 0x10	2, 4, 8, 12, or 16 depending on product SKU
			[31:16]	(Reserved)	0	
		ECX	[7:0]	Level Number - Same value as ECX input	1	Level 1
			[15:8]	Level Type	2	Core level
			[31:16]	(Reserved)	-	0
		EDX	[31:0]	x2APIC ID the current logical processor	Varies	
	2+	EAX	[31:0]	(Reserved)	0	
		EBX	[31:0]	(Reserved)	0	
		ECX	[31:0]	Original ECX	2+	
		EDX	[31:0]	(Reserved)	0	

2.2.7.13 CPUID Leaf Ch — Reserved

CPUID leaf Ch is not supported and is reserved. Zeros are returned.

2.2.7.14 CPUID Leaf Dh — Intel® Memory Protection Extensions (Intel® MPX), XSAVE Feature

CPUID leaf Dh has six sub-leaves (0 through 4, and 8) and is shown in Table 2-12, "CPUID Leaf Dh". The other sub-leaves are reserved.

Table 2-12. CPUID Leaf Dh (Sheet 1 of 2)

Leaf [EAX] (Hex)	Sub-leaf [ECX] (Hex)	CPUID Results	Bits	Meaning	Returned Value	What Value Indicates
D	0	EAX	0	**X87 State** - Legacy Floating Point (x87/MMX)	1	Legacy FP state can be managed by XSAVE
			1	**SSE State** - Intel® Streaming SIMD Extensions (Intel® SSE)	1	Intel® SSE state can be managed by XSAVE
			2	**AVX State** - Advanced Vector Extensions (Intel® AVX)	0	Intel® AVX state cannot be managed by XSAVE
			3	**BNDREGS State** - Intel® Memory Protection Extensions (Intel® MPX) BNDREGS	1	Intel® MPX Bound Registers (BNDREGS) can be managed by XSAVE
			4	**BNDCSR State** - Intel® Memory Protection Extensions (Intel® MPX) BNDCSR	1	Intel® MPX Bound Control and Status Register (BNDCSR) can be managed by XSAVE
			[7:5]	**AVX-512 State** - Intel® Advanced Vector Extensions 512 (Intel® AVX-512)	0	Intel® AVX-512 not supported and cannot can be managed by XSAVE
			8	**PT State** - Intel® Processor Trace (Intel® PT), used for IA32_XSS (MSR DA0h)	0	Intel® PT MSRs state cannot can be managed by XSAVE
			9	**PKRU State** - Protection-key feature's register PKRU	0	PKRU state cannot can be managed by XSAVE
			[31:10]	(Reserved)	0	
		EBX	[31:0]	Maximum size required for features enabled in XCR0	0x240	576 bytes
		ECX	[31:0]	Max size required by all processor supported features	0x440	1088 bytes
		EDX	[31:0]	(Reserved)	0	
	1	EAX	0	Availability of XSAVEOPT	1	Available
			1	Support of XSAVEC and compact extensions of legacy XSTROR	1	Supported
			2	Support of XGETBV Leaf 1	1	Supported
			3	Support of XSAVES and XRSTORS instructions, and IA32_XSS (MSR DA0h)	1	Supported
			[31:4]	(Reserved)	0	
		EBX	[31:0]	Maximum size required for features enabled in XCR0 | IA32_XSS (MSR DA0h)	0x240	576 bytes
		ECX	[7:0]	(Reserved)	0	
			8	**PT State** - Intel® Processor Trace (Intel® PT)	1	Corresponding bit in IA32_XSS (MSR DA0h) can be set
			[31:9]	(Reserved)	0	
		EDX	[31:0]	(Reserved)	0	

Table 2-12. CPUID Leaf Dh (Sheet 2 of 2)

D	2	EAX	[31:0]	(Reserved)	0	
		EBX	[31:0]	(Reserved)	0	
		ECX	[31:0]	(Reserved)	0	
		EDX	[31:0]	(Reserved)	0	
	3	EAX	[31:0]	Intel® Memory Protection Extensions (Intel® MPX) - Size of feature state-save area	0x40	64 bytes
		EBX	[31:0]	Intel® MPX - Offset of feature state-save area	0x3C0	960 bytes
		ECX	[31:0]	(Reserved)	0	
		EDX	[31:0]	(Reserved)	0	
	4	EAX	[31:0]	Intel® MPX - Size of feature state-save area	0x40	64 bytes
		EBX	[31:0]	Intel® MPX - Offset of feature state-save area	0x400	1024 bytes
		ECX	[31:0]	(Reserved)	0	
		EDX	[31:0]	(Reserved)	0	
	8	EAX	[31:0]	Intel® Processor Trace (Intel® PT) - Size of Intel® PT state-save area	0x80	128 bytes
		EBX	[31:0]	(Reserved)	0	
		ECX	0	Intel® PT - Supervisor State	1	Intel® PT is supported in IA32_XSS (MSR DA0h)
			[31:1]	(Reserved)	0	
		EDX	[31:0]	(Reserved)	0	
	All other values of ECX	EAX	[31:0]	(Reserved)	0	
		EBX	[31:0]	(Reserved)	0	
		ECX	[31:0]	(Reserved)	0	
		EDX	[31:0]	(Reserved)	0	

2.2.7.15 CPUID Leaf Eh — Reserved

CPUID leaf Eh is not supported and is reserved. Zeros are returned.

2.2.7.16 CPUID Leaf Fh — Platform and Cache Quality of Service (QoS)

CPUID leaf Fh, Platform QoS Monitoring Enumeration and Cache QoS Monitoring Capability, is not supported and is reserved. Zeros are returned.

2.2.7.17 CPUID Leaf 10h — Platform and Cache QoS Enforcement Enumeration

CPUID leaf 10h contains three sub-leaves and is show in Table 2-13, "CPUID Leaf 10h".

Table 2-13. CPUID Leaf 10h

Leaf [EAX] (Hex)	Sub-leaf [ECX] (Hex)	CPUID Results	Bits	Meaning	Returned Value	What Value Indicates
10	0	EAX	[31:0]	(Reserved)	0	
		EBX	0	(Reserved)	0	
			1	L3 Cache	0	SoC has no L3 Cache
			2	L2 Cache	1	Supports L2 Cache QoS Enforcement
			[31:3]	(Reserved)	0	
		ECX	[31:0]	(Reserved)	0	
		EDX	[31:0]	(Reserved)	0	
	1	EAX	[31:0]	(Reserved)	0	
		EBX	[31:0]	(Reserved)	0	
		ECX	[31:0]	(Reserved)	0	
		EDX	[31:0]	(Reserved)	0	
	2	EAX	[4:0]	Length of Masks (minus 1)	7	8
			[31:5]	(Reserved)	0	
		EBX	[31:0]	Bitmask	0	
		ECX	[31:0]	(Reserved)	0	
		EDX	[15:0]	Highest COS number supported for this ResID (minus 1)	3	4 is highest number
			[31:16]	(Reserved)	0	
	3+	EAX	[31:0]	(Reserved)	0	
		EBX	[31:0]	(Reserved)	0	
		ECX	[31:0]	(Reserved)	0	
		EDX	[31:0]	(Reserved)	0	

2.2.7.18 CPUID Leaf 11h — Reserved

CPUID leaf 11h is not supported and is reserved. Zeros are returned.

2.2.7.19 CPUID Leaf 12h — Reserved

CPUID leaf 12h is not supported and is reserved. Zeros are returned.

2.2.7.20 CPUID Leaf 13h — Reserved

CPUID leaf 13h is not supported and is reserved. Zeros are returned.

2.2.7.21 CPUID Leaf 14h — Intel® Processor Trace (Intel® PT) Enumeration

CPUID leaf 14h has two sub-leaves and is shown in Table 2-14, "CPUID Leaf 14h".

Table 2-14. CPUID Leaf 14h (Sheet 1 of 2)

Leaf [EAX] (Hex)	Sub-leaf [ECX] (Hex)	CPUID Results	Bits	Meaning	Returned Value	What Value Indicates
14	0	EAX	[31:0]	Maximum valid sub-leaf	1	Only sub-leaves 0 and 1 are valid
		EBX	0	CR3 Filtering Support	1	IA32_RTIT_CTL (MSR 570h) can be set to 1, and that IA32_RTIT_CR3_MATCH (MSR 572h) can be accessed
			1	Support for Cycle-Accurate Mode and Configurable PSB	1	Supported
			2	Support for IP filtering, TraceStop filtering, and MTC timing packet	1	Supported
			3	Support for Processor Trace MSRs preserved across warm reset	1	Supported
			[31:4]	(Reserved)	0	
		ECX	0	Support of ToPA Output scheme	1	Supported. Tracing can be enabled with the ToPA bit of IA32_RTIT_CTL (MSR 570h)
			1	ToPA Tables Support Multiple Output Regions	1	Supported
			2	Support of Single-Range Output scheme	1	Supported

2.2.7.22 CPUID Leaf 15h — Time Stamp Counter (TSC) and Crystal Clock Ratio

CPUID leaf 15h is the last Basic CPUID leaf.

Table 2-15. Basic CPUID Leaf 15h

Leaf [EAX] (Hex)	Sub-leaf [ECX] (Hex)	CPUID Results	Bits	Meaning	Returned Value	What Value Indicates
15	n/a	EAX	[31:0]	Denominator of TSC/crystal clock ratio	3	3
		EBX	[31:0]	Numerator of TSC/crystal clock ratio	0xC0	192
		ECX	[31:0]	(Reserved)	0	
		EDX	[31:0]	(Reserved)	0	

2.2.7.23 CPUID Leaves 16h through 7FFFFFFFh — Reserved

CPUID leaves 16h through 7FFFFFFFh are not supported and are reserved. Each of these leaves produces the same EAX, EBX, ECX, and EDS values as leaf 15h.

CPUID leaves greater than 80000000h are also reserved and produce the same EAX, EBX, ECX, and EDS values as leaf 15h.

2.2.7.24 CPUID Leaf 80000000h — Maximum EAX Value for CPUID Instruction

Table 2-16. Extended CPUID Leaf 80000000h

Leaf [EAX] (Hex)	Sub-leaf [ECX] (Hex)	CPUID Results	Bits	Meaning	Returned Value	What Value Indicates
80000000	n/a	EAX	[31:0]	Maximum input value in EAX for Extended Function CPUID information	0x80000008	0x80000008 is the maximum value
		EBX	[31:0]	(Reserved)	0	
		ECX	[31:0]	(Reserved)	0	
		EDX	[31:0]	(Reserved)	0

80000008	n/a	EAX	[7:0]	Number of Physical Address Bits	0x27	39 bits
			[15:8]	Number of Linear Address Bits	0x30	48 bits
			[31:16]	(Reserved)	0	
		EBX	[31:0]	(Reserved)	0	
		ECX	[31:0]	(Reserved)	0	
		EDX	[31:0]	(Reserved)	0	

§ §

3 System Address Map

In addition to the Intel Atom® cores, the SoC contains two other units, the Innovation Engine (IE) and Intel® Management Engine (ME), that execute the Intel® architecture instruction set. Each has its own Memory Space, I/O Space and PCI domain. This document refers to these three units as:

- Host Root Space - Associated with the Intel Atom® cores
- IE Root Space - Associated with the IE instruction-execution unit
- Intel® ME Root Space - Associated with the Intel® ME instruction-execution unit

This Chapter describes the Host Root Space, which includes the Configuration Space, Memory Space, and I/O Space of the SoC. Information is provided to show Memory Address Space configuration and how to access Sideband Registers and Configuration Space.

Model-Specific Registers (MSRs) are accessed by executing Read MSR (RDMSR) and Write MSR (WRMSR) instructions. CPU Identification Registers are accessed via CPUID instruction.

3.1 Host Root Space—Memory Space

The Memory Space address map for the Host Root Space is shown in Table 3-1, "Host Memory Space Address Map". The Memory-Mapped I/O (MMIO) that is relocatable in Host Memory Space is shown in Table 3-2, "Relocatable MMIO in Host Memory Space".

The SoC implements 40 address bits providing 1,024 GB of addressable Host Root Memory Space for use by the CPU and devices. This is the address space accessible by memory reads and writes. These addresses are generated by the processor and also by integrated and external I/O devices. The target of the read and write transactions can be system memory or integrated memory and external I/O devices. For PCI compliance the devices and SoC internal circuitry provide a full 64-bit address space. Even so, addresses greater than 1,024 GB (40 address bits) never address a physical resource in the SoC, and are always terminated with an error.

Note: The ultimate subtractive-decode agent in Host Root Space is the Primary-to-Sideband Bridge (P2SB) and not the Low Pin Count (LPC) controller. Any transaction reaching the P2SB which does not match a valid mapped region is terminated. Such transactions are either dropped for Posted Requests or result in an Unsupported Request (UR) for Non-Posted Requests.

3.1.1 Host Memory Space—Regions and Boundaries

Table 3-1. Host Memory Space Address Map (Sheet 1 of 3)

Memory Address Range Name [Size]	Start Address or Base Address (Hexadecimal)	End Address or Range (Hexadecimal)	Dependency/Comments
DOS DRAM (0 to 1 MB)			
DRAM [640 KB]	0000_0000	0009_FFFF	DOS_DRAM
VGA (A Segment and B Segment) [128 KB]	000A_0000	000B_FFFF	A and B segments' VGA region of memory must be configured before first access and may target one and only one of these: • PCIe Root Port which has VGAE (bit 3) of its Bridge Control Register (BCTL) is set. • Legacy Block • DRAM in SBFT mode when ABSEGINDRAM (bit 2) of the B_CR_BMISC_0_0_0_MCHBAR register is set. ***Note:*** The SoC does not support SMM in the A and B segments of memory (the VGA region).
DRAM (C Segment and D Segment) [128 KB]	000C_0000	000D_FFFF	The SoC does not support ISA Expansion region. This area always maps to system DRAM. Access is from the CPU only, no inbound access support—an inbound access will be aborted.
Extended System BIOS (E Segment) [64 KB]	000E_0000	000E_FFFF	Reads and Writes to E segment are to DRAM. ***Note:*** The SoC does not support reading from the BIOS boot interface via the E segment. Access from CPU only, no inbound access support.

Table 3-1. Host Memory Space Address Map (Sheet 2 of 3)

Memory Address Range Name [Size]	Start Address or Base Address (Hexadecimal)	End Address or Range (Hexadecimal)	Dependency/Comments
System BIOS (Upper) (F segment) [64 KB]	000F_0000	000F_FFFF	Reads and Writes to F segment are to DRAM. ***Note:*** The SoC does not support reading from the BIOS boot interface via the F segment. Access from CPU only, no inbound access support.
Lower DRAM Window (1 MB to TOLUD minus 1)			
DRAM [1 MB]	00F0_0000	0100_0000	The SoC does not support ISA hole. This range is always mapped to DRAM.
TSEG	B-unit System Management Mode Memory Base (TSEGMB_0_0_0_PCI)	BGSM_0_0_0_PCI minus 1	TSEG is locked by BIOS by setting the appropriate levels in TSEGMB_0_0_0_PCI and BGSM_0_0_0_PCI.
BGSM	B-unit Graphics Stolen Memory Base (BGSM_0_0_0_PCI)	TOLUD minus 1	For the SoC, the BGSM_0_0_0_PCI range is not applicable. Even so, BGSM_0_0_0_PCI must be programmed since it affects TSEG.
Low MMIO (TOLUD to 4 GB)			
ABORT	FEB0_0000	FEBF_FFFF	CRAB Abort page region
IOxAPIC	FEC0_0000	FEC0_0040	IOxAPIC space. Within FECx_x000 to FECx_x040, BIOS configures the window using APIC Range Select (IOAC.ASEL) and APIC Enable (IOAC.AEN). The IOAC register is in the P2SB Bridge device. ***Note:*** Intel only validates the range FEC0_0000 to FEC0_0040.
HPET	FED0_0000	FED0_03FF	High performance event timer. Although FED0_0000 through FED0_33FF are configurable, only FED0_0000 through FED0_03FF is expected.
TPM	FED4_0000	FED4_0FFF	TPM1.2 range
xHCI DbC	FED6_0000	FED6_0FFF	The OS must be informed that this address range is reserved. No other MMIO must overlap range.
Local APIC	FEE0_0000	FEEF_FFFF	APIC space used to send MSIs to the CPU and INTR ACKs to legacy block.
BIOS4 - Feature space for LPC	FF00_0000	FF0F_FFFF	BDE.0
	FF10_0000	FF1F_FFFF	BDE.1
	FF20_0000	FF2F_FFFF	BDE.2
	FF30_0000	FF3F_FFFF	BDE.3
BIOS4 - Data space for SPI and LPC	FF40_0000	FF4F_FFFF	BDE.0
	FF50_0000	FF5F_FFFF	BDE.1
	FF60_0000	FF6F_FFFF	BDE.2
	FF70_0000	FF7F_FFFF	BDE.3

Table 3-1. Host Memory Space Address Map (Sheet 3 of 3)

Memory Address Range Name [Size]	Start Address or Base Address (Hexadecimal)	End Address or Range (Hexadecimal)	Dependency/Comments
Low MMIO (TOLUD to 4 GB) (continued)			
BIOS3 - Feature space for LPC	FF80_0000	FF87_FFFF	BDE.8
	FF88_0000	FF8F_FFFF	BDE.9
	FF90_0000	FF97_FFFF	BDE.10
	FF98_0000	FF9F_FFFF	BDE.11
	FFA0_0000	FFA7_FFFF	BDE.12
	FFA8_0000	FFAF_FFFF	BDE.13
	FFB0_0000	FFB7_FFFF	BDE.14
BIOS3 - Feature space for LPC	FFB8_0000	FFBF_FFFF	BDE.15; always enabled
BIOS3 - Data space for SPI and LPC	FFC0_0000	FFC7_FFFF	BDE.8
	FFC8_0000	FFCF_FFFF	BDE.9
	FFD0_0000	FFD7_FFFF	BDE.10
	FFD8_0000	FFDF_FFFF	BDE.11
	FFE0_0000	FFE7_FFFF	BDE.12
	FFE8_0000	FFEF_FFFF	BDE.13
	FFF0_0000	FFF7_FFFF	BDE.14
BIOS2 - Data space for SPI and LPC	FFF8_0000	FFFB_FFFF	BDE.15; always enabled
BIOS - Data space for SPI and LPC	FFFC_0000	FFFF_FFFF	This BIOS region is enabled by default and can not be disabled. Reset boot vector is FFFF_FFF0.
ECAM Base Address	PCIEXBAR_LO_0_0_0_PCI and PCIEXBAR_HI_0_0_0_PCI	PCIEXBAR plus 256 MB in 32-bit address space	PCI Express Enhanced Configuration Access Mechanism (ECAM) location. PCI and PCIe Configuration Space accessible as memory-mapped accesses.
Protected Memory (Low) for VT-d	PLMBASE_VTDBAR	PLMLIMIT_VTDBAR	Area of protected memory located <4GB for VT-d.
4 GB to TOUUD-1 -- High DRAM Window			
High DRAM	1_0000_0000	TOUUD-1	High Main Memory. Top of Upper Usable DRAM.
TOUUD to 1024 GB -- High MMIO			
High MMIO	TOUUD	1024 GB	High MMIO for 64-bit MMIO
Protected Memory (High) for VT-d	PHMBASE_VTDBAR	PHMLIMIT_VTDBAR	Area of protected memory located >4GB for VT-d.

3.1.2 Host Memory Space—Relocatable Memory-Mapped I/O

Table 3-2, "Relocatable MMIO in Host Memory Space" lists the Memory-Mapped I/O that is relocatable in Host Memory Space. The I/O listed as being in 32-bit address space can be configured within the "Low MMIO" region shown in Table 3-1, "Host Memory Space Address Map". The I/O listed as being in 64-bit address space can be configured within the "High MMIO or Low MMIO" region of the same table.

Table 3-2. Relocatable MMIO in Host Memory Space (Sheet 1 of 5)

Memory Address Range Name [Size]	Start Address or Base Address (Hexadecimal)	End Address or Range (Hexadecimal)	Dependency/Comments
Dedicated Integrated Root Port for Intel® QuickAssist Technology	D6:F0 MEMBASE MEMLIMIT	variable length in 32-bit address space	As defined by the Memory Base register and Memory Limit register in the Function Configuration Space.
	D6:F0 PFBASEU PFBASE and PFLIMITU PFLIMIT	variable length in 64-bit address space	As defined by the Prefetchable Memory Base register (Upper and Lower) and Prefetchable Memory Limit register (Upper and Lower) in the Function Configuration Space. The two Upper registers are for 64-bit addressing.
Intel® QuickAssist Technology	Bus x:D0:F0 PSECRAMUBAR PSECRAMLBAR	512 KB in 64-bit address space	Intel® QuickAssist Technology, PF Memory Base Address Register
PCI Express RP[0] *Root Port Cluster 0, Root Port 0*	D9:F0 EXPPTMBAR (BAR1,BAR0)	128 KB in 64-bit address space	As defined by the Base Address Register 0 (BAR0) and Base Address Register 1 (BAR1) in the Function Configuration Space.
	D9:F0 MEMBASE MEMLIMIT	variable length in 32-bit address space	As defined by the Memory Base register and Memory Limit register in the Function Configuration Space.
	D9:F0 PFBASEU PFBASE and PFLIMITU PFLIMIT	variable length in 64-bit address space	As defined by the Prefetchable Memory Base register (Upper and Lower) and Prefetchable Memory Limit register (Upper and Lower) in the Function Configuration Space. The two Upper registers are for 64-bit addressing.
PCI Express RP[1] *Root Port Cluster 0, Root Port 1*	D10:F0 EXPPTMBAR (BAR1,BAR0)	128 KB in 64-bit address space	As defined by the Base Address Register 0 (BAR0) and Base Address Register 1 (BAR1) in the Function Configuration Space.
	D10:F0 MEMBASE MEMLIMIT	variable length in 32-bit address space	As defined by the Memory Base register and Memory Limit register in the Function Configuration Space.
	D10:F0 PFBASEU PFBASE and PFLIMITU PFLIMIT	variable length in 64-bit address space	As defined by the Prefetchable Memory Base register (Upper and Lower) and Prefetchable Memory Limit register (Upper and Lower) in the Function Configuration Space. The two Upper registers are for 64-bit addressing.
PCI Express RP[2] *Root Port Cluster 0, Root Port 2*	D11:F0 EXPPTMBAR (BAR1,BAR0)	128 KB in 64-bit address space	As defined by the Base Address Register 0 (BAR0) and Base Address Register 1 (BAR1) in the Function Configuration Space.
	D11:F0 MEMBASE MEMLIMIT	variable length in 32-bit address space	As defined by the Memory Base register and Memory Limit register in the Function Configuration Space.
	D11:F0 PFBASEU PFBASE and PFLIMITU PFLIMIT	variable length in 64-bit address space	As defined by the Prefetchable Memory Base register (Upper and Lower) and Prefetchable Memory Limit register (Upper and Lower) in the Function Configuration Space. The two Upper registers are for 64-bit addressing.

Table 3-2. Relocatable MMIO in Host Memory Space (Sheet 2 of 5)

Memory Address Range Name [Size]	Start Address or Base Address (Hexadecimal)	End Address or Range (Hexadecimal)	Dependency/Comments
PCI Express RP[3] *Root Port Cluster 0, Root Port 3*	D12:F0 EXPPTMBAR (BAR1,BAR0)	128 KB in 64-bit address space	As defined by the Base Address Register 0 (BAR0) and Base Address Register 1 (BAR1) in the Function Configuration Space.
	D12:F0 MEMBASE MEMLIMIT	variable length in 32-bit address space	As defined by the Memory Base register and Memory Limit register in the Function Configuration Space.
	D12:F0 PFBASEU PFBASE and PFLIMITU PFLIMIT	variable length in 64-bit address space	As defined by the Prefetchable Memory Base register (Upper and Lower) and Prefetchable Memory Limit register (Upper and Lower) in the Function Configuration Space. The two Upper registers are for 64-bit addressing.
PCI Express RP[4] *Root Port Cluster 1, Root Port 0*	D14:F0 EXPPTMBAR (BAR1,BAR0)	128 KB in 64-bit address space	As defined by the Base Address Register 0 (BAR0) and Base Address Register 1 (BAR1) in the Function Configuration Space.
	D14:F0 MEMBASE MEMLIMIT	variable length in 32-bit address space	As defined by the Memory Base register and Memory Limit register in the Function Configuration Space.
	D14:F0 PFBASEU PFBASE and PFLIMITU PFLIMIT	variable length in 64-bit address space	As defined by the Prefetchable Memory Base register (Upper and Lower) and Prefetchable Memory Limit register (Upper and Lower) in the Function Configuration Space. The two Upper registers are for 64-bit addressing.
PCI Express RP[5] *Root Port Cluster 1, Root Port 1*	D15:F0 EXPPTMBAR (BAR1,BAR0)	128 KB in 64-bit address space	As defined by the Base Address Register 0 (BAR0) and Base Address Register 1 (BAR1) in the Function Configuration Space.
	D15:F0 MEMBASE MEMLIMIT	variable length in 32-bit address space	As defined by the Memory Base register and Memory Limit register in the Function Configuration Space.
	D15:F0 PFBASEU PFBASE and PFLIMITU PFLIMIT	variable length in 64-bit address space	As defined by the Prefetchable Memory Base register (Upper and Lower) and Prefetchable Memory Limit register (Upper and Lower) in the Function Configuration Space. The two Upper registers are for 64-bit addressing.
PCI Express RP[6] *Root Port Cluster 1, Root Port 2*	D16:F0 EXPPTMBAR (BAR1,BAR0)	128 KB in 64-bit address space	As defined by the Base Address Register 0 (BAR0) and Base Address Register 1 (BAR1) in the Function Configuration Space.
	D16:F0 MEMBASE MEMLIMIT	variable length in 32-bit address space	As defined by the Memory Base register and Memory Limit register in the Function Configuration Space.
	D16:F0 PFBASEU PFBASE and PFLIMITU PFLIMIT	variable length in 64-bit address space	As defined by the Prefetchable Memory Base register (Upper and Lower) and Prefetchable Memory Limit register (Upper and Lower) in the Function Configuration Space. The two Upper registers are for 64-bit addressing.

Table 3-2. Relocatable MMIO in Host Memory Space (Sheet 3 of 5)

Memory Address Range Name [Size]	Start Address or Base Address (Hexadecimal)	End Address or Range (Hexadecimal)	Dependency/Comments
PCI Express RP[7] *Root Port Cluster 1, Root Port 3*	D17:F0 EXPPTMBAR (BAR1,BAR0)	128 KB in 64-bit address space	As defined by the Base Address Register 0 (BAR0) and Base Address Register 1 (BAR1) in the Function Configuration Space.
	D17:F0 MEMBASE MEMLIMIT	variable length in 32-bit address space	As defined by the Memory Base register and Memory Limit register in the Function Configuration Space.
	D17:F0 PFBASEU PFBASE and PFLIMITU PFLIMIT	variable length in 64-bit address space	As defined by the Prefetchable Memory Base register (Upper and Lower) and Prefetchable Memory Limit register (Upper and Lower) in the Function Configuration Space. The two Upper registers are for 64-bit addressing.
SMBus 2.0 Controller - Host	D18:F0 SMTBAR (BAR1,BAR0)	1 KB in 64-bit address space	SMBus 2.0 Controller (Host)
SATA Controller 0	D19:F0 ABAR (BAR5)	2 KB in 32-bit address space	AHCI Base Address for SATA 3.1 Controller 0
SATA Controller 1	D20:F0 ABAR (BAR5)	2 KB in 32-bit address space	AHCI Base Address for SATA 3.1 Controller 1
USB Combo Controller	D21:F0 MBAR (BAR1,BAR0)	64 KB in 64-bit address space	USB3/USB2 combo controller
Dedicated Integrated Root Port for LAN Controller 0	D22:F0 MEMBASE MEMLIMIT	variable length in 32-bit address space	As defined by the Memory Base register and Memory Limit register in the Function Configuration Space.
	D22:F0 PFBASEU PFBASE and PFLIMITU PFLIMIT	variable length in 64-bit address space	As defined by the Prefetchable Memory Base register (Upper and Lower) and Prefetchable Memory Limit register (Upper and Lower) in the Function Configuration Space. The two Upper registers are for 64-bit addressing.
LAN Controller 0	Bus y:D0:Fn (BAR1, BAR0)	128 KB in 64-bit address space	LAN port controller, independent per function
	Bus y:D0:Fn BAR2	32B in 64-bit address space	LAN port controller, independent per function
	Bus y:D0:Fn (BAR5, BAR4)	16 KB in 64-bit address space	LAN port MSI-X, independent per function
Dedicated Integrated Root Port for LAN Controller 1	D23:F0 MEMBASE MEMLIMIT	variable length in 32-bit address space	As defined by the Memory Base register and Memory Limit register in the Function Configuration Space.
	D23:F0 PFBASEU PFBASE and PFLIMITU PFLIMIT	variable length in 64-bit address space	As defined by the Prefetchable Memory Base register (Upper and Lower) and Prefetchable Memory Limit register (Upper and Lower) in the Function Configuration Space. The two Upper registers are for 64-bit addressing.

Table 3-2. Relocatable MMIO in Host Memory Space (Sheet 4 of 5)

Memory Address Range Name [Size]	Start Address or Base Address (Hexadecimal)	End Address or Range (Hexadecimal)	Dependency/Comments
LAN Controller 1	Bus z:D0:Fn (BAR1, BAR0)	128 KB in 64-bit address space	LAN port controller, independent per function
	Bus z:D0:Fn BAR2	32B in 64-bit address space	LAN port controller, independent per function
	Bus z:D0:Fn (BAR5, BAR4)	16 KB in 64-bit address space	LAN port MSI-X, independent per function
Intel® ME HECI 1	D24:F0 HECI1_MMIO_MBAR	4 KB in 64-bit address space	
Intel® ME HECI 2	D24:F1 HECI2_MMIO_MBAR	4 KB in 64-bit address space	
Intel® ME KT	D24:F3 KT_HOST_MEMBAR	4 KB in 32-bit address space	Intel® ME Keyboard and Text (KT) Redirection
Intel® ME HECI 3	D24:F4 HECI3_MMIO_MBAR	4 KB in 64-bit address space	
HS-UART Controller 0	D26:F0 MEMBA	256 Bytes in 32-bit address space	HS-UART
HS-UART Controller 1	D26:F1 MEMBA	256 Bytes in 32-bit address space	HS-UART

Table 3-2. Relocatable MMIO in Host Memory Space (Sheet 5 of 5)

Memory Address Range Name [Size]	Start Address or Base Address (Hexadecimal)	End Address or Range (Hexadecimal)	Dependency/Comments
PMC	D31:F2 PBASE	512 B in 32-bit address space	PMC memory space
SMBus 2.0 Controller - Legacy	D31:F4 SMBMBAR	256B in 64-bit space as configured in PSF address space	SMBus 2.0 Controller (Legacy). Used for SPD interface to memory modules.
SPI Controller	D31:F5 BIOS_SPI_BAR0	4KB in 32-bit address space	SPI memory space

3.2 Host Root Space—I/O Space

The SoC implements 64 kilobytes plus three (65,539 decimal) bytes of I/O Space addressing. For I/O instructions that access the highest-addressed ports (FFFDh - FFFFh), there are situations where the three bytes beyond the 64-KB boundary are accessed. There are no resources for these highest-addressed three bytes.

For example, a four-byte read of I/O address FFFEh results in reading two data bytes within the 64-KB boundary and two data bytes beyond the 64-KB boundary. The latter two data bytes have no resources and must be ignored.

The location of the I/O Port register being written to, or read from, via an I/O instruction (IN, INS, OUT, OUTS) is calculated by the SoC. The register can be physically located within the SoC, LPC device, SPI device, or on a PCI Express* device connected to one of the integrated Root Ports.

The primary subtractive-decode agent in Host Root Space is the Primary-to-Sideband Bridge (P2SB) and not the Low Pin Count (LPC) controller. Any transaction reaching the P2SB which does not match a valid mapped region is terminated. Such transactions are either dropped for Posted Requests or result in an Unsupported Request (UR) for Non-Posted Requests.

Warning: Each SoC PCIe* integrated Root Port can be configured by the Operating System (OS) and BIOS to claim a portion of I/O space addresses. When an I/O instruction accesses an I/O Port within this claimed portion, the transaction is routed to the devices on the particular Root Port. The OS and BIOS must ensure that the integrated PCIe Root Ports' claimed portions of I/O space are configured to not overlap the addresses of the I/O Port registers, mostly legacy device registers, located within the SoC.

The fixed-address I/O Port registers are in Table 3-3, "Host Fixed I/O Address Space".

The relocatable (BARs) I/O Port registers are in Table 3-4, "Host Relocatable I/O Address Space".

3.2.1 Host I/O Space—Fixed I/O Addresses

See Table 3-3, "Host Fixed I/O Address Space". The SoC calculates the physical location of an I/O Port register based on a number of conditions. The fixed-address ranges are either positively decoded in the System Agent or subtractively routed to the Primary to Sideband Bridge (P2SB).

In Table 3-3, "Host Fixed I/O Address Space":

- For address ranges listed as having NEG (negative) address decode, an I/O instruction is routed to the device listed in the table. This happens only if there is no enabled device with a BAR that instead captures the I/O address. If there is no BAR that captures the transaction, then the target device of the NEG decode must be enabled.
  - If the target device of the NEG decode is disabled, transactions to the address range are terminated.
- When an address range is listed as having a POS (positive) address decode and the address range is enabled, the I/O transaction is routed to a relocatable BAR. See Table 3-4, "Host Relocatable I/O Address Space". The target device responding to the I/O address can be integrated within or downstream of one of the PCIe Root Ports if the address is within the Root Port's I/O Base and Limit registers.
  - If the target device is disabled, transactions to the address range are terminated.
  - If the POS address range is disabled, the transaction is routed to the LPC controller.
- For address ranges listed as having Fabric address decode, the destination of the I/O transaction is determined by registers and configuration settings of the SoC. Falling into this category are COM1/COM2 I/O address which can be assigned to HSUART and the VGA Enabled (BCTL.VGAE=1) of the Root Ports. Here, if a positive decode of the I/O address is made, the I/O transaction is routed to the appropriate destination.

Table 3-3. Host Fixed I/O Address Space (Sheet 1 of 4)

Address (hex)	Address Decode	Targets	Register Control

3.3.1 How to Access Registers in PCI Configuration Space

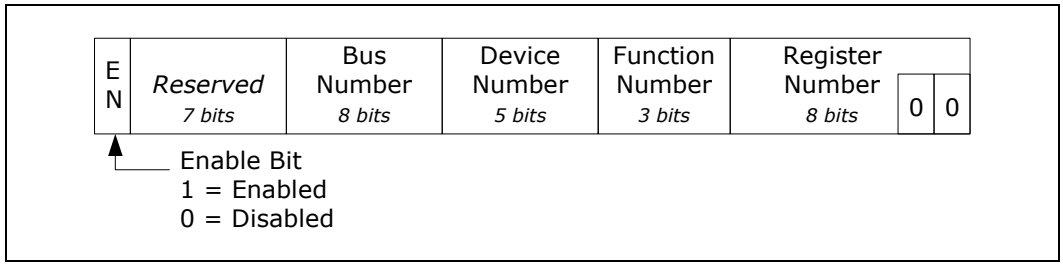
Access to the PCI configuration space registers is performed through one of two Configuration Access Methods (CAMs):

- I/O indexed - PCI compatible Configuration Access Mechanism (CAM)
- Memory mapped - PCI Express Enhanced Configuration Access Mechanism (ECAM)

CAM provides access to the first 256 bytes of the configuration registers for each of the 65,536 possible Functions in a system. It involves performing a DWORD I/O instruction to I/O address CF8h (CONFIG_ADDRESS) followed by another DWORD I/O instruction to I/O address CFCh (CONFIG_DATA). Bit 31 of CF8h must be set to a 1 for a Configuration Request cycle to be generated. CAM is described in the "Software Generation of Configuration Transactions" section of the *PCI Express Base Specification Revision 3.0*.

Figure 3-2, "DWORD Format of CONFIG_ADDRESS at I/O Address CF8h" shows the format of the DWORD for CF8h.

Figure 3-2. DWORD Format of CONFIG_ADDRESS at I/O Address CF8h



ECAM was introduced with PCI Express* and extends each function's configuration space to 4,096 bytes. The exact implementation details are product specific, and a general description of the ECAM is provided in the "PCI Express Enhanced Configuration Access" section of *PCI Express Base Specification Revision 3.0*.

The SoC implements ECAM through the Host Root Memory Space. There is a 256-MB relocatable region of memory addresses that provides access to all 4,096 bytes of configuration space for all 65,536 possible functions. This region can be located on a 256-MB memory address boundary within the first 4 GB addresses of Host Memory Space. See Table 3-1, "Host Memory Space Address Map". A 32-bit base memory address is defined by the PCIEXBAR_LO_0_0_0_PCI and PCIEXBAR_HI_0_0_0_PCI registers which are located in Configuration Space at offsets 60h and 64h or Bus 0, Device 0, Function 0.

ECAM utilizes a flat memory-mapped address space to access device configuration registers. This address space is reported by the system firmware to the OS. When using ECAM, in order to maintain compatibility with the PCI configuration addressing mechanisms, system software must access the extended configuration space using 32-bit data operations (32-bit aligned) only. These 32-bit operations include byte enables allowing only appropriate bytes within the DWORD to be accessed. Locked transactions to the PCI Express memory-mapped configuration address space are not supported. All changes made using either the CAM or the ECAM are equivalent.

To access Configuration Space via the ECAM:

1. Use the CAM to enable the ECAM by writing 1 to bit 0 of PCIEXBAR_LO_0_0_0_PCI.
2. Use the CAM to write an appropriate ECAM base address into PCIEXBAR (PCIEXBAR_LO_0_0_0_PCI and PCIEXBAR_HI_0_0_0_PCI).
3. Calculate the memory-mapped address of the Configuration Register to be accessed:
   Memory Address =
   PCIEXBAR +
   Bus Number * 1 MB +
   Device Number * 32 KB +
   Function Number * 4 KB +
   Configuration Register Offset
4. Use a memory write or memory read cycle to the calculated memory-mapped address to write or read the PCI Configuration Register.

If the PCI Bus Number is zero, the SoC generates a Type 0 Configuration Request cycle. If the PCI Bus Number is non-zero, the SoC generates a Type 1 Configuration Request cycle.

3.4 Host Root Space - Host Sideband Register Access

3.4.1 Using SBREG_BAR Method

The SBREG_BAR access method is safe for SoC product SKUs that have multiple threads. It is the required method for accessing the Host Sideband registers.

The SoC provides access to its Host Sideband registers through a relocatable, 16-MB area of Host Memory Space. The base address is the 64-bit SBREG_BAR (SBREG_BAR, SBREG_BARH) register located in P2SB Bridge's Host Configuration Space B:0, D:31, F:1, offset 10h and 14h. The access mechanism allows direct mapping to 16 bits of byte-addressable register space for each of the integrated Host Sideband registers.

All accesses to the SBREG_BAR region of Host Memory Space are DWord-aligned DWords.

- Writes larger than one DWord are completed normally, but the write data beyond the first DWord is discarded.
- Reads larger than one DWord result in a Unsupported Request (UR) response.
- Byte enables within the DWord are honored normally, enabling accesses of less than one DWord.

3.4.2 Accessing System Agent Sideband Registers

BIOS needs to access the B_CR_BMISC_0_0_0_MCHBAR (BMISC) Sideband register of the SoC System Agent in order to set certain access boundaries of Host Memory Space.

To access this and other special System Agent registers, the SoC provides a secure, Memory-Mapped I/O (MMIO) aperture at the 64 bit memory address defined by MCHBAR_LO_0_0_0_PCI and MCHBAR_HI_0_0_0_PCI to expose certain, internal registers of the System Agent. The MCHBAR base address registers are defined in Host Configuration Space at Bus 0, Device 0, Function 0, offset 48h and 4Ch. Not all System Agent Registers are accessible in this aperture.

3.5 Key Registers Mentioned in this Chapter

The registers used to configure the system Host Memory-Space map are listed here. This information is provided primarily for BIOS developers.

3.5.1 Key Registers in Host Configuration Space

The registers listed in Table 3-6, "Configuration Registers Used to Configure Host Memory Space" are accessed using the CAM method described previously. Once the PCIEXBAR is set using CAM, these registers are also accessible using ECAM.

Table 3-6. Configuration Registers Used to Configure Host Memory Space (Sheet 1 of 2)

PCI Bus, Device, Function (decimal)	Offset (hex)	Register Short Name	Description
SoC System Agent Registers[1]			
B0,D0,F0	48	MCHBAR_LO_0_0_0_PCI	Memory Controller Hub Base Address Register (MCHBAR). Used for accessing certain Host Sideband Registers
	4C	MCHBAR_HI_0_0_0_PCI	
	54	DEVEN_0_0_0_PCI	Used to enable/hide SoC resources
	60	PCIEXBAR_LO_0_0_0_PCI	PCI Express Enhanced Configuration Access Mechanism (ECAM) location
	64	PCIEXBAR_HI_0_0_0_PCI	
	A8	TOUUD_LO_0_0_0_PCI	Top of Upper Usable DRAM TOUUD
	AC	TOUUD_HI_0_0_0_PCI	
	B0	BDSM_0_0_0_PCI	Base address of the Data Stolen Memory (DSM)
	B4	BGSM_0_0_0_PCI	Base address of the Graphics Stolen Memory (GSM)
	B8	TSEGMB_0_0_0_PCI	Base address of TSEG DRAM memory
	BC	TOLUD_0_0_0_PCI	Top of Lower Usable DRAM (TOLUD) range and start of the Lower MMIO Address range
SPI Controller[2]			
B0,D31,F5	D8	BIOS_SPI_BDE	BIOS Decode Enable (BDE) register when BIOS is resident on SPI.
LPC Controller[3]			
B0,D31,F0	84	LGIR1	LPC Generic I/O Range #1
	88	LGIR2	LPC Generic I/O Range #2
	8C	LGIR3	LPC Generic I/O Range #3
	90	LGIR4	LPC Generic I/O Range #4
	D8	BDE	BIOS Decode Enable (BDE) register when BIOS is resident on the LPC bus.

Table 3-6. Configuration Registers Used to Configure Host Memory Space (Sheet 2 of 2)

PCI Bus, Device, Function (decimal)	Offset (hex)	Register Short Name	Description
Primary to Side Band (P2SB) Bridge and Integrated Error Handler (IEH)			
B0,D31,F1	10	SBREG_BAR	Lower DWORD of the base address for Host Sideband register access.
	14	SBREG_BARH	Upper DWORD of the base address for Host Sideband register access.
	54	RCFG	Routing Configuration
	64	IOAC	IOxAPIC Configuration
PCI Express Integrated Root Port Cluster 0			
B0,D9,F0	3E	BCTL	Bridge Control Register - Root Port 0
B0,D10,F0	3E	BCTL	Bridge Control Register - Root Port 1
B0,D11,F0	3E	BCTL	Bridge Control Register - Root Port 2
B0,D12,F0	3E	BCTL	Bridge Control Register - Root Port 3
PCI Express Integrated Root Port Cluster 1			
B0,D14,F0	3E	BCTL	Bridge Control Register - Root Port 4
B0,D15,F0	3E	BCTL	Bridge Control Register - Root Port 5
B0,D16,F0	3E	BCTL	Bridge Control Register - Root Port 6
B0,D17,F0	3E	BCTL	Bridge Control Register - Root Port 7

1. The System Agent automatically shadows these accesses to certain other SoC registers. These registers must not be accessed by BIOS via sideband.
2. The sampled Boot BIOS Strap (BBS) hard strap determines whether the BIOS Decode Enable is taken from the SPI Controller function B0,D31,F5 or from the LPC function B0,D31,F0.
3. The sampled LPC Decode Select hard strap determines whether the B0,D31,F0 BIOS Decode Enable belongs to the LPC Controller.

3.5.2 Key Registers in Host Memory Space

Table 3-7. Relocatable Host Memory-Mapped Aperture to Access Certain System Agent Registers

Base Address Register (BAR) Short Name	Offset from BAR (hex)	Register Short Name	Description
MCHBAR_LO_0_0_0_PCI, MCHBAR_HI_0_0_0_PCI	6800	B_CR_BMISC_0_0_0_MCHBAR	Miscellaneous Configuration Register. BIOS must use MCHBAR to program BMISC.
	6C80	B_CR_DEFVTDBAR_0_0_0_MCHBAR	Default VTd Base Address

3.5.3 Key Registers in Host I/O Space

Table 3-8. Fixed-Address Host I/O-Mapped Registers to Access Configuration Space

I/O Address (hexadecimal)	Register Short Name	Description
CF8	CONFIG_ADDRESS	DWORD containing the Configuration Register address. See Figure 3-2, "DWORD Format of CONFIG_ADDRESS at I/O Address CF8h".
CFC	CONFIG_DATA	DWORD containing the Configuration Register data.

§ §

4 Strapping and Configuration

This chapter describes how to configure the SoC through the use of hard and soft straps and provides descriptions on what the different strapping options do. This chapter will cover two kinds of strapping configurations: hard straps or pin straps and soft straps. This chapter will also briefly address in-field programmable fuses pertaining to the Innovation Engine (IE) for more information please refer to Chapter 37, "Innovation Engine."

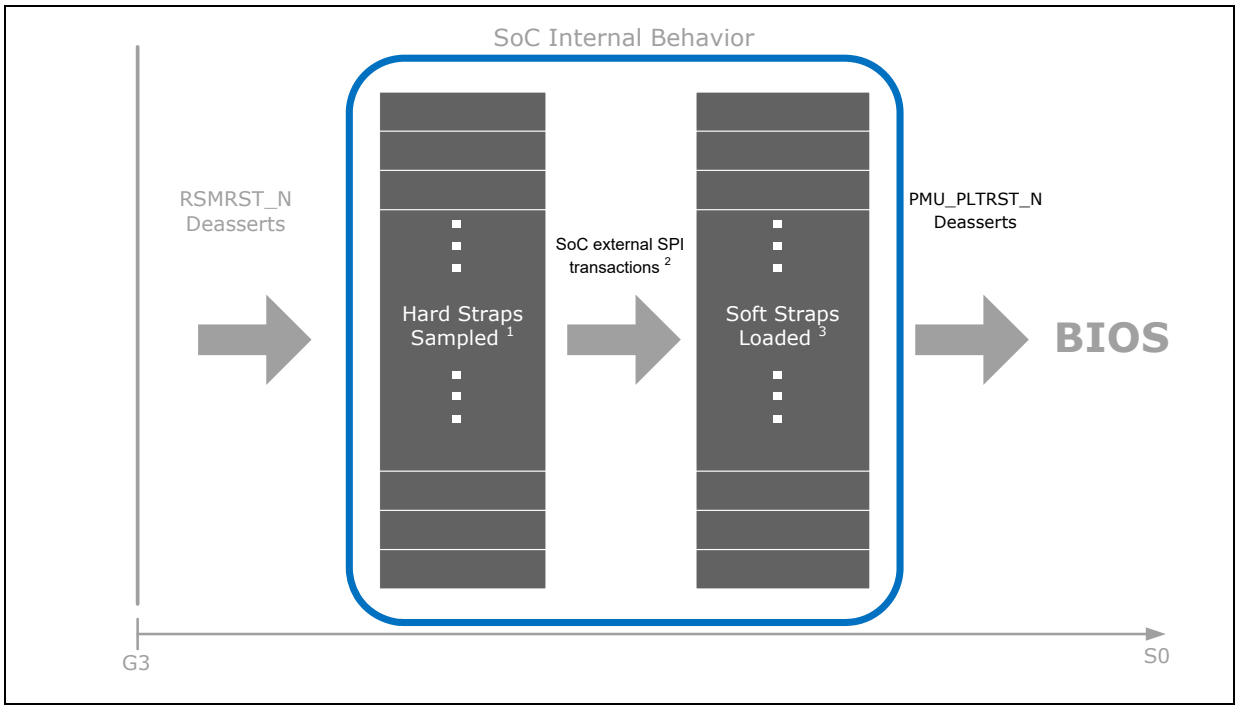
Strapping is needed to enable, disable, or alter default configurations in the SoC. This chapter will provide the descriptions of these strapping signals, their functionality and the configurations they support. For Soft Straps, please refer to Section 4.2, "SoC Soft Straps" in this chapter.

For this SoC, hard straps are the earliest form of user-defined configuration available in the SoC boot sequence. Hard straps are connected to a physical ball or pin depending on the SoC's package and thus are typically very few in number. Some hard straps, will drive a separate function such as a GPIO from the same SoC ball or pin after the hard strap sampling period, which ends 400 ns after the deassertion of the signal RSMRST_N. If hard straps are not set properly, a user is likely to see unexpected complications while trying to boot the SoC. This includes the possibility of no code being fetched from the boot flash memory device since hard straps are responsible for configuring which boot interface will be used by the SoC. It is recommended that customers take precautions and allow themselves the flexibility to easily configure hard straps in their designs through the use of jumpers or other means when first starting a design and are still performing their design validation with the SoC. This allows customers to easily reconfigure hard straps and avoid potentially strenuous reworks to their design. A customer can choose to remove these jumpers or other means for the production version of their design to save on BOM cost. Please refer to Section 4.1, "SoC Hard (Pin) Straps" of this chapter for more information on configuring hard straps.

Soft straps are the second earliest form of user-defined configuration available in the SoC boot sequence and unlike hard straps they are numerous. This SoC has over 2000 soft strap bits which live in the descriptor region of the boot flash memory device. Some soft straps rely on one soft strap bit to configure one setting in the SoC, other soft straps require four or more soft strap bits to configure one setting in the SoC. This chapter will refer to a soft strap as a single or multiple soft strap bits that are required to configure one SoC setting and are listed in Table 4-3, "Flash Descriptor Soft Straps." To be able to load the soft straps into the SoC, it is necessary to read them from the boot flash memory device connected to the SoC which will trigger transactions between the SoC and the device where the soft straps are stored at. i.e. if using a SPI flash memory device to store the soft straps, the user should be able to see and monitor the SPI transactions happening between the SoC and the SPI flash memory device when the SoC is reading the soft straps from the SPI device. Soft straps are required for many of the SoC controllers to come out of reset and as such it is necessary that soft straps are fetched by the SoC in order to continue with the SoC boot sequence. If no soft straps are found by the SoC, the SoC will stop its power on sequence before the signal PMU_SLP_S45_N deasserts. Soft Straps are fetched before the reset vector fetches the first BIOS instruction.

Figure 4-1, "Strap Loading Flow" shows that the strap loading flow starts with the deassertion of the reset signal RSMRST_N, after which the hard straps are sampled followed by the soft straps. The SoC requires that the platform SUSCLK is stable before soft straps are fetched from the boot flash memory device attached to the SoC through the SPI interface. Additionally, the SoC needs to finish reading soft straps before PMU_SLP_S45_N deasserts or the SoC will not progress further in its power on sequence. After PMU_PLTRST_N deasserts, the board follows the boot sequencing flow to the BIOS.

Figure 4-1. Strap Loading Flow



Notes:

1. Hard straps are responsible for configuring which boot interface will be used by the SoC and hence where the SoC will try to read the soft straps from. Please refer to table Table 4-2, "Boot interface Hard Strap/ Pin Strap Configurations" for more information.
2. Platform SUSCLK must be stable before SPI transactions are initiated.
3. Soft Straps live in the descriptor region of the boot memory flash device that can reside over the SPI interface. The SoC needs to finish reading soft straps before the signal PMU_SLP_S45_N deasserts or the SoC will not progress further in its power on sequence.

4.1 SoC Hard (Pin) Straps

Hard straps are configuration signals connected to a physical ball or pin in the SoC depending on the SoC packaging, hence sometimes hard straps are also called pin straps. Since hard straps are connected to a single ball or pin, each hard strap configures a different SoC setting and can only have one of two values: 0 (low) or 1 (high). In order to configure the SoC hard strap to a 1 (high), a pull up is required. In order to configure the SoC hard strap to a 0 (low), a pull down is required. To configure a hard strap pull up (PU) or pull down (PD), a customer can choose to use the SoC internal hard strap default PU/PD or they can force the hard strap with an external PU/PD implemented on the platform.

When configuring hard straps with the SoC internal PU/PD, there is no need to connect the hard strap ball or pin to any termination on the board, it can be left floating. However, there is no way to configure the SoC internal hard strap from a PU to a PD or vice-versa, so the hard strap default will always be either a PU or a PD. See Table 4-1, "SoC Hard Straps/Pin Straps and Descriptions" to check the internal SoC hard strap default PU/PD. When a customer does not require the hard strap setting associated with the default internal SoC PU/PD, an external PU resistor tied to a voltage rail or a PD resistor tied to ground is required to be used on the platform.

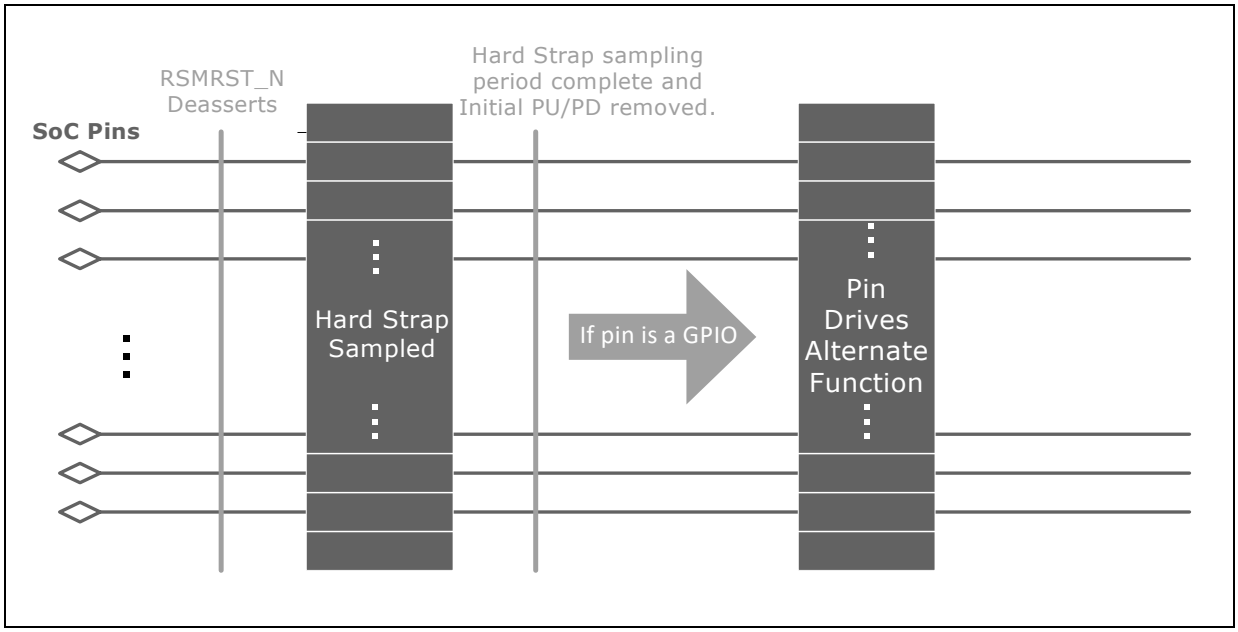
When configuring hard straps with an external PU/PD implemented on the board, the internal SoC PU/PD has to be forced to a new state by the external PU/PD. It is recommended that customers take precautions and allow themselves the flexibility to easily configure hard straps in their designs though the use of jumpers or other means when first starting a design and are still performing their design validation with the SoC. This allows to easily reconfigure hard straps and avoid potentially strenuous reworks to the design. These jumpers or other means can be removed for the production version of the design to save on BOM cost.

Each of the hard strap pins is briefly configured as an SoC input during system power on and its state is sampled during the hard strap sampling period which ends 400 ns after the deassertion of the resume reset signal RSMRST_N; the state of the SoC pin or ball is subsequently latched by the SoC hardware. The platform SUSCLK does not need to be stable for hard straps to be sampled.

After the hard strap sampling period, the internal SoC PU/PD associated with the hard straps are removed and if the SoC pin or ball is also a GPIO, then the SoC will drive the GPIO as the alternate function. The GPIO pin should not be driven by an external device during the hard strap sampling period. Customer should take precautions to ensure this does not happen during the SoC power on sequence. If an external PU/PD was used on the hard strap and the pin is used as a GPIO after the hard strap sampling period, then the external PU/PD on the platform will also affect the GPIO signal. For more information on the hard strap pins refer to Table 4-1, "SoC Hard Straps/Pin Straps and Descriptions" for alternate functions refer to Section 39.1, "Directory of Signal Names and Pin Names". For an illustration see Figure 4-2, "Hard Strap Functionality".

Hard straps are responsible for configuring which boot interface will be used by the SoC to read soft straps and fetch BIOS code from. If hard straps are set incorrectly, soft straps will not be fetched and the SoC will not boot. Please refer to Table 4-2, "Boot interface Hard Strap/ Pin Strap Configurations" for more information.

Figure 4-2. Hard Strap Functionality



Note: It is important to ensure that pin straps are always connected to the correct voltage rail when pulled up. Most hard straps are tied to the V3P30 rail Voltage Group, with the exception of "Top Swap Override" Hard Strap which is in GPIO[3] Pin and should be tied to V1P8 Voltage Rail. Also the if the GPIO pin is connected to an external device, that external device should not drive the hard strap for at least the duration of the hard strap sampling period.

In Table 4-1, "SoC Hard Straps/Pin Straps and Descriptions", hard strap pins default to inputs on power up. Their hard strap value is sampled within 400 ns of the rising edge (0 -> 1) of the active-low resume reset signal RSMRST_N. Most hard straps are tied to the V3P30 rail Voltage Group, with the exception of "Top Swap Override" Hard Strap which is tied to pin GPIO[3] and should be tied to V1P8 Voltage Rail.

Table 4-1. SoC Hard Straps/Pin Straps and Descriptions (Sheet 1 of 3)

Hard Strap	Pin Name	SoC Ball Location	Internal PU/PD[1]	Description
Boot BIOS Strap (BBS)	ERROR_N[1]	BR58	20K PD	This Hard Strap tells the SoC from which interface the BIOS code will be fetched • 0 = SPI • 1 = LPC ***Note:*** Please see table Table 4-2, "Boot interface Hard Strap/ Pin Strap Configurations" for information on how to set the Boot BIOS Strap (BBS), LPC Decode Select hard straps properly.
LPC Decode Select	ERROR_N[0]	BL52	20K PD	This Hard Strap tells the SoC to use the LPC interface. • 0 = Low Pin Count (LPC) • 1 = Reserved ***Note:*** The system board must supply a 3.3V voltage to the VCC_LPC_ESPI_3P3_1P8 rail in order for the interface to work. Connecting to the 1.8V rail is not supported. ***Note:*** Please see table Table 4-2, "Boot interface Hard Strap/ Pin Strap Configurations" for information on how to set the Boot BIOS Strap (BBS), LPC Decode Select hard straps properly.
Reserved for Intel	MCERR_N	BN52	20K PD	This Hard Strap must always be set to 0. Either through internal PD or an external PD.
Flash Security Override	IERR_N	BW50	20K PD	• 0 = Flash descriptor security locked (default). The security measures defined in the Flash Descriptor will be in effect. • 1 = Flash descriptor security unlocked ***Notes:*** 1. The internal pull-down is disabled after PLTRST_N deasserts. 2. Asserting Flash Security Override Hard Strap high on the rising edge of PWROK will also halt Intel ME after SoC bring up and disable runtime Intel ME features. This is a debug mode and must not be asserted after manufacturing/debug. 3. This signal is in the Suspend well (V3P30). 4. This hard strap might be named MFG_MODE_STRAP on other IA products.
No TCO Reboot Enable	GPIO[12]	BN56	20K PD	This Hard Strap tells the SoC to enable/disable the Total Cost of Ownership (TCO) watch dog timer (WDT) system reboot feature after the second WDT timeout. • 0 = Default State (the system will reboot after second WDT timeout) • 1 = Stop the TCO watchdog timer from rebooting the system after the second timeout. ***Note:*** More information on TCO see Section 16.6, "Total Cost of Ownership (TCO)".

Table 4-1. SoC Hard Straps/Pin Straps and Descriptions (Sheet 2 of 3)

Hard Strap	Pin Name	SoC Ball Location	Internal PU/PD[1]	Description
Top Swap Override	GPIO[3]	BN44	20K PD	• 0 = Top-swap feature is disabled. • 1 = Top-swap feature is enabled. ***Note:*** For more information on Top-Swap override see Section 56.2.12, "BIOS Control (BC)—Offset DCh" on page 2657.
Forces ME into Recovery Mode	ME_RCVR_N	BE44	20K PU	This signal can be configured via the FITc tool to be on 147 GPIO pins or not available. The default is pin GPIO148. This signal has an internal 20K pull-up to voltage 1.05V with a jumper option to a 1K pull-down resistor on platform. • 0 = Recovery mode • 1 = Normal operating mode for Intel ME. The default for production systems must be normal operating mode. ***Note:*** This signal will immediately put the ME in recovery mode when driven low. By default, driving the signal high will put the ME back in operational mode. A FITc configuration setting can be used to configure the system for legacy mode where operational mode will not be entered until the next reset.
Reserved for Intel	RSVD_BY58	BY58	20K PU	This signal has to be sampled in its default "Internal PU/PD" state. Platform cannot drive this signal until > 400ns after RSMRST_N de-asserts.
Reserved for Intel	ERROR_N[2]	CA50	20K PD	This signal has to be sampled in its default "Internal PU/PD" state. Platform cannot drive this signal until > 400ns after RSMRST_N de-asserts.
Reserved for Intel	LAN0_PORT0_SDP[3]	BA69	20K PU	This signal has to be sampled in its default "Internal PU/PD" state. Platform cannot drive this signal until > 400ns after RSMRST_N de-asserts.
Reserved for Intel	LAN0_PORT1_SDP[3]	W58	20K PU	This signal has to be sampled in its default "Internal PU/PD" state. Platform cannot drive this signal until > 400ns after RSMRST_N de-asserts.
Reserved for Intel	GPIO[0]	BF70	20K PU	This signal has to be sampled in its default "Internal PU/PD" state. Platform cannot drive this signal until > 400ns after RSMRST_N de-asserts.
Reserved for Intel	GPIO[1]	BK69	20K PU	This signal has to be sampled in its default "Internal PU/PD" state. Platform cannot drive this signal until > 400ns after RSMRST_N de-asserts.
Reserved for Intel	GPIO[2]	BK71	20K PU	This signal has to be sampled in its default "Internal PU/PD" state. Platform cannot drive this signal until > 400ns after RSMRST_N de-asserts.

Table 4-1. SoC Hard Straps/Pin Straps and Descriptions (Sheet 3 of 3)

Hard Strap	Pin Name	SoC Ball Location	Internal PU/PD[1]	Description
Reserved for Intel	SATA0_SDOUT	BU57	20K PU	This signal has to be sampled in its default "Internal PU/PD" state. Platform cannot drive this signal until > 400ns after RSMRST_N de-asserts.
Reserved for Intel	SMB_LAN_ALRT_N	BN66	20K PU	This signal has to be sampled in its default "Internal PU/PD" state. Platform cannot drive this signal until > 400ns after RSMRST_N de-asserts.
Reserved for Intel	SUS_STAT_N	BV58	20K PU	This signal has to be sampled in its default "Internal PU/PD" state. Platform cannot drive this signal until > 400ns after RSMRST_N de-asserts.
Reserved for Intel	FLEX_CLK_SE[0]	BG48	20K PD	This signal has to be sampled in its default "Internal PU/PD" state. Platform cannot drive this signal until > 400ns after RSMRST_N de-asserts.
Reserved for Intel	FLEX_CLK_SE[1]	CA48	20K PU	This signal has to be sampled in its default "Internal PU/PD" state. Platform cannot drive this signal until > 400ns after RSMRST_N de-asserts.
Reserved for Intel	UART0_TXD	CA52	20K PD	This signal has to be sampled in its default "Internal PU/PD" state. Platform cannot drive this signal until > 400ns after RSMRST_N de-asserts.
Reserved for Intel	UART1_TXD	BN59	20K PU	This signal has to be sampled in its default "Internal PU/PD" state. Platform cannot drive this signal until > 400ns after RSMRST_N de-asserts.

Notes:
1. The internal PU/PD is only applied during the hard strap sampling period.
2. Strap sampling period is 400 ns after the deassertion of the RSMRST_N signal.

In order for the SoC to properly fetch BIOS code from the flash storage device over the SPI interface the hard strap Reserved for Intel (MCERR_N) has to be tied low (0) even if the LPC Decode Select (ERROR_N[0]) hard strap is tied low (0) which selects the LPC interface.

Please refer to Table 4-2, "Boot interface Hard Strap/ Pin Strap Configurations" for guidance on configuring the SoC boot interface and where the SoC will fetch BIOS code from. Failure to follow the hard strap configurations in the table below may cause the SoC to not come out of reset.

Table 4-2. Boot interface Hard Strap/ Pin Strap Configurations

		Hard Straps	
Boot interface	**LPC Enabled**	**Boot BIOS Strap (ERROR_N[1]) Internal 20K PD**	**LPC Decode Select (ERROR_N[0]) Internal 20K PD**
SPI	**LPC**	0	0
LPC	**LPC**	1	0

4.2 SoC Soft Straps

Soft straps are used to set and configure various features and configurations. Soft strap information is stored within the flash descriptor (region 0) of the Serial Peripheral Interface (SPI) firmware image (which resides on the SPI interface) and removes the need to use pull-up/pull-down resistors to hard strap most SoC features. At boot, the SPI controller reads the soft strap content from the SPI Flash and then distributes it to the various SoC controllers.

Soft Straps are configured utilizing the Intel FITc tool that is provided in the latest Intel® Server Platform Services Firmware Release for Harrisonville Microserver Platforms kit. It is recommended to use the latest version of the tool since that every time the kit is updated, so is the FITc tool.

The SoC provides the ability to use any of the 20 high speed I/O (HSIO) lanes as long as the number of HSIO lanes enabled is lesser than or equal to the number of HSIO lanes allowed on the SKU via fuses. For more information on how this flow works, see Figure 10-3, "Intel® ME-BIOS/UEFI Interactions in a System with Intel® SPS Firmware". HSIO lanes are configured via soft straps and allow the user to select the SoC controller that the HSIO lane will be connected to. If the HSIO lane is configured to either PCIe Gen 3/ SATA Gen 3/ USB3.0 then the HSIO lane will count as being used. However, if it is desired to disable a particular HSIO lane so that the HSIO lane will not count toward the maximum HSIO lane limit imposed by the SKU, then the soft strap configuration setting of "0x2; HSIO Lane not used" must be programed into the HSIO Lane Assignment soft straps. In addition to configuring the SoC FIA via the HSIO Lane Assignment soft straps to select the number of HSIO lanes used and the SoC controllers they connect to, it is also necessary to configure the individual SoC controllers via soft straps to ensure proper SoC behavior. Please follow the following guidance:

- For each HSIO lane assigned to a SATA controller in the HSIO Lane Assignment soft strap section, configure the respective SATA controller to receive the HSIO lane via the HSIO Lane Configuration from SATA Controller section.
- For each HSIO lane assigned to a PCIe root port cluster in the HSIO Lane Assignment soft strap section, configure the respective PCIe root port cluster to support the desired PCIe configuration by configuring settings such as enabling PCIe root ports in the PCIe Bifurcation and Settings section. Once a PCIe root port is disabled via soft strap, it cannot be enabled via BIOS or registers, soft straps take priority.
- For each SoC HSIO controller being used, make sure that it is enabled via the soft straps found in the SoC Feature Disable. Once an SoC controller is disabled via soft strap, it cannot be turned back on unless the soft strap region is updated in the descriptor region of the boot memory flash device and an A/C power cycle is performed on the system.

Some of the SoC soft straps can also be configured without the need to flash the boot flash memory device with a new soft strap configuration in the descriptor region. Instead BIOS is able to request the ME over a HECI message that certain soft straps be reconfigured after a global reset when booting the SoC. For information on how this flow works, please see Figure 10-3, "Intel® ME-BIOS/UEFI Interactions in a System with Intel® SPS Firmware." The soft straps that are able to be dynamically updated by this feature are limited to the following:

- FIA Mux configuration - HSIO Lane Assignment soft straps
- HSIO lane configuration for SATA controllers - HSIO Lane Configuration from SATA Controller soft straps
- PCIe root port cluster configuration (PCIe Bifurcation and Settings) - PCIe* Root Port Cluster [0-1] - "Root Port [0-7] Enable" soft straps
- PCIe root port cluster configuration (PCIe Bifurcation and Settings) - PCIe* Root Port Cluster [0-1] - "Root Port [0-7] x1 Slot Width" soft straps

Note: If no soft straps are found by the SoC, the SoC will stop its power on sequence before PMU_SLP_S45_N deasserts. Soft Straps are fetched before the reset vector fetches the first BIOS instruction.

The Flash Descriptor Soft Straps Table 4-3, "Flash Descriptor Soft Straps" are grouped by SoC features rather than the numerical order of soft straps in the descriptor region of the SPI Flash image.

Table 4-3. Flash Descriptor Soft Straps (Sheet 1 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
Power Delivery						
1	+ 4h	15	DRAM VDDQ Voltage Rail - SVID Support	0x0; SVID for VDDQ Disabled 0x1; SVID for VDDQ Enabled	0x1	Tells the SoC if the VDDQ voltage rail supports Serial Voltage Identification (SVID) via SVID_CLK, SVID_DATA and SVID_ALERT pins. If SVID is disabled then the VDDQ rail is static.
2	+ 8h	0	LAN Controller 0 - Powered in S5 Enable	0x0; Not powered in S5 WoL not supported 0x1; Powered in S5 WoL possible	0x1	Tells the SoC that LAN Controller 0 is powered in S5 power state which allows Wake on LAN (WoL) support. **Note:** Setting this strap to "0x0; Not powered in S5; WoL not supported" will cause LAN Controller 0 and 1 to not support WoL regardless of the "LAN Controller 1 Powered in S5 Enable" soft strap setting.
3	+ Ch	0	LAN Controller 1 - Powered in S5 Enable	0x0; Not powered in S5 WoL not supported 0x1; Powered in S5 WoL possible	0x1	Tells the SoC that LAN Controller 1 is powered in S5 power state which allows Wake on LAN support **Note:** LAN Controller 0 Powered in S5 must be set to "Powered in S5; WoL possible" for LAN Controller 1 to function in S5

Table 4-3. Flash Descriptor Soft Straps (Sheet 2 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
Power Sequence and Reset - PMC Knobs and Settings						
4	+ 10h	9:8	t573 Timing: COREPWROK to PMU_PLTRST_N Delay	0x0; 100 ms (default) 0x1; 50 ms 0x2; 5 ms 0x3; 1 ms	0x0	Tell the SoC to control timing t573 which is the minimum timing from the assertion of COREPWROK and the de-assertion of the PMU_PLTRST_N signal **Note:** The default setting of 100ms is chosen to be conservative, but the typical preferred setting is expected to be 1ms.
6	+ 18h	11:8	IE FW Launch Time - Out Multiplier	0x0; 8 sec 0x1; 16 sec 0x2; 24 sec 0x3; 32 sec 0x4; 40 sec 0x5; 48 sec 0x6; 56 sec 0x7; 64 sec 0x8; 72 sec 0x9; 80 sec 0xA; 88 sec 0xB; 96 sec 0xC; 104 sec 0xD; 112 sec 0xE; 120 sec 0xF; 128 sec	0x0	Tells the SoC the watch dog timer time before assuming the IE FW is hung on boot and the system needs to be reset. **Note:** Soft Strap "SS6 bit [17] - IE FW Host Boot Preparation Enable" has to be enabled for this strap to have any effect.
6	+ 18h	16	AG3E Boot Select	0x0; System will boot to S0. 0x1; System wait for wake event (S4/S5).	0x1	Tells the SoC to return the system to S0 or S4/S5 power states after power is applied for the first time. Refer to Section 16.10.2, "Initiating State Changes when in the G3 Mechanical-Off State" for additional information about G3 transitions to the S0 and S5 states. **Note:** If the system lost power in S4, then it will return to an S4-like state. In the S5 state, power button or any enabled wake events that were preserved through the power failure are valid wake events and will return the system to S0. See Chapter 16, "Initiating State Changes when in the G3 Mechanical-Off State".
6	+ 18h	17	IE FW Host Boot Preparation Enable	0x0; Do not wait for IE FW 0x1; Wait for IE FW	0x0	Tells the SoC to wait / do not wait for positive indication from IE FW before proceeding with Host boot.
6	+ 18h	29	PMU_RESETBUTTON_N De-bounce	0x0; 16-ms de-bounce 0x1; No de-bounce	0x0	Tells the SoC to de-bounce the PMU_RESETBUTTON_N pin for 16-ms.

Table 4-3. Flash Descriptor Soft Straps (Sheet 3 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
SoC Feature Disable						
5	+ 14h	0	LAN Controller 0 Disable	0x0; LAN Ctrl 0 Enabled 0x1; LAN Ctrl 0 Disabled	0x0	Tells the SoC to disable LAN Controller 0. **Note:** Setting this strap to "LAN Controller 0 Disabled" will cause LAN Controller 1 not to function.
5	+ 14h	1	LAN Controller 1 Disable	0x0; LAN Ctrl 1 Enabled 0x1; LAN Ctrl 1 Disabled	0x0	Tells the SoC to disable LAN Controller 1. **Note**: LAN Controller 0 Disable strap must be set to "LAN Ctrl 0 Enabled" for LAN Controller 1 to function.
5	+ 14h	2	SATA Controller 0 Disable	0x0; SATA Ctrl 0 Enabled 0x1; SATA Ctrl 0 Disabled	0x0	Tells the SoC to disable SATA Controller 0. **Note:** Disabling SATA Controller 0 has no effect on SATA Controller 1 functionality. If set to "SATA Ctrl 0 Disabled" set the soft straps "HSIO Lane 4-11 Select" to a setting that is NOT the "SATA" setting. Also set soft straps "SATA Controller 0 - Assign HSIO Lane 4-11 to Port 0-7" to setting "0x1 - HSIO Lane Not assigned to SATA Controller 0" If the SoC SATA is used then one of the following soft straps must also be set to enabled: SS 5 bit [4] PCIe Root Port Cluster 0 Disable OR SS 5 bit [5] PCIe Root Port Cluster 1 Disable OR SS 5 bit [7] USB Combo Controller Disable AND the requirements in this SATA NOTE must be met.
5	+ 14h	3	SATA Controller 1 Disable	0x0; SATA Ctrl 1 Enabled 0x1; SATA Ctrl 1 Disabled	0x0	Tells the SoC to disable SATA Controller 1. **Note:** Disabling SATA Controller 1 has no effect on SATA Controller 0 functionality. If set to "SATA Ctrl 0 Disabled" set the soft straps "HSIO Lane 12-19 Select" to a setting that is NOT the "SATA" setting. Also set soft straps "SATA Controller 1 - Assign HSIO Lane 12-19 to Port 0-7" to setting "0x1 - HSIO Lane Not assigned to SATA Controller 1" If the SoC SATA is used then one of the following soft straps must also be set to enabled: SS 5 bit [4] PCIe Root Port Cluster 0 Disable OR SS 5 bit [5] PCIe Root Port Cluster 1 Disable OR SS 5 bit [7] USB Combo Controller Disable AND the requirements in this SATA NOTE must be met.

Table 4-3. Flash Descriptor Soft Straps (Sheet 4 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
5	+ 14h	4	PCIe Root Port Cluster 0 Disable	0x0; PCIe Root Port Cluster 0 Enabled 0x1; PCIe Root Port Cluster 0 Disabled	0x0	Tells the SoC to disable PCIe Root Port Cluster 0. **Note:** Disabling PCIe Root Port Cluster 0 has no effect on PCIe Root Port Cluster 1 functionality. If set to "PCIe Root Port Cluster 0 Disabled" set the soft straps "HSIO Lane 4-7 Select" to a setting that is NOT the "PCIe" setting. HSIO Lanes 0-3 will be unusable and should be set to setting "0x2 - HSIO Lane not used" in the soft straps "HSIO Lane 0-3 Select".
5	+ 14h	5	PCIe Root Port Cluster 1 Disable	0x0; PCIe Root Port Cluster 1 Enabled 0x1; PCIe Root Port Cluster 1 Disabled	0x0	Tells the SoC to disable PCIe Root Port Cluster 1. **Note:** Disabling PCIe Root Port Cluster 1 has no effect on PCIe Root Port Cluster 0 functionality. If set to "PCIe Root Port Cluster 1 Disabled" set the soft straps "HSIO Lane 8-15 Select" to a setting that is NOT the "PCIe" setting.
5	+ 14h	6	Intel® QuickAssist Technology Disable	0x0; Intel® QAT Enabled 0x1; Intel® QAT Disabled	0x0	Tells the SoC to disable the Intel® QuickAssist Technology. **Note:** This strap has no effect if your SKU does not support Intel® QuickAssist Technology.
5	+ 14h	7	USB Combo Controller Disable	0x0; USB Combo Controller Enabled 0x1; USB Combo Controller Disabled	0x0	Tells the SoC to disable the USB Combo Controller (USB 2.0 + USB 3.0). **Note:** If set to "USB Combo Controller Disabled" set the soft straps "HSIO Lane 16-19 Select" to a setting that is NOT the "USB 3.0" setting.
5	+ 14h	8	eMMC Controller Disable	0x0; eMMC Enabled 0x1; eMMC Disabled	0x0	Tells the SoC to disable the eMMC (Embedded Multi-Media Card) Controller.
5	+ 14h	17	LAN Controller 0 - Port 1 Disable	0x0; LAN Controller 0 Port 1 Enabled 0x1; LAN Controller 0 Port 1 Disabled	0x0	Tells the SoC to disable Port 1 of LAN Controller 0. **Note**: This assumes that the "LAN Controller 0 Disable" soft strap is set to "LAN Ctrl 0 Enabled".
5	+ 14h	19	LAN Controller 1 - Port 1 Disable	0x0; LAN Controller 1 Port 1 Enabled 0x1; LAN Controller 1 Port 1 Disabled	0x0	Tells the SoC to disable Port 1 of LAN Controller 1. **Note:** Enabling LAN Controller 1 assumes LAN controller 1 is enabled in your SKU and the "LAN Controller 0/1 Disable" soft straps is set to "LAN Ctrl 0/1 Enabled".

Table 4-3. Flash Descriptor Soft Straps (Sheet 5 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
SoC Boot DDR Frequency						
7	+ 1Ch	7:4	SoC Boot DDR Frequency	0x0; Use SoC Fuse Value 0x9; 1866 0xA; 2133 0xB; 2400 **Note:** All other combinations are Reserved	0x0	Limits the speed of the SoC memory controlled during boot. This can be used to avoid SPD reset during MRC training.
BMC and BMC-less Mode Error logging						
5	+ 14h	20	SMB TCO Watch Dog Timer Disable	0x0 -BMC-less Mode: TCO WDT is enabled and any WDT timeout would be escalated to a global reset. If SS7 bit 1 is set to enable, then the error causing the WDT timeout would be logged in SUS_SCRATCH_1 register bit 0. 0x1 -BMC Mode: Prevents TCO WDT from escalating to a global reset due to errors in internal SoC IPs. This allows the BMC to be able to collect error data before global reset. Errors can be fetched from the integrated error handler (IEH).	0x0	Tells the SoC to disable the SMB TCO Watch Dog Timer. **Note:** This SMB TCO WDT is internal to PMC and is intended to be used in conjunction with SS7 bit [1] - "BMC and BMC-less Mode SUS_SCRATCH_1 bit[0] Error logging Enable" soft strap to help capture data should a crash happen under system configurations with or without BMC.
7	+ 1Ch	1	BMC and BMC-less Mode SUS_SCRATCH_1 bit[0] Error logging Enable	0x0 - SUS_SCRATCH_1 bit[0] Error logging Disabled. 0x1 -SUS_SCRATCH_1 bit[0] Error logging Enable.	0x0	When this bit is set, periodically check the status of the IEH and the RCC to check for errors that are impeding a warm reset. If errors are found, then log them into SUS_SCRATCH_1 bit[0].

Table 4-3. Flash Descriptor Soft Straps (Sheet 6 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
High-Speed I/O (HSIO) Configuration						
HSIO Lane Assignment						
21	+ 54h	19:18	HSIO Lane 0 Select	0x1; PCIe 0x2; HSIO Lane not used	Board Dependent	Tells the SoC to select if HSIO_RX_D [0] and HSIO_TX_D [0] pins are PCIe or not used.
21	+ 54h	21:20	HSIO Lane 1 Select	0x1; PCIe 0x2; HSIO Lane not used	Board Dependent	Tells the SoC to select if HSIO_RX_D [1] and HSIO_TX_D [1] pins are PCIe or not used.
21	+ 54h	23:22	HSIO Lane 2 Select	0x1; PCIe 0x2; HSIO Lane not used	Board Dependent	Tells the SoC to select if HSIO_RX_D [2] and HSIO_TX_D [2] pins are PCIe or not used.
21	+ 54h	25:24	HSIO Lane 3 Select	0x1; PCIe 0x2; HSIO Lane not used	Board Dependent	Tells the SoC to select if HSIO_RX_D [3] and HSIO_TX_D [3] pins are PCIe or not used.
19	+ 4Ch	9:8	HSIO Lane 4 Select	0x0; SATA 0x1; PCIe 0x2; HSIO Lane not used	Board Dependent	Tells the SoC to select if HSIO_RX_D [4] and HSIO_TX_D [4] pins are SATA, PCIe or not used. **Note:** Set soft strap "SATA Controller 0 - Assign HSIO Lane 4 to Port 0" to match this selection.
19	+ 4Ch	11:10	HSIO Lane 5 Select	0x0; SATA 0x1; PCIe 0x2; HSIO Lane not used	Board Dependent	Tells the SoC to select if HSIO_RX_D [5] and HSIO_TX_D [5] pins are SATA, PCIe or not used. **Note:** Set soft strap "SATA Controller 0 - Assign HSIO Lane 5 to Port 1" to match this selection.
19	+ 4Ch	13:12	HSIO Lane 6 Select	0x0; SATA 0x1; PCIe 0x2; HSIO Lane not used	Board Dependent	Tells the SoC to select if HSIO_RX_D [6] and HSIO_TX_D [6] pins are SATA, PCIe or not used. **Note:** Set soft strap "SATA Controller 0 - Assign HSIO Lane 6 to Port 2" to match this selection.
20	+ 50h	1:0	HSIO Lane 7 Select	0x0; SATA 0x1; PCIe 0x2; HSIO Lane not used	Board Dependent	Tells the SoC to select if HSIO_RX_D [7] and HSIO_TX_D [7] pins are SATA, PCIe or not used. **Note:** Set soft strap "SATA Controller 0 - Assign HSIO Lane 7 to Port 3" to match this selection.
20	+ 50h	3:2	HSIO Lane 8 Select	0x0; SATA 0x1; PCIe 0x2; HSIO Lane is not Used	Board Dependent	Tells the SoC to select if HSIO_RX_D [8] and HSIO_TX_D [8] pins are SATA, PCIe or not used. **Note:** Set soft strap "SATA Controller 0 - Assign HSIO Lane 8 to Port 4" to match this selection.

Table 4-3. Flash Descriptor Soft Straps (Sheet 7 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
20	+ 50h	5:4	HSIO Lane 9 Select	0x0; SATA 0x1; PCIe 0x2; HSIO Lane not used	Board Dependent	Tells the SoC to select if HSIO_RX_D [9] and HSIO_TX_D [9] pins are SATA, PCIe or not used. **Note:** Set soft strap "SATA Controller 0 - Assign HSIO Lane 9 to Port 5" to match this selection.
20	+ 50h	7:6	HSIO Lane 10 Select	0x0; SATA 0x1; PCIe 0x2; HSIO Lane not used	Board Dependent	Tells the SoC to select if HSIO_RX_D [10] and HSIO_TX_D [10] pins are SATA, PCIe or not used. **Note:** Set soft strap "SATA Controller 0 - Assign HSIO Lane 10 to Port 6" to match this selection.
20	+ 50h	9:8	HSIO Lane 11 Select	0x0; SATA 0x1; PCIe 0x2; HSIO Lane not used	Board Dependent	Tells the SoC to select if HSIO_RX_D [11] and HSIO_TX_D [11] pins are SATA, PCIe or not used. **Note:** Set soft strap "SATA Controller 0 - Assign HSIO Lane 11 to Port 7" to match this selection.
20	+ 50h	11:10	HSIO Lane 12 Select	0x0; SATA 0x1; PCIe 0x2; HSIO Lane not used	Board Dependent	Tells the SoC to select if HSIO_RX_D [12] and HSIO_TX_D [12] pins are SATA, PCIe or not used. **Note:** Set soft strap "SATA Controller 1 - Assign HSIO Lane 12 to Port 0" to match this selection.
20	+ 50h	13:12	HSIO Lane 13 Select	0x0; SATA 0x1; PCIe 0x2; HSIO Lane not used	Board Dependent	Tells the SoC to select if HSIO_RX_D [13] and HSIO_TX_D [13] pins are SATA, PCIe or not used. **Note:** Set soft strap "SATA Controller 1 - Assign HSIO Lane 13 to Port 1" to match this selection.
20	+ 50h	15:14	HSIO Lane 14 Select	0x0; SATA 0x1; PCIe 0x2; HSIO Lane not used	Board Dependent	Tells the SoC to select if HSIO_RX_D [14] and HSIO_TX_D [14] pins are SATA, PCIe or not used. **Note:** Set soft strap "SATA Controller 1 - Assign HSIO Lane 14 to Port 2" to match this selection.
21	+ 54h	17:16	HSIO Lane 15 Select	0x0; SATA 0x1; PCIe 0x2; HSIO Lane not used	Board Dependent	Tells the SoC to select if HSIO_RX_D [15] and HSIO_TX_D [15] pins are SATA, PCIe or not used. **Note:** Set soft strap "SATA Controller 1 - Assign HSIO Lane 15 to Port 3" to match this selection.

Table 4-3. Flash Descriptor Soft Straps (Sheet 8 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
20	+ 50h	25:24	HSIO Lane 16 Select	0x0; USB 3.0 0x1; SATA 0x2; HSIO Lane not used	Board Dependent	Tells the SoC to select if HSIO_RX_D [16] and HSIO_TX_D [16] pins are SATA or USB 3.0 or not used. **Note:** Set soft strap "SATA Controller 1 - Assign HSIO Lane 16 to Port 4" to match this selection.
20	+ 50h	27:26	HSIO Lane 17 Select	0x0; USB 3.0 0x1; SATA 0x2; HSIO Lane not used	Board Dependent	Tells the SoC to select if HSIO_RX_D [17] and HSIO_TX_D [17] pins are SATA or USB 3.0 or not used. **Note:** Set soft strap "SATA Controller 1 - Assign HSIO Lane 17 to Port 5" to match this selection.
20	+ 50h	29:28	HSIO Lane 18 Select	0x0; USB 3.0 0x1; SATA 0x2; HSIO Lane not used	Board Dependent	Tells the SoC to select if HSIO_RX_D [18] and HSIO_TX_D [18] pins are SATA or USB 3.0 or not used. **Note:** Set soft strap "SATA Controller 1 - Assign HSIO Lane 18 to Port 6" to match this selection.
20	+ 50h	31:30	HSIO Lane 19 Select	0x0; USB 3.0 0x1; SATA 0x2; HSIO Lane not used	Board Dependent	Tells the SoC to select if HSIO_RX_D [19] and HSIO_TX_D [19] pins are SATA or USB 3.0 or not used. **Note:** Set soft strap "SATA Controller 1 - Assign HSIO Lane 19 to Port 7" to match this selection.

Table 4-3. Flash Descriptor Soft Straps (Sheet 9 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
HSIO Lane Configuration from SATA Controller						
26	+ 68h	1:0	SATA Controller 0 - Assign HSIO Lane 4 to Port 0	0x0; HSIO Lane 4 Statically assigned to SATA Controller 0 Port 0 0x1; HSIO Lane 4 Not assigned to SATA Controller 0 Port 0	Board Dependent	Tells the SoC SATA Controller 0 if HSIO_RX_D [4] and HSIO_TX_D [4] pins are assigned to Port 0 **Note:** Set the "HSIO Lane 4 Select" soft strap to match this selection
26	+ 68h	3:2	SATA Controller 0 - Assign HSIO Lane 5 to Port 1	0x0; HSIO Lane 5 Statically assigned to SATA Controller 0 Port 1 0x1; HSIO Lane 5 Not assigned to SATA Controller 0 Port 1	Board Dependent	Tells the SoC SATA Controller 0 if HSIO_RX_D [5] and HSIO_TX_D [5] pins are assigned to Port 1 **Note:** Set the "HSIO Lane 5 Select" soft strap to match this selection
26	+ 68h	5:4	SATA Controller 0 - Assign HSIO Lane 6 to Port 2	0x0; HSIO Lane 6 Statically assigned to SATA Controller 0 Port 2 0x1; HSIO Lane 6 Not assigned to SATA Controller 0 Port 2	Board Dependent	Tells the SoC SATA Controller 0 if HSIO_RX_D [6] and HSIO_TX_D [6] pins are assigned to Port 2 **Note:** Set the "HSIO Lane 6 Select" soft strap to match this selection
26	+ 68h	7:6	SATA Controller 0 - Assign HSIO Lane 7 to Port 3	0x0; HSIO Lane 7 Statically assigned to SATA Controller 0 Port 3 0x1; HSIO Lane 7 Not assigned to SATA Controller 0 Port 3	Board Dependent	Tells the SoC SATA Controller 0 if HSIO_RX_D [7] and HSIO_TX_D [7] pins are assigned to Port 3 **Note:** Set the "HSIO Lane 7 Select" soft strap to match this selection
26	+ 68h	9:8	SATA Controller 0 - Assign HSIO Lane 8 to Port 4	0x0; HSIO Lane 8 Statically assigned to SATA Controller 0 Port 4 0x1; HSIO Lane 8 Not assigned to SATA Controller 0 Port 4	Board Dependent	Tells the SoC SATA Controller 0 if HSIO_RX_D [8] and HSIO_TX_D [8] pins are assigned to Port 4 **Note:** Set the "HSIO Lane 8 Select" soft strap to match this selection
26	+ 68h	11:10	SATA Controller 0 - Assign HSIO Lane 9 to Port 5	0x0; HSIO Lane 9 Statically assigned to SATA Controller 0 Port 5 0x1; HSIO Lane 9 Not assigned to SATA Controller 0 Port 5	Board Dependent	Tells the SoC SATA Controller 0 if HSIO_RX_D [9] and HSIO_TX_D [9] pins are assigned to Port 5 **Note:** Set the "HSIO Lane 9 Select" soft strap to match this selection
26	+ 68h	13:12	SATA Controller 0 - Assign HSIO Lane 10 to Port 6	0x0; HSIO Lane 10 Statically assigned to SATA Controller 0 Port 6 0x1; HSIO Lane 10 Not assigned to SATA Controller 0 Port 6	Board Dependent	Tells the SoC SATA Controller 0 if HSIO_RX_D [10] and HSIO_TX_D [10] pins are assigned to Port 6 **Note:** Set the "HSIO Lane 10 Select" soft strap to match this selection
26	+ 68h	15:14	SATA Controller 0 - Assign HSIO Lane 11 to Port 7	0x0; HSIO Lane 11 Statically assigned to SATA Controller 0 Port 7 0x1; HSIO Lane 11 Not assigned to SATA Controller 0 Port 7	Board Dependent	Tells the SoC SATA Controller 0 if HSIO_RX_D [11] and HSIO_TX_D [11] pins are assigned to Port 7 **Note:** Set the "HSIO Lane 11 Select" soft strap to match this selection
27	+ 6Ch	1:0	SATA Controller 1 - Assign HSIO Lane 12 to Port 0	0x0; HSIO Lane 12 Statically assigned to SATA Controller 1 Port 0 0x1; HSIO Lane 12 Not assigned to SATA Controller 1 Port 0	Board Dependent	Tells the SoC's SATA Controller 1 if HSIO_RX_D [12] and HSIO_TX_D [12] pins are assigned to Port 0 **Note:** Set the "HSIO Lane 12 Select" soft strap to match this selection

Table 4-3. Flash Descriptor Soft Straps (Sheet 10 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
27	+ 6Ch	3:2	SATA Controller 1 - Assign HSIO Lane 13 to Port 1	0x0; HSIO Lane 13 Statically assigned to SATA Controller 1 Port 1 0x1; HSIO Lane 13 Not assigned to SATA Controller 1 Port 1	Board Dependent	Tells the SoC's SATA Controller 1 if HSIO_RX_D [13] and HSIO_TX_D [13] pins are assigned to Port 1 **Note:** Set the "HSIO Lane 13 Select" soft strap to match this selection
27	+ 6Ch	5:4	SATA Controller 1 - Assign HSIO Lane 14 to Port 2	0x0; HSIO Lane 14 Statically assigned to SATA Controller 1 Port 2 0x1; HSIO Lane 14 Not assigned to SATA Controller 1 Port 2	Board Dependent	Tells the SoC SATA Controller 1 if HSIO_RX_D [14] and HSIO_TX_D [14] pins are assigned to Port 2 **Note:** Set the "HSIO Lane 14 Select" soft strap to match this selection
27	+ 6Ch	7:6	SATA Controller 1 - Assign HSIO Lane 15 to Port 3	0x0; HSIO Lane 15 Statically assigned to SATA Controller 1 Port 3 0x1; HSIO Lane 15 Not assigned to SATA Controller 1 Port 3	Board Dependent	Tells the SoC SATA Controller 1 if HSIO_RX_D [15] and HSIO_TX_D [15] pins are assigned to Port 3 **Note:** Set the "HSIO Lane 15 Select" soft strap to match this selection
27	+ 6Ch	9:8	SATA Controller 1 - Assign HSIO Lane 16 to Port 4	0x0; HSIO Lane 16 Statically assigned to SATA Controller 1 Port 4 0x1; HSIO Lane 16 Not assigned to SATA Controller 1 Port 4	Board Dependent	Tells the SoC SATA Controller 1 if HSIO_RX_D [16] and HSIO_TX_D [16] pins are assigned to Port 4 **Note:** Set the "HSIO Lane 16 Select" soft strap to match this selection
27	+ 6Ch	11:10	SATA Controller 1 - Assign HSIO Lane 17 to Port 5	0x0; HSIO Lane 17 Statically assigned to SATA Controller 1 Port 5 0x1; HSIO Lane 17 Not assigned to SATA Controller 1 Port 5	Board Dependent	Tells the SoC SATA Controller 1 if HSIO_RX_D [17] and HSIO_TX_D [17] pins are assigned to Port 5 **Note:** Set the "HSIO Lane 17 Select" soft strap to match this selection
27	+ 6Ch	13:12	SATA Controller 1 - Assign HSIO Lane 18 to Port 6	0x0; HSIO Lane 18 Statically assigned to SATA Controller 1 Port 6 0x1; HSIO Lane 18 Not assigned to SATA Controller 1 Port 6	Board Dependent	Tells the SoC SATA Controller 1 if HSIO_RX_D [18] and HSIO_TX_D [18] pins are assigned to Port 6 **Note:** Set the "HSIO Lane 18 Select" soft strap to match this selection
27	+ 6Ch	15:14	SATA Controller 1 - Assign HSIO Lane 19 to Port 7	0x0; HSIO Lane 19 Statically assigned to SATA Controller 1 Port 7 0x1; HSIO Lane 19 Not assigned to SATA Controller 1 Port 7	Board Dependent	Tells the SoC SATA Controller 1 if HSIO_RX_D [19] and HSIO_TX_D [19] pins are assigned to Port 7 **Note:** Set the "HSIO Lane 19 Select" soft strap to match this selection

Table 4-3. Flash Descriptor Soft Straps (Sheet 11 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
PCIe Bifurcation and Settings						
PCIe Root Port Cluster 0						
PCIe RP Cluster 0 - RP Enable						
24	+ 60h	0	PCIe Root Port Cluster 0 - Root Port 0 Enable	0x0; RP0 Disabled 0x1; RP0 Enabled	0x1	If soft strap "PCIe Root Port Cluster 0 Disable" is set to "PCIe Root Port Cluster 0 Enabled" tell the SoC to enable Root Port 0 ***Note:*** If Root port is set to "0x0 - RP0 Disabled" then BIOS will not be able to turn it back on. Soft Straps have priority. Bifurcation control register BIFCTL0[2:0] configuration should take into account any disabled root ports via soft straps.
24	+ 60h	1	PCIe Root Port Cluster 0 - Root Port 1 Enable	0x0; RP1 Disabled 0x1; RP1 Enabled	0x1	If soft strap "PCIe Root Port Cluster 0 Disable" is set to "PCIe Root Port Cluster 0 Enabled" tell the SoC to enable Root Port 1 ***Note:*** If Root port is set to "0x0 - RP1 Disabled" then BIOS will not be able to turn it back on. Soft Straps have priority. Bifurcation control register BIFCTL0[2:0] configuration should take into account any disabled root ports via soft straps.
24	+ 60h	2	PCIe Root Port Cluster 0 - Root Port 2 Enable	0x0; RP2 Disabled 0x1; RP2 Enabled	0x1	If soft strap "PCIe Root Port Cluster 0 Disable" is set to "PCIe Root Port Cluster 0 Enabled" tell the SoC to enable Root Port 2 ***Note:*** If Root port is set to "0x0 - RP2 Disabled" then BIOS will not be able to turn it back on. Soft Straps have priority. Bifurcation control register BIFCTL0[2:0] configuration should take into account any disabled root ports via soft straps.
24	+ 60h	3	PCIe Root Port Cluster 0 - Root Port 3 Enable	0x0; RP3 Disabled 0x1; RP3 Enabled	0x1	If soft strap "PCIe Root Port Cluster 0 Disable" is set to "PCIe Root Port Cluster 0 Enabled" tell the SoC to enable Root Port 3 ***Note:*** If Root port is set to "0x0 - RP3 Disabled" then BIOS will not be able to turn it back on. Soft Straps have priority. Bifurcation control register BIFCTL0[2:0] configuration should take into account any disabled root ports via soft straps.

Table 4-3. Flash Descriptor Soft Straps (Sheet 12 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
						PCIe RP Cluster 0 - RP x1 Link Width Enable
24	+ 60h	27:24	PCIe Root Port Cluster 0 - Root Port 0 x1 Link Width Enable	0x0; RP Link Width set by BICTRL register 0xF; x1	0x0	If soft straps "PCIe Root Port Cluster 0 Disable" and "PCIe Root Port Cluster 0 - Root Port 0 Enable" are set to Enable, tell the SoC to set RP 0 link width to x1. **Note:** If setting this soft strap to the "x1" configuration and desiring to use the other HSIO lane for the SATA controller, make sure to set the respective HSIO and SATA controller soft straps accordingly.
24	+ 60h	31:28	PCIe Root Port Cluster 0 - Root Port 1 x1 Link Width Enable	0x0; RP Link Width set by BICTRL register 0xF; x1	0x0	If soft straps "PCIe Root Port Cluster 0 Disable" and "PCIe Root Port Cluster 0 - Root Port 1 Enable" are set to Enable, tell the SoC to set RP 1 link width to x1. **Notes:** - If setting this soft strap to the "x1" configuration and desiring to use the other HSIO lane for the SATA controller, make sure to set the respective HSIO and SATA controller soft straps accordingly.
25	+ 64h	3:0	PCIe Root Port Cluster 0 - Root Port 2 x1 Link Width Enable	0x0; RP Link Width set by BICTRL register 0xF; x1	0x0	If soft straps "PCIe Root Port Cluster 0 Disable" and "PCIe Root Port Cluster 0 - Root Port 2 Enable" are set to Enable, tell the SoC to set RP 2 link width to x1. **Notes:** - If setting this soft strap to the "x1" configuration and desiring to use the other HSIO lane for the SATA controller, make sure to set the respective HSIO and SATA controller soft straps accordingly.
25	+ 64h	7:4	PCIe Root Port Cluster 0 - Root Port 3 x1 Link Width Enable	0x0; RP Link Width set by BICTRL register 0xF; x1	0x0	If soft straps "PCIe Root Port Cluster 0 Disable" and "PCIe Root Port Cluster 0 - Root Port 3 Enable" are set to Enable, tell the SoC to set RP 3 link width to x1. **Notes:** - If setting this soft strap to the "x1" configuration and desiring to use the other HSIO lane for the SATA controller, make sure to set the respective HSIO and SATA controller soft straps accordingly.

Table 4-3. Flash Descriptor Soft Straps (Sheet 13 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
						PCIe RP Cluster 0 - SRIS Enable
25	+ 64h	25	PCIe Root Port Cluster 0 - Root Port 0 SRIS Enable	0x0; RP 0 SRIS Disabled 0x1; RP 0 SRIS Enabled	0x0	If soft strap "PCIe Root Port Cluster 0 Disable" is set to "PCIe Root Port Cluster 0 Enabled" tell the SoC to enable Separate Reference Clocks with Independent Spread Spectrum Clocking (SRIS) for Root Port 0. SRIS is supported at Gen 1, and 2. **Note:** Refer to the SOSCTL.SRISEN register.
25	+ 64h	26	PCIe Root Port Cluster 0 - Root Port 1 SRIS Enable	0x0; RP 1 SRIS Disabled 0x1; RP 1 SRIS Enabled	0x0	If soft strap "PCIe Root Port Cluster 0 Disable" is set to "PCIe Root Port Cluster 0 Enabled" tell the SoC to enable Separate Reference Clocks with Independent Spread Spectrum Clocking (SRIS) for Root Port 1. SRIS is supported at Gen 1, and 2. **Note:** Refer to the SOSCTL.SRISEN register.
25	+ 64h	27	PCIe Root Port Cluster 0 - Root Port 2 SRIS Enable	0x0; RP 2 SRIS Disabled 0x1; RP 2 SRIS Enabled	0x0	If soft strap "PCIe Root Port Cluster 0 Disable" is set to "PCIe Root Port Cluster 0 Enabled" tell the SoC to enable Separate Reference Clocks with Independent Spread Spectrum Clocking (SRIS) for Root Port 2. SRIS is supported at Gen 1, 2and 2 **Note:** Refer to the SOSCTL.SRISEN register.
25	+ 64h	28	PCIe Root Port Cluster 0 - Root Port 3 SRIS Enable	0x0; RP 3 SRIS Disabled 0x1; RP 3 SRIS Enabled	0x0	If soft strap "PCIe Root Port Cluster 0 Disable" is set to "PCIe Root Port Cluster 0 Enabled" tell the SoC to enable Separate Reference Clocks with Independent Spread Spectrum Clocking (SRIS) for Root Port 3. SRIS is supported at Gen 1, and 2 **Note:** Refer to the SOSCTL.SRISEN register.

Table 4-3. Flash Descriptor Soft Straps (Sheet 14 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
PCIe Root Port Cluster 1						
PCIe RP Cluster 1 - RP Enable						
22	+ 58h	0	PCIe Root Port Cluster 1 - Root Port 4 Enable	**0x0;** RP4 Disabled **0x1;** RP4 Enabled	0x1	If soft strap "PCIe Root Port Cluster 1 Disable" is set to "PCIe Root Port Cluster 1 Enabled" tell the SoC to enable Root Port 4. ***Note:*** If Root port is set to "0x0 - RP4 Disabled" then BIOS will not be able to turn it back on. Soft Straps have priority. Bifurcation control register BIFCTL0[2:0] configuration should take into account any disabled root ports via soft straps.
22	+ 58h	1	PCIe Root Port Cluster 1 - Root Port 5 Enable	**0x0**; RP5 Disabled **0x1**; RP5 Enabled	0x1	If soft strap "PCIe Root Port Cluster 1 Disable" is set to "PCIe Root Port Cluster 1 Enabled" tell the SoC to enable Root Port 5 ***Note:*** If Root port is set to "0x0 - RP5 Disabled" then BIOS will not be able to turn it back on. Soft Straps have priority. Bifurcation control register BIFCTL0[2:0] configuration should take into account any disabled root ports via soft straps.
22	+ 58h	2	PCIe Root Port Cluster 1 - Root Port 6 Enable	**0x0;** RP6 Disabled **0x1;** RP6 Enabled	0x1	If soft strap "PCIe Root Port Cluster 1 Disable" is set to "PCIe Root Port Cluster 1 Enabled" tell the SoC to enable Root Port 6 ***Note:*** If Root port is set to "0x0 - RP6 Disabled" then BIOS will not be able to turn it back on. Soft Straps have priority. Bifurcation control register BIFCTL0[2:0] configuration should take into account any disabled root ports via soft straps.
22	+ 58h	3	PCIe Root Port Cluster 1 - Root Port 7 Enable	**0x0;** RP7 Disabled **0x1;** RP7 Enabled	0x1	If soft strap "PCIe Root Port Cluster 1 Disable" is set to "PCIe Root Port Cluster 1 Enabled" tell the SoC to enable Root Port 7 ***Note:*** If Root port is set to "0x0 - RP7 Disabled" then BIOS will not be able to turn it back on. Soft Straps have priority. Bifurcation control register BIFCTL0[2:0] configuration should take into account any disabled root ports via soft straps.

Table 4-3. Flash Descriptor Soft Straps (Sheet 15 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
						PCIe RP Cluster 1 - RP x1 Link Width Enable
22	+ 58h	27:24	PCIe Root Port Cluster 1 - Root Port 4 x1 Link Width Enable	0x0; RP Link Width set by BICTRL register 0xF; x1	0x0	If soft straps "PCIe Root Port Cluster 1 Disable" and "PCIe Root Port Cluster 1 - Root Port 4 Enable" are set to Enable, tell the SoC to set RP 4 link width to x1. **Notes:** - If setting this soft strap to the "x1" configuration and desiring to use the other HSIO lane for the SATA controller, make sure to set the respective HSIO and SATA controller soft straps accordingly.
22	+ 58h	31:28	PCIe Root Port Cluster 1 - Root Port 5 x1 Link Width Enable	0x0; RP Link Width set by BICTRL register 0xF; x1	0x0	If soft straps "PCIe Root Port Cluster 1 Disable" and "PCIe Root Port Cluster 1 - Root Port 5 Enable" are set to Enable, tell the SoC to set RP 5 link width to x1. **Notes:** - If setting this soft strap to the "x1" configuration and desiring to use the other HSIO lane for the SATA controller, make sure to set the respective HSIO and SATA controller soft straps accordingly.
23	+ 5Ch	3:0	PCIe Root Port Cluster 1 - Root Port 6 x1 Link Width Enable	0x0; RP Link Width set by BICTRL register 0xF; x1	0x0	If soft straps "PCIe Root Port Cluster 1 Disable" and "PCIe Root Port Cluster 1 - Root Port 6 Enable" are set to Enable, tell the SoC to set RP 6 link width to x1. **Notes:** - If setting this soft strap to the "x1" configuration and desiring to use the other HSIO lane for the SATA controller, make sure to set the respective HSIO and SATA controller soft straps accordingly.
23	+ 5Ch	7:4	PCIe Root Port Cluster 1 - Root Port 7 x1 Link Width Enable	0x0; RP Link Width set by BICTRL register 0xF; x1	0x0	If soft straps "PCIe Root Port Cluster 1 Disable" and "PCIe Root Port Cluster 1 - Root Port 7 Enable" are set to Enable, tell the SoC to set RP 7 link width to x1. **Notes:** - If setting this soft strap to the "x1" configuration and desiring to use the other HSIO lane for the SATA controller, make sure to set the respective HSIO and SATA controller soft straps accordingly.

Table 4-3. Flash Descriptor Soft Straps (Sheet 16 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
						PCIe RP Cluster 1 - SRIS Enable
23	+ 5Ch	25	PCIe Root Port Cluster 1 - Root Port 4 SRIS Enable	**0x0;** RP 4 SRIS Disabled **0x1;** RP 4 SRIS Enabled	0x0	If soft strap "PCIe Root Port Cluster 1 Disable" is set to "PCIe Root Port Cluster 1 Enabled" tell the SoC to enable Separate Reference Clocks with Independent Spread Spectrum Clocking (SRIS) for Root Port 4. SRIS is supported at Gen 1, and 2. **Note:** Refer to the SOSCTL.SRISEN register.
23	+ 5Ch	26	PCIe Root Port Cluster 1 - Root Port 5 SRIS Enable	**0x0;** RP 5 SRIS Disabled **0x1;** RP 5 SRIS Enabled	0x0	If soft strap "PCIe Root Port Cluster 1 Disable" is set to "PCIe Root Port Cluster 1 Enabled" tell the SoC to enable Separate Reference Clocks with Independent Spread Spectrum Clocking (SRIS) for Root Port 5. SRIS is supported at Gen 1, and 2. **Note:** Refer to the SOSCTL.SRISEN register.
23	+ 5Ch	27	PCIe Root Port Cluster 1 - Root Port 6 SRIS Enable	**0x0;** RP 6 SRIS Disabled **0x1;** RP 6 SRIS Enabled	0x0	If soft strap "PCIe Root Port Cluster 1 Disable" is set to "PCIe Root Port Cluster 1 Enabled" tell the SoC to enable Separate Reference Clocks with Independent Spread Spectrum Clocking (SRIS) for Root Port 6. SRIS is supported at Gen 1, and 2. **Note:** Refer to the SOSCTL.SRISEN register.
23	+ 5Ch	28	PCIe Root Port Cluster 1 - Root Port 7 SRIS Enable	**0x0;** RP 7 SRIS Disabled **0x1;** RP 7 SRIS Enabled	0x0	If soft strap "PCIe Root Port Cluster 1 Disable" is set to "PCIe Root Port Cluster 1 Enabled" tell the SoC to enable Separate Reference Clocks with Independent Spread Spectrum Clocking (SRIS) for Root Port 7. SRIS is supported at Gen 1, and 2. **Note:** Refer to the SOSCTL.SRISEN register.

Table 4-3. Flash Descriptor Soft Straps (Sheet 17 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
External Clocks						
5	+ 14h	21	HSIO Spread Spectrum Clocking Disable	0x0: Enable HSIO Spread Spectrum Clocking 0x1: Disable HSIO Spread Spectrum Clocking	0x0	Tells the SoC if HSIO Spread Spectrum Clock (SSC) will be disabled from the time the clock is first output by the SoC for PCIe, SATA, and XHCI. ***Note:*** Should BIOS configure this setting, disabling the HSIO SSC will not take effect until after memory training during BIOS execution.
15	+ 3Ch	2	DDR Spread Spectrum Clock (SSC) Modulator Disable	0x0; DDR SSC Disabled 0x1; DDR SSC Enabled	0x1	Tells the SoC if DDR Spread Spectrum Clock (SSC) modulator will be disabled.
CLK_OUT_D 0 Configuration						
15	+ 3Ch	8	Force CLK_OUT_D 0	0x0; CLK_OUT_D 0 will respond to PCIE_CLKREQ_N[x] pins configured through soft straps (CLK_OUT_D 0 ; PCIE_CLKREQ_N[x]). 0x1; Output Clock to CLK_OUT_D 0 at all times regardless of clkreq setting.	Board Dependent	Tells the SoC to output 100 MHz Clock to CLK_OUT_DP[0] and CLK_OUT_DN[0] ***Note:*** There is no option to disable CLK_OUT_D 0. Instead we can prevent a clock from being sent by setting this soft strap to option: "0x0; CLK_OUT_D 0 will respond to PCIE_CLKREQ_N[x] pins configured through soft straps" as well as setting all the CLK_OUT_D 0 - PCIE_CLKREQ_N[0-7] soft straps to: "0x0; Clock will not respond to PCIE_CLKREQ_N[x] pin."
15	+ 3Ch	16	CLK_OUT_D 0 - PCIE_CLKREQ_N[0]	0x0; Clock will not respond to PCIE_CLKREQ_N[0] pin. 0x1; Clock will respond to PCIE_CLKREQ_N[0] pin.	Board Dependent	If soft strap "Force CLK_OUT_D 0" is set to respond to PCIE_CLKREQ_N[x]" then tell the SoC if CLK_OUT_DP[0] and CLK_OUT_DN[0] will respond to PCIE_CLKREQ_N[0] pin.
15	+ 3Ch	17	CLK_OUT_D 0 - PCIE_CLKREQ_N[1]	0x0; Clock will not respond to PCIE_CLKREQ_N[1] pin. 0x1; Clock will respond to PCIE_CLKREQ_N[1] pin.	Board Dependent	If soft strap "Force CLK_OUT_D 0" is set to respond to PCIE_CLKREQ_N[x]" then tell the SoC if CLK_OUT_DP[0] and CLK_OUT_DN[0] will respond to PCIE_CLKREQ_N[1]
15	+ 3Ch	18	CLK_OUT_D 0 - PCIE_CLKREQ_N[2]	0x0; Clock will not respond to PCIE_CLKREQ_N[2] pin. 0x1; Clock will respond to PCIE_CLKREQ_N[2] pin.	Board Dependent	If soft strap "Force CLK_OUT_D 0" is set to respond to PCIE_CLKREQ_N[x]" then tell the SoC if CLK_OUT_DP[0] and CLK_OUT_DN[0] will respond to PCIE_CLKREQ_N[2]

Table 4-3. Flash Descriptor Soft Straps (Sheet 18 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
15	+ 3Ch	19	CLK_OUT_D 0 - PCIE_CLKREQ_N[3]	0x0; Clock will not respond to PCIE_CLKREQ_N[3] pin. 0x1; Clock will respond to PCIE_CLKREQ_N[3] pin.	Board Dependent	If soft strap "Force CLK_OUT_D 0" is set to respond to PCIE_CLKREQ_N[x]" then tell the SoC if CLK_OUT_DP[0] and CLK_OUT_DN[0] will respond to PCIE_CLKREQ_N[3]
15	+ 3Ch	20	CLK_OUT_D 0 - PCIE_CLKREQ_N[4]	0x0; Clock will not respond to PCIE_CLKREQ_N[4] pin. 0x1; Clock will respond to PCIE_CLKREQ_N[4] pin.	Board Dependent	If soft strap "Force CLK_OUT_D 0" is set to respond to PCIE_CLKREQ_N[x]" then tell the SoC if CLK_OUT_DP[0] and CLK_OUT_DN[0] will respond to PCIE_CLKREQ_N[4]
15	+ 3Ch	21	CLK_OUT_D 0 - PCIE_CLKREQ_N[5]	0x0; Clock will not respond to PCIE_CLKREQ_N[5] pin. 0x1; Clock will respond to PCIE_CLKREQ_N[5] pin.	Board Dependent	If soft strap "Force CLK_OUT_D 0" is set to respond to PCIE_CLKREQ_N[x]" then tell the SoC if CLK_OUT_DP[0] and CLK_OUT_DN[0] will respond to PCIE_CLKREQ_N[5]
15	+ 3Ch	22	CLK_OUT_D 0 - PCIE_CLKREQ_N[6]	0x0; Clock will not respond to PCIE_CLKREQ_N[6] pin. 0x1; Clock will respond to PCIE_CLKREQ_N[6] pin.	Board Dependent	If soft strap "Force CLK_OUT_D 0" is set to respond to PCIE_CLKREQ_N[x]" then tell the SoC if CLK_OUT_DP[0] and CLK_OUT_DN[0] will respond to PCIE_CLKREQ_N[6]
15	+ 3Ch	23	CLK_OUT_D 0 - PCIE_CLKREQ_N[7]	0x0; Clock will not respond to PCIE_CLKREQ_N[7] pin. 0x1; Clock will respond to PCIE_CLKREQ_N[7] pin.	Board Dependent	If soft strap "Force CLK_OUT_D 0" is set to respond to PCIE_CLKREQ_N[x]" then tell the SoC if CLK_OUT_DP[0] and CLK_OUT_DN[0] will respond to PCIE_CLKREQ_N[7]
CLK_OUT_D 1 Configuration						
15	+ 3Ch	9	Force CLK_OUT_D 1	0x0; CLK_OUT_D 1 will respond to PCIE_CLKREQ_N[x] pins configured through soft straps (CLK_OUT_D 1 ; PCIE_CLKREQ_N[x]). 0x1; Output Clock to CLK_OUT_D 1 at all times regardless of clkreq setting.	Board Dependent	Tells the SoC to output 100 MHz Clock to CLK_OUT_DP[1] and CLK_OUT_DN[1] ***Note:*** There is no option to disable CLK_OUT_D 1. Instead we can prevent a clock from being sent by setting this soft strap to option: "0x0; CLK_OUT_D 1 will respond to PCIE_CLKREQ_N[x] pins configured through soft straps" as well as setting all the CLK_OUT_D 1 - PCIE_CLKREQ_N[0-7] soft straps to: "0x0; Clock will not respond to PCIE_CLKREQ_N[x] pin."
15	+ 3Ch	24	CLK_OUT_D 1 - PCIE_CLKREQ_N[0]	0x0; Clock will not respond to PCIE_CLKREQ_N[0] pin. 0x1; Clock will respond to PCIE_CLKREQ_N[0] pin.	Board Dependent	If soft strap "Force CLK_OUT_D 1" is set to respond to PCIE_CLKREQ_N[x]" then tell the SoC if CLK_OUT_DP[1] and CLK_OUT_DN[1] will respond to PCIE_CLKREQ_N[0] pin.
15	+ 3Ch	25	CLK_OUT_D 1 - PCIE_CLKREQ_N[1]	0x0; Clock will not respond to PCIE_CLKREQ_N[1] pin. 0x1; Clock will respond to PCIE_CLKREQ_N[1] pin.	Board Dependent	If soft strap "Force CLK_OUT_D 1" is set to respond to PCIE_CLKREQ_N[x]" then tell the SoC if CLK_OUT_DP[1] and CLK_OUT_DN[1] will respond to PCIE_CLKREQ_N[1]

Table 4-3. Flash Descriptor Soft Straps (Sheet 19 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
15	+ 3Ch	26	CLK_OUT_D 1 - PCIE_CLKREQ_N[2]	0x0; Clock will not respond to PCIE_CLKREQ_N[2] pin. 0x1; Clock will respond to PCIE_CLKREQ_N[2] pin.	Board Dependent	If soft strap "Force CLK_OUT_D 1" is set to respond to PCIE_CLKREQ_N[x]" then tell the SoC if CLK_OUT_DP[1] and CLK_OUT_DN[1] will respond to PCIE_CLKREQ_N[2]
15	+ 3Ch	27	CLK_OUT_D 1 - PCIE_CLKREQ_N[3]	0x0; Clock will not respond to PCIE_CLKREQ_N[3] pin. 0x1; Clock will respond to PCIE_CLKREQ_N[3] pin.	Board Dependent	If soft strap "Force CLK_OUT_D 1" is set to respond to PCIE_CLKREQ_N[x]" then tell the SoC if CLK_OUT_DP[1] and CLK_OUT_DN[1] will respond to PCIE_CLKREQ_N[3]
15	+ 3Ch	28	CLK_OUT_D 1 - PCIE_CLKREQ_N[4]	0x0; Clock will not respond to PCIE_CLKREQ_N[4] pin. 0x1; Clock will respond to PCIE_CLKREQ_N[4] pin.	Board Dependent	If soft strap "Force CLK_OUT_D 1" is set to respond to PCIE_CLKREQ_N[x]" then tell the SoC if CLK_OUT_DP[1] and CLK_OUT_DN[1] will respond to PCIE_CLKREQ_N[4]
15	+ 3Ch	29	CLK_OUT_D 1 - PCIE_CLKREQ_N[5]	0x0; Clock will not respond to PCIE_CLKREQ_N[5] pin. 0x1; Clock will respond to PCIE_CLKREQ_N[5] pin.	Board Dependent	If soft strap "Force CLK_OUT_D 1" is set to respond to PCIE_CLKREQ_N[x]" then tell the SoC if CLK_OUT_DP[1] and CLK_OUT_DN[1] will respond to PCIE_CLKREQ_N[5]
15	+ 3Ch	30	CLK_OUT_D 1 - PCIE_CLKREQ_N[6]	0x0; Clock will not respond to PCIE_CLKREQ_N[6] pin. 0x1; Clock will respond to PCIE_CLKREQ_N[6] pin.	Board Dependent	If soft strap "Force CLK_OUT_D 1" is set to respond to PCIE_CLKREQ_N[x]" then tell the SoC if CLK_OUT_DP[1] and CLK_OUT_DN[1] will respond to PCIE_CLKREQ_N[6]
15	+ 3Ch	31	CLK_OUT_D 1 - PCIE_CLKREQ_N[7]	0x0; Clock will not respond to PCIE_CLKREQ_N[7] pin. 0x1; Clock will respond to PCIE_CLKREQ_N[7] pin.	Board Dependent	If soft strap "Force CLK_OUT_D 1" is set to respond to PCIE_CLKREQ_N[x]" then tell the SoC if CLK_OUT_DP[1] and CLK_OUT_DN[1] will respond to PCIE_CLKREQ_N[7]
CLK_OUT_D 2 Configuration						
15	+ 3Ch	10	Force CLK_OUT_D 2	0x0; CLK_OUT_D 2 will respond to PCIE_CLKREQ_N[x] pins configured through soft straps (CLK_OUT_D 2 ; PCIE_CLKREQ_N[x]). 0x1; Output Clock to CLK_OUT_D 2 at all times regardless of clkreq setting.	Board Dependent	Tells the SoC to output 100 MHz Clock to CLK_OUT_DP[2] and CLK_OUT_DN[2] ***Note:*** There is no option to disable CLK_OUT_D 2. Instead we can prevent a clock from being sent by setting this soft strap to option: "0x0; CLK_OUT_D 2 will respond to PCIE_CLKREQ_N[x] pins configured through soft straps" as well as setting all the CLK_OUT_D 2 - PCIE_CLKREQ_N[0-7] soft straps to: "0x0; Clock will not respond to PCIE_CLKREQ_N[x] pin."
16	+ 40h	0	CLK_OUT_D 2 - PCIE_CLKREQ_N[0]	0x0; Clock will not respond to PCIE_CLKREQ_N[0] pin. 0x1; Clock will respond to PCIE_CLKREQ_N[0] pin.	Board Dependent	If soft strap "Force CLK_OUT_D 2" is set to respond to PCIE_CLKREQ_N[x]" then tell the SoC if CLK_OUT_DP[2] and CLK_OUT_DN[2] will respond to PCIE_CLKREQ_N[0] pin.

Table 4-3. Flash Descriptor Soft Straps (Sheet 20 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
16	+ 40h	1	CLK_OUT_D 2 - PCIE_CLKREQ_N[1]	0x0; Clock will not respond to PCIE_CLKREQ_N[1] pin. 0x1; Clock will respond to PCIE_CLKREQ_N[1] pin.	Board Dependent	If soft strap "Force CLK_OUT_D 2" is set to respond to PCIE_CLKREQ_N[x]" then tell the SoC if CLK_OUT_DP[2] and CLK_OUT_DN[2] will respond to PCIE_CLKREQ_N[1]
16	+ 40h	2	CLK_OUT_D 2 - PCIE_CLKREQ_N[2]	0x0; Clock will not respond to PCIE_CLKREQ_N[2] pin. 0x1; Clock will respond to PCIE_CLKREQ_N[2] pin.	Board Dependent	If soft strap "Force CLK_OUT_D 2" is set to respond to PCIE_CLKREQ_N[x]" then tell the SoC if CLK_OUT_DP[2] and CLK_OUT_DN[2] will respond to PCIE_CLKREQ_N[2]
16	+ 40h	3	CLK_OUT_D 2 - PCIE_CLKREQ_N[3]	0x0; Clock will not respond to PCIE_CLKREQ_N[3] pin. 0x1; Clock will respond to PCIE_CLKREQ_N[3] pin.	Board Dependent	If soft strap "Force CLK_OUT_D 2" is set to respond to PCIE_CLKREQ_N[x]" then tell the SoC if CLK_OUT_DP[2] and CLK_OUT_DN[2] will respond to PCIE_CLKREQ_N[3]
16	+ 40h	4	CLK_OUT_D 2 - PCIE_CLKREQ_N[4]	0x0; Clock will not respond to PCIE_CLKREQ_N[4] pin. 0x1; Clock will respond to PCIE_CLKREQ_N[4] pin.	Board Dependent	If soft strap "Force CLK_OUT_D 2" is set to respond to PCIE_CLKREQ_N[x]" then tell the SoC if CLK_OUT_DP[2] and CLK_OUT_DN[2] will respond to PCIE_CLKREQ_N[4]
16	+ 40h	5	CLK_OUT_D 2 - PCIE_CLKREQ_N[5]	0x0; Clock will not respond to PCIE_CLKREQ_N[5] pin. 0x1; Clock will respond to PCIE_CLKREQ_N[5] pin. Board Dependent	If soft strap "Force CLK_OUT_D 3" is set to respond to PCIE_CLKREQ_N[x]" then tell the SoC if CLK_OUT_DP[3] and CLK_OUT_DN[3] will respond to PCIE_CLKREQ_N[4]
16	+ 40h	13	CLK_OUT_D 3 - PCIE_CLKREQ_N[5]	0x0; Clock will not respond to PCIE_CLKREQ_N[5] pin. 0x1; Clock will respond to PCIE_CLKREQ_N[5] pin.	Board Dependent	If soft strap "Force CLK_OUT_D 3" is set to respond to PCIE_CLKREQ_N[x]" then tell the SoC if CLK_OUT_DP[3] and CLK_OUT_DN[3] will respond to PCIE_CLKREQ_N[5]
16	+ 40h	14	CLK_OUT_D 3 - PCIE_CLKREQ_N[6]	0x0; Clock will not respond to PCIE_CLKREQ_N[6] pin. 0x1; Clock will respond to PCIE_CLKREQ_N[6] pin.	Board Dependent	If soft strap "Force CLK_OUT_D 3" is set to respond to PCIE_CLKREQ_N[x]" then tell the SoC if CLK_OUT_DP[3] and CLK_OUT_DN[3] will respond to PCIE_CLKREQ_N[6]
16	+ 40h	15	CLK_OUT_D 3 - PCIE_CLKREQ_N[7]	0x0; Clock will not respond to PCIE_CLKREQ_N[7] pin. 0x1; Clock will respond to PCIE_CLKREQ_N[7] pin.	Board Dependent	If soft strap "Force CLK_OUT_D 3" is set to respond to PCIE_CLKREQ_N[x]" then tell the SoC if CLK_OUT_DP[3] and CLK_OUT_DN[3] will respond to PCIE_CLKREQ_N[7]

Table 4-3. Flash Descriptor Soft Straps (Sheet 22 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
CLK_OUT_D 4 Configuration						
15	+ 3Ch	12	Force CLK_OUT_D 4	0x0; CLK_OUT_D 4 will respond to PCIE_CLKREQ_N[x] pins configured through soft straps (CLK_OUT_D 4 ; PCIE_CLKREQ_N[x]). 0x1; Output Clock to CLK_OUT_D 4 at all times regardless of clkreq setting.	Board Dependent	Tells the SoC to output 100 MHz Clock to CLK_OUT_DP[4] and CLK_OUT_DN[4] ***Note:*** There is no option to disable CLK_OUT_D 4. Instead we can prevent a clock from being sent by setting this soft strap to option: "0x0; CLK_OUT_D 4 will respond to PCIE_CLKREQ_N[x] pins configured through soft straps" as well as setting all the CLK_OUT_D 4 - PCIE_CLKREQ_N[0-7] soft straps to: "0x0; Clock will not respond to PCIE_CLKREQ_N[x] pin."
16	+ 40h	16	CLK_OUT_D 4 - PCIE_CLKREQ_N[0]	0x0; Clock will not respond to PCIE_CLKREQ_N[0] pin. 0x1; Clock will respond to PCIE_CLKREQ_N[0] pin.	Board Dependent	If soft strap "Force CLK_OUT_D 4" is set to respond to PCIE_CLKREQ_N[x]" then tell the SoC if CLK_OUT_DP[4] and CLK_OUT_DN[4] will respond to PCIE_CLKREQ_N[0] pin.
16	+ 40h	17	CLK_OUT_D 4 - PCIE_CLKREQ_N[1]	0x0; Clock will not respond to PCIE_CLKREQ_N[1] pin. 0x1; Clock will respond to PCIE_CLKREQ_N[1] pin.	Board Dependent	If soft strap "Force CLK_OUT_D 4" is set to respond to PCIE_CLKREQ_N[x]" then tell the SoC if CLK_OUT_DP[4] and CLK_OUT_DN[4] will respond to PCIE_CLKREQ_N[1]
16	+ 40h	18	CLK_OUT_D 4 - PCIE_CLKREQ_N[2]	0x0; Clock will not respond to PCIE_CLKREQ_N[2] pin. 0x1; Clock will respond to PCIE_CLKREQ_N[2] pin.	Board Dependent	If soft strap "Force CLK_OUT_D 4" is set to respond to PCIE_CLKREQ_N[x]" then tell the SoC if CLK_OUT_DP[4] and CLK_OUT_DN[4] will respond to PCIE_CLKREQ_N[2]
16	+ 40h	19	CLK_OUT_D 4 - PCIE_CLKREQ_N[3]	0x0; Clock will not respond to PCIE_CLKREQ_N[3] pin. 0x1; Clock will respond to PCIE_CLKREQ_N[3] pin.	Board Dependent	If soft strap "Force CLK_OUT_D 4" is set to respond to PCIE_CLKREQ_N[x]" then tell the SoC if CLK_OUT_DP[4] and CLK_OUT_DN[4] will respond to PCIE_CLKREQ_N[3]
16	+ 40h	20	CLK_OUT_D 4 - PCIE_CLKREQ_N[4]	0x0; Clock will not respond to PCIE_CLKREQ_N[4] pin. 0x1; Clock will respond to PCIE_CLKREQ_N[4] pin.	Board Dependent	If soft strap "Force CLK_OUT_D 4" is set to respond to PCIE_CLKREQ_N[x]" then tell the SoC if CLK_OUT_DP[4] and CLK_OUT_DN[4] will respond to PCIE_CLKREQ_N[4]
16	+ 40h	21	CLK_OUT_D 4 - PCIE_CLKREQ_N[5]	0x0; Clock will not respond to PCIE_CLKREQ_N[5] pin. 0x1; Clock will respond to PCIE_CLKREQ_N[5] pin.	Board Dependent	If soft strap "Force CLK_OUT_D 4" is set to respond to PCIE_CLKREQ_N[x]" then tell the SoC if CLK_OUT_DP[4] and CLK_OUT_DN[4] will respond to PCIE_CLKREQ_N[5]
16	+ 40h	22	CLK_OUT_D 4 - PCIE_CLKREQ_N[6]	0x0; Clock will not respond to PCIE_CLKREQ_N[6] pin. 0x1; Clock will respond to PCIE_CLKREQ_N[6] pin.	Board Dependent	If soft strap "Force CLK_OUT_D 4" is set to respond to PCIE_CLKREQ_N[x]" then tell the SoC if CLK_OUT_DP[4] and CLK_OUT_DN[4] will respond to PCIE_CLKREQ_N[6]

Table 4-3. Flash Descriptor Soft Straps (Sheet 23 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
16	+ 40h	23	CLK_OUT_D 4 - PCIE_CLKREQ_N[7]	0x0; Clock will not respond to PCIE_CLKREQ_N[7] pin. 0x1; Clock will respond to PCIE_CLKREQ_N[7] pin.	Board Dependent	If soft strap "Force CLK_OUT_D 4" is set to respond to PCIE_CLKREQ_N[x]" then tell the SoC if CLK_OUT_DP[4] and CLK_OUT_DN[4] will respond to PCIE_CLKREQ_N[7]
Flex Clocks Configuration						
16	+ 40h	29:24	FLEX_CLK_SE[0] - Frequency	0x04; 50 MHz 0x06; 33.3 MHz 0x08; 25 MHz 0x22; 48 MHz	0x22	Tells the SoC what frequency to output from FLEX_CLK_SE[0].
16	+ 40h	30	FLEX_CLK_SE[0] - Isolation Enable	0x1; Wait to drive the clocks to ground until after DDR Domains are powered on 0x0; Drive clocks by default (shortly after RSMRST_N)	0x0	This soft strap can help prevent driving a clock into an unpowered domain.
17	+ 44h	5:0	FLEX_CLK_SE[1] - Frequency	0x04; 50 MHz 0x06; 33.3 MHz 0x08; 25 MHz 0x22; 48 MHz	0x22	Tells the SoC what frequency to output from FLEX_CLK_SE[1].
17	+ 44h	6	FLEX_CLK_SE[1] - Isolation Enable	0x1; Wait to drive the clocks to ground until after DDR Domains are powered on 0x0; Drive clocks by default (shortly after RSMRST_N)	0x0	Isolates FlexIO Clock 1 when host_powergood_rst_b is active to prevent driving clock into an unpowered domain.

Table 4-3. Flash Descriptor Soft Straps (Sheet 24 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
SPI						
9	+ 24h	0	SPI - Dual Output Fast Read Enable (DORE)	0x0; Dual Output Read is disabled 0x1; Dual Output Read is enabled	0x1	Tells the SoC SPI controller if Dual Output Fast Read (DORE) instructions are supported. This will only take effect if the SPI flash device connected to the SPI controller also supports DORE in its SFDP table and has the Dual Output bit and the Fast Read Support bit enabled in the FLCOMP register inside the SPI flash descriptor region. ***Note:*** Only one soft strap between DORE/DIORE/QORE/QIORE SPI modes can be enabled at a time. i.e. if DORE is enabled via soft strap, then DIORE/QORE/QIORE soft straps must be set to disabled via soft strap.
9	+ 24h	1	SPI - Dual I/O Fast Read Enable (DIORE)	0x0; Dual I/O Read is disabled 0x1; Dual I/O Read is enabled	0x1	Tells the SoC SPI controller if Dual I/O Fast Read (DIORE) instructions are supported. This will only take effect if the SPI flash device connected to the SPI controller also supports DIORE in its SFDP table and has the Dual Output bit and the Fast Read Support bit enabled in the FLCOMP register inside the SPI flash descriptor region. ***Note:*** Only one soft strap between DORE/DIORE/QORE/QIORE SPI modes can be enabled at a time. i.e. if DORE is enabled via soft strap, then DIORE/QORE/QIORE soft straps must be set to disabled via soft strap.
9	+ 24h	2	SPI - Quad Output Fast Read Enable (QORE)	0x0; Quad Output Read is disabled 0x1; Quad Output Read is enabled	0x1	Tells the SoC SPI controller if Quad Output Fast Read (QORE) instructions are supported. This will only take effect if the SPI flash device connected to the SPI controller also supports QORE in its SFDP table and has the Dual Output bit and the Fast Read Support bit enabled in the FLCOMP register inside the SPI flash descriptor region. ***Note:*** Only one soft strap between DORE/DIORE/QORE/QIORE SPI modes can be enabled at a time. i.e. if DORE is enabled via soft strap, then DIORE/QORE/QIORE soft straps must be set to disabled via soft strap.

Table 4-3. Flash Descriptor Soft Straps (Sheet 25 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
9	+ 24h	3	SPI - Quad I/O Fast Read Enable (QIORE)	0x0; Quad I/O Read is disabled 0x1; Quad I/O Read is enabled	0x1	Tells the SoC SPI controller if Quad I/O Fast Read (QIORE) instructions are supported. This will only take effect if the SPI flash device connected to the SPI controller also supports QIORE in its SFDP table and has the Dual Output bit and the Fast Read Support bit enabled in the FLCOMP register inside the SPI flash descriptor region. ***Note:*** Only one soft strap between DORE/DIORE/QORE/QIORE SPI modes can be enabled at a time. i.e. if DORE is enabled via soft strap, then DIORE/QORE/QIORE soft straps must be set to disabled via soft strap.
9	+ 24h	6:4	SPI - Boot Block Size	0x0; 64KB; Invert A16 if Top Swap is enabled 0x1; 128KB; Invert A17 if Top Swap is enabled 0x2; 256KB; Invert A18 if Top Swap is enabled 0x3; 512KB; Invert A19 if Top Swap is enabled 0x4; 1MB; Invert A20 if Top Swap is enabled	0x0	Tells the SoC if the size of the Top Swap boot block when booting from the SPI interface. **Note**: If boot interface is LPC, this strap has not effect and the Boot block size is 64 KB
9	+ 24h	8	SPI - Enable Delay before write busy poll	0x1; SPI controller may delay the start of issuing read_status to poll for flash device busy after a write operation (enabled) 0x0; SPI controller must start polling immediately after issuing the write command (disabled)	0x0	Tells the SoC if SPI delay before write busy poll is enabled
9	+ 24h	9	SPI - Enable Delay before erase busy poll	0x1; SPI controller may delay the start of issuing read_status to poll for flash device busy after an erase operation (enabled) 0x0; SPI controller must start polling immediately after issuing the erase command. (disabled)	0x0	Tells the SoC if SPI delay before erase busy poll is enabled
9	+ 24h	10	SPI - Enable Delay before RPMC busy poll	0x1; SPI controller may delay the start of polling for flash device busy after an RPMC operation (enabled) 0x0; SPI controller must start polling immediately after issuing any RPMC command. (disabled)	0x0	Tells the SoC if SPI delay before RPMC busy poll is enabled

Table 4-3. Flash Descriptor Soft Straps (Sheet 26 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
9	+ 24h	11	SPI - Enable device 0 deep power down	0x1; flash controller implements enter/exit deep power down to this device if it discovers capability via SFDP (enabled) 0x0; flash controller does not implement enter/exit deep power down for this device (disabled)	0x0	Tells the SoC to implement SPI device 0 (Flash) deep power down
9	+ 24h	12	SPI - Enable device 1 deep power down	0x1; flash controller implements enter/exit deep power down to this device if it discovers capability via SFDP (enabled) 0x0; flash controller does not implement enter/exit deep power down for this device (disabled)	0x0	Tells the SoC to implement SPI device 1 (Flash) deep power down
9	+ 24h	13	SPI - Host Software Sequencing Enable	0x0 - Host SW sequencing is disabled. Default to HW sequencing. 0x1 - Host SW sequencing is enabled along with HW sequencing.	0x0	Tells the SoC that SPI SW sequencing is supported in addition to HW sequencing. This soft strap takes precedence over BIOS_DLOCK.SSEQLOCKDN and BIOS_HSFSTS_CTL.FLOCKDN registers. Should it be set to 0x0, these registers become RO and cannot enable SPI SW sequencing. ***Note:*** SPI SW Sequencing is intended as a backup to HW sequencing.
9	+ 24h	27:25	SPI - Resume Hold off Delay (tRHD)	0x0; 0us 0x1; 2us 0x2; 4us 0x3; 6us 0x4; 8us 0x5; 10us 0x6; 12us 0x7; 14us	0x4	Tells the SoC to specify the time after the completion of a pri_op before the flash controller sends the resume instruction. If a new pri_op is eligible to be issued prior to the end of this delay time then the pri_op is issued and the timer is re-initialized to tRHD.
9	+ 24h	31:30	SPI - Resume to suspend Timing	0x0; 128 us 0x1; 256 us 0x2; 512 us 0x3; no ceiling, use the SFDP values	0x3	Tells the SoC the maximum value for the write and erase resume to suspend intervals
10	+ 28h	10:8	SPI - TPM Clock Frequency	0x2; 48 MHz 0x4; 30 MHz 0x6; 17 MHz	0x6	Tells the SoC what clock frequency to use when talking to TPM on SPI ***Note:*** To control the speed of the instructions between the SoC SPI controller and the SPI flash memory boot device connected to it, configure the FLCOMP register inside the SPI flash descriptor region.

Table 4-3. Flash Descriptor Soft Straps (Sheet 27 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
10	+ 28h	14	SPI - Ignore Fixed FLMSTR Permission	0x0; FLMSTR fixed permission to regions is enabled 0x1; FLMSTR fixed permission to regions may be disabled	0x0	Tells the SoC to ignore Fixed FLMSTR Permission settings that are set in the FLMSTR registers inside the descriptor region of the SPI flash memory boot device connected to the SoC to force the SPI controller to ignore each Master's default permission to its own region(s). This affects FLMSTR default permissions and a software master's capability to extend permission to its region(s).
11	+ 2Ch	31:0	SPI - Global Protected Range default (GPRD)	Value: Hex	0x00000000	Tells the SoC to set the default value of the GPR0 register in the SPI Flash Controller as a security feature. This soft strap value is intended to be configured by customer.

Table 4-3. Flash Descriptor Soft Straps (Sheet 28 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
PECI						
0	+ 0h	6:0	PECI - Target Write Address	Value: Hex	0x4C	The SoC reads this strap and programs the ADDR0 field of the Target Address Control Register (TACTRL) located at sideband Port CEh, offset 228h.
1	+ 4h	26:20	PECI - Target Read Address	Value: Hex	0x4B	The SoC reads this strap and programs the GPTRADR field of the General Control Register (GPBRCTRL) located at sideband Port CEh, offset 240h
Top Swap Override						
30	+ 78h	1	Protected Range Top Swap Override Enable	0x0; PRR_TS_OVR is Read Only (disabled) 0x1; Allows PRR_TS_OVR register to be Read/Write. (enabled)	0x0	Tells the SoC if Protected Range Top Swap Override is enabled by setting the permission to register **PRR_TS_OVR** to Read/Write or Read Only.
TPM over SPI or LPC						
30	+ 78h	0	TPM Over SPI or LPC Select	0x0 - TPM on LPC 0x1 -TPM on SPI	0x0	Tells the SoC to enable TPM on SPI or LPC interfaces. The Intel Manageability Engine (ME) consumes this soft strap.

Table 4-3. Flash Descriptor Soft Straps (Sheet 29 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
Intel® Management Engine (Intel® ME)						
14	+ 38h	1	ME ROM - Intel® Trace Hub Soft Enable	0x0; Tracing is disabled 0x1; Tracing is enabled	0x0	This soft strap enables Intel Trace Hub-based tracing in ME ROM. **Note:** In order to use Intel Trace Hub over USB3.0, SS14 bit[17] - "ME - Intel® Direct Connect Interface Enabled" must be set to 0x1 - Enabled.
14	+ 38h	17	ME - Intel® Direct Connect Interface Enabled	0x0; Intel® DCI Disabled 0x1; Intel® DCI Enabled	0x0	Tells the SoC to enable Intel® Direct Connect Interface (Intel® DCI). **Note:** This is required to enable debugging over USB3.0 interface. This soft strap is also required for Intel Trace Hub to work over USB3.0 For more information on Intel DCI. See EDS Chapter 38.4
14	+ 38h	21	ME - Intel® Trace Hub - Emergency Mode	0x0; ROM Tracing Emergency mode disabled 0x1; ROM Tracing Emergency mode enabled	0x0	Tells the SoC to enable ROM Tracing in the base platform ME image. This is for DEBUG ONLY should not be set for production environment **Note:** Enabling this soft strap will increase the ME loading time due to ME outputting Debug traces and thus increase overall system boot time.
Intel® ME SMBus Management Transport 0 - SMT 0 Configuration						
31	+ 7Ch	8	ME SMBus Management Transport 1 - SMT 0 SMBus Enable	0x0; SMT disabled 0x1; SMT enabled	0x1	Tells the SoC that SMT0 is enabled and connected to the SMBus. Disabled means that the device is not connected to the SMBus Pins.
35	+ 8Ch	17:16	ME SMBus Management Transport (SMT) 0 - SMBus Clock	0x1; Standard (100 KHz) 0x2; Fast Mode (400 KHz) 0x3; Fast Mode Plus (1 MHz)	0x1	Tells the SoC the speed the physical bus must operate at. **Note:** It is up to the system designer to ensure that all devices on the same SMBus segment are capable of operating at the programmed speed.
33	+ 84h	8	ME SMBus Management Transport (SMT) 0 - Host SMBus Address Enable	0x0; Host SMBus Target Address disabled 0x1; Host SMBus Target Address enabled	0x0	Tells the SoC SMT controller that it is the SMBus segment owner and any device sending a request to Address 10h should be claimed by the SMT controller. When set, enables HW to accept write cycles targeting address 10h and enables target logic to ACK Host SMBus address (10h) on the SMBus. **Note:** This bit must be set to "1" when HW is configured to support MCTP and chipset is the SMBus Segment Owner.

Table 4-3. Flash Descriptor Soft Straps (Sheet 30 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
31	+ 7Ch	16	ME SMBus Management Transport (SMT) 0 - General Purpose (GP) Target Address Enable	0x0; GP Target Address is Disabled 0x1; GP Target Address is Enabled	0x0	Tells the SoC to enable the target slave address of the SMT Controller so that it can communicate with externally initiated Block Read commands. (Address Enable Bit) **Note:** The 'Enable' for this address is programmed through this soft strap. HW does not take any action based on the value of this soft strap. It is simply provided to FW for reading.
31	+ 7Ch	23:17	ME SMBus Management Transport (SMT) 0 - General Purpose (GP) Target Address	Value: Hex	0x00	Tells the SoC the 7-bit configurable target slave address of the SMT Controller so that it can communicate with externally initiated Block Read commands. **Note:** This address has to be configured so that it does not conflict with other devices on the SMBus network.
32	+ 80h	16	ME SMBus Management Transport (SMT) 0 - I^2C Address Enable	0x0; I^2C Target Address disabled 0x1; I^2C Target Address enabled	0x0	Tells the SoC to enable the target slave address of the SMT Controller so that it can communicate as a slave over I^2C (Address Enable Bit)
31	+ 7Ch	30:24	ME SMBus Management Transport (SMT) 0 - I^2C Address	Value: Hex	0x00	Tells the SoC the 7-bit configurable target slave address of the SMT Controller so that it can communicate as a slave over I^2C. **Notes:** I^2C address of the SMT logic for support of I^2C target. All I^2C protocol transactions targeting this address will be ACKd by the HW if the TPOLICY.I2C_EN register is set. -This address has to be configured so that it does not conflict with other devices on the SMBus network.
32	+ 80h	24	ME SMBus Management Transport (SMT) 0 - Alert Sending Device (ASD) Address Enable	0x0; ASD Target Address disabled 0x1; ASD Target Address enabled	0x0	Tells the SoC to enable the target slave address of the SMT Controller so that it can communicate as a slave using ASD protocol. (Address Enable Bit)
32	+ 80h	6:0	ME SMBus Management Transport (SMT) 0 - Alert Sending Device (ASD) Address	Value: Hex	0x00	Tells the SoC the 7-bit configurable target slave address of the SMT Controller so that it can communicate as a slave using ASD protocol. **Notes:** -This address has to be configured so that it does not conflict with other devices on the SMBus network. -SMBus address of the SMT logic for support of ASF protocol. All ASF protocol transactions targeting this address will be ACKed by the HW if the TPOLICY.ASD_EN register is set.

Table 4-3. Flash Descriptor Soft Straps (Sheet 31 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
33	+ 84h	0	ME SMBus Management Transport (SMT) 0 - MCTP Address Enable	0x0; MCTP Target Address disabled 0x1; MCTP Target Address enabled	0x0	Tells the SoC to enable the target slave address of the SMT Controller so that it can communicate as a slave using MCTP protocol. (Address Enable Bit)
32	+ 80h	14:8	ME SMBus Management Transport (SMT) 0 - MCTP Address	Value: Hex	0x00	Tells the SoC the 7-bit configurable target slave address of the SMT Controller so that it can communicate as a slave using MCTP protocol. **Note:** MCTP address of the SMT logic. All MCTP protocol transactions targeting this address will be ACKd by the HW if the TPOLICY.MCTP_EN register is set.
33	+ 84h	31:16	ME SMBus Management Transport (SMT) 0 - Alert Standard Format (ASF) Unique Device Identifier (UDID) B118 (Subsystem Vendor ID)	Value: Hex	0x0000	Tells the SoC the ASF UDID Subsystem Vendor ID: Enter a 16 bit subsystem Vendor ID **Note:** To be configured in conjunction with the ASF UDID Subsystem Device ID Soft Strap -The master uses this to query devices on the SMBus network.
34	+ 88h	15:0	ME SMBus Management Transport (SMT) 0 - Alert Standard Format (ASF) Unique Device Identifier (UDID) B118 (Subsystem Device ID)	Value: Hex	0x0000	Tells the SoC the ASF UDID Subsystem Device ID: Enter a 16 bit subsystem Device ID **Note:** To be configured in conjunction with the ASF UDID Subsystem Vendor ID Soft Strap -The master uses this to query devices on the SMBus network.
34	+ 88h	31:16	ME SMBus Management Transport (SMT) 0 - MCTP Unique Device Identifier (UDID) B1512 (Subsystem Vendor ID)	Value: Hex	0x0000	Tells the SoC the MCTP UDID Subsystem Vendor ID: Enter a 16 bit subsystem Vendor ID **Note:** To be configured in conjunction with the MCTP UDID Subsystem Device ID Soft Strap -The master uses this to query devices on the SMBus network.
35	+ 8Ch	15:0	ME SMBus Management Transport (SMT) 0 - MCTP Unique Device Identifier (UDID) B1512 (Subsystem Device ID)	Value: Hex	0x0000	Tells the SoC the MCTP UDID Subsystem Device ID: Enter a 16 bit subsystem Device ID **Note:** To be configured in conjunction with the MCTP UDID Subsystem Vendor ID Soft Strap -The master uses this to query devices on the SMBus network.

Table 4-3. Flash Descriptor Soft Straps (Sheet 32 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
Intel® ME SMBus Management Transport 1 - SMT 1 Configuration						
36	+ 90h	8	ME SMBus Management Transport (SMT) 1 - SMT 1 SMBus Enable	0x0; SMT disabled 0x1; SMT enabled	0x1	Tells the SoC that SMT1 is enabled and connected to the SMBus. Disabled means that the device is not connected to the SMBus Pins.
40	+ A0h	17:16	ME SMBus Management Transport (SMT) 1 - SMBus Clock	0x1; Standard (100 KHz) 0x2; Fast Mode (400 KHz) 0x3; Fast Mode Plus (1 MHz)	0x1	Tells the SoC the speed the physical bus must operate at. **Note:** It is up to the system designer to ensure that all devices on the same SMBus segment are capable of operating at the programmed speed.
38	+ 98h	8	ME SMBus Management Transport (SMT) 1 - Host SMBus Address Enable	0x0; Host SMBus Target Address disabled 0x1; Host SMBus Target Address enabled	0x0	Tells the SoC SMT controller that it is the SMBus segment owner and any device sending a request to Address 10h should be claimed by the SMT controller. When set, enables HW to accept write cycles targeting address 10h and enables target logic to ACK Host SMBus address (10h) on the SMBus. **Note:** This bit must be set to "1" when HW is configured to support MCTP and chipset is the SMBus Segment Owner.
36	+ 90h	16	ME SMBus Management Transport (SMT) 1 - General Purpose (GP) Target Address Enable	0x0; GP Target Address is Disabled 0x1; GP Target Address is Enabled	0x0	Tells the SoC to enable the target slave address of the SMT Controller so that it can communicate with externally initiated Block Read commands. (Address Enable Bit) **Note:** The 'Enable' for this address is programmed through this soft strap. HW does not take any action based on the value of this soft strap. It is simply provided to FW for reading.
36	+ 90h	23:17	ME SMBus Management Transport (SMT) 1 - General Purpose (GP) Target Address	Value: Hex	0x00	Tells the SoC the 7-bit configurable target slave address of the SMT Controller so that it can communicate with externally initiated Block Read commands. **Note:** This address has to be configured so that it does not conflict with other devices on the SMBus network.
37	+ 94h	16	ME SMBus Management Transport (SMT) 1 - I^2C Address Enable	0x0; I^2C Target Address disabled 0x1; I^2C Target Address enabled	0x0	Tells the SoC to enable the target slave address of the SMT Controller so that it can communicate as a slave over I^2C (Address Enable Bit).

Table 4-3. Flash Descriptor Soft Straps (Sheet 33 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
36	+ 90h	30:24	ME SMBus Management Transport (SMT) 1 - I^2C Address	Value: Hex	0x00	Tells the SoC the 7-bit configurable target slave address of the SMT Controller so that it can communicate as a slave over I^2C. **Notes:** I^2C address of the SMT logic for support of I^2C target. All I^2C protocol transactions targeting this address will be ACKd by the HW if the TPOLICY.I2C_EN register is set. -This address has to be configured so that it does not conflict with other devices on the SMBus network.
37	+ 94h	24	ME SMBus Management Transport (SMT) 1 - Alert Sending Device (ASD) Address Enable	0x0; ASD Target Address disabled 0x1; ASD Target Address enabled	0x0	Tells the SoC to enable the target slave address of the SMT Controller so that it can communicate as a slave using ASD protocol. (Address Enable Bit)
37	+ 94h	6:0	ME SMBus Management Transport (SMT) 1 - Alert Sending Device (ASD) Address	Value: Hex	0x00	Tells the SoC the 7-bit configurable target slave address of the SMT Controller so that it can communicate as a slave using ASD protocol. **Notes:** -This address has to be configured so that it does not conflict with other devices on the SMBus network. -SMBus address of the SMT logic for support of ASF protocol. All ASF protocol transactions targeting this address will be ACKed by the HW if the TPOLICY.ASD_EN register is set.
38	+ 98h	0	ME SMBus Management Transport (SMT) 1 - MCTP Address Enable	0x0; MCTP Target Address disabled 0x1; MCTP Target Address enabled	0x0	Tells the SoC to enable the target slave address of the SMT Controller so that it can communicate as a slave using MCTP protocol. (Address Enable Bit)
37	+ 94h	14:8	ME SMBus Management Transport (SMT) 1 - MCTP Address	Value: Hex	0x00	Tells the SoC the 7-bit configurable target slave address of the SMT Controller so that it can communicate as a slave using MCTP protocol. **Note:** MCTP address of the SMT logic. All MCTP protocol transactions targeting this address will be ACKd by the HW if the TPOLICY.MCTP_EN register is set.
38	+ 98h	31:16	ME SMBus Management Transport (SMT) 1 - Alert Standard Format (ASF) Unique Device Identifier (UDID) B118 (Subsystem Vendor ID)	Value: Hex	0x0000	Tells the SoC the ASF UDID Subsystem Vendor ID: Enter a 16 bit subsystem Vendor ID **Note:** To be configured in conjunction with the ASF UDID Subsystem Device ID Soft Strap -The master uses this to query devices on the SMBus network.

Table 4-3. Flash Descriptor Soft Straps (Sheet 34 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
39	+ 9Ch	15:0	ME SMBus Management Transport (SMT) 1 - Alert Standard Format (ASF) Unique Device Identifier (UDID) B118 (Subsystem Device ID)	Value: Hex	0x0000	Tells the SoC the ASF UDID Subsystem Device ID: Enter a 16 bit subsystem Device ID **Note:** To be configured in conjunction with the ASF UDID Subsystem Vendor ID Soft Strap -The master uses this to query devices on the SMBus network.
39	+ 9Ch	31:16	ME SMBus Management Transport (SMT) 1 - MCTP Unique Device Identifier (UDID) B1512 (Subsystem Vendor ID)	Value: Hex	0x0000	Tells the SoC the MCTP UDID Subsystem Vendor ID: Enter a 16 bit subsystem Vendor ID **Note:** To be configured in conjunction with the MCTP UDID Subsystem Device ID Soft Strap -The master uses this to query devices on the SMBus network.
40	+ A0h	15:0	ME SMBus Management Transport (SMT) 1 - MCTP Unique Device Identifier (UDID) B1512 (Subsystem Device ID)	Value: Hex	0x0000	Tells the SoC the MCTP UDID Subsystem Device ID: Enter a 16 bit subsystem Device ID **Note:** To be configured in conjunction with the MCTP UDID Subsystem Vendor ID Soft Strap -The master uses this to query devices on the SMBus network.

Table 4-3. Flash Descriptor Soft Straps (Sheet 35 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
Intel® ME SMBus Management Transport 2 - SMT 2 Configuration						
41	+ A4h	8	ME SMBus Management Transport (SMT) 2 - SMT 2 SMBus Enable	0x0; SMT disabled 0x1; SMT enabled	0x1	Tells the SoC that SMT2 is enabled and connected to the SMBus. Disabled means that the device is not connected to the SMBus Pins.
45	+ B4h	17:16	ME SMBus Management Transport (SMT) 2 - SMBus Clock	0x1; Standard (100 KHz) 0x2; Fast Mode (400 KHz) 0x3; Fast Mode Plus (1 MHz)	0x1	Tells the SoC the speed the physical bus must operate at. **Note:** It is up to the system designer to ensure that all devices on the same SMBus segment are capable of operating at the programmed speed.
43	+ ACh	8	ME SMBus Management Transport (SMT) 2 - Host SMBus Address Enable	0x0; Host SMBus Target Address disabled 0x1; Host SMBus Target Address enabled	0x0	Tells the SoC SMT controller that it is the SMBus segment owner and any device sending a request to Address 10h should be claimed by the SMT controller. When set, enables HW to accept write cycles targeting address 10h and enables target logic to ACK Host SMBus address (10h) on the SMBus. **Note:** This bit must be set to "1" when HW is configured to support MCTP and chipset is the SMBus Segment Owner.
41	+ A4h	16	ME SMBus Management Transport (SMT) 2 - General Purpose (GP) Target Address Enable	0x0; GP Target Address is Disabled 0x1; GP Target Address is Enabled	0x0	Tells the SoC to enable the target slave address of the SMT Controller so that it can communicate with externally initiated Block Read commands. (Address Enable Bit) **Note:** The 'Enable' for this address is programmed through this soft strap. HW does not take any action based on the value of this soft strap. It is simply provided to FW for reading.
41	+ A4h	23:17	ME SMBus Management Transport (SMT) 2 - General Purpose (GP) Target Address	Value: Hex	0x00	Tells the SoC the 7-bit configurable target slave address of the SMT Controller so that it can communicate with externally initiated Block Read commands. **Notes:** -This address has to be configured so that it does not conflict with other devices on the SMBus network.
42	+ A8h	16	ME SMBus Management Transport (SMT) 2 - I^2C Address Enable	0x0; I^2C Target Address disabled 0x1; I^2C Target Address enabled	0x0	Tells the SoC to enable the target slave address of the SMT Controller so that it can communicate as a slave over I^2C (Address Enable Bit)

Table 4-3. Flash Descriptor Soft Straps (Sheet 36 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
41	+ A4h	30:24	ME SMBus Management Transport (SMT) 2 - I^2C Address	Value: Hex	0x00	Tells the SoC the 7-bit configurable target slave address of the SMT Controller so that it can communicate as a slave over I^2C. **Notes:** - address of the SMT logic for support of I^2C target. All I^2C protocol transactions targeting this address will be ACKd by the HW if the TPOLICY.I2C_EN register is set. -This address has to be configured so that it does not conflict with other devices on the SMBus network.
42	+ A8h	24	ME SMBus Management Transport (SMT) 2 - Alert Sending Device (ASD) Address Enable	0x0; ASD Target Address disabled 0x1; ASD Target Address enabled	0x0	Tells the SoC to enable the target slave address of the SMT Controller so that it can communicate as a slave using ASD protocol. (Address Enable Bit)
42	+ A8h	6:0	ME SMBus Management Transport (SMT) 2 - Alert Sending Device (ASD) Address	Value: Hex	0x00	Tells the SoC the 7-bit configurable target slave address of the SMT Controller so that it can communicate as a slave using ASD protocol. **Notes:** -This address has to be configured so that it does not conflict with other devices on the SMBus network. -SMBus address of the SMT logic for support of ASF protocol. All ASF protocol transactions targeting this address will be ACKed by the HW if the TPOLICY.ASD_EN register is set.
43	+ ACh	0	ME SMBus Management Transport (SMT) 2 - MCTP Address Enable	0x0; MCTP Target Address disabled 0x1; MCTP Target Address enabled	0x0	Tells the SoC to enable the target slave address of the SMT Controller so that it can communicate as a slave using MCTP protocol. (Address Enable Bit)
42	+ A8h	14:8	ME SMBus Management Transport (SMT) 2 - MCTP Address	Value: Hex	0x00	Tells the SoC the 7-bit configurable target slave address of the SMT Controller so that it can communicate as a slave using MCTP protocol. **Note:** MCTP address of the SMT logic. All MCTP protocol transactions targeting this address will be ACKd by the HW if the TPOLICY.MCTP_EN register is set.
43	+ ACh	31:16	ME SMBus Management Transport (SMT) 2 - Alert Standard Format (ASF) Unique Device Identifier (UDID) B118 (Subsystem Vendor ID)	Value: Hex	0x0000	Tells the SoC the ASF UDID Subsystem Vendor ID: Enter a 16 bit subsystem Vendor ID **Note:** To be configured in conjunction with the ASF UDID Subsystem Device ID Soft Strap -The master uses this to query devices on the SMBus network.

Table 4-3. Flash Descriptor Soft Straps (Sheet 37 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
44	+ B0h	15:0	ME SMBus Management Transport (SMT) 2 - Alert Standard Format (ASF) Unique Device Identifier (UDID) B118 (Subsystem Device ID)	Value: Hex	0x0000	Tells the SoC the ASF UDID Subsystem Device ID: Enter a 16 bit subsystem Device ID **Note:** To be configured in conjunction with the ASF UDID Subsystem Vendor ID Soft Strap -The master uses this to query devices on the SMBus network.
44	+ B0h	31:16	ME SMBus Management Transport (SMT) 2 - MCTP Unique Device Identifier (UDID) B1512 (Subsystem Vendor ID)	Value: Hex	0x0000	Tells the SoC the MCTP UDID Subsystem Vendor ID: Enter a 16 bit subsystem Vendor ID **Note:** To be configured in conjunction with the MCTP UDID Subsystem Device ID Soft Strap -The master uses this to query devices on the SMBus network.
45	+ B4h	15:0	ME SMBus Management Transport (SMT) 2 - MCTP Unique Device Identifier (UDID) B1512 (Subsystem Device ID)	Value: Hex	0x0000	Tells the SoC the MCTP UDID Subsystem Device ID: Enter a 16 bit subsystem Device ID **Note:** To be configured in conjunction with the MCTP UDID Subsystem Vendor ID Soft Strap -The master uses this to query devices on the SMBus network.

Table 4-3. Flash Descriptor Soft Straps (Sheet 38 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
Innovation Engine (IE)						
47	+ BCh	13	IE Disable	0x0; IE is enabled 0x1; IE is disabled	0x0	Tells the SoC to Disable the Innovation Engine (IE)
47	+ BCh	14	IE ROM - SMT Log Enable	0x0; ROM log to SMT Disabled 0x1; ROM log to SMT Enabled	0x0	Tells the SoC to Enable the IE ROM log to SMT0 **Note:** IE will run if IE Verified Boot is enabled even if this SS disables the IE.
IE SMBus Management Transport 0 - SMT 0 Configuration						
48	+ C0h	8	IE SMBus Management Transport (SMT) 0 - SMT 0 SMBus Enable	0x0; SMT0 disabled 0x1; SMT0 enabled	0x1	Tells the SoC that SMT0 is enabled and connected to the SMBus. Disabled means that the device is not connected to the SMBus Pins.
52	+ D0h	17:16	IE SMBus Management Transport (SMT) 0 - SMBus Clock	0x1; Standard (100 KHz) 0x2; Fast Mode (400 KHz) 0x3; Fast Mode Plus (1 MHz)	0x1	Tells the SoC the speed the physical bus must operate at. **Note:** It is up to the system designer to ensure that all devices on the same SMBus segment are capable of operating at the programmed speed.
50	+ C8h	8	IE SMBus Management Transport (SMT) 0 - Host SMBus Address Enable	0x0; Host SMBus Target Address disabled 0x1; Host SMBus Target Address enabled	0x0	Tells the SoC SMT controller that it is the SMBus segment owner and any device sending a request to Address 10h should be claimed by the SMT controller. When set, enables HW to accept write cycles targeting address 10h and enables target logic to ACK Host SMBus address (10h) on the SMBus. **Note:** This bit must be set to "1" when HW is configured to support MCTP and chipset is the SMBus Segment Owner.
48	+ C0h	16	IE SMBus Management Transport (SMT) 0 - General Purpose (GP) Target Address Enable	0x0; GP Target Address is Disabled 0x1; GP Target Address is Enabled	0x0	Tells the SoC to enable the target slave address of the SMT Controller so that it can communicate with externally initiated Block Read commands. (Address Enable Bit) **Note:** The 'Enable' for this address is programmed through this soft strap. HW does not take any action based on the value of this soft strap. It is simply provided to FW for reading.
48	+ C0h	23:17	IE SMBus Management Transport (SMT) 0 - General Purpose (GP) Target Address	Value: Hex	0x00	Tells the SoC the 7-bit configurable target slave address of the SMT Controller so that it can communicate with externally initiated Block Read commands. **Note:** This address has to be configured so that it does not conflict with other devices on the SMBus network.

Table 4-3. Flash Descriptor Soft Straps (Sheet 39 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
49	+ C4h	16	IE SMBus Management Transport (SMT) 0 - I^2C Address Enable	0x0; I^2C Target Address disabled 0x1; I^2C Target Address enabled	0x0	Tells the SoC to enable the target slave address of the SMT Controller so that it can communicate as a slave over I^2C (Address Enable Bit)
48	+ C0h	30:24	IE SMBus Management Transport (SMT) 0 - I^2C Address	Value: Hex	0x00	Tells the SoC the 7-bit configurable target slave address of the SMT Controller so that it can communicate as a slave over I^2C. **Notes:** -I^2C address of the SMT logic for support of I^2C target. All I^2C protocol transactions targeting this address will be ACKd by the HW if the TPOLICY.I2C_EN register is set. -This address has to be configured so that it does not conflict with other devices on the SMBus network.
49	+ C4h	24	IE SMBus Management Transport (SMT) 0 - Alert Sending Device (ASD) Address Enable	0x0; ASD Target Address disabled 0x1; ASD Target Address enabled	0x0	Tells the SoC to enable the target slave address of the SMT Controller so that it can communicate as a slave using ASD protocol. (Address Enable Bit)
49	+ C4h	6:0	IE SMBus Management Transport (SMT) 0 - Alert Sending Device (ASD) Address	Value: Hex	0x00	Tells the SoC the 7-bit configurable target slave address of the SMT Controller so that it can communicate as a slave using ASD protocol. **Notes:** -This address has to be configured so that it does not conflict with other devices on the SMBus network. -SMBus address of the SMT logic for support of ASF protocol. All ASF protocol transactions targeting this address will be ACKed by the HW if the TPOLICY.ASD_EN register is set.
50	+ C8h	0	IE SMBus Management Transport (SMT) 0 - MCTP Address Enable	0x0; MCTP Target Address disabled 0x1; MCTP Target Address enabled	0x0	Tells the SoC to enable the target slave address of the SMT Controller so that it can communicate as a slave using MCTP protocol. (Address Enable Bit)
49	+ C4h	14:8	IE SMBus Management Transport (SMT) 0 - MCTP Address	Value: Hex	0x00	Tells the SoC the 7-bit configurable target slave address of the SMT Controller so that it can communicate as a slave using MCTP protocol. **Note:** MCTP address of the SMT logic. All MCTP protocol transactions targeting this address will be ACKd by the HW if the TPOLICY.MCTP_EN register is set.

Table 4-3. Flash Descriptor Soft Straps (Sheet 40 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
50	+ C8h	31:16	IE SMBus Management Transport (SMT) 0 - Alert Standard Format (ASF) Unique Device Identifier (UDID) B118 (Subsystem Vendor ID)	Value: Hex	0x0000	Tells the SoC the ASF UDID Subsystem Vendor ID: Enter a 16 bit subsystem Vendor ID **Note:** To be configured in conjunction with the ASF UDID Subsystem Device ID Soft Strap -The master uses this to query devices on the SMBus network.
51	+ CCh	15:0	IE SMBus Management Transport (SMT) 0 - Alert Standard Format (ASF) Unique Device Identifier (UDID) B118 (Subsystem Device ID)	Value: Hex	0x0000	Tells the SoC the ASF UDID Subsystem Device ID: Enter a 16 bit subsystem Device ID **Note:** To be configured in conjunction with the ASF UDID Subsystem Vendor ID Soft Strap -The master uses this to query devices on the SMBus network.
51	+ CCh	31:16	IE SMBus Management Transport (SMT) 0 - MCTP Unique Device Identifier (UDID) B1512 (Subsystem Vendor ID)	Value: Hex	0x0000	Tells the SoC the MCTP UDID Subsystem Vendor ID: Enter a 16 bit subsystem Vendor ID **Note:** To be configured in conjunction with the MCTP UDID Subsystem Device ID Soft Strap -The master uses this to query devices on the SMBus network.
52	+ D0h	15:0	IE SMBus Management Transport (SMT) 0 - MCTP Unique Device Identifier (UDID) B1512 (Subsystem Device ID)	Value: Hex	0x0000	Tells the SoC the MCTP UDID Subsystem Device ID: Enter a 16 bit subsystem Device ID **Note:** To be configured in conjunction with the MCTP UDID Subsystem Vendor ID Soft Strap -The master uses this to query devices on the SMBus network.

Table 4-3. Flash Descriptor Soft Straps (Sheet 41 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
IE SMBus Management Transport 1 - SMT 1 Configuration						
53	+ D4h	8	IE SMBus Management Transport (SMT) 1 - SMT 1 SMBus Enable	0x0; SMT1 disabled 0x1; SMT1 enabled	0x1	Tells the SoC that SMT1 is enabled and connected to the SMBus. Disabled means that the device is not connected to the SMBus Pins.
57	+ E4h	17:16	IE SMBus Management Transport (SMT) 1 - SMBus Clock	0x1; Standard (100 KHz) 0x2; Fast Mode (400 KHz) 0x3; Fast Mode Plus (1 MHz)	0x1	Tells the SoC the speed the physical bus must operate at. **Note:** It is up to the system designer to ensure that all devices on the same SMBus segment are capable of operating at the programmed speed.
55	+ DCh	8	IE SMBus Management Transport (SMT) 1 - Host SMBus Address Enable	0x0; Host SMBus Target Address disabled 0x1; Host SMBus Target Address enabled	0x0	Tells the SoC SMT controller that it is the SMBus segment owner and any device sending a request to Address 10h should be claimed by the SMT controller. When set, enables HW to accept write cycles targeting address 10h and enables target logic to ACK Host SMBus address (10h) on the SMBus. **Note:** This bit must be set to **"1"** when HW is configured to support MCTP and chipset is the SMBus Segment Owner.
53	+ D4h	16	IE SMBus Management Transport (SMT) 1 - General Purpose (GP) Target Address Enable	0x0; GP Target Address is Disabled 0x1; GP Target Address is Enabled	0x0	Tells the SoC to enable the target slave address of the SMT Controller so that it can communicate with externally initiated Block Read commands. (Address Enable Bit) **Note:** The 'Enable' for this address is programmed through this soft strap. HW does not take any action based on the value of this soft strap. It is simply provided to FW for reading.
53	+ D4h	23:17	IE SMBus Management Transport (SMT) 1 - GP Target Address	Value: Hex	0x00	Tells the SoC the 7-bit configurable target slave address of the SMT Controller so that it can communicate with externally initiated Block Read commands. **Note:** This address has to be configured so that it does not conflict with other devices on the SMBus network.
54	+ D8h	16	IE SMBus Management Transport (SMT) 1 - I^2C Address Enable	0x0; I^2C Target Address disabled 0x1; I^2C Target Address enabled	0x0	Tells the SoC to enable the target slave address of the SMT Controller so that it can communicate as a slave over I^2C (Address Enable Bit)

Table 4-3. Flash Descriptor Soft Straps (Sheet 42 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
53	+ D4h	30:24	IE SMBus Management Transport (SMT) 1 - I^2C Address	Value: Hex	0x00	Tells the SoC the 7-bit configurable target slave address of the SMT Controller so that it can communicate as a slave over I^2C. **Notes:** -I^2C address of the SMT logic for support of I^2C target. All I^2C protocol transactions targeting this address will be ACKd by the HW if the TPOLICY.I2C_EN register is set. -This address has to be configured so that it does not conflict with other devices on the SMBus network.
54	+ D8h	24	IE SMBus Management Transport (SMT) 1 - Alert Sending Device (ASD) AddressEnable	0x0; ASD Target Address disabled 0x1; ASD Target Address enabled	0x0	Tells the SoC to enable the target slave address of the SMT Controller so that it can communicate as a slave using ASD protocol. (Address Enable Bit)
54	+ D8h	6:0	IE SMBus Management Transport (SMT) 1 - Alert Sending Device (ASD) Address	Value: Hex	0x00	Tells the SoC the 7-bit configurable target slave address of the SMT Controller so that it can communicate as a slave using ASD protocol. **Notes:** -This address has to be configured so that it does not conflict with other devices on the SMBus network. -SMBus address of the SMT logic for support of ASF protocol. All ASF protocol transactions targeting this address will be ACKed by the HW if the TPOLICY.ASD_EN register is set.
55	+ DCh	0	IE SMBus Management Transport (SMT) 1 - MCTP Address Enable	0x0; MCTP Target Address disabled 0x1; MCTP Target Address enabled	0x0	Tells the SoC to enable the target slave address of the SMT Controller so that it can communicate as a slave using MCTP protocol. (Address Enable Bit)
54	+ D8h	14:8	IE SMBus Management Transport (SMT) 1 - MCTP Address	Value: Hex	0x00	Tells the SoC the 7-bit configurable target slave address of the SMT Controller so that it can communicate as a slave using MCTP protocol. **Note:** MCTP address of the SMT logic. All MCTP protocol transactions targeting this address will be ACKd by the HW if the TPOLICY.MCTP_EN register is set.
55	+ DCh	31:16	IE SMBus Management Transport (SMT) 1 - Alert Standard Format (ASF) Unique Device Identifier (UDID) B118 (Subsystem Vendor ID)	Value: Hex	0x0000	Tells the SoC the ASF UDID Subsystem Vendor ID: Enter a 16 bit subsystem Vendor ID **Notes:** -To be configured in conjunction with the ASF UDID Subsystem Device ID Soft Strap -The master uses this to query devices on the SMBus network.

Table 4-3. Flash Descriptor Soft Straps (Sheet 43 of 59)

FITC SoC SS #	FPSBA + Offset	Bits	Soft Strap Name	Soft Strap Value List	Default Value	Description
56	+ E0h	15:0	IE SMBus Management Transport (SMT) 1 - Alert Standard Format (ASF) Unique Device Identifier (UDID) B118 (Subsystem Device ID)	Value: Hex	0x0000	Tells the SoC the ASF UDID Subsystem Device ID: Enter a 16 bit subsystem Device ID **Notes:** -To be configured in conjunction with the ASF UDID Subsystem Vendor ID Soft Strap -The master uses this to query devices on the SMBus network.
56	+ E0h	31:16	IE SMBus Management Transport (SMT) 1 - MCTP Unique Device Identifier (UDID) B1512 (Subsystem Vendor ID)	Value: Hex	0x0000	Tells the SoC the MCTP UDID Subsystem Vendor ID: Enter a 16 bit subsystem Vendor ID **Notes:** -To be configured in conjunction with the MCTP UDID Subsystem Device ID Soft Strap -The master uses this to query devices on the SMBus network.

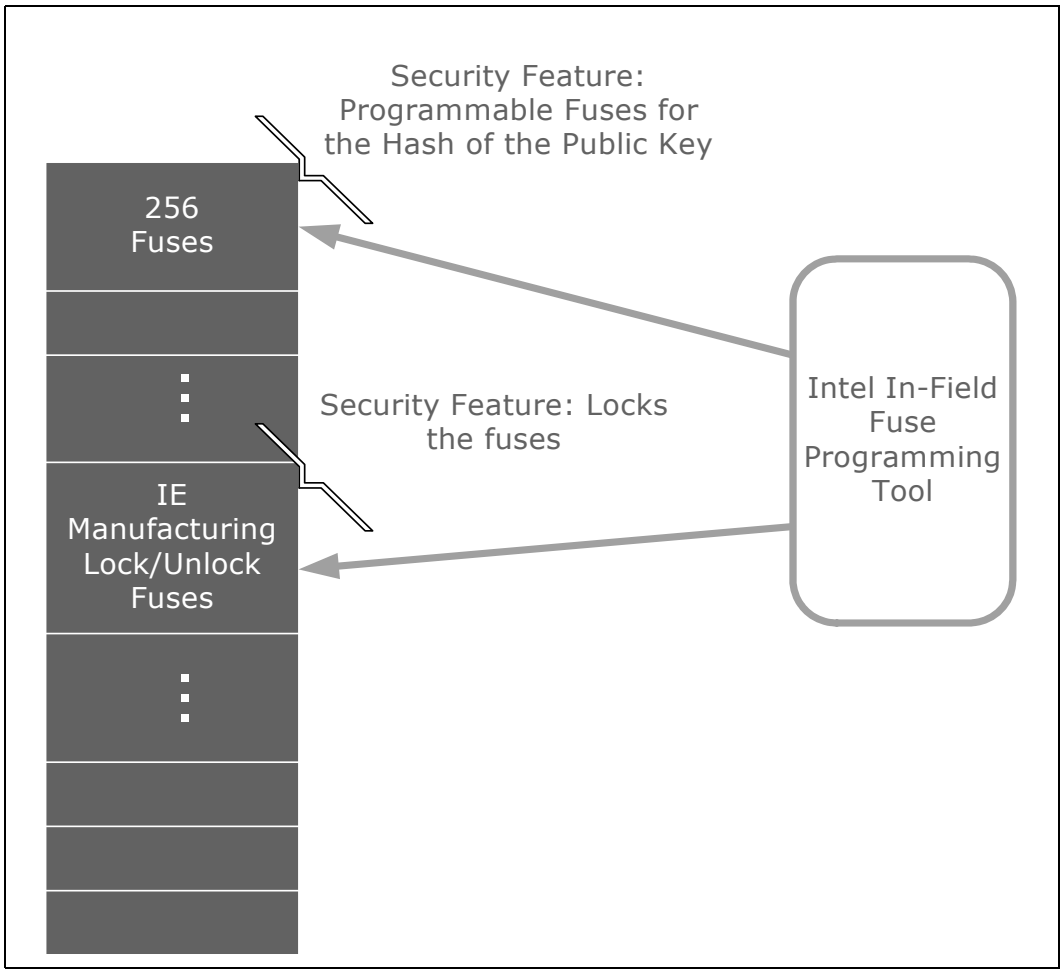
4.3 Fuses Pertaining to the Innovation Engine (IE)

Note: **Intel recommends that customers perform the IE manufacturing lock step described below, even if not using the Innovation Engine, to eliminate any in field security risk.**

There is a set of fuses pertaining to the Innovation Engine (IE) that must be configured with an Intel in-field fuse programming tool. See Figure 4-3, "IE Fuses." These fuses have to be programmed as a security measure to set the hash of the public cryptographic key by the OEM in order for them to use the IE. After the hash of the public key is set, the tool will complete an IE manufacturing lock process flow to finalize the IE. For more information, refer to Chapter 37, "Innovation Engine."

Figure 4-3. IE Fuses



§ §

5 System Agent and Root Complex

5.1 Introduction

The SoC contains a System Agent block that provides the main interface with the processor cores and the other integrated elements. The I/O Fabric provides the connections to the PCI Express* Root Ports and the integrated I/O devices.

The system agent and memory fabric includes the coherence engine for handling all the coherent transactions, data-path to merge coherent and non-coherent traffic, write combining buffers to merge both coherent and non-coherent partial writes and provide the single point of global observation for all transactions. The coherent and memory fabric interfaces to I/O devices through a standard I/O Fabric root complex.

Figure 5-1. What is Covered in This Chapter

Software Developer's Manual (SDM)	-	-	*Intel® 64 and IA-32 Architectures Software Developer's Manual*

5.2 Features

- 40-bit physical, 48-bit linear memory-space addressing
- 20 programmable isolated memory regions (IMR)
- Patrol scrub engine performs a DDR memory scrub to fix correctable memory errors in the background
- Support for xAPIC interrupt architecture:
  - Legacy interrupts (SMI#, INIT#, INTR#, NMI) from IO agents
- Support for x2APIC:
  - In x2APIC mode, APIC registers are accessed through Model Specific Register (MSR) interfaces.
- PCI Express Advanced Error Reporting (AER) support
- MSI signaling
- INTx signaling
- Internal command and data path parity coverage
- Internal RAM parity coverage

5.3 Root Complex

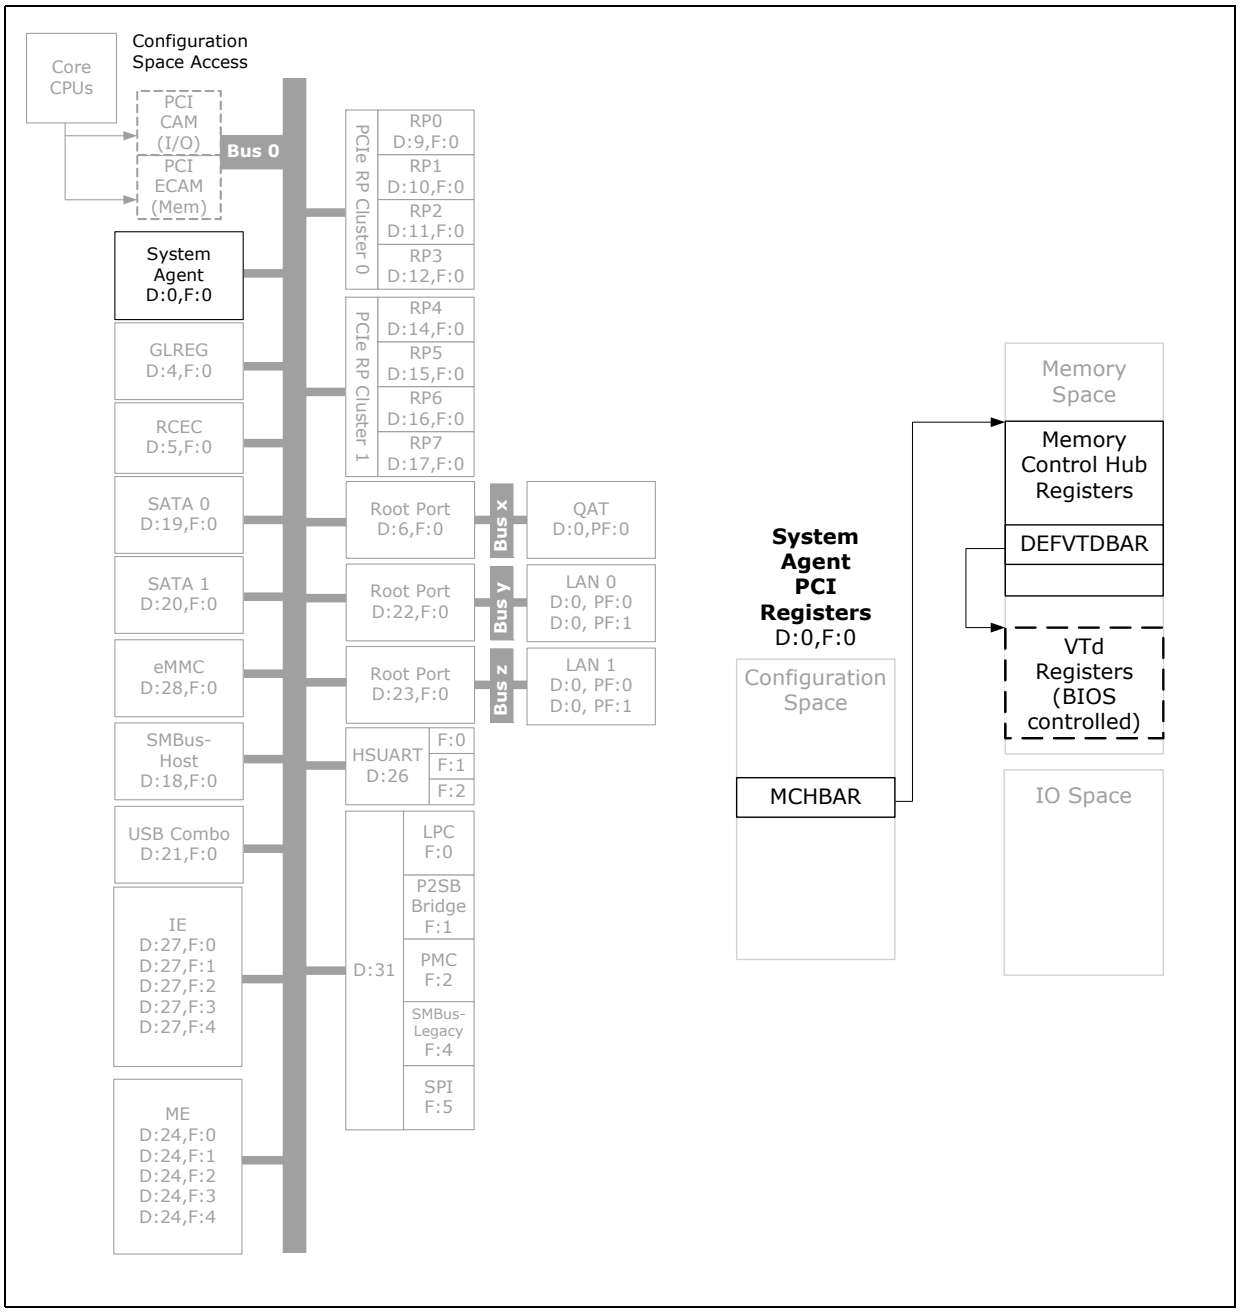
The Host Root Complex, also called the Primary Scalable Fabric (PSF), implements the bus 0 interconnect of a PCI Express* Root Complex. The root complex contains the internal Root Complex Event Collector (RCEC) which is a sub-agent of the Primary to Side Band Bridge (P2SB). The Root Complex is also where the Global and Local Error control and reporting are located as well as most of the SoC Reliability, Availability, and Serviceability (RAS) capabilities. See Chapter 6, “Reliability, Availability and Serviceability (RAS)”.

There is a PCI hierarchy for the Host/IA cores, a hierarchy for Innovation Engine (IE), and one for the Intel® Management Engine (Intel® ME).

5.4 Register Map

Figure 5-2 shows the associated registers from a system software viewpoint.

Figure 5-2. Register Map



5.4.1 Registers in Configuration Space

6 Reliability, Availability and Serviceability (RAS)

6.1 SoC RAS Overview

This chapter describes the features provided by the SoC for the development of high RAS (Reliability, Availability, Serviceability) systems. RAS refers to three main features associated with system's robustness. These features are summarized as follows:

- **Reliability:** Refers to how often errors occur in the system, and whether the system can recover from an error condition.
- **Availability:** Refers to how flexible the system resources can be allocated or redistributed for the system utilizations and system recovery from errors.
- **Serviceability:** Refers to how well the system reports and handles events related to errors.

The SoC is designed to approach the RAS capabilities of Intel® Xeon® processors designed for servers.

6.2 Signal Descriptions

The signal descriptions pertaining to this chapter are shown in Table 6-1, "Signal Names and Descriptions". For additional signal information, including whether a signal is assigned to shared-function pin or can be used as a Customer GPIO signals see Chapter 26, "Customer General-Purpose I/O (GPIO)". The Direction/Type column of Table 6-1, "Signal Names and Descriptions" is interpreted as follows:

- O = Output signal. The SoC has driver circuit.

Table 6-1. Signal Names and Descriptions

Signal Name	Direction	Shared	Description
ERROR_N[0] ERROR_N[1] ERROR_N[2]	O	Yes	**Error:** These active-low signals indicate to the external circuitry the severity of a detected error: • ERROR_N[0] - Correctable Error • ERROR_N[1] - Non-Fatal Error • ERROR_N[2] - Fatal Error While the SoC active-low output signal PMU_PLTRST_N is asserted, these signals are not valid and must be ignored by the platform board circuitry.
IERR_N	O	Yes	**Internal Error:** This active-low signal indicates to the external circuitry that the SoC has detected an error. While the SoC active-low output signal PMU_PLTRST_N is asserted, this signal is not valid and must be ignored by the platform board circuitry.
MCERR_N	O	Yes	**Machine-Check Error:** This active-low signal indicates to the external circuitry that the SoC has detected a Machine Check error. While the SoC active-low output signal PMU_PLTRST_N is asserted, this signal is not valid and must be ignored by the platform board circuitry.

6.3 Feature Summary

- Machine Check Architecture (MCA) implemented which provides MCA Bank registers for Core, L2 Cache, System Agent, Memory Controller, and Power-Management Unit.
  - Error Cloaking and Dual Signaling (MSR 52h) to optionally hide errors from the operating system
  - Corrected Machine-Check error Interrupt (CMCI) that eliminates polling by generating a local interrupt based on programmable threshold values for accumulated MCA corrected errors
- Parity-protected internal data paths of the System Agent circuitry and the interface between the System Agent and the processor cores/L2-cache.
- Parity-protected command and data for the internal I/O system fabric. Parity errors are logged
- Memory Controllers supports ECC, data scrambling, patrol scrubbing and demand scrubbing
- Advanced Error Reporting (AER) supported which provides OS-level error recovery form system errors and also system debug:
  - PCI Express* Root Ports
  - Root Complex Integrated Endpoints: SMBus-Host function; Global/Local Integrated Error Handler (IEH) function
  - Integrated LAN Controllers
  - Integrated Intel® QuickAssist Technology (Intel® QAT) Controller
  - PCI Express* Root Ports (but not the Virtual Root Ports)
- Virtual partitioning with:
  - Enhanced Intel® Virtualization Technology (Intel® VT) for IA-32, Intel® 64 and Intel® Architecture (Intel® VT-x)
  - Intel® Virtualization Technology (Intel® VT) for Directed I/O (Intel® VT-d)
- Error Injection for validation of system error-handling software

6.4 Architectural Overview

This RAS chapter provides information related to the SoC error detection and error reporting mechanisms. The SoC provides Machine Check Architecture to detect and report hardware errors in the CPU cores, L2 Cache, system memory, and the SoC System Agent. The SoC also provides a set of Global Error Registers that are based on a number of Local Error Registers to detect and report SoC-internal hardware errors as well as hardware errors detected by the integrated I/O devices. A number of these I/O devices also support Advanced Error Reporting (AER) which is an optional PCI Express* Extended Capability.

In some cases, these mechanisms are configured to generate interrupts or system events.

Some SoC internal controllers provide ways of maintaining high levels of system availability when hardware errors are detected. Error-correcting logic, transaction retries, and degraded operation are examples.

6.4.1 Error Classification

The ACPI and PCIe* specifications classify errors. This classification separates hardware errors that result in degraded performance from those that result in functional failures:

- Correctable Errors
- Uncorrectable Errors

Uncorrectable hardware errors can be further classified as:

  — Non-Fatal Error

  — Fatal Error

In many cases, just the terms Correctable, Non-Fatal and Fatal are used to classify hardware errors.

6.4.2 Error Detection and Reporting Mechanisms

Machine Check Errors are defined for the SoC. See Section 6.6, "Machine Check Architecture (MCA)". They are accessible to software via Model Specific Registers (MSRs). Errors in the CPU cores, L2 cache, and System Agent are reported as Machine Check Error MSRs.

Besides SoC errors reported through the Machine Check Architecture (MCA), local device errors are detected, logged and reported by the SoC through Global Error registers. These registers are accessible to software via Host Root Configuration Space and Host Root Memory Space. System Agent and peripheral I/O device errors are reported in this manner. There are five types of local devices:

- PCIe Root Ports.
- PCIe Endpoints behind the Virtual Root Ports
- PCIe Root Complex Integrated Endpoints
- Legacy PCI devices
- Non-PCI devices

The manner in which each of the five local device types deals with local errors are explained in Section 6.13, "Overview of SoC Error Registers". There is a set of Global Error registers that summarize the Local Error registers and can be configured to generate an SMI or NMI.

In addition to providing software access to error registers, the SoC provides output signal pins to notify external hardware circuitry that an error has been detected. The severity of the error is also provided on signal pins. Descriptions for all five of these output signal pins are in Table 6-1, "Signal Names and Descriptions". External circuitry can use the SoC SMBus-PECI interface to read various internal registers containing error information.

6.5 Availability Features

6.5.1 System Memory

The SoC Memory Controllers support Single-Bit Error Correction using ECC. The controllers also provide Data Scrambling, Patrol Scrubbing and Demand Scrubbing.

6.5.1.1 Single Bit Error Correction

The memory controllers support ECC. Single-bit errors are corrected and Correctable Errors reported and logged.

6.5.1.2 DRAM Data Scrubbing

Data scrubbing features require the use of Error Correction Codes (ECC) in the system memory design.

Demand Scrubbing writes correct data back to memory for any read request that returns with a correctable data error. The DEMAND_SCRUB_ENABLE field (bit 3) of the B-Unit Control (B_CR_BCTRL2) register enables Demand Scrubbing when set to 1. The B_CR_BCTRL2 register is located in Host Root Memory Space at MCHBAR plus offset 6D70h.

Patrol Scrubbing ensures that data with a Correctable Error does not remain in DRAM long enough to stand a significant chance of further corruption and become an Uncorrectable Error. If enabled, the Patrol Scrubbing generates memory requests at a programmed interval. If a correctable error is detected by a scrubbing request, Demand Scrubbing is used to correct the error. The PAT_SCRUB_ENABLE field (bit 31) of the Patrol Scrub Configuration (DPATROL_SCRUB_CFG) register enables Patrol Scrubbing when set to 1. The DPATROL_SCRUB_CFG register is located in Host Root Memory Space at SBREG_BAR plus offset 10_00B0h. For Memory Controller 1, the DCS register is located at SBREG_BAR, offset 12_00B0h. Various registers first need to be setup by BIOS in order to deploy Patrol Scrubbing.

See Section 6.16, “Error Reporting Flow — Non-PCI devices” for SoC error reporting during scrubbing.

6.5.1.3 DRAM Data Scrambling

As an option, the SoC Memory Controllers provide DRAM Data Scrambling which is a technique to reduce noise on the internal power-supply rails and improve signal integrity. Across the 72 Data/ECC bits of the DQ/ECC bus, it drives very close to 50% ones and 50% zeros in every cycle. This eliminates the worst-case situation where all bits of the bus would simultaneously drive high or drive low.

Data Scrambling is available for both ECC and non-ECC memory platform designs.

Form Memory Controller 0, the SCRAMBLE_ENABLE field (bit 23) of the DRAM Control and Status (DCS) register, when set to 1, the data lanes (DDR0_DQ[63:0]) and the ECC lanes (DDR0_ECC[7:0]) will be scrambled, otherwise no scrambling will occur. The DCS register is located in Host Root Memory Space at SBREG_BAR plus offset 10_0170h. For Memory Controller 1, the DCS register is located at SBREG_BAR, offset 12_0170h.

6.5.2 PCI Express Root Ports

The *PCI Express Base Specification*, Revision 3.0 defines a standard set of error-reporting mechanisms. The SoC supports them all including Error Poisoning and Advanced Error Reporting (AER). The error reporting mechanism and the error registers are described in Section 6.12, "SoC UnCore and I/O Error Reporting".

Besides error detection, logging and reporting, the SoC PCI Express Root Ports support:

- Data Link Layer 32-bit CRC (LCRC) and Retry Management — see sub-section 3.5 "Data Integrity" of the Data Link Layer section in the *PCI Express Base Specification*, Revision 3.0.
- Transaction Layer end-to-end 32-bit CRC (ECRC) — see sub-section 2.7 "Data Integrity" of the Transaction Layer section in the *PCI Express Base Specification*, Revision 3.0.
  - — Supported by the PCIe Root Ports but not on the three Virtual Root Ports.
- Link Retraining and Dynamic Link Width Reduction upon link failure.
  - — Supported by the PCIe Root Ports but does not apply to the three Virtual Root Ports.

When PCIe Link Retraining fails, the SoC PCIe interface provides a mechanism to recover from the failed link. The PCIe link is capable of operating in different link widths. The SoC supports PCIe Root Port operation in x8, x4, and x2. In case of a persistent link failure, the PCIe link can fall back to a smaller link width, as small as x1, in attempt to recover from the error. As an example, a PCIe x8 link can fall back to a x4 link. If necessary, it can be further reduced to a x2 link, and then to X1 link. This mechanism enables continuation of system operation in case of PCIe link failures. Additional information can be found in Section 11.4.5, "Degraded Mode".

6.6 Machine Check Architecture (MCA)

Machine Check Architecture is a mechanism for detecting and reporting hardware (machine) errors in the CPU and UnCore. For the SoC, MCA is not used to report I/O-based errors.

This section provides the necessary details for the operating software to handle Machine Check Exceptions (MCE). Some operating systems hook the Machine Check Architecture (MCA) exception vector (18h) to allow system-crash analysis. Like some other Intel processors, the SoC has been enhanced to allow the machine state to be preserved across the assertion of the Platform Reset. The BIOS does not modify the MCA registers following the assertion of Platform Reset. This allows the operating system to enhance the exception handler by having this information available following a reboot after an error has occurred. Only upon the assertion (the signal transition from low to high) of the COREPWROK input signal (indicating POWERGOOD, power-on) is the machine-check architecture state re-initialized.

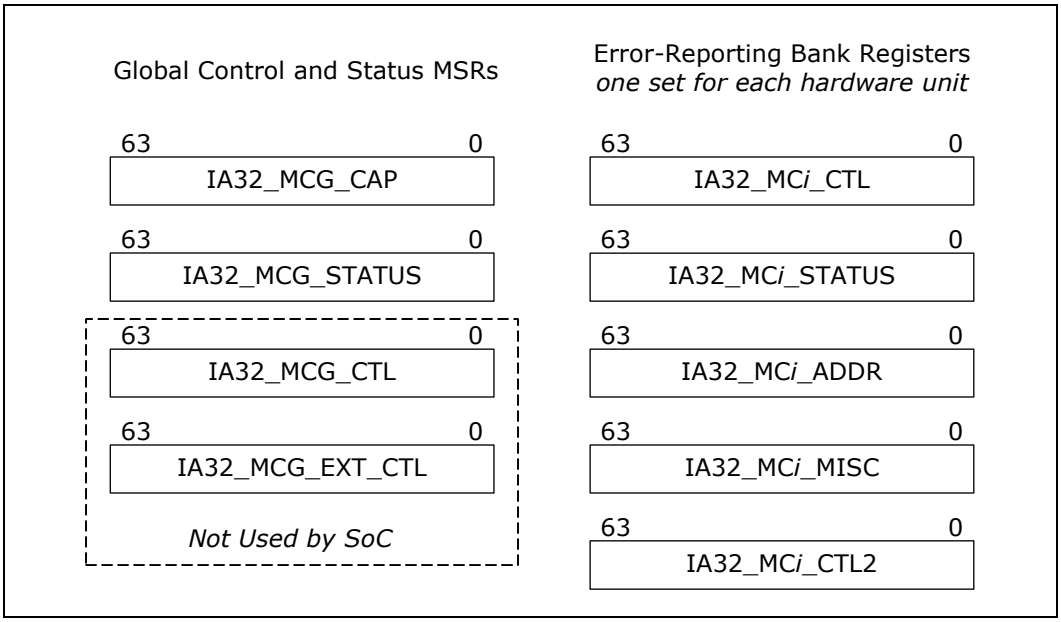
All MCA state information is accessible via the Model-Specific Register (MSR) accesses using the Read MSR (RDMSR) and Write MSR (WRMSR) instructions. RDMSR and WRMSR are described in Volume 2, Chapter 4 of the *Intel® 64 and IA-32 Architectures Software Developer's Manual*. The machine-check architecture is described in Volume 3, Chapter 15, of the same manual.

Intel® architecture defines two classifications of MCA MSRs:

1. Machine Check Global Control and Status registers.
2. Machine Check Error-Reporting Bank registers.

The SoC does not implement the IA32_MCG_CTL and IA32_MCG_EXT_CTL Global Control and Status MSRs. See Figure 6-1, "SoC Machine Check MSRs — Global Control and Bank Registers".

Figure 6-1. SoC Machine Check MSRs — Global Control and Bank Registers



6.6.1 Machine Check MSR Addresses

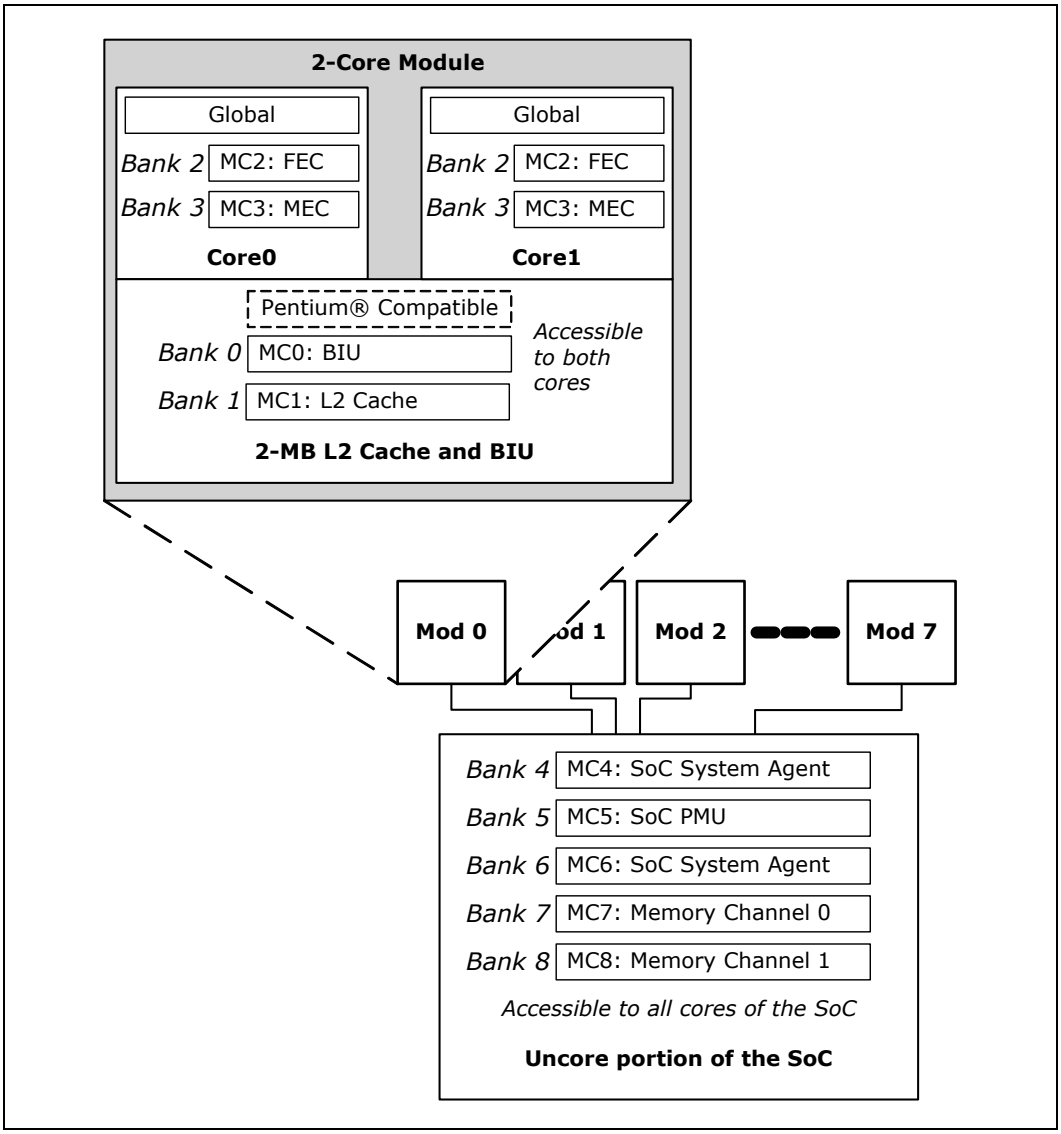
The machine check MSRs are accessed via the RDMSR and WRMSR processor instructions.

Table 6-3 lists the MSR addresses and Figure 6-2, "SoC Core, Module, and Package Machine Check Registers" shows the core, module, and SoC package with respect to each Machine Check register.

Table 6-3. SoC Machine Check MSR Addresses

Register Type	Function	Register	Register Address
MC Bank 0	Module - Bus Interface Unit (BIU)	IA32_MC0_STATUS IA32_MC0_ADDR	401h 402h
MC Bank 1	Module - L2 Cache	IA32_MC1_STATUS IA32_MC1_ADDR	405h 406h
MC Bank 2	Core - Fetch Execution Cluster (FEC)	IA32_MC2_STATUS IA32_MC2_ADDR	409h 40Ah
MC Bank 3	Core - Memory Execution Cluster (MEC)	IA32_MC3_CTL IA32_MC3_STATUS IA32_MC3_ADDR	40Ch 40Dh 40Eh
MC Bank 4	SoC System Agent	IA32_MC4_STATUS IA32_MC4_ADDR IA32_MC4_MISC	411h 412h 413h
MC Bank 5	SoC Power Management Unit (PMU)	IA32_MC5_STATUS IA32_MC5_ADDR IA32_MC5_MISC	415h 416h 417h
MC Bank 6	SoC System Agent	IA32_MC6_STATUS IA32_MC6_ADDR	419h 41Ah
MC Bank 7	Memory Channel 0	IA32_MC7_STATUS IA32_MC7_MISC	41Dh 41Fh
MC Bank 8	Memory Channel 1	IA32_MC8_STATUS IA32_MC8_MISC	421h 423h

Figure 6-2. SoC Core, Module, and Package Machine Check Registers



6.6.2 Enhancements to MCA Error Reporting

The SoC provides support of Error Cloaking and Dual Signaling (MSR 52h) to optionally hide errors from the operating system. Corrected Machine-Check error Interrupt (CMCI) enhancement is also supported.

6.6.2.1 Error Cloaking

The Error Cloaking feature allows BIOS to hide Correctable Errors from the Operating System (OS). The Model-Specific Register (MSR) MSR_SMM_MCA_CONTROL (MSR 52h) contains a control bit to mask corrected errors during non-System-Management-Mode (non-SMM) accesses.

Non-SMM reads to MCi_STATUS registers will return 0 instead of the actual status value if, MCi_STATUS RDMSR reports a VALID CORRECTED error (VAL=1,UC=0) and CERR_RD_STATUS_IN_SMM_ONLY (in MSR0x52) is set. See Table 6-4, "MSR_SMM_MCA_CONTROL (MSR 52h) — Enhanced MCA Control".

6.6.2.2 Dual Signaling

The Dual Signaling feature allows SMM firmware to handle, and possibly clear-out, errors before the Operating System sees them.

In the MCA flow, if PEND_SMI_ON_MCA bit is set in MSR 52h, the SoC creates a pending System Management Interrupt (SMI) on the core. This flow relies on the MCA broadcast (and consistent opt-in and subsequent pending of SMI) to get the SMI pending on all threads. See Table 6-4, "MSR_SMM_MCA_CONTROL (MSR 52h) — Enhanced MCA Control".

Table 6-4. MSR_SMM_MCA_CONTROL (MSR 52h) — Enhanced MCA Control

Bit	Register Field	Access Type	Description
31:10	Reserved	-	Reserved
9	PEND_SMI_ON_MCA	RW	Pend SMI on MCA
8:1		-	Reserved
0	CERR_RD_STATUS_IN_SMM_ONLY	RW	When set to 1, Valid (VAL=1), Correctable Error (UC=0) CPU MCA Status can only be read when the CPU is in System Management Mode (SMM). Otherwise read 0 if VAL=1 and UC=0. This bit is package-scope and mapped by microcode to an UnCore SCP.

6.6.2.3 Corrected Machine-Check error Interrupt (CMCI)

CMCI is an architectural enhancement to the MCA. It provides capabilities beyond those of threshold-based error reporting. With threshold-based error reporting, software is limited to use periodic polling to query the status of hardware corrected Machine-Check errors.

CMCI provides a signaling mechanism to deliver a local interrupt based on threshold values that software can program in bits [14:0] of the Machine-Check Bank IA32_MCi_CTL2 MSRs.

CMCI is disabled by default. The MCG_CMCI_P bit of the IA32_MCG_CAP Global Machine Check register, when set, indicates that the SoC has the CMCI capability. Bit 30 of each IA32_MCi_CTL2 register must be checked to see whether the particular Machine-Check Bank has the CMCI-signaling capability. CMCI is not affected by the CR4.MCE bit, and it is not affected by the IA32_MCi_CTL MSRs. The L2 Cache, SoC internal fabric, and Memory Controller Machine-Check Banks support CMCI signaling.

Corrected Machine-Check Errors detected in the UnCore portion of the SoC (see Figure 6-2, "SoC Core, Module, and Package Machine Check Registers") generate a CMCI to all processor cores of the SoC. There is no provision for one processor to signal a CMCI to other processor within a system.

The processor's APIC Local Vector Table (LVT) has a LVT CMCI register that specifies interrupt Delivery Mode (NMI, SMI, etc.) and Vector when an overflow condition of corrected machine check error count reaching a threshold value occurred in a machine check bank supporting CMCI.

6.7 Advanced Error Reporting (AER)

6.7.1 AER and the PCIe Root Ports and RCEC

Advanced Error Reporting (AER) is supported on these integrated devices:

- PCI Express* Root Ports.
- Root Complex Integrated Endpoints:
  - — SMBus-Host function
  - — Host Bridge (Global/Local Error function)
- Integrated LAN Controllers
- Integrated Intel® QuickAssist Technology (Intel® QAT) Controller

The RCEC and the PCIe Root Ports with the AER capability not only generate system errors (Correctable, Non-Fatal, and Fatal) from received, or internally-generated, error Messages, each can generate an interrupt for each of the three error categories.

The RCEC_ROOTERRCMD register (ROOTERRCMD for each of the eight Root Ports and three Virtual Root Ports) in Host Root Configuration Space provides an enable/disable for each of the three error categories.

For both Root Ports and Root Complex Event Collectors, in order for a received error Message or an internally generated error Message to generate an interrupt enabled by this register, the error Message must be enabled for "transmission" by the Root Port or Root Complex Event Collector.

The interrupt generated to the host is either an INTx message or an MSI/MSI-X interrupt, depending which type of interrupt-reporting mechanism is enabled for the RCEC or Root Port.

The RCEC_ROOTERRSTS register (ROOTERRSTS for the Root Ports) reports status of error Messages (ERR_COR, ERR_NONFATAL, and ERR_FATAL) received by the RCEC (or Root Port), and of errors detected by the RCEC/Root Port itself (which are treated conceptually as if the RCEC/Root Port had sent an error Message to itself). The RCEC provide this only for the two Root Complex Integrated Endpoints is serves — the SMBus-Host function and the Global/Local Integrated Error Handler function.

When an error is received by the RCEC or Root Port, the respective first error bit is Set and the Requester ID is logged in the RCEC_ERRSRCID (ERRSRCID for Root Ports) register.

For additional details, see Section 7.10 "Advanced Error Reporting Capability" of the *PCI Express Base Specification Revision 3.0*.

6.8 Intel® Virtualization Technology (Intel® VT)

The SoC provides hardware support for isolating & restricting device accesses to the owner of the partition managing the device. Virtual partitioning is provided as:

- Enhanced Intel® Virtualization Technology (Intel® VT) for IA-32, Intel® 64 and Intel® Architecture (Intel® VT-x)
- Intel® Virtualization Technology (Intel® VT) for Directed I/O (Intel® VT-d)

See Section 2.2.2, "Intel® Virtualization Technology".

6.9 Error Injection

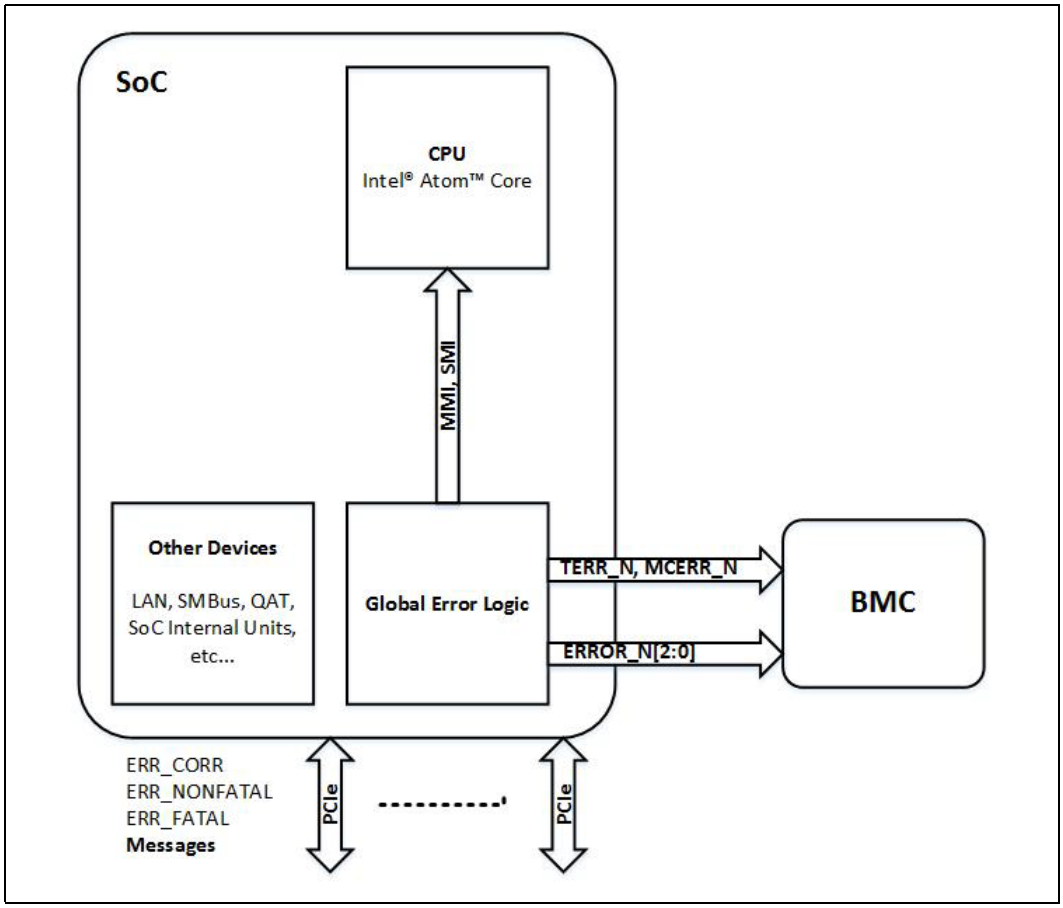
Error injection can be used to validate system error-handling software. The SoC supports:

- Writable Machine Check Architecture (MCA) banks.
- Out-of band access to the MCA registers
- The PCI Express Root Ports support the Windows Hardware Error Architecture (WHEA) capability. The dedicated Virtual Root Ports for the Intel® QuickAssist Technology and LAN Controllers do not have the WHEA capability.
- Each of the two DRAM memory controllers has error injection on write/read data paths including address/source match. See Section 6.16.2, "Error Injection Control and Registers — Memory Controller".

6.10 SoC UnCore and I/O Error Handling

Figure 6-3, "Intel Atom® Processor C3000 Product Family Error Reporting" shows high level error handling scheme. The SoC receives PCIe error messages from downstream devices. The SoC logs these errors and other internal device errors. More details are provided in the following sections.

Figure 6-3. Intel Atom® Processor C3000 Product Family Error Reporting



6.11 Hardware Error Classification and System Events

In the SoC, hardware errors are classified as two types:

- Correctable Errors
- Uncorrectable Errors

This classification separates hardware errors that result in degraded performance from those that result in functional failures.

Uncorrectable hardware errors can be further classified as:

- Non-Fatal Error
- Fatal Error

Classifying hardware errors in this way provides the platform with ways to map a hardware error to a suitable handling mechanism. Each severity can trigger a System Event according to the GLREG Global System Event Map (GLREG_GSYSEVTMAP) register located in Host Root Configuration Space at B0;D5;F0, offset 250h. The System Event choices are either generate a Non-Maskable Interrupt (NMI), a System Management Interrupt (SMI), or generate no System Event.

The GLREG_GSYSEVTMAP register provides software the flexibility to map an Uncorrectable Error to the suitable error severity. For example, a platform design may choose to map an Uncorrectable DRAM ECC Error as a Non-Fatal Error while another platform design may require mapping the same error as a Fatal Error.

The software/firmware can choose to alter the default mapping after power-on.

6.11.1 Correctable Errors

At power-on, the GLREG_GSYSEVTMAP register is default-set to map Correctable Errors to an SMI System Event.

Hardware correctable errors include those error conditions where the system recovers without any loss of information. The hardware corrects these errors, and no software intervention is required. For example, a link CRC error which is corrected by the data link level retry is considered a correctable error.

- An error is corrected by the hardware without software intervention. System operation is degraded, but its functionality is not compromised
- A correctable error is logged and reported in a implementation specific manner:
  - Upon the immediate detection of the correctable error
  - Upon the accumulation of errors reaching to a threshold

6.11.2 Uncorrectable Errors

At power-on, the GLREG_GSYSEVTMAP register is default-set to map Non-Fatal Uncorrectable Correctable Errors to an SMI System Event.

An uncorrected error is a hardware error condition that cannot be corrected by the hardware or by the firmware. Uncorrected errors are either fatal or non-fatal.

6.11.2.1 Fatal Errors

A fatal hardware error is an uncorrected or uncontained error condition that is determined to be unrecoverable by the hardware. When a fatal uncorrected error occurs, the system is restarted to prevent propagation of the error.

6.11.2.2 Non-Fatal Errors

A non-fatal hardware error is an uncorrected error condition from which the Operating System or firmware can attempt recovery by trying to correct the error. These are also referred to as correctable or recoverable errors.

Isolating non-fatal from fatal errors provides system management software the opportunity to recover from the error without reset and disturbing other transactions in progress. Devices not associated with the transaction in error are not impacted by the error. An example of recoverable error is an ECC uncorrectable error that affects only the data portion of a transaction:

- The error is not corrected by the hardware and requires software intervention for correction
- The error is not corrected. Data integrity is compromised, but system operation is not compromised
- This error requires immediate logging and reporting of the error to the CPU

6.11.3 Software Correctable Errors

Software correctable errors are considered as a recoverable error. These errors include those error conditions where the system recovers without any loss of information. Software intervention is required to correct these errors:

- This error requires immediate logging and reporting of the error to the CPU
- The firmware or other system software layers take corrective actions

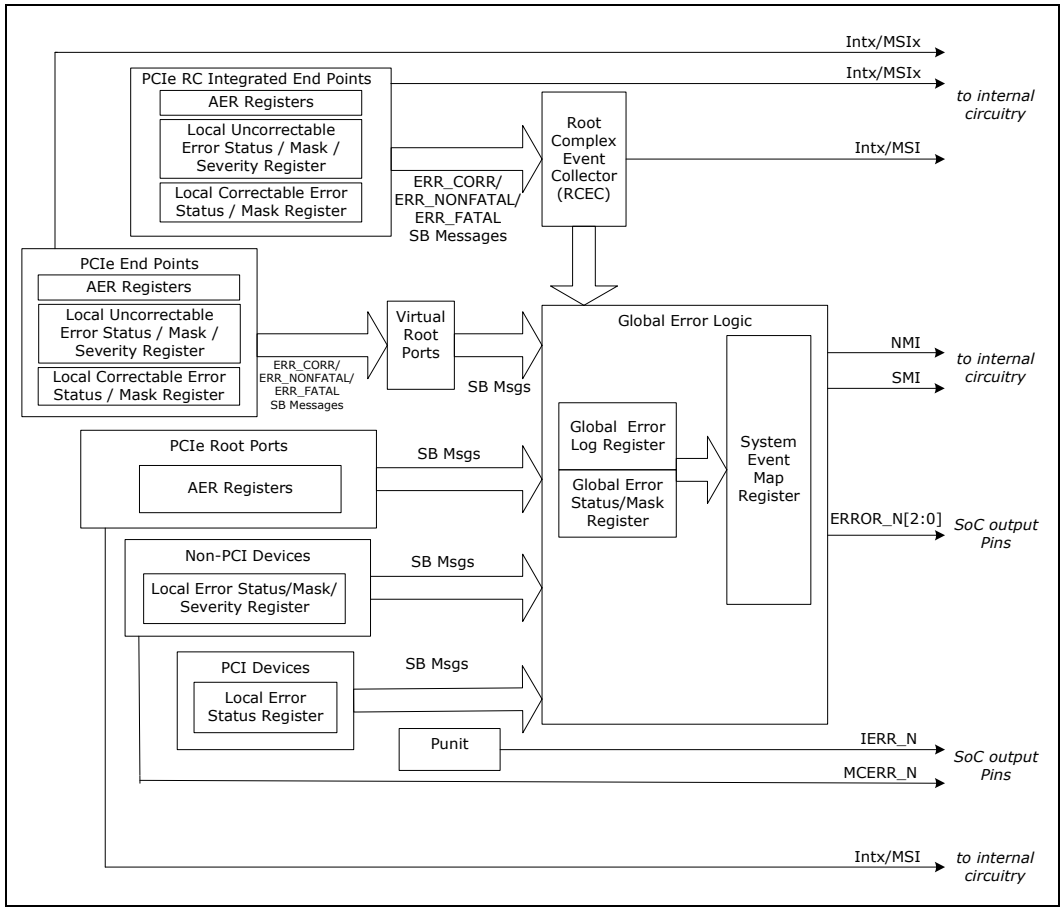
Data integrity is not compromised with such errors.

6.12 SoC UnCore and I/O Error Reporting

The SoC logs and reports the detected errors via "system event" generations. In the context of error reporting, a system event is an event that notifies the system of the error. Two types of system events can be generated -- an NMI or SMI to the SoC, or an ERROR_N[2:0] pins indication to the platform. The SoC responds to a system event (NMI or SMI) and takes the appropriate action to handle the error. An external agent such as BMC may monitor ERROR_N[2:0] pins to determine the health of SoC and interrupt the SoC. In some severe error cases, if the SoC is no longer responding to system events resulting from an error(s), the ERROR_N[2:0], IERR_N, and MCERR_N pins provide a way to notify an external agent of the error. The external agent can then perform a reset to recover the Denverton SoC functionality.

The Figure 6-4 illustrates internal and external error reporting. The SoC receives PCIe error messages from downstream devices. The SoC logs these errors and other internal errors.

Figure 6-4. Error Handling Architecture



The SoC detects errors from the PCIe* links and the SoC internal device errors. The errors are first logged and mapped to an error severity, and then mapped to a system event(s) for error reporting.

SoC error-reporting features are summarized below. Details are in the following sections:

- Detects and logs PCIe links and SoC internal device errors
- First error/next error detection and logging for correctable/uncorrectable local errors
- Allows flexible mapping of local uncorrectable errors to fatal or non-fatal error classes
- First/next error detection and logging for correctable, non-fatal, and fatal global errors
- Flexible error reporting using multiple reporting mechanisms
- Supports PCIe error reporting mechanism based on the Root Complex Event Collector (RCEC)

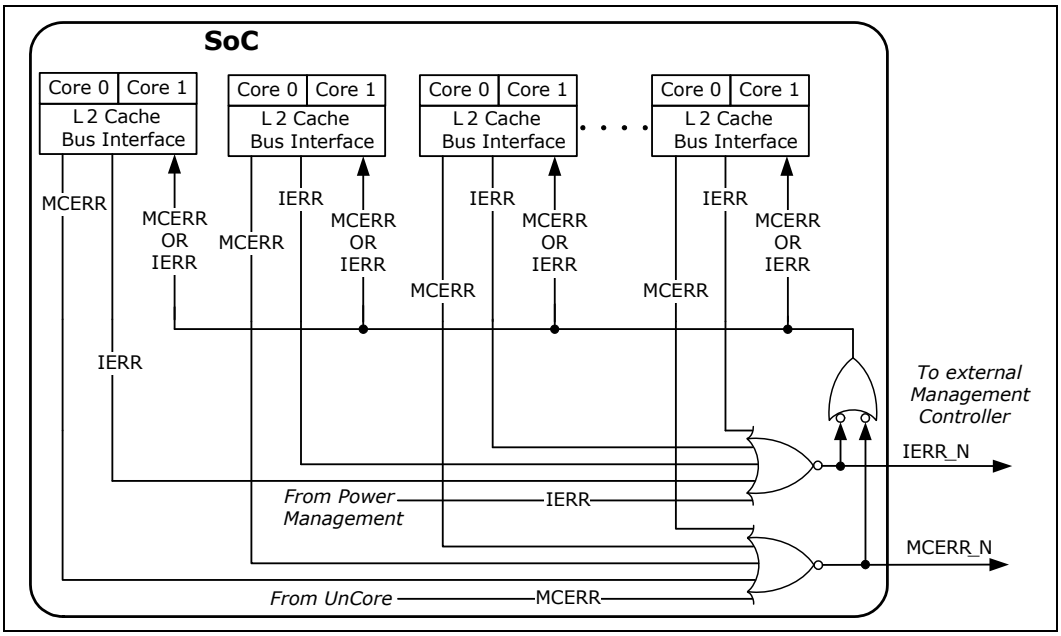
The SoC provides direct mapping of system errors to NMI or SMI. The System Error (SERR) mechanism is not used to do this.

6.12.1 Reporting Error to an External Device

Detected errors can be forwarded to an external device (e.g., a BMC) using the SoC ERROR_N[2:0] signal pins.

The SoC escalates machine check errors (MCERR_B) and unrecoverable internal errors (IERR) to the external BMC and to the CPU cores for handling non-maskable and other fatal errors in the system. See Figure 6-5. The MCERR_N and IERR_N signals are broadcast to the CPU and to the external platform.

Figure 6-5. MCERR and IERR Handling



The MCERR_N signal signifies a catastrophic internal error, a condition which requires immediate attention or possibly shutdown. When this error occurs, the processor core may not be able to execute reliably through the INT18 handler. The following are some possible cases of such catastrophic errors:

- Retirement watchdog time-out from the core
- Internal error detected by the SoC power management circuitry

The MCERR_N signal signifies a machine check error occurred and that SoC Machine Check Architecture registers, accessible through the MSRRD and MSRWR instructions, may have additional information concerning the error.

Note: Board designs must not consider IERR_N and MCERR_N valid until after the PMU_PLTRST_N (Platform Reset) signal is deasserted by the SoC. When the SoC is powered-up or a cold boot, the IERR_N and MCERR_N signals may be unstable and falsely signal an internal error or machine check error before the platform reset is deasserted by the SoC.

6.12.2 PCI Express INTx and MSI

PCIe INTx and MSI are supported via PCIe standard error reporting. The SoC forwards MSI generated from downstream PCIe devices to the CPU. Also, PCIe Root ports and RCEC in the SoC generate Intx/MSI interrupts for error reporting if enabled. See PCIe specification for details on PCIe standard and advanced error reporting capability.

6.13 Overview of SoC Error Registers

The SoC contains sets of error registers to support error reporting. These error registers are assumed to be sticky unless specified otherwise. Sticky means the values of the registers are retained even after a hard reset — they can only be cleared by software or by power-on reset.

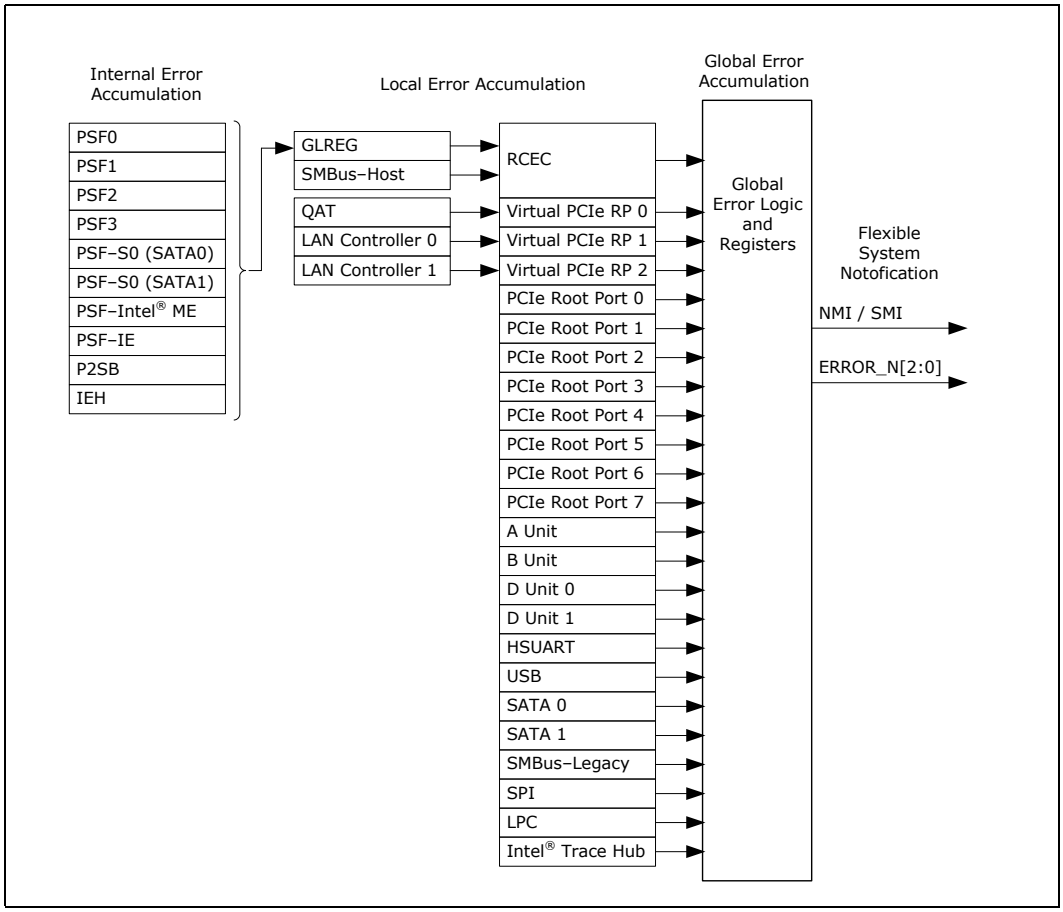
There are two levels of hierarchy for the SoC error registers:

- Local Error Registers
- Global Error Registers

See Figure 6-6, "Local and Global Error Register Structure". The Local Error Registers are associated with the local, integrated devices. The Global Error Registers collect the errors reported by the Local Error Registers and map them to system events and/or to SoC output signal pins.

Note: The PSF, IEH, P2SB, A, B, C, and D Units are physical functions within the SoC. They are part of the internal fabric that handles I/O transactions to/from the CPU cores and the system memory subsystem. This document does not provide details of these internal functions other than errors they detect and report.

Figure 6-6. Local and Global Error Register Structure



6.13.1 Local Error Registers

Table 6-5, "Local Error Register General Descriptions" provides a general description of the SoC Local Error registers. Not all SoC error-detecting mechanisms implement all of these registers. Some have additional Local Error registers not listed here.

Table 6-5. Local Error Register General Descriptions

Local Error Register Name	Local Error Register Description
Uncorrectable Errors	
Uncorrectable Error Status (not AER)	When a specific Uncorrectable Error associated with an SoC local interface occurs, its corresponding bit in this error status register is set. Each error can be individually masked by the Uncorrectable Error Mask register. A masked error bit is not set for any subsequent detected error and is not recorded or reported in the Uncorrectable Header Log register and does not update the Uncorrectable FERR/NERR registers.
Uncorrectable Error Mask (not AER)	
Uncorrectable Error Status (AER)	The Uncorrectable Error Status register reports error status of individual correctable error sources on a PCI Express device Function. Software may clear an error status by writing a 1 to the respective error bit. When the respective bit is set in the Uncorrectable Error Mask, the error is set in the Uncorrectable Error Status register, but it is not reported to the PCI Express Root Complex via a PCI Express Error Signaling Message, and the Header Log and First Error Pointer registers are unmodified.
Uncorrectable Error Mask (AER)	
Uncorrectable Error Severity	Controls whether an individual error is reported as a Non-Fatal (register = 0) or Fatal (register = 1) error.
First Uncorrectable Error	The First Uncorrectable Error Register (FERR) logs the first occurrence of an error, while the Next Uncorrectable Error Register (NERR) logs the subsequent occurrence of the errors. The Uncorrectable FERR and NERR do not log errors that are masked. The Uncorrectable FERR log remains valid and unchanged from the first error detection until the clearing of the corresponding Uncorrectable FERR error bit in the Uncorrectable Error Status Register by software.
Next Uncorrectable Error	
Uncorrectable Header Log (not AER)	Logs the header of the first Uncorrectable Error associated with the particular local interface.
Correctable Errors	
Correctable Error Status (not AER)	When a specific Correctable Error associated with an SoC local interface occurs, its corresponding bit in this error status register is set. Each error can be individually masked by the Correctable Error Mask register. A masked error bit is not set for any subsequent detected error and is not recorded or reported in the Uncorrectable Header Log register and does not update the Correctable FERR/NERR registers.
Correctable Error Mask (not AER)	
Correctable Error Status (AER)	The Correctable Error Status register reports error status of individual correctable error sources on a PCI Express device Function. Software may clear an error status by writing a 1 to the respective error bit. When the respective bit is set in the Correctable Error Mask, the error is set in the Correctable Error Status register, but it is not reported to the PCI Express Root Complex via a PCI Express Error Signaling Message, and the Header Log and First Error Pointer registers are unmodified.
Correctable Error Mask (AER)	
First Correctable Error	The First Correctable Error Register (FERR) logs the first occurrence of an error, while the Next Correctable Error Register (NERR) logs the subsequent occurrence of the errors. The Correctable FERR and NERR do not log errors that are masked. The Correctable FERR log remains valid and unchanged from the first error detection until the clearing of the corresponding Correctable FERR error bit in the Correctable Error Status Register by software.
Next Correctable Error	
Correctable Header Log (not AER)	Logs the header of the first Correctable Error associated with the particular local interface.
AER Specific	
Advanced Error Capabilities and Control (AER)	Identifies AER capabilities and the bit position of the first error reported in the (AER) Uncorrectable Error Status register.
Advanced Error Header Log (AER)	Header (four DWords) of the Transaction-Level Packet (TLP) associated with the error.

6.13.2 SoC Global Error Registers

The SoC provides Global Error Registers and circuitry. The Global Error Registers are not defined in any industry specification. The provide a quick way for software to start searching for the error that caused the system error-reporting event.

Table 6-6. List of SoC Global Error Registers

Host Root Configuration Space B0:D4:F0 Offset (hex)	Global Error Register	Register Name
200	GLREG_GCOERRSTS	Global Correctable Error Status
204	GLREG_GNFERRSTS	Global Non-Fatal Error Status
208	GLREG_GFAERRSTS	Global Fatal Error Status
20C	GLREG_GERRMSK	Global Error Mask
228	GLREG_GTIME	Global Error Timer
230	GLREG_GCOFERRTIME	Global Correctable FERR Error Time Stamp
238	GLREG_GNFFERRTIME	Global Nonfatal FERR Error Time Stamp
240	GLREG_GFAFERRTIME	Global Fatal FERR Error Time Stamp
248	GLREG_GSYSEVTSTS	Global System Event Status
24C	GLREG_GSYSEVTMSK	Global System Event Mask
250	GLREG_GSYSEVTMAP	Global System Event Map
254	GLREG_ERRPINCTRL	Error Pin Control
258	GLREG_ERRPINSTS	Error Pin Status
25C	GLREG_ERRPINDATA	Error Pin Data

6.13.3 First Error and Next Error Log Registers

This section pertains to both Local Error logging and Global Error logging. The error-log registers names contain FERR (First Error) and NERR (Next Error). First Errors and Next Errors are captured at both the local level (correctable and uncorrectable) and Global level (correctable, non-fatal and fatal). PCI Express specifies its own error-logging mechanism which is not be described here and can be found in the *PCI Express Base Specification Revision 3.0*.

For Global Error logging, the SoC categorizes a detected error based on the error severity:

- Fatal Error
- Non-Fatal Error
- Correctable Error

Each category includes two sets of error logging:

- First Error register (FERR)
- Next Error register (NERR)

The FERR register stores the information associated with the first detected error, while NERR stores the information associated with the subsequent detected errors after the first error. Both FERR and NERR log the error status in the same format. They indicate errors that can be detected by the SoC with one bit assigned to each type of error. The first error event is indicated by setting the corresponding bit in the FERR status register; a subsequent error is indicated by setting the corresponding bit in the NERR register. In addition, the local FERR registers logs the header of the erroneous cycle. Both First Error and Next Error trigger system events.

Once the First Error and the Next Error have been indicated and logged, the log registers for that error remain valid until either

The first error bit is clear in the associated error status register, or

A reset after loss of power.

Software clears an error bit by writing 1 to the corresponding bit position in the error status register.

The SoC uses this procedure tor updating the FERR and NERR registers and error logs:

1. First Error event is indicated by setting the corresponding bit in the FERR status register, a subsequent error is indicated by setting the corresponding bit in the NERR status register.
2. If the same error occurs before the FERR status register bit is cleared, it is not logged in the NERR status register.
3. In the case of simultaneous multiple errors with same severity, any two errors may be logged in FERR and NERR registers.
4. Updates to error status and error log registers appear atomic to the software.
5. Once the information of the first error is logged in the FERR log register, the logging of FERR log registers is disabled until the corresponding FERR error status is cleared by the software.
6. Error status registers, Error Mask registers and Error Log registers are cleared by the power-on reset only. The contents of Error Log registers are preserved across a reset (while power-good is sensed).

6.13.4 General Local and Global Error-Register Flow

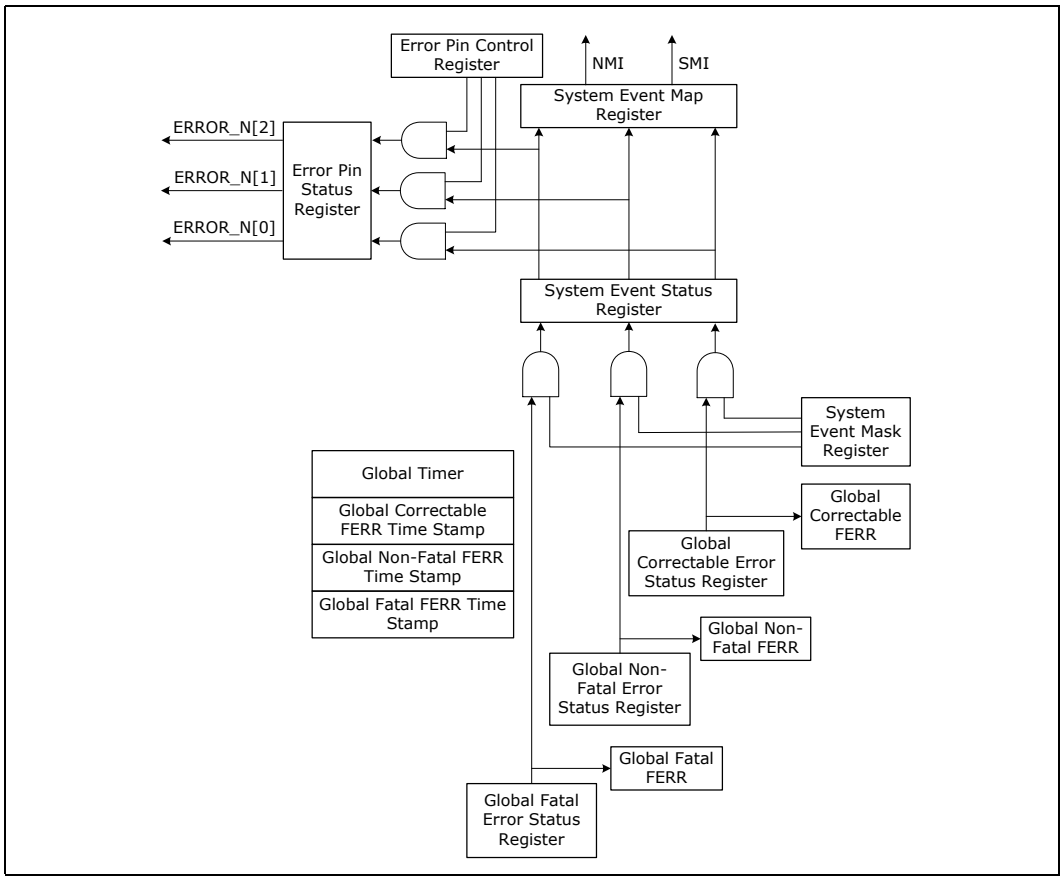
1. Upon a detection of a Local error, the corresponding Local error status is set if the error is unmasked. Otherwise the error bit is not set and the error is not propagated upstream towards the SoC Root Complex.
2. The Local uncorrectable error is mapped to its associated error severity defined by the Uncorrectable Error Severity register. Setting of the Local Error Status register bit causes the logging of the error. Fatal and Non-fatal errors are logged in the Local Uncorrectable FERR and NERR registers, while correctable errors are logged in the Local Correctable FERR and NERR registers. PCI Express errors are logged according to the PCI Express specification.
3. The local FERR and NERR logging events are forwarded to the Global FERR and NERR registers. The report of Local FERR/NERR sets the corresponding Global Error Status bit if the particular global error is unmasked. Otherwise the global error bit is not set and the error is propagated. As mentioned in Section 6.13.3, "First Error and Next Error Log Registers", the Global FERR logs the first occurrence of local FERR event in the SoC while the Global NERR logs the subsequent local NERR event.
4. Correctable error is logged in the Global Correctable FERR/NERR registers, Non-Fatal is logged in the Global Non-Fatal FERR/NERR registers, and Fatal error is logged in the Global Fatal FERR/NERR registers.
5. The Global Error Status register reports the error with its associated error severity to the Global System Event Status (GLREG_GSYSEVTSTS) register. The system event status is generated if the system event reporting is unmasked for the error severity in the Global System Event Mask (GLREG_GSYSEVTMSK) register. Otherwise the bit is not set and the error is not reported.
6. Setting of the system event bit triggers a system event generation according the mapping defined in the Global System Event Map (GLREG_GSYSEVTMAP) register. The associated system event is generated for the error severity and the error indication dispatched to the CPU/BMC (interrupt for CPU or Error Pin for BMC).
7. The global log and local log registers provide the information to identify the source of the error. Software can read the log registers and clear the global and local error status bits.
8. Since the error status bits are edge triggered, a 0-to-1 transition is required to set the bit again. While the error status bit (local, global, or system event) is set to 1, all incoming error reporting to the respective error status register is ignored (no 0-to-1 transition).
    a. When a write occurs to clear the Local Error Status bit, the local error register circuitry re-evaluates the "OR" output of its error bits and reports it to the Global Error register. However, if the Global Error Status bit is already set, then the report is ignored.
    b. When write occurs to clear error status bit, the Global Error register circuitry re-evaluates the "OR output" of its error bits and reports it to the Global System Event Status (GLREG_GSYSEVTSTS) register. However, if the system event status bit is already set, then the report is not generated.
    c. Software can optionally mask or unmask the system event generation (interrupt or error pin) for an error severity in the Global System Event Mask (GLREG_GSYSEVTMSK) register while clearing the Local and Global error registers.

9. Software has the following options for clearing error status registers:
   a. Read the Global and Local Error Log registers to identify the source of the error. Clear local error bits. This does not cause the generation of an interrupt with the global bit still set. Then clear the global error bit and write to the local error register again with all 0s. Writing 0s to the local status does not clear any status bits, but will cause the re-evaluation of the error status bits. An error is reported if there are any uncleared local error bits.
   b. Read the Global and Local Error Log registers to identify the source of the error and mask the error reporting for the error severity. Clear the system event and global error status bits. This causes the setting of the system event status bit if there are other global bits still set. Then clear the local error status bits. This causes the setting of the Global Error Status bit if there are other local error bits still set. Then unmask the system event to cause the SoC to report the error.
10. The FERR register logs the information of the first error detected by the associated error status register (Local or Global). The FERR log remains unchanged until all bits in the respective error status register are cleared by the software. When all error bits are cleared, FERR logging is re-enabled.

6.13.5 Global System Event Reporting

Provided that the Global System Event Mask (GLREG_GSYSEVTMSK) register is not set to prevent the generation of system events, the Global System Event Map (GLREG_GSYSEVTMAP) register determines which system event is generated to the CPU for a given Global Error severity. See Figure 6-7, "Global Error Registers and System Event Reporting".

Figure 6-7. Global Error Registers and System Event Reporting



Each severity (Fatal, Non-Fatal, Correctable) is programmable to generate either an NMI, SMI or not generate a system event. The default settings are:

- Fatal Error - Generate an NMI
- Non-Fatal Error - Generate an SMI
- Correctable Error - Generate an SMI

The Global System Event can also be generated to the platform board through the SoC output signal pins which are shown in Table 6-1, "Signal Names and Descriptions".

- ERROR_N[2] - Fatal Error
- ERROR_N[1] - Non-Fatal Error
- ERROR_N[0] - Correctable Error

The programmable Error Pin Control (GLREG_ERRPINCTRL) register determines how these error pins function. Each pin can also be disabled by this register. The signal pin can be configured to assert when a Global Error of its associated severity is set in the Global System Event Status (GLREG_GSYSEVTSTS) register. It can also be configured to operate as a programmed-controlled signal similar to a general-purpose I/O signal.

The Error Pin Data (GLREG_ERRPINDATA) register provides the data value when the error pin is configured as a program-controlled output signal. The assertion and deassertion of each of the three ERROR_N pins can be programmed. The particular error-pin signal follows the value programmed here. This mechanism only functions when 2-bit Error Enable field of the Error Pin Control (GLREG_ERRPINCTRL) register is set to 01 for the particular Error Pin Data bit.

ERROR_N[1] and ERROR_N[0] are default set to operate in this program-controlled mode. ERROR_N[0] is default-set to assert the pin's signal when a Fatal error is set in the Global System Event Status (GLREG_GSYSEVTSTS) register.

6.13.6 Error Counters

The Error Counters allow the system management controller to monitor the component's health by periodically reporting the Correctable Error Count. The error RAS structure already provides a First Error status and a Second Error status. Because the response time of system management is on the order of milliseconds, it is not possible to read and clear the error logs in time to detect short bursts of errors across the component. Over a long period of time the software uses these values to monitor the rate of change in error occurrences. This helps identify potential component degradations, especially with respect to the system memory interface.

6.13.6.1 Error Counter Requirements

A register with one-hot encoding selects the error types that participate in error counting. It is unlikely that more than one error will occur within a cluster at a given time. Therefore, it is not necessary to count more than one occurrence in one clock cycle. The selection register ORs together all of the selected error types to form a single count enable. This means that only one increment of the counter occurs for one or all types selected. Register attributes are set to write-1-to-clear.

Each of these clusters has a set of error counter/control registers.

- The IEH device (B0:D4:F0) contains a seven-bit Error Counter (ERRCNT[6:0]) in the Uncorrectable Error Counter (GLREG_LUNCERRCNT) register located in Host Root Configuration Space, offset 294h.
  - GLREG_LUNCERRCNT bit 7 (ERR_OVF) is an overflow bit. All eight bits of the register are sticky with a write logic 1 to clear.
- Each of the two D-Units of the SoC System Agent contains an eight-bit Error Counter (UNCCNT[7:0]) field in its Uncorrectable Error Counter (DERRCNT) register located in Host Root Memory Space at SBREG_BAR plus offset 10_0130h (D-Unit 0) and 12_0130h (D-Unit 1).
  - UNCCNT bit 7 is an overflow bit. All eight bits of the UNCCNT field of the register are sticky with a write logic 1 to clear.
- The B-Unit of the System Agent contains a 15-bit Error Counter (ERR_CNT[14:0]) in the Uncorrectable Error Count (B_CR_UNCERRCNT_0_0_0_MCHBAR) register located in Host Root Memory Space at MCHBAR plus offset 6E1Ch.
  - B_CR_UNCERRCNT_0_0_0_MCHBAR register bit 15 (OVERFLOW) is an overflow bit. Bits [15:0] bits of the register are sticky with a write logic 1 to clear.
- The A-Unit of the System Agent contains a 15-bit Error Counter (ERR_CNT[14:0]) in the Uncorrectable Error Count (A_CR_UNCERRCNT_0_0_0_MCHBAR) register located in Host Root Memory Space at MCHBAR plus offset 65A0h.
  - A_CR_UNCERRCNT_0_0_0_MCHBAR register bit 15 (OVERFLOW) is an overflow bit. Bits [15:0] bits of the register are sticky with a write logic 1 to clear.
- The A-Unit of the System Agent contains a 15-bit Error Counter (ERR_CNT[14:0]) in the Correctable Error Count (A_CR_CORERRCNT_0_0_0_MCHBAR) register located in Host Root Memory Space at MCHBAR plus offset 65B8h.
  - A_CR_CORERRCNT_0_0_0_MCHBAR register bit 15 (OVERFLOW) is an overflow bit. Bits [15:0] bits of the register are sticky with a write logic 1 to clear.

6.14 Error Reporting Flow — PCI Express Devices/Functions

- PCIe Root Ports 0 through 7
- Virtual PCIe Root Ports 0 through 2
- PCIe Endpoints behind the Virtual Root Ports
  - — Intel® QuickAssist Technology agent
  - — LAN Controller 0 and 1
- PCIe Root Complex Integrated Endpoints via RCEC
  - — SMBus - Host Controller
  - — Integrated Error Handler (IEH) agent

The PCI Express* architecture provides three complementary mechanisms which allow the agent detecting an error to alert the system or another device that an error has occurred. The three mechanisms are:

- Through the Completion Status of a transaction
- In-band Error-Signaling Messages
- Error Forwarding (also known as data poisoning)

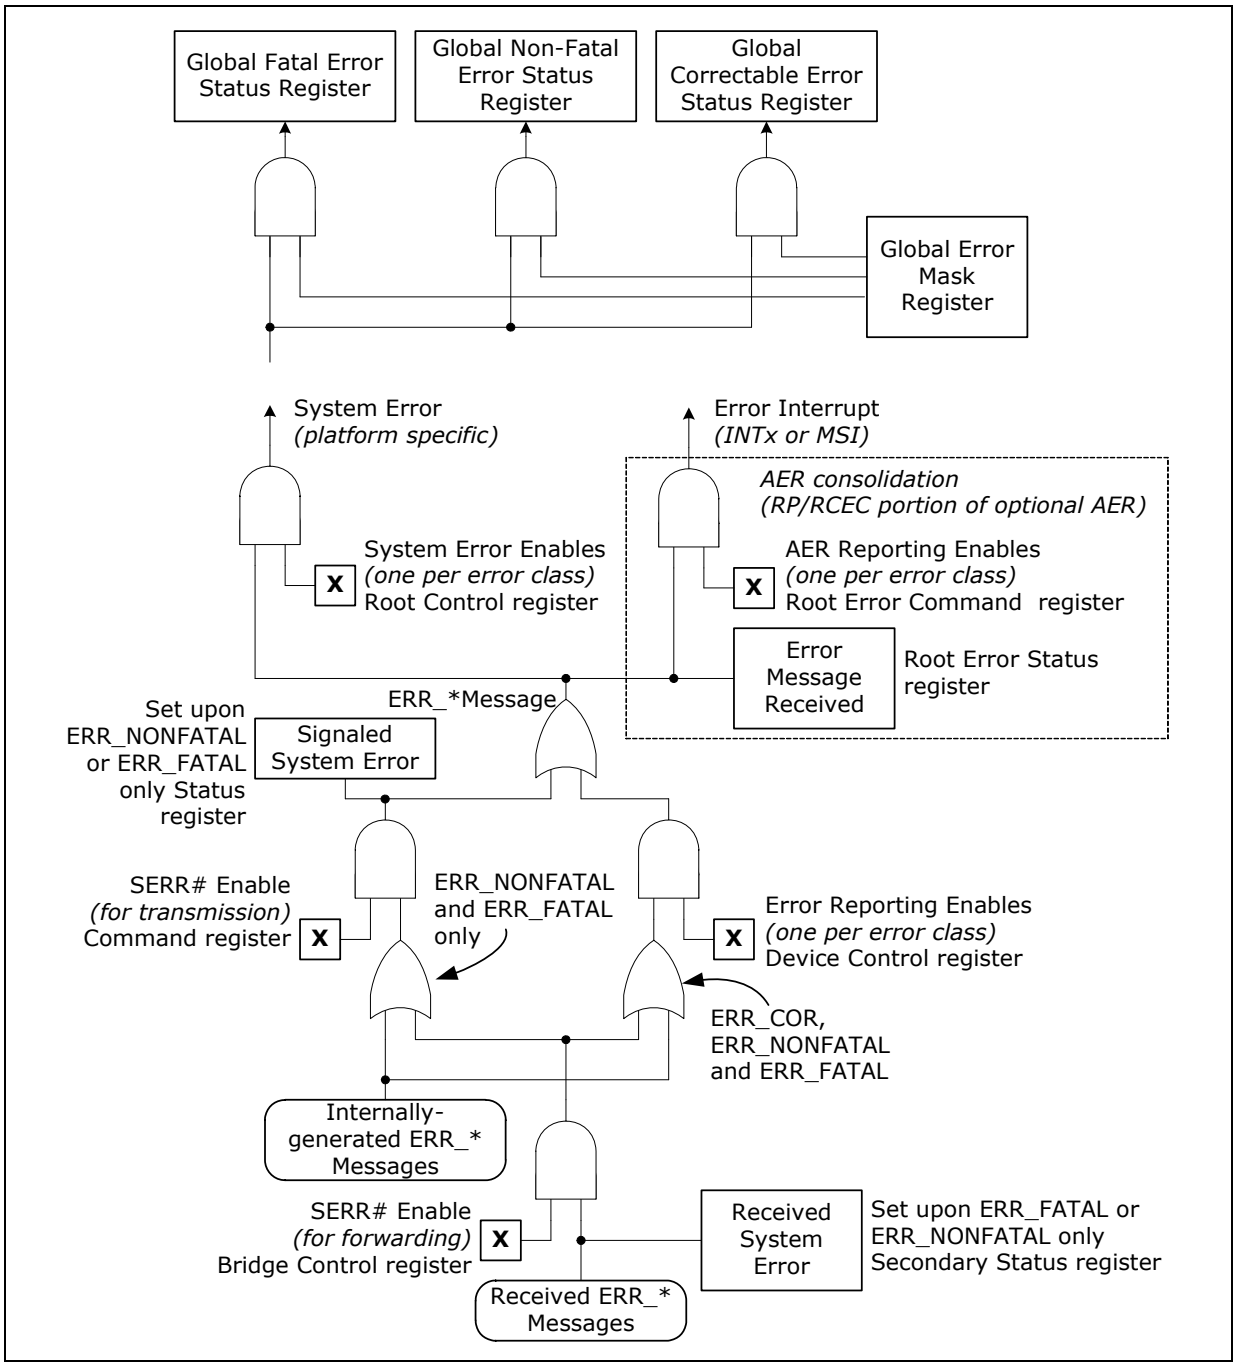
Section 6.2.7 “Error Listing and Rules” of the *PCI Express Base Specification Revision 3.0* lists the actions that an error-detecting agent is expected to take to report and log an error using the above mechanisms. Section 2.2.8.3 “Error Signaling Messages” of the same specification defines the Error Signaling Messages that are used to signal errors that occur on specific PCI Express transactions and errors that are not necessarily associated with a particular transaction. These Messages are initiated by the agent that detected the error. The three Error Signaling Messages are:

- ERR_COR - The device/function detected a Correctable Error.
- ERR_NONFATAL - The device/function detected a Non-Fatal Error.
- ERR_FATAL - The device/function detected a Fatal Error.

6.14.1 Upstream Flow of Error Signal Messages

The upstream flow of the agents' Error Signal Messages to the SoC Global Error Registers is shown in Figure 6-8, "PCIe Error Signaling and Logging". PCI Express endpoint devices attached to the SoC Root Ports send these to the Root Ports where they are channeled along with the Root Port internal errors to the SoC Global Error Registers.

Figure 6-8. PCIe Error Signaling and Logging



6.14.2 How a PCIe Device Determines Which Error Message to Send

Section 6.2 "Error Signaling and Logging" of the *PCI Express Base Specification Revision 3.0* describes the PCIe In-band Error-Signaling Messages. It also provides a flowchart showing how the PCIe device/function determines which error Message, if any, to send to the SoC Root Complex.

All of the flow diagrams provided above show how the Advanced Error Reporting Capability (AER), an optional PCI Express Extended Capability, affects the flow. All of the PCI Express Devices/Functions mentioned in this sub-section have the AER Capability.

Besides the AER Capability, each PCIe device/function has a Device Status register that is part of its PCI Express Capability structure and contains indications of detected errors. Each PCIe device/function also has a Device Control Register that is part of its PCI Express Capability structure. This register contains bits that, in conjunction with other bits, provides software the capability to mask (prevent) the ERR_COR, ERR_NONFATAL, and ERR_FATAL error signaling messages from being transmitted towards the Root Complex.

If an individual error is masked when it is detected, its error status bit is still affected, but no error reporting Message is sent to the Root Complex, and the Header Log and First Error Pointer registers are unmodified. See Section 6.2.3.2.2 "Masking Individual Errors" and the flowchart in Section 6.2.5. "Sequence of Device Error Signaling and Logging Operations" in the *PCI Express Base Specification Revision 3.0*.

The Root Complex internally translates these error indications into platform-level events. This includes setting a possible NMI or SMI (interrupt), and ERROR_N[2:0] output signal pins.

Since they are part of the SoC Root Complex, the Root Ports, Virtual Root Ports, and RCEC interface directly to the SoC Global Registers rather than use the PCIe Error-Signaling Messages mentioned above. Each determines the error severity based on what is programmed in its PCIe Root Control (ROOTCTL) register and, as an option, sends the error to the SoC Global Registers.

As a PCIe Root Complex Integrated Endpoint (RCiE), the SMBus-Host Controller (B0:D18:F0) uses the SoC Root Complex Event Collector (RCEC) to pass errors to the Global Error logic and registers. As part of its AER Capability structure, the RCECs Root Error Status (RCEC_ROOTERRSTS) register and the Error Source Identification (RCEC_ERRSRCID) register that are used to capture the SMBus-Host Controller errors. They are located in Host Root Configuration Space at B0:D5:F0, offsets 130h and 134h respectively. For this to all happen the error signaling messages must be sent to the RCEC and not blocked by the SMBus-Host's Device Control Register that is part of its PCI Express Capability structure. RCEC also has the AER Root Error Command register (RCEC_ROOTERRCMD) at offset 12Ch that can be used to prevent error signaling messages from going to the Root Complex and the Global Error logic and registers.

Also as an RCiE, the SoC Integrated Error Handler (IEH) agent (B0:D4:F0) accumulates internal fabric hardware errors, all considered uncorrectable errors, and report them to the RCEC to pass-on to the Global Error logic/registers and generate an NMI or SMI, and optionally assert the SoC ERROR_N[2:0] output signal pins. This is done through Uncorrectable Internal Error (UIE), bit 22 of the RCEC Uncorrectable Error Status (RCEC_ERRUNCSTS) register located in Host Root Configuration Space at B0:D5:F0, offset 104h.

According to the *PCI Express Base Specification Revision 3.0*, the only method of recovering from an Uncorrectable Internal Error is reset or hardware replacement.

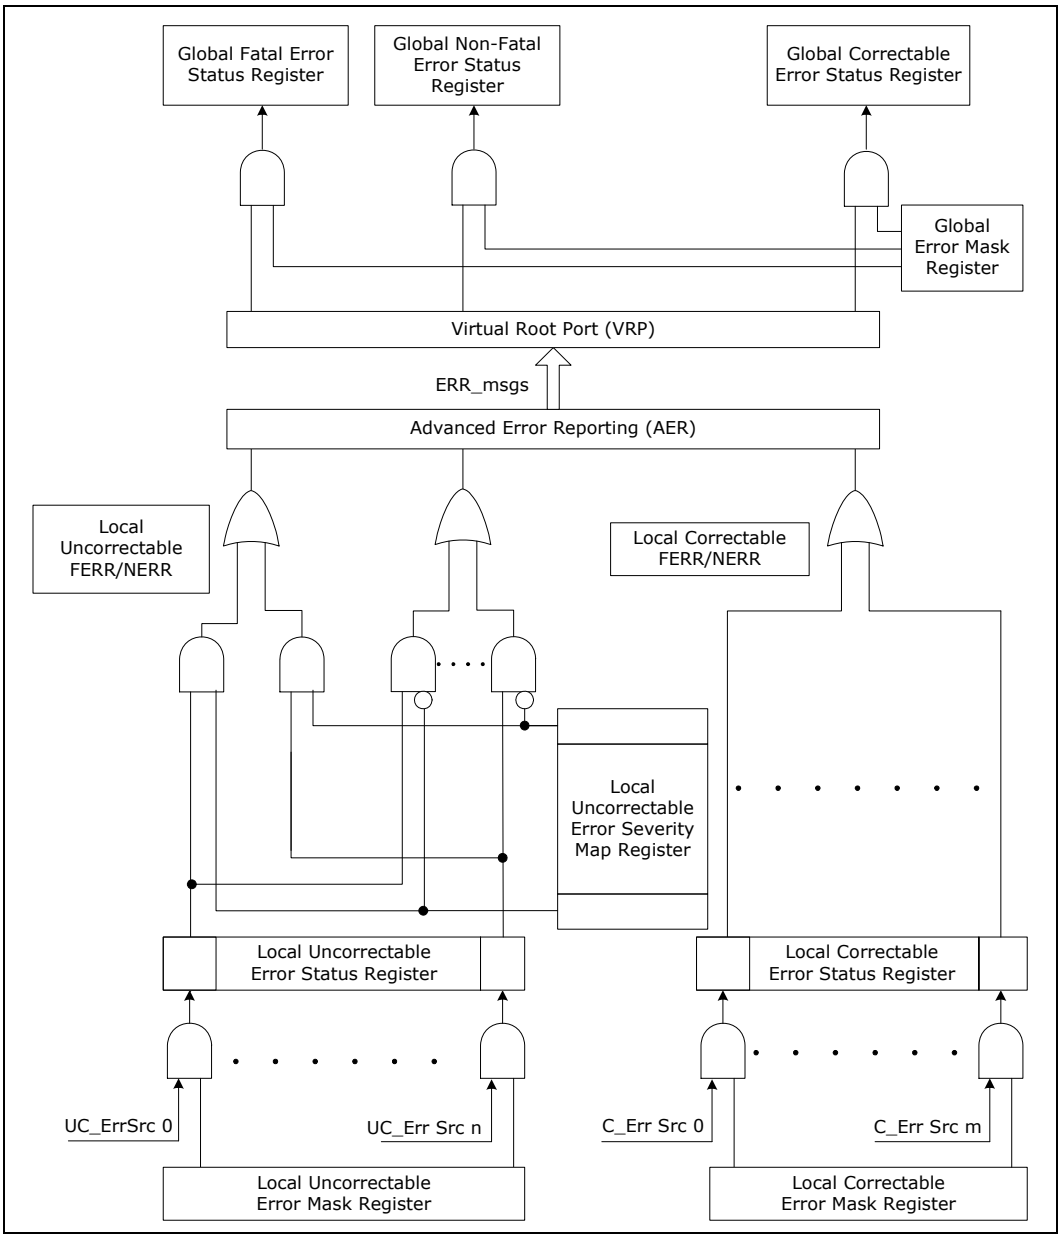
Like RCEC for the SMBus-Host mentioned above, each of the SoC PCIe Root Ports and Virtual Root Ports, as part of its AER Capability structure, has a Root Error Status (ROOTERRSTS) register and an Error Source Identification (ERRSRCID) register to capture errors signaled to them and the transaction Requester ID. Each also has a Root Error Command (ROOTERRCMD) that can be used to prevent error-signaling messages from propagating to the Root Complex and the Global Error logic and registers.

Note: SoC Machine Check events do not occur from hardware errors detected by PCIe agents.

6.14.3 PCIe Endpoint Devices Behind Virtual Root Port Error Handling

The integrated Intel® QuickAssist Technology controller and the integrated LAN Controllers are PCI Express endpoint devices. Each is attached to a dedicated "Virtual" Root Port (VRP). Each has Local Error Registers and an Error Signaling Message flow to the SoC Global Error Registers that is shown in Figure 6-9, "Error Signaling and Logging for PCIe Root Complex Integrated Endpoints."

Figure 6-9. Error Signaling and Logging for PCIe Root Complex Integrated Endpoints



These PCIe endpoint devices support AER registers for logging and reporting internal fabric and device specific errors. Device-specific errors are logged into Local Error registers and reported using Uncorrectable Internal Error Status (Bit 22) of ERRUNCSTS register and Corrected Internal Status (Bit 14) of the ERRUNCSTS register.

6.14.4 PCI Express Root Ports

While PCIe Root Port error reporting is described in the *PCI Express Base Specification Revision 3.0*, the following paragraphs highlight important aspects of PCIe Root port error reporting mechanism.

6.14.4.1 Unsupported Transactions and Unexpected Completions

If a SoC Root Port receives a legal PCIe-defined packet that is not included in PCIe supported transactions, the SoC treats that packet as an unsupported transaction and follows the PCIe rules for handling Unsupported Requests (UR). If the Root Port receives a Completion with a Requester ID set as the Root Port's Requester ID and there is no matching request outstanding, then this is considered an Unexpected Completion (UC). Also, the SoC Root Ports detects malformed packets from the PCI Express interface and reports them as errors per the PCI Express specification.

If a SoC Root Port receives a Type 0 Intel Vendor-Defined message that terminates at the SoC Root Complex and does not recognize it as a valid Intel-supported message, the message is handled by the SoC as an Unsupported Request (UR) with the appropriate error escalation defined in The PCI Express specification. For Type 1 Vendor-Defined messages which terminate at the Root Complex, the SoC simply discards the message with no further action.

6.14.4.2 Unconnected Ports

If a CPU transaction targets a PCIe link that is not connected to any device or the link is down (DL_Down status is received by the Root Port), the SoC treats this as a Master Abort situation. This is required for PCI bus scans to non-existent devices to go through without creating any other side effects. If the transaction is non-posted, The SoC returns all F's. Note that accesses by CPU to the Root Port registers corresponding to an unconnected PCIe interface does not generate an error.

6.14.5 Internal Errors — SMBus-Host Controller

The SMBus-Host Controller report its internal errors in the SMBus-Host Error Status (ERRSTS) register located in Host Root Memory Space located at SMTBAR, offset 18h.

The ERRAERMSK register located at SMTBAR, offset 14h, can be programmed to prevent individual SMBus-Host internal errors (ERRSTS) from also setting the Uncorrectable Internal Error (UIE) status, bit 22 of the SMBus-Host's AER Uncorrectable Error Status (ERRUNCSTS) register located in Host Root Configuration Space at B0:D18:F0, offset 104h. Whether or not the UIE error is signaled to the RCEC and Global Error logic depends on the setting of Uncorrectable Internal Error Mask (UIEM), bit 22 of the SMBus-Host's AER ERRUNCMSK register located at offset 108h.

6.14.6 Local Error Registers

The following tables list the registers associated with the error control, status, and reporting flow for the PCIe devices/functions of the SoC:

- Table 6-7, "Local Error Registers — PCI Express Root Ports"
- Table 6-8, "Local Error Registers — PCI Express RCEC and RCiEP Functions"
- Table 6-9, "Local Error Registers — PCI Express Functions Attached to Virtual Root Ports"

Register details are in the register chapters of this document. Also, reference the *PCI Express Base Specification Revision 3.0* for error register architectural details.

Table 6-7. Local Error Registers — PCI Express Root Ports

Location in Host Root Configuration Space	PCIe RP0 - RP7	Virtual PCIe RP0 - RP2	Register Name
PCI Header Type 1	PCICMD	PCICMD	Command
	PCISTS	PCISTS	Status
	SECSTS	SECSTS	Secondary status
	BCTL	BCTL	Bridge Control
PCIe Capability	DEVCTL	DEVCTL	Device Control
	DEVSTS	DEVSTS	Device Status
	ROOTCTL	ROOTCTL	Root Control
AER Capability	ERRUNCSTS	ERRUNCSTS	Uncorrectable Error Status
	ERRCORSTS	ERRCORSTS	Correctable Error Status
	AERCAPCTL	AERCAPCTL	AER Capabilities & Control
	AERHDRLOG1	AERHDRLOG1	Header Log (one entry)
	AERHDRLOG2	AERHDRLOG2	
	AERHDRLOG3	AERHDRLOG3	
	AERHDRLOG4	AERHDRLOG4	
	ROOTERRCMD	ROOTERRCMD	Root Error Command
	ROOTERRSTS	ROOTERRSTS	Root Error Status
	ERRSRCID	ERRSRCID	Error Source Identification

Table 6-8. Local Error Registers — PCI Express RCEC and RCiEP Functions

Location in Host Root Configuration Space	RCEC	SMBus-Host	Integrated Error Handler	Register Name
PCI Header Type 0	RCEC_PCICMD	PCICMD	GLREG_PCICMD	Command
	RCEC_PCISTS	PCISTS	GLREG_PCISTS	Status
PCIe Capability	RCEC_DEVCTL	DEVCTL	GLREG_DEVCTL	Device Control
	RCEC_DEVSTS	DEVSTS	RCEC_DEVSTS	Device Status
	RCEC_ROOTCTL			Root Control
AER Capability	RCEC_ERRUNCSTS	AERCAPHDR		Uncorrectable Error Status
	RCEC_ERRCORSTS	ERRUNCSEV		Correctable Error Status
	RCEC_ERRCORMSK	ERRCORSTS		Correctable Error Mask
	RCEC_AERCAPCTL	ERRCORMSK		AER Capabilities & Control
	RCEC_AERHDRLOG1	AERCAPCTL		Header Log (one entry)
	RCEC_AERHDRLOG2	AERHDRLOG1		
	RCEC_AERHDRLOG3	AERHDRLOG2		
	RCEC_AERHDRLOG4	AERHDRLOG3		
	RCEC_ROOTERRCMD	AERHDRLOG4		Root Error Command
	RCEC_ROOTERRSTS			Root Error Status
	RCEC_ERRSRCID			Error Source Identification

Table 6-9. Local Error Registers — PCI Express Functions Attached to Virtual Root Ports

Location in Host Root Configuration Space	LAN Primary Function and Virtual Functions	Intel® QuickAssist Technology Primary Function	Intel® QuickAssist Technology Virtual Functions	Register Name
PCI Header Type 0	CMD_STAT_REG	PPCICMD	PCICMD	Command
		PPCISTS	PCISTS	Status
PCIe Capability	DCTL_DSTS	PPDCNTL	DEVCTL	Device Control
		PPDSTAT	DEVSTS	Device Status
AER Capability	UEV	PPAERUCSEV	ERRUNCSEV	Uncorrectable Error Severity
	CES	PPAERCS	ERRCORSTS	Correctable Error Status
	CEM	PPAERCM	ERRCORMSK	Correctable Error Mask
	AECC	PPAERCAPCTL	AERCAPCTL	AER Capabilities & Control
	HL_DW1	PPAERHDRLOG1	AERHDRLOG1	Header Log (one entry)
	HL_DW2	PPAERHDRLOG2	AERHDRLOG2	
	HL_DW3	PPAERHDRLOG3	AERHDRLOG3	
	HL_DW4	PPAERHDRLOG4	AERHDRLOG4	

6.15 Error Reporting Flow — Legacy PCI Devices/Functions

- SATA0 and SATA1 Controllers
- USB Combo Controller
- LPC Controller
- SMBus - Legacy Controller
- SPI Controller
- HSUART Controller
- Intel® Trace Hub

Section 2.2.5 "Error Reporting Pins" of the *PCI Local Bus Specification, Revision 3.0*, defines the Parity Error (PERR#) and System Error (SERR#) error-reporting signal pins. According to the specification, these error signals can be enabled/disabled in the PCI Command register. PERR# is only used for the reporting of data parity errors during all PCI transactions except a Special Cycle. SERR# is for reporting address parity errors, data parity errors on the Special Cycle command, or any other system error where the result will be catastrophic. According to the specification, when an agent issues the SERR#, a non-maskable interrupt (NMI) is generated.

While there are no SoC signal pins involved, the integrated PCI devices/functions of the SoC use a similar way to report transaction errors to the SoC Root Complex, which internally translates error indications to platform-level events. An SERR# is considered an Uncorrectable, Fatal Error by the SoC. The SoC has no equivalent to PCI Parity Error PERR# signal because there is no true, physical PCI bus within the SoC. Even so, the SoC internal I/O fabric does detect and report internal parity errors to the SoC RCEC.

The Command (offset 4) and Status (offset 6) registers in device's Host Root Configuration Space play a role in how the device reports errors and the transaction errors that are detected. See Section 3.7.4 "Error Reporting" of the *PCI Local Bus Specification, Revision 3.0* for additional details.

Besides using its PCI Status register to report SERR# errors, the SATA Controllers report Fatal Errors in the General Configuration (SATAGC) register located at offset 9Ch of the SATA Configuration Space.

Besides a PCI Status register, the USB Combo Controller reports Fatal Errors in the USB Status (USBSTS) register located in Host Root Memory Space at MBAR plus offset 84h.

The LPC, SMBus - Legacy, SPI, and HSUART Controllers can each report a detected Uncorrectable Fatal Error through its PCI Device Status Register (STS) located at offset 6h for the function in Host Root Configuration Space. The Local Error Registers for the Intel® Trace Hub are not documented in this document.

The Error Status of each of the legacy PCI devices is represented in the SoC Global Error Register.

Errors detected by the SoC Legacy PCI devices are routed to the SoC Global Error logic/registers and can generate an NMI or SMI, and optionally assert the SoC ERROR_N[2:0] output signal pins. Machine Check events do not occur from these types of hardware errors.

6.15.1 Local Error Registers

Table 6-10, "Local Error Registers — SATA, USB, LPC and SMBus-Legacy" and Table 6-11, "Local Error Registers — SPI and HSUART" list the registers associated with the error control, status, and reporting flow for the PCIe devices/functions of the SoC.

Table 6-10. Local Error Registers — SATA, USB, LPC and SMBus-Legacy

Location in Host Root Configuration Space	SATA	USB Combo	LPC	SMBus-Legacy	Register Name
PCI Header Type 0	CMD	CMD	CMD	CMD	Command
	STS	STS	STS	DS	Status
Device-Specific	SATAGC	XHCC1			n/a
		XHCC3			n/a
		USBSTS			n/a

Table 6-11. Local Error Registers — SPI and HSUART

Location in Host Root Configuration Space	SPI	HSUART	Register Name
PCI Header Type 0	BIOS_SPI_STS_CMD	CMD_STAT_REG	Command
			Status
Device-Specific	BIOS_SPI_UR_STS_CTL	DSC	n/a

6.16 Error Reporting Flow — Non-PCI devices

These internal devices do not use the PCI or PCIe error-reporting mechanisms. These devices are part of the SoC UnCore (System Agent) and power control circuitry.

- System Agent - A Unit
- System Agent - B Unit
- System Agent - D Unit 0
- System Agent - D Unit 1
- SoC Power Management Unit (PMU)

The A, B, and two D Units of the SoC System Agent, also referred to as the "UnCore," protect the internal data interfaces with parity. Temporarily-stored data are protected with byte parity. The UnCore reports internal hardware errors by generating Machine Check Errors (MCERR) to the CPUs (MC Banks 6, 4, 7, and 8 respectively). The MCERR can also be routed to the MCERR_N output signal pin of the SoC. See Figure 6-5, "MCERR and IERR Handling." System Agent detected errors can also be routed directly to the SoC Global Error logic and logged in the SoC Global Error registers. See Figure 6-6, "Local and Global Error Register Structure."

The SoC Power Management Unit (PMU) detects Internal Errors (IERR) and can generate Machine Check events (MC Bank 5) to the CPUs. The IERR can also be routed to the IERR_N output signal pin of the SoC. See Figure 6-5, "MCERR and IERR Handling."

The D Units 0 and 1 detect and correct single-bit ECC (Correctable) errors. These can generate CMCI. See Section 6.6.2.3, "Corrected Machine-Check error Interrupt (CMCI)."

The SoC detects and logs Correctable Errors and Uncorrectable Errors encountered during DRAM memory Patrol Scrubbing and Demand Scrubbing. These can generate a Machine Check event and MCERR_N output signal. As an option, these errors can also be routed to the Uncorrectable (Double Bit) Read Error, bit 1 (UCE), and the Correctable (Single Bit) Read Error, bit 0 (SBE), of the DRAM Error Status (DERRSTS) register. The DERRSTS register is located in Host Root Memory Space at SBREG_BAR plus offset 10_0124h. For Memory Controller 1, the DERRSTS register is located at SBREG_BAR, offset 12_0124h. From there they can be routed to the SoC Global Error logic/registers and generate an NMI or SMI, and optionally assert the SoC ERROR_N[2:0] output signal pins.

PMU hardware errors also can generate Machine Check events and generate the IERR_N and MCERR_N signal pins. However, the PMU errors are not reported directly to the Global Error logic/registers. Instead they are reported by the Integrated Error Handler (IEH) through the GLREG (B0:D4:F0). This is similar to the flow used by the SoC I/O fabric. See Section 6.17, "Error Reporting Flow — I/O Fabric."

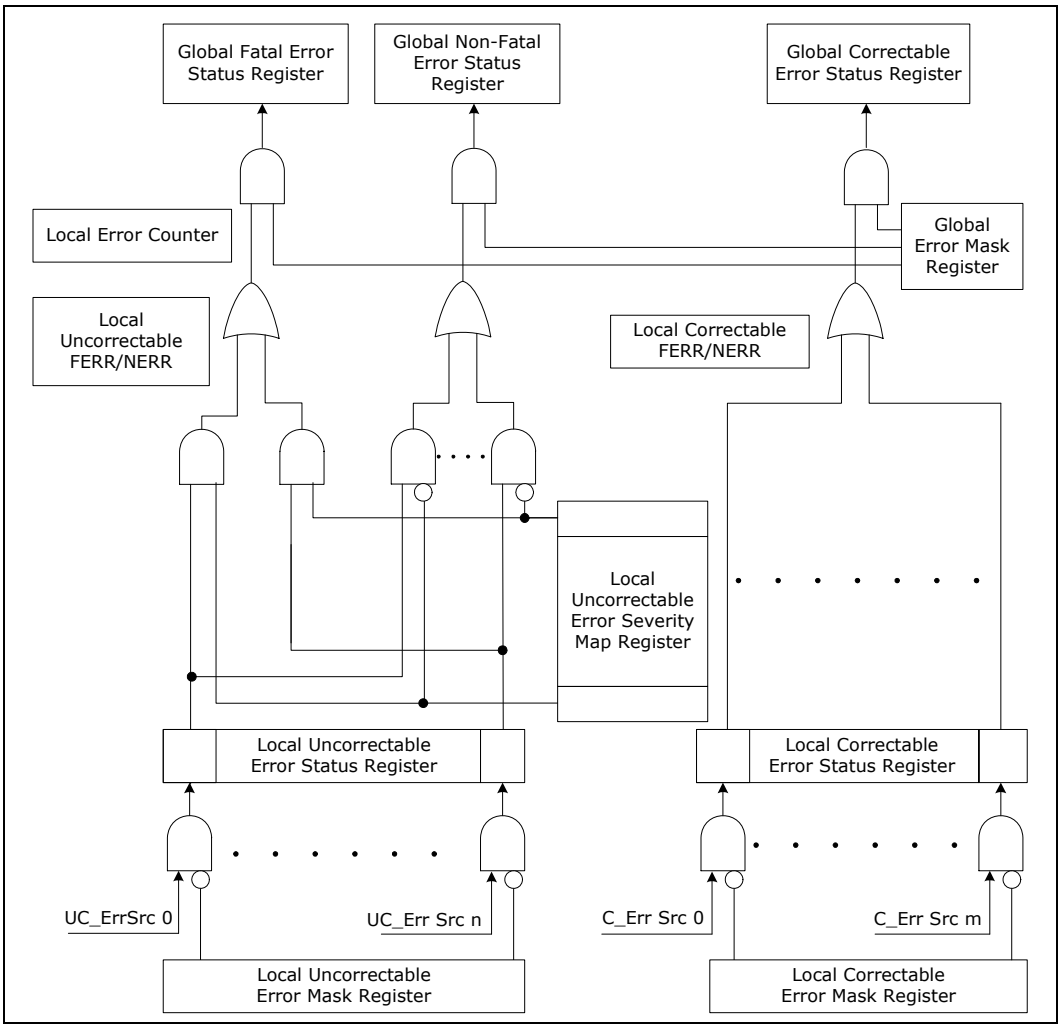
6.16.1 Local Error Registers

Both Correctable Errors and Uncorrectable Errors are reported and logged at the local level. See Figure 6-10, "Error Signaling and Logging for Non-PCI Devices."

The Uncorrectable Error Severity Register further categorizes the error as a Fatal Error or Non-Fatal Error. Error reporting can be masked. The First Error and Next Error are logged for each unit and a selectable error counter register is available.

The Local Error registers are listed in Table 6-12, "Local Error Registers — A-Unit and B-Unit" and Table 6-13, "Local Error Registers — D-Units."

Figure 6-10. Error Signaling and Logging for Non-PCI Devices



The local errors of the A-Unit, B-Unit, and the two D-Units are units are accumulated and directed to bits of the SoC Global Error Registers as shown in Figure 6-6, "Local and Global Error Register Structure."

The A-Unit and B-Unit Local Error registers and logs are located in Host Root Memory Space as offset addresses from MCHBAR:

- A-Unit: Offset 6588h through 65B8h
- B-Unit: Offset 6E04h through 6E3Ch

Table 6-12. Local Error Registers — A-Unit and B-Unit

A-Unit	B-Unit	Register Name
A_CR_UNCERRSTS_0_0_0_MCHBAR	B_CR_UNCERRSTS_0_0_0_MCHBAR	Uncorrectable Error Status Register
A_CR_UNCERRMSK_0_0_0_MCHBAR	B_CR_UNCERRMSK_0_0_0_MCHBAR	Uncorrectable Error Mask Register
A_CR_UNCERRSEV_0_0_0_MCHBAR	B_CR_UNCERRSEV_0_0_0_MCHBAR	Uncorrectable Error Severity Register
A_CR_UNCFERRSTS_0_0_0_MCHBAR	B_CR_UNCFERRSTS_0_0_0_MCHBAR	First Uncorrectable Error Register
A_CR_UNCNERRSTS_0_0_0_MCHBAR	B_CR_UNCNERRSTS_0_0_0_MCHBAR	Next Uncorrectable Error Register
A_CR_UNCERRCNTSEL_0_0_0_MCHBAR	B_CR_UNCERRCNTSEL_0_0_0_MCHBAR	Uncorrectable Error Select Register
A_CR_UNCERRCNT_0_0_0_MCHBAR	B_CR_UNCERRCNT_0_0_0_MCHBAR	Uncorrectable Error Count
A_CR_CORERRSTS_0_0_0_MCHBAR	B_CR_CORERRSTS_0_0_0_MCHBAR	Correctable Error Status Register
A_CR_CORERRMSK_0_0_0_MCHBAR	B_CR_CORERRMSK_0_0_0_MCHBAR	Correctable Error Mask Register
A_CR_CORFERRSTS_0_0_0_MCHBAR		First Correctable Error Register
A_CR_CORNERRSTS_0_0_0_MCHBAR		Next Correctable Error Register
A_CR_CORERRCNTSEL_0_0_0_MCHBAR		Correctable Error Count Select
A_CR_CORERRCNT_0_0_0_MCHBAR		Correctable Error Count
	B_CR_DPHDRLOG_LO_0_0_0_MCHBAR	Data Parity Header Log
	B_CR_DPHDRLOG_HI_0_0_0_MCHBAR	
	B_CR_DPADDRLOG_LO_0_0_0_MCHBAR	Data Parity Address Log
	B_CR_DPADDRLOG_HI_0_0_0_MCHBAR	
	B_CR_DERRADDRLOG_LO_0_0_0_MCHBAR	Error Address Log
	B_CR_DERRADDRLOG_HI_0_0_0_MCHBAR	
A_CR_PARITY_CTL_0_0_0_MCHBAR	B_CR_PARITY_CTL_0_0_0_MCHBAR	Parity and Error Injection Control
A_CR_IOMMU_PARITYINJ		Parity Error Injection

The D-Units report single-bit errors and double-bit errors that occur during reads of system memory. SoC internal buffer errors and DDR interface command and address parity errors are also reported. Memory errors are reported when Demand Scrub and Patrol Scrub are performed. D-Unit0 is Memory Controller 0 and D-Unit1 is Memory Controller 1. The Local Error registers are listed in Table 6-13, "Local Error Registers — D-Units."

The D-Unit Local Error registers are located in Host Root Memory Space as offset addresses from SBREGBAR:

- D-Unit0: Offset 10_0120h through 10_0130h
- D-Unit1: Offset 12_0120h through 12_0130h

The D-Unit Local Error logs and counters are located in Host Root Memory Space as offset addresses from SBREGBAR:

- D-Unit0: Offset 10_0064h through 10_0090h
- D-Unit1: Offset 12_0064h through 12_0090h

Table 6-13. Local Error Registers — D-Units

D-Unit 0	D-Unit 1	Register Name
UCELOG	UCELOG	Uncorrectable Error Log
UCEADDR	UCEADDR	Uncorrectable Error Address
SBELOG	SBELOG	Correctable (Single Bit) Error Log
SBEADDR	SBEADDR	Correctable Error Address
SBECNT0	SBECNT0	SBE Count for Rank 0
SBECNT1	SBECNT1	SBE Count for Rank 1
SBECNT2	SBECNT2	SBE Count for Rank 2
SBECNT3	SBECNT3	SBE Count for Rank 3
SBEACC0	SBEACC0	SBE Accumulator for Rank 0
SBEACC1	SBEACC1	SBE Accumulator for Rank 1
SBEACC2	SBEACC2	SBE Accumulator for Rank 2
SBEACC3	SBEACC3	SBE Accumulator for Rank 3
FERRNERR	FERRNERR	First Error and Next Error Register
DERRSTS	DERRSTS	Error Status Register
DERRMSKSEV	DERRMSKSEV	Error Mask and Severity
DERRCNTSEL	DERRCNTSEL	Uncorrectable Error Count Select
DERRCNT	DERRCNT	Uncorrectable Error Count
ERRINJCTL	ERRINJCTL	Error Injection Control
ERRINJADDR	ERRINJADDR	Error Injection Address
ERRINJAMSK	ERRINJAMSK	Error Injection Address Mask
ERRINJDATA0	ERRINJDATA0	Error Injection Data 0
ERRINJDATA1	ERRINJDATA1	Error Injection Data 1

6.16.2 Error Injection Control and Registers — Memory Controller

The SoC provide an error-injection mechanism for the D-Unit. The control, address, mask and data for this mechanism is located in Host Root Memory Space as offset addresses from SBREGBAR:

- D-Unit0: Offset 10_0134h through 10_0144h
- D-Unit1: Offset 12_0134h through 12_0144h

The error-injection registers are listed in Table 6-13, "Local Error Registers — D-Units."

6.17 Error Reporting Flow — I/O Fabric

The internal I/O fabric is parity protected. Both the command and data paths of the internal I/O fabric are end-to-end parity protected. The System Agent checks the I/O fabric parity on the command when a command is received from an I/O agent. If a command parity error is detected the packet is dropped and an error is reported. In addition, the System Agent does not accept new requests from the faulty I/O agent.

When an I/O agent receives a request from the System Agent, the I/O agent checks for both command and data parity. If a command parity error is detected, the agent drops the request and logs the error.

For Root Ports, if a data parity error is detected from a request from the System Agent, the Root Port forwards the error (also known as data poisoning) by setting the set the EP bit in the Transaction-Level Packet (TLP) of the request and forwards the request downstream over the PCI Express link. The Root Port also sets bit 15, Detected Parity Error (DPE), of its Primary Status Register (offset 6h) and sets bit 12, Poisoned TLP Status, of its Uncorrectable Error Status Register that is part of the AER capability structure. The Root Port indicates this non-fatal event to the Root Complex by sending a ERR_COR message with bit 13, Advisory Non-Fatal Error Status, of its AER Correctable Error Status Register.

6.17.1 Local Error Registers

The I/O fabric Local Errors are reported by the Integrated Error Handler (IEH) through the GLREG (B0:D4:F0) device-specific registers in Host Root Configuration Space starting at offset 280h. All I/O fabric errors are Uncorrectable Errors. See Table 6-14, "Local Error Registers — Integrated Error Handler (IEH)." All of these Uncorrectable Errors are also reported to the RCEC (B0:D5:F0) using Uncorrectable Internal Error (UIE) status (Bit 22) of the RCEC_ERRUNCSTS register.

Table 6-14. Local Error Registers — Integrated Error Handler (IEH)

Location in Host Root Configuration Space	GLREG	Register Name
Device-Specific	GLREG_LERRUNCSTS	Uncorrectable Error Status
	GLREG_LERRUNCMSK	Uncorrectable Error Mask
	GLREG_LFERRUNCSTS	Uncorrectable First Error Status
	GLREG_LNERRUNCSTS	Uncorrectable Next Error Status
	GLREG_LUNCERRCNTSEL	Uncorrectable Error Counter Selection
	GLREG_LUNCERRCNT	Uncorrectable Error Counter
	GLREG_LFERRHDRLOG1	Header Log (one entry)
	GLREG_LFERRHDRLOG2	
	GLREG_LFERRHDRLOG3	
	GLREG_LFERRHDRLOG4	

6.18 SoC Error Handling Summary

Table 6-15, "Summary of Default Error Logging and Responses" summarizes many of the SoC-detected hardware errors, their error severity, and the Local and Global Error registers used to report and log them.

Table 6-15. Summary of Default Error Logging and Responses (Sheet 1 of 10)

ID	Error	Error Type (Default Severity)	Transaction Response	Default Error Logging[1]
Integrated Error Handler Errors				
A0	IEH Detected Configuration Register Parity Error	Uncorrectable (Fatal)	The SoC detects and logs the error.	FERR/NERR is logged in IEH and Global Fatal Error Log registers: GLREG_LERRUNCSTS GLREG_LFERRUNCSTS GLREG_LNERRUNCSTS GLREG_LFERRHDRLOG GLREG_GFAERRSTS GLREG_GFAFERRSTS GLREG_GFANERRSTS GLREG_GFAFERRTIME Header is logged.
A1	Configuration agent detected Fabric Command Parity Error		Internal I/O Bus Command Parity errors are detected at the output of the upstream and downstream queues when a request is granted. Further arbiter grants are inhibited.	
A2	Configuration Agent Fabric Data Parity Error		SoC detects and logs the error.	
A3	Configuration agent detected negatively decoded transaction Error		SoC detects and logs the error.	
A4	Internal Fabric detected Command Parity Error		Internal fabric command parity errors are detected at the output of the upstream and downstream queues when a request is granted. Further arbiter grants are inhibited.	
A5	Internal Fabric detected Command Parity Error		Internal fabric command parity errors are detected at the output of the upstream and downstream queues when a request is granted. Further arbiter grants are inhibited.	
A6	Internal Fabric detected Command Parity Error		Internal fabric command parity errors are detected at the output of the upstream and downstream queues when a request is granted. Further arbiter grants are inhibited.	
A7	Internal Fabric detected Command Parity Error		Internal fabric command parity errors are detected at the output of the upstream and downstream queues when a request is granted. Further arbiter grants are inhibited.	
A8	Internal Fabric detected Command Parity Error		Internal fabric command parity errors are detected at the output of the upstream and downstream queues when a request is granted. Further arbiter grants are inhibited.	
A9	Internal Fabric detected Command Parity Error		Internal fabric command parity errors are detected at the output of the upstream and downstream queues when a request is granted. Further arbiter grants are inhibited.	
A10	Internal Fabric Intel® ME detected Command Parity Error		Internal fabric command parity errors are detected at the output of the upstream and downstream queues when a request is granted. Further arbiter grants are inhibited.	

Table 6-15. Summary of Default Error Logging and Responses (Sheet 2 of 10)

ID	Error	Error Type (Default Severity)	Transaction Response	Default Error Logging[1]
B-Unit Errors				
B0	Read data correctable ECC error	Correctable	Read data is corrected and written back to memory	FERR/NERR is logged in Bunit and Global Fatal Error Log Registers: BCORERRSTS BCORFERRSTS BCORNERRSTS GLREG_GCOERRSTS GLREG_GCOFERRSTS GLREG_GCONERRSTS GLREG_GCOFERRTIME These are also logged in Bunit MCA bank registers.
B1	Unexpected Completion	Uncorrectable (Fatal)	SoC detects and logs the error.	FERR/NERR is logged in Bunit and Global Fatal Error Log Registers: BUNCERRSTS BUNCFERRSTS BUNCNERRSTS GLREG_GFAERRSTS GLREG_GFAFERRSTS GLREG_GFANERRSTS GLREG_GFAFERRTIME These are also logged in Bunit MCA bank registers.
B2	BRAM Write Data Parity Error			
B3	Memory Controller to SSA Data Parity Error			
B4	Source Address Decoder (SAD) Error			
B5	Ucode/xucode Errors			
B6	Read data uncorrectable ECC Error		Read data is sent with bad parity to the B-Unit.	
B8	Protected Memory region space violated Error		Protected memory violation	

Table 6-15. Summary of Default Error Logging and Responses (Sheet 3 of 10)

ID	Error	Error Type (Default Severity)	Transaction Response	Default Error Logging[1]
LAN Controllers Errors				
C0	Advisory Non-fatal Error (ANFE)	Correctable		Error is logged in GbE Local and Global Correctable Error Log registers: CES GCORERRSTS GCORFERRSTS GCORNERRSTS GCORFERRTIME
C1	Bad TLP Error (PTLPE)	Uncorrectable (Non-Fatal)	ERR_Non-fatal sent to root complex. Header is logged. A poisoned completion is ignored and the request can be retried after timeout. If enabled, the error is reported.	Error is logged in GbE Local and Global Non-fatal Error Log Registers: UES GNERRST GNFERRST GNNERRST GNFERRTIME
C2	Completion Timeout Error (CTE)		Error severity is non-fatal (default case): Send error message If advisory Retry the request once and send advisory error message on each failure. If fails, send uncorrectable error message. Error severity is defined as fatal: Send uncorrectable error message	
C3	Completer Abort Error (CAE)		ERR_Non-fatal sent to root complex. Header is logged. Send completion with CA.	
C4	Unexpected Completion Error (UCE)		ERR_Non-fatal sent to root complex. Header is logged. Discard TLP.	
C5	Unsupported Request Error (URE)		ERR_Non-fatal sent to root complex. Header is logged. Send completion with UR.	
C6	Malformed TLP Error (MTLPE)	Uncorrectable (Fatal)	ERR_Fatal sent to root complex. Header is logged. Drop the packet and free FC credits.	Error is logged in GbE Local and Global Fatal Error Log Registers: UES GFERRST GFFERRST GFNERRST GFFERRTIME

Table 6-15. Summary of Default Error Logging and Responses (Sheet 4 of 10)

ID	Error	Error Type (Default Severity)	Transaction Response	Default Error Logging[1]
Memory Controller Errors				
D0	Patrol Scrub/Demand scrub correctable ECC Error	Correctable	Read data is corrected and written back to memory	FERR/NERR is logged in Dunit and Global Fatal Error Log Registers: DERRSTS DFERRNERR SBELOG UCELOG GLREG_GFAERRSTS GLREG_GFAFERRSTS GLREG_GFANERRSTS GLREG_GFAFERRTIME These are also logged in Dunit MCA bank registers.
D1	Write Data Buffer read parity Error	Uncorrectable (Fatal)		
D2	Patrol scrub uncorrectable ECC Error		Read data is sent with bad parity to the B-Unit.	
D3	Demand read uncorrectable ECC Error		Read data is sent with bad parity to the B-Unit.	
D4	DDR4 Add/Cmd parity Error			

Table 6-15. Summary of Default Error Logging and Responses (Sheet 5 of 10)

ID	Error	Error Type (Default Severity)	Transaction Response	Default Error Logging[1]
PCIe* Root Port Errors				
E0	Receiver Error (RE)	Correctable	Respond per *PCI-E Specification*	Log error per PCI Express* AER requirements for these correctable errors/message. If the PCIe correctable error is forwarded to the Global Error registers, the error is logged in Global Correctable Log registers: GCOERRST GCOFERRST GCONERRST GLREG_GCOFERRTIME
E1	Bad TLP Error (BTLPE)			
E2	Bad DLLP Error (BDLLPE)			
E3	Replay Number Rollover Error (RNRE)			
E4	Replay Timer Time-out Error (RTTE)			
E5	Header Log Overflow Error (HLOE)			
E6	Received ERR_COR Message from Downstream Device			
E7	Poisoned TLP Error (PTLPE)	Uncorrectable (Non-Fatal)	SoC logs the error.	Log error per PCI Express AER requirements for the corresponding error/message. If the PCIe uncorrectable error is forwarded to the Global Error registers, the error is logged in Global Non-Fatal Log registers: GNFERRST GNFFERRST GNFNERRST GNFFERRTIME
E8	Completion Time-out Error (CTE)			
E9	Completer Abort Error (CAE)			
E10	Unexpected Completion Error (UCE)		Respond Per *PCI-E Specification*	
E11	Unsupported Request Error (URE)		SoC logs the error.	
E12	ACS Violation Error (ACSE)			
E13	MC Blocked TLP Error (MCE)			
E14	Atomic Egress Blocked Error (AEBE)			
E15	Received ERR_NONFATAL Message from Downstream Device		Respond per *PCI-E Specification*	
E16	Data Link Protocol Error (DLPE)	Uncorrectable (Fatal)	Respond per *PCI-E Specification*	Log error per PCI Express AER requirements for the corresponding error/message. If the PCIe uncorrectable error is forwarded to the Global Error registers, the error is logged in Global Fatal Log registers: GFAERRST GFAFERRST GFANERRST GLREG_GFAFERRTIME
E17	Surprise Link Down Error (SLDE)			
E18	Flow Control Error (FCE)			
E19	Receiver Overflow Error (ROE)			
E20	Malformed TLP Error (MTLPE)			
E21	Uncorrectable Internal Error (UIE)			
E22	Received ERR_FATAL Message from Downstream Device

ID	Error	Error Type (Default Severity)	Transaction Response	Default Error Logging[1]
SMBus Errors				
F0	Retry Error (RETRYERR): An error due to SMT master transaction exceeding (non-collision) retry count as specified in RPOLICY.RETRY	Uncorrectable (Fatal)	The SoC detects and logs the error.	FERR/NERR is logged in the Global Fatal Error Log registers: SMT_ERRUNCSTS SMT_FERRUNCSTS SMT_NERRUNCSTS SMT_FERRHDRLOG GLREG_GFAERRSTS GLREG_GFAFERRSTS GLREG_GFANERRSTS GLREG_GFAFERRTIME

Table 6-15. Summary of Default Error Logging and Responses (Sheet 7 of 10)

ID	Error	Error Type (Default Severity)	Transaction Response	Default Error Logging[1]
Intel® QAT Errors				
G0	Advisory Non-fatal Error (ANFE)	Correctable	ERR_COR sent to root complex	Error is logged in Intel® QAT Local and Global Correctable Error Log Registers: PPAERCS/VPAERCS GCORERRST GCORFERRST GCORNERRST GCORFERRTIME
G1	Corrected Internal Error (CIE)			
G2	Poisoned TLP Error (PTLPE)	Uncorrectable (Non-fatal)	Poisoned completions: ERR_COR Posted Write: ERR_NONFATAL NP Write: ERR_NONFATAL; Completion returned with UR	Error is logged in Intel® QAT Local and Global Non-fatal Error Log Registers: PPAERUCS/VPAERUCS PPAERHDRLOG/VPAERHDRLOG GNERRST GNFERRST GNNERRST GNFERRTIME
G3	Completion Timeout Error (CTE)		ERR_COR sent to root complex	
G4	Completer Abort Error (CAE)		P: request: ERR_NONFATAL NP request: ERR_COR; return completion with CA status	
G5	Unexpected Completion Error (UCE)		ERR_COR; completion is dropped	
G6	Unsupported Request Error (URE)		P: ERR_NONFATAL NP: ERR_COR; return completion with UR status	
G7	Malformed TLP Error (MTLPE)	Uncorrectable (Fatal)	ERR_NONFATAL (if sev = 0) ERR_FATAL (if sev = 1); When a malformed packet is detected, the packet is dropped and the error is logged.	Error is logged in Intel® QAT Local and Global Fatal Error Log Registers: PPAERUCS/VPAERUCS PPAERHDRLOG/VPAERHDRLOG GFERRST GFFERRST GFNERRST GFFERRTIME
G8	Uncorrectable Internal Error (UIE)		ERR_NONFATAL (if sev = 0) ERR_FATAL (if sev = 1)	
SATA Errors				
H0	When a set event occurs to configuration bits SATAGC.URD=1, during SATAGC.URRE=1 and CMD.SEE=1 for controller 1.	Uncorrectable (Fatal)	Treat as UR and initiate DO_SERR	Error is logged in PCISTS and Global Fatal Error Log registers: PCISTS GLREG_GFAERRSTS GLREG_GFAFERRSTS GLREG_GFANERRSTS GLREG_GFAFERRTIME
H1	When a set event occurs to configuration bits STS.DPE=1 during CMD.PEE=1 and CMD.SEE=1 for controller 1.		For MMR/CFG access, no update on destination & UR for NP req. Error logged and Do_SERR initiated. For SATA data downstream, poison CRC but no error logging or reporting	
H2	When a set event occurs to configuration bits STS.STA=1 during CMD.SEE=1 for controller 1.		Initiate DO_SERR.	

Table 6-15. Summary of Default Error Logging and Responses (Sheet 8 of 10)

ID	Error	Error Type (Default Severity)	Transaction Response	Default Error Logging[1]
USB Errors				
J0	Received downstream completion with unsupported request status	Uncorrectable (Fatal)	Set PCI space STS.RMA, and; Set MMIO space USBSTS.HSE. Note that USBSTS.HSE = 1, and USBCMD.HSEE = 1 will trigger Out-Of-Band error indication from Fresco IP, and SoC I/O fabric Gasket will set STS.SSE and send SERR if XHCC1.RMTASERR = 1 and CMD.SERR = 1. Drop cycles (return credits) and signal unsuccessful completion.	Error is logged in PCISTS and Global Fatal Error Log registers: PCISTS, USBSTS GLREG_GFAERRSTS GLREG_GFAFERRSTS GLREG_GFANERRSTS GLREG_GFAFERRTIME
J1	Received downstream completion with completer abort status		Set PCI space STS.RTA, and; Set MMIO space USBSTS.HSE. Note that USBSTS.HSE = 1, and USBCMD.HSEE = 1 will trigger Out-Of-Band error indication from Fresco IP, and SoC I/O fabric Gasket will set STS.SSE and send SERR if XHCC1.RMTASERR = 1 and CMD.SERR = 1. Drop cycles (return credits) and signal unsuccessful completion.	
J2	Received downstream memory cycles when PMCS.DS = D3.			
J3	Received downstream memory cycles when CMD.MSE = 0.			
J4	Received downstream memory cycles which is out of range due to recent memory space/limit change.			
J5	Received downstream memory cycles crossing QW aligned address boundary.			
J6	Received downstream request with error poisoned.			
J7	Received downstream completion with error poisoned.			
J8	Internal fabric Data parity error		The SoC detects and logs the error.	
J9	Internal fabric command parity error		The SoC detects and logs the error.	

Table 6-15. Summary of Default Error Logging and Responses (Sheet 9 of 10)

ID	Error	Error Type (Default Severity)	Transaction Response	Default Error Logging[1]
LPC Errors				
K0	LPC Sync Error	Uncorrectable (Fatal)	SoC detects and logs the error.	Error is logged in PCISTS and Global Fatal Error Log registers: PCISTS GLREG_GFAERRSTS GLREG_GFAFERRSTS GLREG_GFANERRSTS GLREG_GFAFERRTIME
HSUART Errors				
L0	HSUART error	Uncorrectable (Fatal)	The SoC detects and logs the error. Do_Serr initiated.	Error is logged in PCISTS and Global Fatal Error Log Registers: PCISTS GLREG_GFAERRSTS GLREG_GFAFERRSTS GLREG_GFANERRSTS GLREG_GFAFERRTIME

Table 6-15. Summary of Default Error Logging and Responses (Sheet 10 of 10)

ID	Error	Error Type (Default Severity)	Transaction Response	Default Error Logging[1]
VT-d Errors				
I6	Tag Array Parity Error during Context Cache Lookup	Correctable	A tag array parity error was detected in the VT-d caches.	Error is logged in Aunit Local and Global Correctable Error Log Registers: GCORERRST GCORFERRST GCORNERRST GCORFERRTIME
I7	Tag Array Parity Error during L2 Lookup			
I8	Tag Array Parity Error during L3 Lookup			
I9	Tag Array Parity Error during L4 Lookup			
I10	IOTLB Tag Array Parity Error			
I11	Data Parity Error during Context Cache Lookup	Uncorrectable (Fatal)	A parity error was detected in the VT-d caches.	FERR/NERR is logged in Aunit and Global Fatal Error Log Registers: AUNCERRSTS AUNCFERRSTS AUNCNERRSTS GLREG_GFAERRSTS GLREG_GFAFERRSTS GLREG_GFANERRSTS GLREG_GFAFERRTIME
I12	Data Parity Error during L2 Lookup			
I13	Data Parity Error during L3 Lookup			
I14	Data Parity Error during L4 Lookup			
I15	IOTLB Data Parity Error			
B8	Protected Memory region space violated Error	Uncorrectable (Fatal)	Protected memory violation	FERR/NERR is logged in Bunit and Global Fatal Error Log Registers: BUNCERRSTS BUNCFERRSTS BUNCNERRSTS GLREG_GFAERRSTS GLREG_GFAFERRSTS GLREG_GFANERRSTS GLREG_GFAFERRTIME
M0	VT-d faults	Uncorrectable (Non-Fatal)	Log error per VT-d spec in Fault Record.	VTDBAR.FRCD

1. This column notes the logging registers used assuming the error severity default remains. The error severity dictates the actual logging registers used upon detecting an error.

6.19 Register Map

Figure 6-11, "Register Map" shows the associated Global and Local Error Registers (GLREG) and the Root Complex Event Collector (RCEC) from a system software perspective.

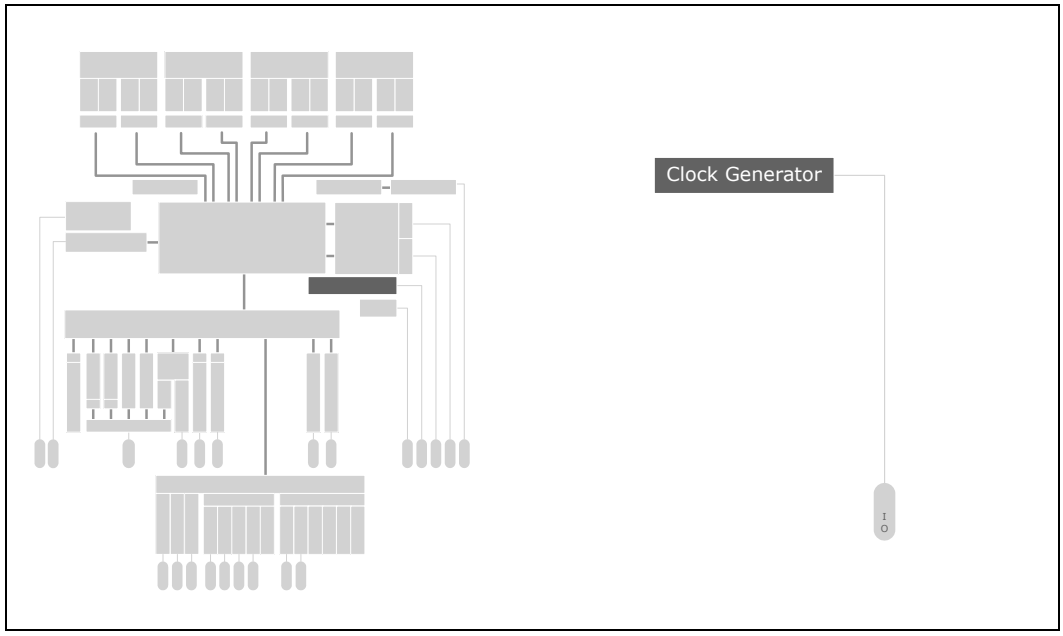
7 Clock Architecture

The SoC requires one external 25-MHz crystal and one external 32.768-kHz crystal for internal clock generation. Some internal clocks can be configured by Soft Straps and by registers accessible to UEFI IA Firmware (BIOS).

Figure 7-1. What is Covered in This Chapter



7.1 Signal Descriptions

The signal descriptions are shown in Table 7-1. For additional signal information, including whether a signal is assigned to shared-function pin or can be used as a Customer GPIO signals see Section 39.1, "Directory of Signal Names and Pin Names" on page 993. The Direction/Type column of Table 7-1 is interpreted as follows:

- I = Input signal. The SoC has receiver circuit.
- O = Output signal. The SoC has driver circuit.
- O-OD = Open-Drain Output. SoC output circuit uses an open-drain driver.
- Differential = Differential signal pair. Two pins: Positive; Negative.

Table 7-1. Signal Names and Descriptions (Sheet 1 of 2)

Signal Names	Direction	Shared	Description
CLK_X1_PAD	I	No	**Clock Crystal - 25 MHz**. The SoC uses the crystal for its internal oscillators and PLLs to generate internal clocks of various speeds which are controlled and distributed throughout the SoC.
CLK_X2_PAD	O	No	
ICLKRCOMP	I,O	No	**ISCLK RCOMP:** Compensation resistor for the CLK_OUT_DP[4:0], CLK_OUT_DN[4:0] differential output signals. The resistor is used by the internal ISCLK circuitry to calibrate the PCIe reference-clock driver impedance to comply with the PCIe specification for REFCLK. To achieve 50-Ω driver/trace impedance, ICLKRCOMP must be connected to a 200-Ω resistor to VSS on the platform board. To achieve a 42.5- Ω driver impedance/trace, a 169-Ω resistor must be used.
RTC_X1_PAD RTC_X2_PAD	I,O	No	**Clock Crystal - 32.768 KHz**: The SoC uses the crystal for its internal Real-Time Clock (RTC) oscillator. The clock is used internally and drives the PMU_SUSCLK output signal.
BVCCRTC_EXTPAD	I,O	No	**External Pad for RTC Power Well:** Must be connected to an external 0.1-µF capacitor on the platform board.
FLEX_CLK_SE[1:0]	O	Yes	**Flex Clock.** These single-ended output signals are general-purpose clocks that can be used by the platform board.
PMU_SUSCLK	O	Yes	Chapter 16, "Power Management Controller (PMC)"
SVID_CLK	O-OD	Yes	Chapter 34, "Power Management"
SATA0_SCLK SATA1_SCLK	O-OD	Yes	Chapter 12, "SATA Controller"
EMMC_CLK	I,O	Yes	Chapter 17, "Embedded Multi-Media Card (eMMC)"
DDR0_CLK_DP[3:0] DDR0_CLK_DN[3:0] DDR1_CLK_DP[3:0] DDR1_CLK_DN[3:0]	O, Differential	No	Chapter 9, "Memory Controller"
CLK_OUT_DP[4:0] CLK_OUT_DN[4:0]	O, Differential	No	Chapter 11, "PCI Express Root Ports (RP)"
LPC_CLKOUT[1:0]	O	Yes	Chapter 20, "Low Pin Count (LPC) Controller"
SMB_LAN_CLK	I,O-OD	Yes	Chapter 13, "LAN Controllers"
LAN0_PORT0_I2C_CLK LAN0_PORT1_I2C_CLK LAN1_PORT0_I2C_CLK LAN1_PORT1_I2C_CLK	I,O-OD	Yes	Chapter 13, "LAN Controllers"
LAN_MDC	O	Yes	Chapter 13, "LAN Controllers"
NCSI_CLK_IN	I	Yes	Chapter 13, "LAN Controllers"
SPI_CLK	I,O	Yes	Chapter 19, "Serial Peripheral Interface (SPI)"
SMB_LEG_CLK	I,O-OD	Yes	Chapter 28, "SMBus Controller - Legacy"
SMB_HOST_CLK	I,O-OD	Yes	Chapter 29, "SMBus Controller - Host"

Table 7-1. Signal Names and Descriptions (Sheet 2 of 2)

Signal Names	Direction	Shared	Description
SMB_PECI_CLK	I,O-OD	Yes	Chapter 30, "SMBus Controller - Platform Environment Control Interface"
SMB_ME_SMT0_CLK	I,O-OD	Yes	Chapter 36, "System Management"
SMB_ME_SMT1_CLK		Yes	
SMB_ME_SMT2_CLK		Yes	
SMB_IE_SMT0_CLK	I,O-OD	Yes	Chapter 37, "Innovation Engine"
SMB_IE_SMT1_CLK		Yes	
SMB_IE_SMT2_CLK		Yes	
TCK	I	No	Chapter 38, "JTAG and Debug Ports"
DFX_PORT_CLK[1:0]	O	Yes	Chapter 38, "JTAG and Debug Ports"

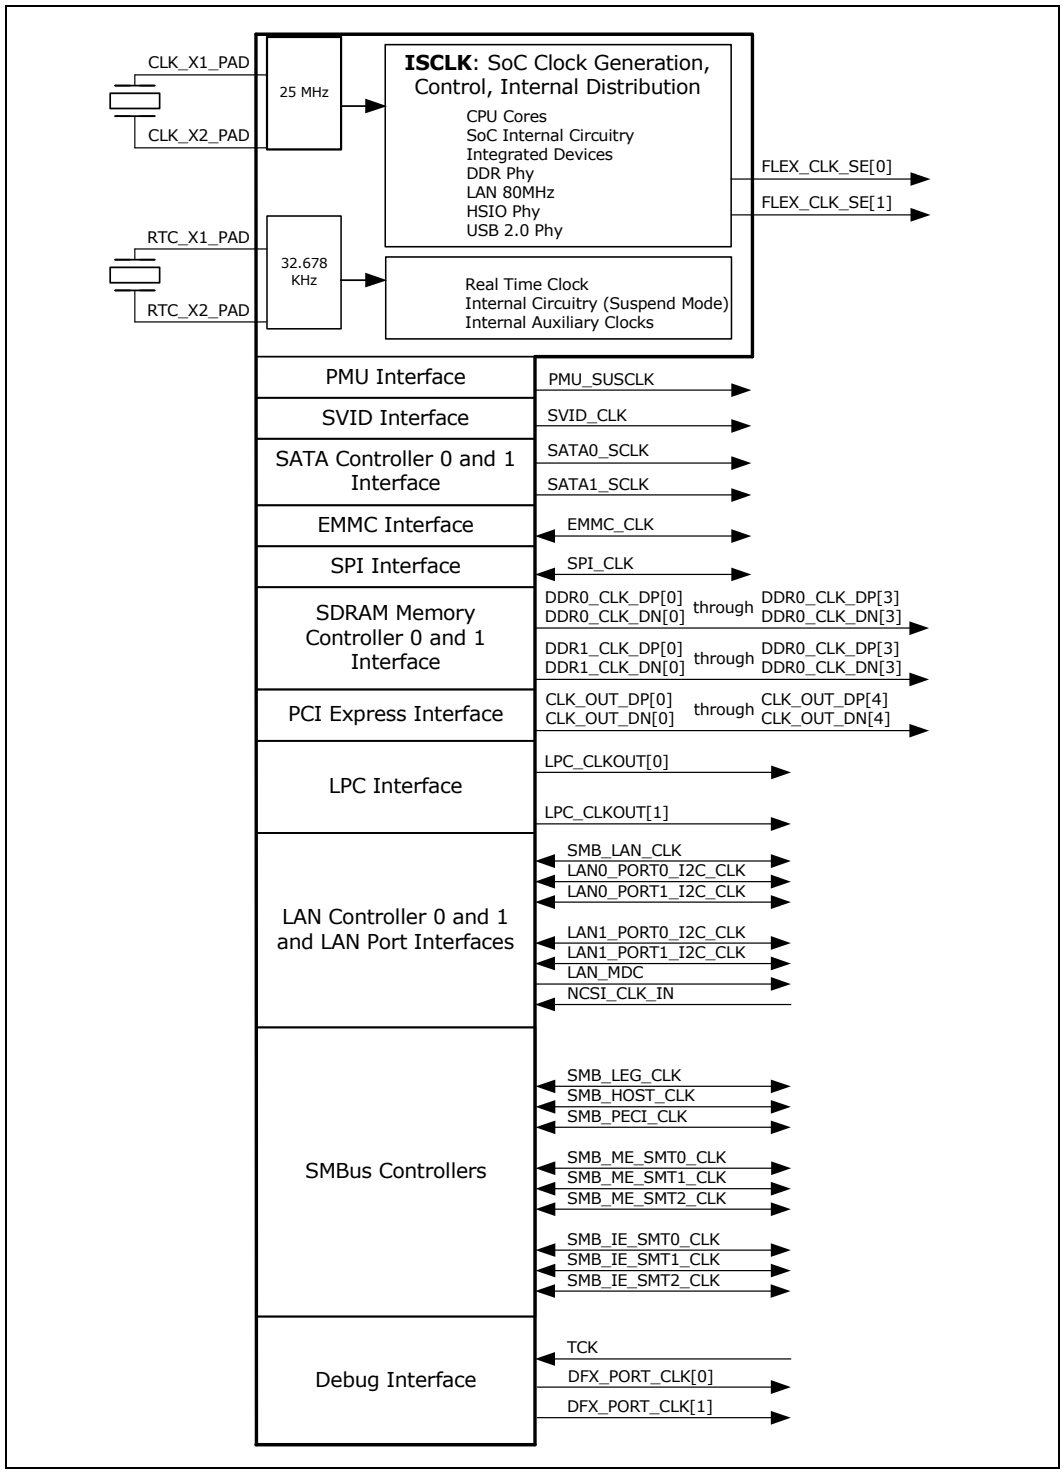
7.2 Feature List

- SoC requires only two crystals to generate the necessary reference clocks.
- Two Flex Clock output signals that are configurable for platform board use.
- Spread-Spectrum Clocking (SSC) and Non-Spread-Spectrum clocking (NSSC) available.
- Five PCI Express output reference clocks provided and can be used without additional buffer circuits.

7.3 Architectural Overview

The SoC clock architecture is shown in Figure 7-2.

Figure 7-2. SoC Clock Architecture



7.3.1 ISCLK

The external 25-MHz crystal serves as the reference for the internal block of clocks called the Internal System Clock (ISCLK). The reference is routed to a number of internal Phase-Locked Loop (PLL) circuits which are then distributed to the CPU cores, internal circuitry and devices.

For external-interface clocks generated by the SoC, both Spread-Spectrum Clocking (SSC) and Non-SSC (NSSC) are supported.

There are two customer-configurable clock features:

- **Spread Spectrum Controls:** This is expected to be enabled by UEFI IA Firmware via an Integrated Clock Control HECI command to Intel® ME.
- **Flex I/O Clock Speed:** The setting is programmable via a soft strap that is applied during reset. Software can read the resultant settings of the two Flex Clocks' speeds by reading bits [5:0] and [13:8] of the ICLK_DWORD8 register in Host Root Memory Space.

7.3.2 Real-Time Clock

The external 32.768-kHz crystal serves as the reference for the integrated Real Time Clock (RTC). It also provides the clock used by circuitry and devices when the SoC is in Suspend Mode (SUS Mode).

Note: All platform board designs must provide this crystal even if the RTC is not needed or SUS Mode is not implemented.

7.3.3 PMU SUS Clock

The SoC provides the PMU_SUSCLK output signal pin that is based on the 32.768-KHz RTC clock. This signal can be used by the platform board.

7.3.4 Flex Clocks

FLEX_CLK_SE[1:0] are two, single-ended, output signals available to the SoC customer as general-purpose clocks that can be used by the platform board. The customer uses Soft Straps (Chapter 4, "Strapping and Configuration") to enable and select one of the supported frequencies for each Flex Clock. The supported frequencies for each Flex Clock are:

- 25 MHZ
- 33 MHz
- 48 MHz
- 50 MHz

7.3.5 SVID Clock

The available clock frequencies for the SVID Clock:

- 16.7 MHZ
- 20 MHZ
- 25 MHz (default)

7.3.6 SATA Serial GPIO (SGPIO) Clock

The clock frequency for the SATA Serial Clocks is 32 KHz.

7.3.7 EMMC Clock

The SoC EMMC clock is 200 MHz.

7.3.8 DDR Clocks

The available clock frequencies for the DDR4 differential clock output signals are product-SKU dependent. The entire list follows:

- 933 MHz (1866 MHz SDRAMs)
- 1067 MHz (2133 MHz SDRAMs)
- 1200 MHz (2400 MHz SDRAMs)

7.3.9 PCI Express Reference Clocks

The clock frequency for the PCI Express* reference clocks is 100 MHz.

7.3.10 SPI Clock

The available clock frequencies for the SPI Clock:

- 17 MHz (default)
- 30 MHz
- 48 MHz

7.3.11 LPC Clocks

The SoC LPC clock is 24 MHz.

7.3.12 LAN I2C Clocks

The available clock frequencies for each of the LAN I2C Clocks are:

- 100 kHz
- 400 kHz
- 1 MHz

7.3.13 LAN MDC Clock

The available clock frequencies for the LAN MDIO management interface clock are:

- 240 kHz (available only with 1 Gb/s Link Speed)
- 2.4 MHz

7.3.14 LAN NC-SI Clock

NCSI_CLK_IN is designed to be driven by the 50-MHz NC-SI generated by the platform board.

7.3.15 SMBus Clocks

The available clock frequencies for each of the SMBus controllers of the SoC are:

- 100 kHz
- 400 kHz
- 1 MHz

7.3.16 Debug and DFx Clocks

- The SoC TCK clock input signal can be 100 MHz maximum
- The SoC DFX_PORT_CLK[1:0] clocks are 667 MHz.

7.3.17 Clocks Generated During the S5 Sleep State

The internal clocks for the USB 3.0 PHY (integrated in the HSIO circuitry), USB Combo Controller, and LAN Controllers are generated even during the S5 Sleep State.

§ §

8 Interrupts and Events

Global interrupt handling is described in this chapter. The types of interrupts are described as well as the routing and mapping of these interrupts to the integrated I/O Advanced Programmable Interrupt Controller (APIC) and 8259 Programmable Interrupt Controller (PIC).

8.1 PCI Interrupts and Routing

The SoC does not provide external INTA# through INTD# PCI interrupt signal pins. The PCI Express* integrated endpoints and the PCIe* interrupt messages internally produce the equivalent of these four interrupt signals for the device. Since the SoC Interrupt and Timer Sub-System (ITSS) implements only 13 registers, some PCI Interrupt Route (PIR) registers must be shared by multiple devices.

To support sharing a PIR register among multiple interrupt sources, the ITSS tracks the interrupt assertion and deassertion separately for each source. An interrupt asserts with the first assertion message and remains asserted until the last deassertion message.

PCI Device numbers 0-4, 7-8, 13, and 28-29 are currently unused by the SoC. PCI Device 0, Device 4, Device 25 and Devices 28-29 do not issue INT[A-D] interrupt message. See following Table 8-1 for details.

Table 8-1. PIRQ Routing Control Information For INT[A-D] Messages (Sheet 1 of 2)

PCI Device	PCI Interrupt Route Register: PIR[12:0]												
Device 0-4	does not send legacy interrupts												
Device 5 Fn0: RCEC				**3**									
Device 6 Fn0: VRP2 (for Intel® QAT)					**4**

Device 25	does not send legacy interrupts												
Device 26 Fn0: HSUART0 Fn1: HSUART1 Fn2: HSUART2											**10**		
Device 27 Fn0: IE.HECI1 Fn1: IE.HECI2 Fn2: IE.PTIO-IDER Fn3: IE.PTIO-KT Fn4: IE.HECI3													**12**
Device 28 Fn0: eMMC											**10**		
Device 29	are unused												
Device 30													
Device 31 Fn0: LPC Fn1: P2SB Fn4: SMBus - Legacy Fn7: Intel® Trace Hub	**0**												

8.1.1 Interrupt Pin Route Overview

There are 13, 16-bit PCI interrupt routing registers. These 13 registers, named PCI Interrupt Route (PIR) 0-12, are located in memory space and sideband port PCI Interrupt Route 0 (PIR0)—Offset 3140h through PCI Interrupt Route 12 (PIR12)—Offset 3158h. Each 16-bit register has four 3-bit fields:

- Interrupt A Pin Route (IAR): INTA# mapping to one of PIRQA# through PIRQH# (0h through 7h)
- Interrupt B Pin Route (IBR): INTB# mapping to one of PIRQA# through PIRQH# (0h through 7h)
- Interrupt C Pin Route (ICR): INTC# mapping to one of PIRQA# through PIRQH# (0h through 7h)
- Interrupt D Pin Route (IDR): INTD# mapping to one of PIRQA# through PIRQH# (0h through 7h)

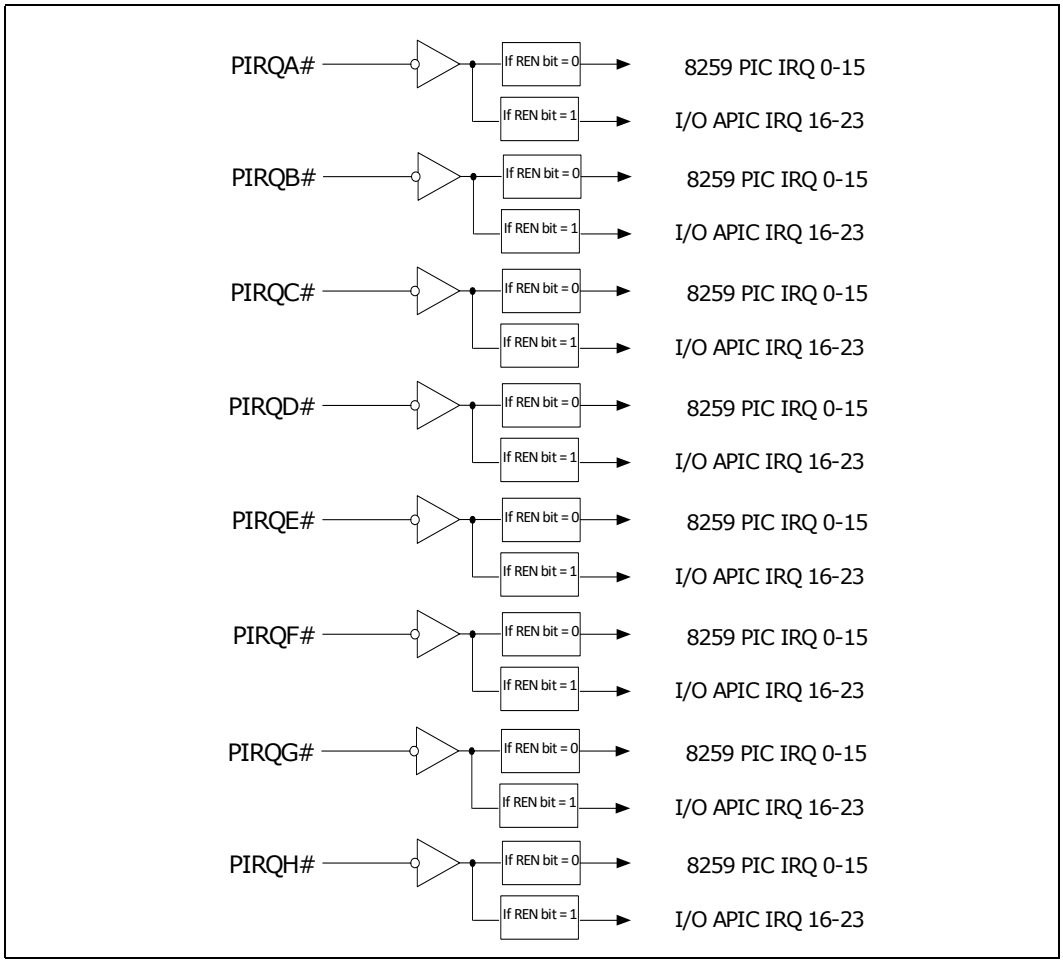
The field values 8h through Fh are invalid.

Note: Each of the eight PIRQx# can represent the interrupt of more than one device and up to four for each device.

PIRQA# through PIRQH# are enabled for routing to 8259 and steered to IRQ0-15; similar steering is done for IOxAPIC to IRQ16-23. Information about programming the 8259 Program Interrupt Controller (PIC) and I/O APIC Controller in Chapter 21, "PIC and I/O APIC Controllers".

The PIRQx is routed to the 8259 PIC mode provided that PIRQx Routing Control Register (PxRC) bit 7 Interrupt Routing Enable (REN) is programmed to 0. When REN is programmed as 1, the particular PIRQx is routed to the APIC mode.

Figure 8-1. PIRQ Routing Control Overview



Note: PIRQx#s are active-low interrupt sources. They are internally inverted before being sent to the PIC. Therefore, the interrupt level reference to the signals at the internal interface of the 8259's, the term "high" indicates "active".

8.1.2 PIRQx Register Decode Table

There are eight, 8-bit routing control registers called PIRQx Routing Control (PxRC), one for each PIRQA through PIRQH. Each of the eight interrupts are routed to one of 11 IRQ inputs of the integrated 8259 PIC according to PxRC bit 3:0 IRQ Routing (IR) field.

PIRQx Routing Control Register (PxRC) bit 7 Interrupt Routing Enable (REN) must be set to 0, the corresponding PIRQ is routed to the legacy 8259 mode. Otherwise, the PIRQ is routed to I/OxAPIC mode.

Table 8-2. PIRQA through PIRQH Routing Register IRQ Decode

PIRQx Register, IR field 3:0	PIRQx Routing to 8259 PIC
0000	Reserved
0001	Reserved
0010	Reserved
0011	IRQ3 of the 8259 PIC
0100	IRQ4 of the 8259 PIC
0101	IRQ5 of the 8259 PIC
0110	IRQ6 of the 8259 PIC
0111	IRQ7 of the 8259 PIC
1000	Reserved
1001	IRQ9 of the 8259 PIC
1010	IRQ10 of the 8259 PIC
1011	IRQ11 of the 8259 PIC
1100	IRQ12 of the 8259 PIC
1101	Reserved
1110	IRQ14 of the 8259 PIC
1111	IRQ15 of the 8259 PIC

8.1.3 Edge- and Level-Triggered Mode

There are two edge/level triggered Control Register ELCR1 (Master) and ELCR2 (Slave) to control edge and level triggered mode selection per interrupt input.

If an ELCR bit is “0”, an interrupt request will be recognized by a low to high transition on the corresponding IRQ input. The IRQ input can remain high without generating another interrupt. If an ELCR bit is “1”, an interrupt request will be recognized by a high level on the corresponding IRQ input and there is no need for an edge detection. The interrupt request must be removed before the End of Interrupt (EOI) command is issued to prevent a second interrupt from occurring.

In both the edge and level triggered modes, the IRQ interrupt (called a spurious interrupt) must remain active until after the falling edge of the first internal INTA#. If the IRQ input goes inactive before this time, a default IRQ7 vector will be returned.

PIRQA# through PIRQH# are defined as level-sensitive interrupts. When routed to a specified IRQ line, the software must change the corresponding ELCR1 or ELCR2 register of the 8259 to a level-sensitive mode.

8.2 Non-Maskable Interrupt (NMI)

NMI is generated internally by serious system events, memory parity errors, some System Errors (SERR), and PCI Express fatal errors.

The NMI is reset by the software by setting the corresponding NMI source enable/disable bit in the NMI Status and Control (NMI_STS_CNT) register.

The 8-bit NMI_STS_CNT register is located in the I/O space at 61h. For the individual GPIO NMI status, enable and routing bit definitions, please see Chapter 26, "Customer General-Purpose I/O (GPIO)".

The NMI is broadcast to all cores in the SoC. Sleeping cores are first awakened. NMI Enable (NMI_EN) register is located in the I/O space at 70h.

The SoC provides interrupt mapping to generate the NMI for various SoC and system events. There is an NMI Control Register (NMI) to indicate current NMI status if any source is asserted. The register NMI is located as a Sideband register accessible in Host Memory Space at offset D0_3330h from the SBREG_BAR base address.

Note: ITSS may escalate other interrupts to NMI. ITSS also may demote NMI to SMI.

8.3 System Management Interrupt (SMI)

The SMI indicates any of several system-level conditions. Examples are:

- Thermal-sensor events
- Throttling activation
- System management RAM access
- Chassis open
- System power button pressed
- System Management Bus (SMBus) events
- Power Management Events (PME)
- PCI Express Hot-Plug* events
- Real Time Clock (RTC) alarm activation
- Various system-state-related activities

An SMI causes the system to enter System Management Mode (SMM). SMM is an operating mode in which all normal execution, including the operating system, is suspended, and special, separate software, usually firmware or a hardware-assisted debugger, is executed in high-privilege mode. The SMI is broadcast to all cores in the SoC. Sleeping cores are first awakened.

SMI Enable register is located in I/O space at 0x30h to enable SMI from different configurable source; SMI Status register is located in I/O space at 0x34h to show SMI status from different configurable source. For the individual GPIO SMI status, enable and routing bit definitions, please see Chapter 26, "Customer General-Purpose I/O (GPIO)".

8.4 System Control Interrupt (SCI)

SCI is a special type of hardware power-management interrupt that is handled directly by the OS, and is not handled by a device driver. It is closely tied to the ACPI model. The operating system uses the SCI interrupt to process ACPI events signaled by GPEs, whether the system is asleep or awake when the event occurs. If the system is in an S0 state, SCI can be caused; if the system is in the S5 state, SCI event will also wake the system.

If not using the I/O APIC for the SCI, the SCI must be routed to IRQ9-IRQ11 of the 8259 PIC. When routed to the 8259 PIC, the SCI is not sharable with the Serial Interrupt (SERIRQ) for that PIC input, but it is shareable with the PIRQA through PIRQH interrupts.

If using an I/O APIC, the SCI is mapped to the I/O APIC interrupt or to an SMI. Mapping SCI events to SMI can be used when a legacy OS is in use. The SCI Enable (SCI_EN) bit of the Power Management 1 Control (PM1_CNT) register controls whether the event is routed as an SCI or an SMI. The PM1_CNT register is located in the I/O space at PCI_Config_ABASE offset 4h.

The SCI routing to the I/O APIC is controlled by the 3-bit SCI IRQ Select (SCIS) field of the ACPI Control (ACTL) register located in the memory space at Bus 0, Device 31, Function 2 offset address 0x44h.

Also, if using the I/O APIC for SCI, the SCI can be mapped to IRQ20-IRQ23 of the I/O APIC, and can be shared with other interrupts. Here the SCI must be programmed for active-low reception. The SCI can also be mapped to IRQ9, IRQ10, of IRQ11 where it must be programmed for active-high reception.

Table 8-3. Routing of SCI to the I/O APIC

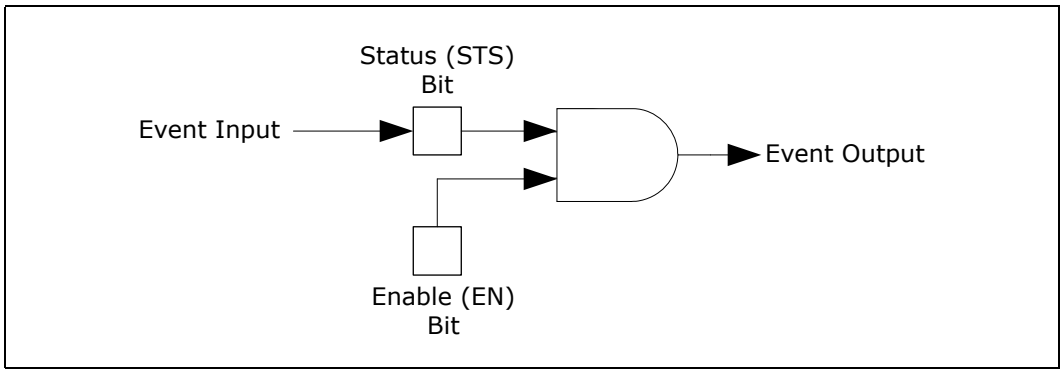
ACTL.SCIS	SCI IRQ Select in 8259	SCI IRQ Select in I/O APIC
000	IRQ9	IRQ9
001	IRQ10	IRQ10
010	IRQ11	IRQ11
011		Reserved
100		IRQ20
101		IRQ21
110		IRQ22
111		IRQ23

Note: Power Management Controller (PMC) may escalate SCI to SMI; otherwise SCI is delivered to ITSS as IRQx for handling.

8.5 GPIO and PMC General Purpose Event (GPE)

Some of the Customer GPIOs can be configured as SoC input-pin signals that can generate an ACPI General Purpose Event (GPE). The SoC Power Management Controller (PMC) can also generate ACPI GPE status. Each SoC GPE status can be enabled to generate a System Control Interrupt (SCI) or a System Management Interrupt (SMI). The GPE register model is shown in Figure 8-2. Notice that the Enable bit does not prevent the Status bit from setting when the event occurs.

Figure 8-2. General Purpose Event (GPE) Register Model



The GPIO controller has seven Dwords of GPE status and enable bits of which two Dwords originate from the GPIO North Community and five Dwords from the GPIO South Community.

Even though there are seven Dwords of GPIO GPE Status and seven Dwords of GPIO GPE Enable groups shown in Table 8-4, only three groups are exposed by the PMC. So BIOS must choose which three groups from the seven to use and make only these three GPE groups visible to software. These three GPIO groups are mapped to 96 sets of status/enable GPE0 register bits grouped as GPE0_DW0, GPE0_DW1 and GPE0_DW2.

The GPIO GPE Status and Enable groups are marked with group number in silicon. GPIO Miscellaneous Configuration Register (MISCCFG) located at

SBREG_BAR offset 0xC50010h and 0xC20010h bit 8-19 shows the default value is group 0, 1, and 2 mapping to GPE0_DW0, GPE0_DW1 and GPE0_DW2. By programming MISCCFG bit 8-19, different group can be assigned to GPE0_DW0, GPE0_DW1 and GPE0_DW2.

Table 8-4. GPE0_DW Group Mapping

0	GPI_GPE_STS_NORTH_ALL_0	0	GPI_GPE_EN_NORTH_ALL_0
1	GPI_GPE_STS_NORTH_ALL_1	1	GPI_GPE_EN_NORTH_ALL_1
2	GPI_GPE_STS_SOUTH_DFX_0	2	GPI_GPE_EN_SOUTH_DFX_0
3	GPI_GPE_STS_SOUTH_GROUP0_0	3	GPI_GPE_EN_SOUTH_GROUP0_0
4	GPI_GPE_STS_SOUTH_GROUP0_1	4	GPI_GPE_EN_SOUTH_GROUP0_1
5	GPI_GPE_STS_SOUTH_GROUP1_0	5	GPI_GPE_EN_SOUTH_GROUP1_0
6	GPI_GPE_STS_SOUTH_GROUP1_1	6	GPI_GPE_EN_SOUTH_GROUP1_1
7	Reserved	7	Reserved

GPE Group Name	Three GPIO GPE Status Group and Three GPIO Enable Group Mapped to GPE Group		
GPE0_DW0	0	GPI_GPE_STS_NORTH_ALL_0	GPE_GPE_EN_NORTH_ALL_0
GPE0_DW1	1	GPI_GPE_STS_SOUTH_ALL_1	GPI_GPE_EN_SOUTH_ALL_1
GPE0_DW2	2	GPI_GPE_STS_SOUTH_DFX_0	GPI_GPE_EN_SOUTH_DFX_0

The SoC Power Management Controller (PMC) has its own set of GPE0 status/enable Dwords (GPE0_DW3). See Chapter 16, "Power Management Controller (PMC)".

The SoC PMC is a proxy for the GPIO GPE0 Enable and Status registers. When accessed from Host I/O Space, software writes/reads all of the GPE0 registers directly to/from the PMC. See Table 8-5 on page 342. The GPE0 registers are described in Chapter 58, "Power Management Controller - B0, D31, F2".

When applicable the SoC PMC forwards these writes/reads to GPIO controller based on the mapping path from PMC to GPIO. The GPIO mapping path is configured by the SoC in the two GPIO Sideband registers, offset 10h of Sideband Ports C2h and C5h. These Sideband Ports are accessible in Host Memory Space using SBREG_BAR.

Table 8-5. Access to the ACPI General Purpose Event Registers

Host I/O Space PCU B0:D31:F2 ABASE+Offset (hex)	ACPI General Purpose Event 0 (GPE0)		Customer GPIO Group
80	Status [31:0]	GPE0_DW0	GPI_GPE_STS_NORTH_ALL_0
90	Enable [31:0]		GPE_GPE_EN_NORTH_ALL_0
84	Status [63:32]	GPE0_DW1	GPI_GPE_STS_NORTH_ALL_1
94	Enable [63:32]		GPI_GPE_EN_NORTH_ALL_1
88	Status [95:64]	GPE0_DW2	GPI_GPE_STS_SOUTH_DFX_0
98	Enable [95:64]		GPI_GPE_EN_SOUTH_DFX_0
8C	Status [127:96]	GPE0_DW3	Reserved
9C	Enable [127:96]		

The programming steps to map the GPIOs to the GPE0 DWords are as follows:

- Program GPIO Miscellaneous Configuration Register (MISCCFG) located at SBREG_BAR offset 0xC50010h and 0xC20010h bit 8-19 to assign a specific GPIO Group to the ACPI GPE0.
  - Program a specific GPIO Group to GPE0[31:0] as GPE0_DW0
  - Program a specific GPIO Group to GPE0[63:32] as GPE0_DW1
  - Program a specific GPIO Group to GPE0[95:64] as GPE0_DW2
- Program PMC GPIO Configuration Register (GPIO_CFG) at PCI_CFG_PWRMBASE offset 120h to assign a specific GPIO register to the ACPI GPE0.
  - Program a specific GPIO Group to GPE0[31:0] as GPE0_DW0
  - Program a specific GPIO Group to GPE0[63:32] as GPE0_DW1
  - Program a specific GPIO Group to GPE0[95:64] as GPE0_DW2
- Enable 96 GPE available to PMC by writing to PMC. PMC forwards the writes to the GPIO based on the mapping in first step.
  - Program GPE0_EN_31_0 at I/O space 0x90h
  - Program GPE0_EN_63_32 at I/O space 0x94h
  - Program GPE0_EN_95_64 at I/O space 0x98h
- Check GPE0 status by reading from PMC. PMC forwards the reads to the GPIO based on mapping in first step.
  - Read GPE0_STS_31_0 at I/O space 0x80h
  - Read GPE0_STS_63_32 at I/O space 0x84h
  - Read GPE0_STS_95-64 at I/O space 0x88h

For individual GPIO GPE event enable and status detail, please refer to Chapter 26, "Customer General-Purpose I/O (GPIO)".

8.6 Message Signaled Interrupt (MSI and MSI-X)

Message Signaled Interrupt (MSI) is an optional feature that enables a device function to request service by using PCI Dword memory write transaction. MSI-X defines a separate optional extension to the basic MSI functionality. During device configuration, each capable PCI function is allocated one or more vectors and the memory-mapped location to write the interrupt messages. Compared to MSI, MSI-X supports a larger number of vectors function, the ability for the OS to program independent address and data values for each vector. Each function in the PCIe Endpoint (EP) supports the MSI capability. MSI-X is supported only for the physical function.

Once an MSI has been generated using MSI-X, its characteristics are similar to an MSI what was generated using an MSI capability record. However, MSI-X supports per-vector masking that is optional for MSI. MSI-X also supports a Function Mask bit. When MSI-X enabled, EP generates an interrupt using a PCIe posted memory write transaction. The address and data of the transaction are determined by the system and programmed in the PCI MSI-X table entry.

8.7 I/O APIC Input Mapping

The SoC has an integrated I/O APIC which supports 0-119 APIC interrupts. Each interrupt has its own unique vector assigned by the software. The interrupt vectors are mapped as shown in Table 8-6.

Table 8-6. I/O APIC Input Mapping (Sheet 1 of 2)

I/O APIC Input	Interrupts Routed to This I/O APIC Input	Note
IRQ0	Cascaded from Master 8259	
IRQ1	Option for SERIRQ (1) or other configurable source including internal ACPI devices, GPIO	5, 6
IRQ2	8254 Counter 0, HPET Timer 0	1, 2, 3
IRQ3	Option for SERIRQ (3) or other configurable source including internal ACPI devices, GPIO	5, 6
IRQ4	Option for SERIRQ (4) or other configurable source including internal ACPI devices, GPIO	5, 6
IRQ5	Option for SERIRQ (5) or other configurable source including internal ACPI devices, GPIO	5, 6
IRQ6	Option for SERIRQ (6) or other configurable source including internal ACPI devices, GPIO	5, 6
IRQ7	Option for SERIRQ (7) or other configurable source including internal ACPI devices, GPIO	5, 6
IRQ8	HPET Timer 1 (Legacy mode if GEN_CFG.LEG_RT_CNF is set), RTC (if GEN_CFG.LEG_RT_CNF is not set)	1, 2, 3
IRQ9	Option for SERIRQ (9) or other configurable source including internal ACPI devices, SCI, GPIO	5, 6
IRQ10	Option for SERIRQ (10) or other configurable source including internal ACPI device, SCI, GPIO	5, 6
IRQ11	Option for SERIRQ (11) or other configurable source including internal ACPI devices, SCI, GPIO or HPET Timer 2	4
IRQ12	Option for SERIRQ (12) or other configurable source including internal ACPI devices and GPIO or HPET Timer 3	5, 6
IRQ13	Option for SERIRQ (13) or other configurable source including internal ACPI devices and GPIO	5, 6
IRQ14	Option for SERIRQ (14) or other configurable source including internal ACPI devices and GPIO	5, 6

Table 8-6. I/O APIC Input Mapping (Sheet 2 of 2)

I/O APIC Input	Interrupts Routed to This I/O APIC Input	Note
IRQ15	Option for SERIRQ (15) or other configurable source including internal ACPI devices and GPIO	5, 6
IRQ16	PIRQA, or other configurable source including internal ACPI devices and GPIO	5
IRQ17	PIRQB, or other configurable source including internal ACPI devices and GPIO	5
IRQ18	PIRQC, or other configurable source including internal ACPI devices and GPIO	5
IRQ19	PIRQD, or other configurable source including internal ACPI devices and GPIO	5
IRQ20	PIRQE, or other configurable source including internal ACPI device, GPIO, SCI, and HPET	5
IRQ21	PIRQF, or other configurable source including internal ACPI devices, GPIO, SCI, and HPET	5
IRQ22	PIRQG, or other configurable source including internal ACPI devices, GPIO, SCI, and HPET	5
IRQ23	PIRQH, or other configurable source including internal ACPI devices and SCI, or GPIO	5
IRQ24:IRQ 118	Other configurable source including internal ACPI devices and GPIO	5
IRQ119	GPIO	5

Notes:
1. General Configuration Register (GEN_CFG) located at the memory space address FED0_0010h has bit 1 as is the Legacy Rout Enable (LEG_RT_CNF).
2. When LEG_RT_CNF is set, the HPET Timer 0 Config and Capabilities (TMR0_CNF_CAP) register and Timer 1 Configuration and Capabilities (TMR1_CNF_CAP) register and TIMER1_INT_ROUT_CNF bits have no impact for timers 0 and 1. TIMER0_CNF_CAP and TIMER1_CNF_CAP are located at the memory-space addresses FED0_0100h and FED0_0120h, respectively.
3. When LEG_RT_CNF is cleared, each of the three HPET timers has its own routing control. The interrupts can be routed to various interrupts in the I/O APIC. See detail in TMRx_CNF_CAP registers.
4. HPET Timer 2 is routed to the APIC as per the routing in the HPET T2C register located at the memory-space addresses FED0_0140h.
5. When programming the polarity of internal interrupt sources on the APIC, interrupts 0 through 15 receives active -high internal interrupt sources; interrupt 16 through 23 receive active-low internal interrupt sources; interrupts 24 through 119 receive active -high internal interrupt sources.
6. SERIRQ is MUXed with GPIO [11] for assertion by external devices. Interrupt SERIRQ is not exposed if the signal is configured as GPIO.

The I/O APIC has a Redirection Table (RT) with an entry for each interrupt source. Each RT entry is individually programmed for trigger mode (edge or level), vector number, and destination processor(s). The interrupt is reported to the appropriate local APIC(s).

For more information about the I/O APIC, see Chapter 21, "PIC and I/O APIC Controllers."

8.8 8259 PIC Input Mapping

The interrupts that can be routed to the input of the integrated 8259 PIC are shown in Table 8-7. The 8259 PIC registers are described in Chapter 21, "PIC and I/O APIC Controllers."

Table 8-7. 8259 PIC Input Mapping

I/O PIC Input	Master or Slave 8259 PIC Input	Interrupts Routed to This PIC Input	Note
IRQ0	Master IRQ0	HPET Timer 0 (Legacy mode if GGEN_CFG.LEG_RT_CNF is set) 8254 Timer 0 (if GGEN_CFG.LEG_RT_CNF is not set)	1
IRQ1	Master IRQ1	Option for SERIRQ (1) or other configurable source including SMB/eMMC	1, 6
IRQ2	Master IRQ2	Cascade from Slave 8259	1, 2
IRQ3	Master IRQ3	Option for SERIRQ (3) or other configurable source including PIRQx and internal ACPI devices	1, 3, 4, 6
IRQ4	Master IRQ4	Option for SERIRQ (4) or other configurable source including PIRQx and internal ACPI devices	1, 3, 4, 6
IRQ5	Master IRQ5	Option for SERIRQ (5) or other configurable source including PIRQx and internal ACPI devices	1, 3, 4, 6
IRQ6	Master IRQ6	Option for SERIRQ (6) or other configurable source including PIRQx and internal ACPI devices	1, 3, 4, 6
IRQ7	Master IRQ7	Option for SERIRQ (7) or other configurable source including PIRQx and internal ACPI devices	1, 3, 4, 6
IRQ8	Slave IRQ0	HPET Timer 1 (Legacy mode if GEN_CFG.LEG_RT_CNF is set) RTC (if GEN_CFG.LEG_RT_CNF is not set)	1
IRQ9	Slave IRQ1	Option for SERIRQ (9) or other configurable source including PIRQx and internal ACPI devices, SCI	1, 3, 4, 6
IRQ10	Slave IRQ2	Option for SERIRQ (10) or other configurable source including PIRQx and internal ACPI device, SCI	1, 3, 4, 5
IRQ11	Slave IRQ3	Option for SERIRQ (11) or other configurable source including PIRQx and internal ACPI devices, SCI, or HPET Timer 2	1, 3, 4, 5, 6
IRQ12	Slave IRQ4	Option for SERIRQ (12) or other configurable source including PIRQx and internal ACPI devices, or HPET Timer 3	1, 3, 4, 6
IRQ13	Slave IRQ5	Option for SERIRQ (13) or other configurable source including internal ACPI devices	1, 6
IRQ14	Slave IRQ6	Option for SERIRQ (14) or other configurable source including PIRQx, GPIO and internal ACPI devices	1, 3, 4, 6
IRQ15	Slave IRQ7	Option for SERIRQ (15) or other configurable source including PIRQx, GPIO and internal ACPI devices	1, 3, 4, 6

Notes:
1. Interrupts can individually be programmed to be edge or level, except for IRQ0, IRQ1, IRQ2, IRQ8, which are always default to edge.
2. The slave 8259 controller is cascaded onto the master 8259 controller through the master controller interrupt input IRQ2.
3. If an interrupt is used for PCI IRQA - IRQH, SCI, it should not be used for ISA-style interrupts (vis SERIRQ).
4. PCI interrupts are mapped to IRQ3, 4, 5, 6, 7, 9, 10, 11, 12, 14, or 15. It can be programmed by PIRQx Routing Control Register at 0xD0003100h -3107h.
5. If IRQ11/IRQ12 used for HPET#2/HPET#3, software should ensure IRQ11 is not shared with any other devices to guarantee the proper operation of HPET#2/HPET#3. The hardware does not prevent sharing of IRQ11/IRQ12.
6. SERIRQ is MUXed with GPIO [11] for assertion by external devices. Interrupt SERIRQ is not exposed if the signal is configured as GPIO.

8.9 Device Interrupt-Generating Capabilities

Integrated devices that generate interrupts are shown in Table 8-8.
Interrupt-generating details of each is located in its individual functional chapter.

Table 8-8. Device Interrupt / Event Sources

Agent	IRQ to ITSS	INTx to ITSS	MSI to CPU	NMI to ITSS	SCI to PMC

§ §

9 Memory Controller

9.1 Introduction

The Memory Controller is a dual channel DDR4 Memory Controller. The SoC supports a 40 or a 72 bit wide DDR4 interface per channel, 32 or 64 bits of data and 4 or 8 bits of ECC, and it does support both ECC and non-ECC DIMMs.

Figure 9-1. What is Covered in This Chapter

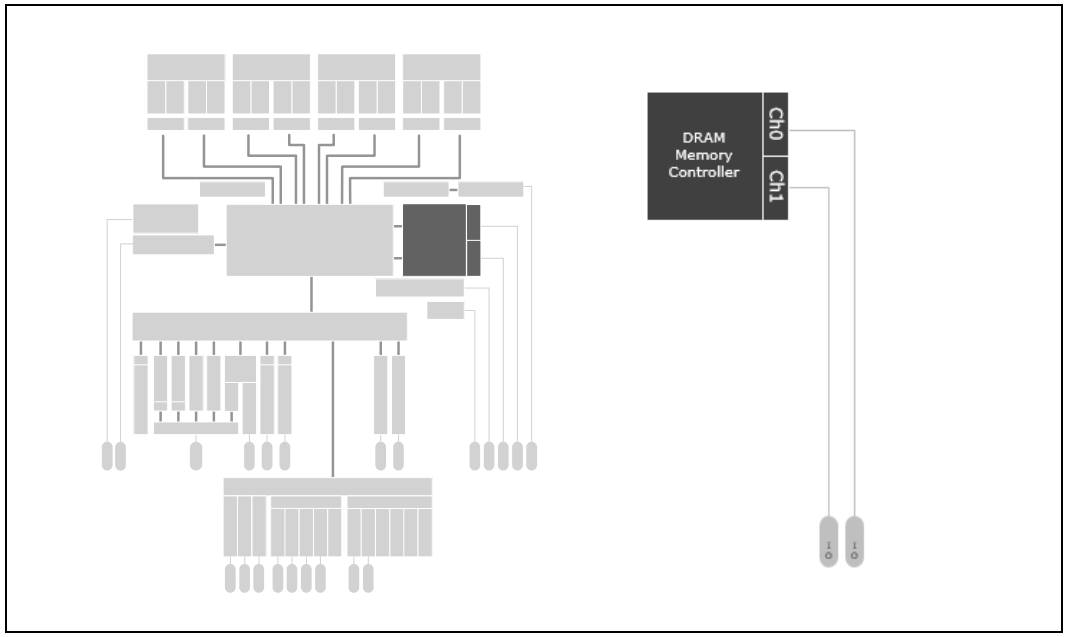

Table 9-1. References

Reference	Revision	Date	Document Title
JESD79-4	-	July 2012	JEDEC DDR4 SDRAM Specification

9.2 Signal Descriptions

The signal descriptions are shown in Table 8-3. For additional signal information, including whether a signal is assigned to shared-function pin or can be used as a Customer GPIO signals see Section 39.1, "Directory of Signal Names and Pin Names" on page 511. The Direction/Type column of Table 8-3 is interpreted as follows:

- I = Input signal. The SoC has receiver circuit.
- O = Output signal. The SoC has driver circuit.
- O-OD = Open-Drain Output. SoC output circuit uses an open-drain driver.
  Differential = Differential signal pair. Two pins: Positive; Negative.

Note: The SoC memory signal pins have SoC-internal termination designed to conform to the DDR4 (JESD79-4) standard. The DDR0_ALERT_N_PAR_ERR_N and DDR1_ALERT_N_PAR_ERR_N SoC input pins do not have any SoC-internal termination. Here the signal termination for each of these signals must be provided by the board design.

Table 9-2. Signal Names and Descriptions (Sheet 1 of 5)

Signal Name	Direction	Shared	Description
Memory Channel 0			
DDR0_DQ[63:0]	I,O	No	**Data Lines:** Bi-directional 64-bit data bus, driven on writes, received on reads. ***Note:*** In 32-bit mode, the lower 32 bits must be used.
DDR0_ECC[7:0]	I,O	No	**ECC Data Lines:** Bi-directional ECC data extending the data bus, driven on writes, received on reads. ***Notes:*** 1. If ECC is used 32 and 64 bit data width requires 8 bits of ECC. 2. The ECC SDRAM device must be of the same type and width as the SDRAM devices used for the data bits.
DDR0_DQS_DN[17:0] DDR0_DQS_DP[17:0]	I,O, Differential	No	**Data Strobes:** During writes, driven by Cell Delay Variation (CDV) offset so as to be centered in the data phase. During reads, driven by memory devices edge aligned with data. The following list matches the data strobe in the data group. DQS_DP/DN[7]: DQ[63:56] DQS_DP/DN[6]: DQ[55:48] DQS_DP/DN[5]: DQ[47:40] DQS_DP/DN[4]: DQ[39:32] DQS_DP/DN[3]: DQ[31:24] DQS_DP/DN[2]: DQ[23:16] DQS_DP/DN[1]: DQ[15:8] DQS_DP/DN[0]: DQ[7:0] If ECC is supported then DQS_DP/DN[8]: ECC[7:0]. For x4 devices, strobe is divided to be high nibble strobe and low nibble strobe. ***Note:*** In 32-bit mode, the lower DQ must be used.
DDR0_MA[13:0]	O	No	**Multiplexed Address:** Provides multiplexed row and column address to memory. Provides the row address for Active commands and the column address and Auto Precharge bit for Read/Write commands to select one location out of the memory array in the respective bank. A10 is sampled during a Precharge command to determine whether the Precharge applies to one bank (A10 LOW) or all banks (A10 HIGH). If only one bank is to be precharged, the bank is selected by BA0 - BA2. The address outputs also provide the op-code during MRS or EMRS commands.

Table 9-2. Signal Names and Descriptions (Sheet 2 of 5)

Signal Name	Direction	Shared	Description
DDR0_MA14_WE_N	O	No	**DDR0_WE_N:** When DDR0_ACT_N_MA[15] signal is high, otherwise DDR0_MA[14].
DDR0_MA15_CAS_N	O	No	**DDR0_CAS_N:** When DDR0_ACT_N_MA[15] signal is high, otherwise DDR0_MA[15].
DDR0_MA16_RAS_N	O	No	**DDR0_RAS_N:** When DDR0_ACT_N_MA[15] signal is high, otherwise DDR0_MA[16].
DDR0_MA17	O	No	**Address Lines:** Provide the row address for ACTIVATE commands and column address for Read/Write commands. This address line is only defined for the x4 configuration.
DDR0_ACT_N_MA[15]	O	No	**Activation Command ACT_N:** Defines the Activation command being entered along with CS_N.
DDR0_CLK_DN[3:0] DDR0_CLK_DP[3:0]	O, Differential	No	**Differential DDR Clock:** All address and control input signals are sampled on the crossing of the positive edge of CK_P and negative edge of CK_N. Output (read) data is referenced to the crossings of CK_P and CK_N (both directions of crossing).
Memory Channel 0 (continued)			
DDR0_CKE[3:0]	O	No	**Clock Enable:** (active high) CKE is used for power control of the DRAM devices. CKE HIGH activates and CKE LOW deactivates DRAM device internal clock signals and device input buffers and output drivers. These are output signals from the SoC.
DDR0_CS_N[3:0]	O	No	**Chip Select:** (active low) These signals determine whether a command is valid in a given cycle for the devices connected to it. All commands are masked when CS_N is registered HIGH. CS_N provides for external rank selection on systems with multiple ranks. CS_N is considered part of the command code.
DDR0_C0	O	No	**Chip ID:** Not supported by the SoC. Board designs shall treat this pin as a No-Connect (NC).
DDR0_BA[1:0]	O	No	**Bank Address:** Defines the bank which is the destination for the current Activate, read, write or precharge command.
DDR0_BG0_BA[2]	O	No	Bank group address.
DDR0_BG1_MA[14]	O	No	Bank group address.
DDR0_ODT[3:0]	O	No	**On-Die Termination Enable:** (active high) ODT (registered HIGH) enables termination resistance internal to the DDR device SDRAM. When the ODT feature is enabled, it is dynamically enabled for the receiver of the data. The SoC does this internally for read data returning from the DRAM devices. For write data to the DRAM devices, the DDR0_ODT[] pins are asserted to enable ODT w/in the DRAM devices themselves. Because ODT consumes power, when the feature is enabled, it is controlled dynamically by the SoC. ODT impacts the DQ and DQS.
DDR0_PAR	O	No	Command and address parity
DDR0_ALERT_N_PAR_ERR_N	I	No	**Alert:** Command and address parity error flag or write data CRC error flag (Note the SoC does not support CRC). There is no SoC-internal termination to this input signal. This SoC input is the receiver of the active-low DDR4 "ALERT_n" signal bus which is possibly driven by more than one system source. Board-level termination is required.

Table 9-2. Signal Names and Descriptions (Sheet 3 of 5)

Signal Name	Direction	Shared	Description
Memory Channel 1			
DDR1_DQ[63:0]	I,O	No	**Data Lines:** Bi-directional 64-bit data bus, driven on writes, received on reads. ***Note:*** In 32-bit mode, the lower 32 bits must be used.
DDR1_ECC[7:0]	I,O	No	**ECC Data Lines:** Bi-directional ECC data extending the data bus, driven on writes, received on reads. ***Notes:*** 1. If ECC is used 32 and 64 bit data width requires 8 bits of ECC. 2. The ECC SDRAM device must be of the same type and width as the SDRAM devices used for the data bits.
DDR1_DQS_DP[17:0] DDR1_DQS_DN[17:0]	I,O, Differential	No	**Data Strobes:** During writes, driven by Cell Delay Variation (CDV) offset so as to be centered in the data phase. During reads, driven by memory devices edge aligned with data. The following list matches the data strobe in the data group. DQS_DP/DN[7]: DQ[63:56] DQS_DP/DN[6]: DQ[55:48] DQS_DP/DN[5]: DQ[47:40] DQS_DP/DN[4]: DQ[39:32] DQS_DP/DN[3]: DQ[31:24] DQS_DP/DN[2]: DQ[23:16] DQS_DP/DN[1]: DQ[15:8] DQS_DP/DN[0]: DQ[7:0] If ECC is supported then DQS_DP/DN[8]: ECC[7:0]. DDR4 supports differential strobes only. For x4 devices, strobe is divided to be high nibble strobe and low nibble strobe. ***Note:*** In 32-bit mode, the lower DQ must be used.
DDR1_MA[13:0]	O	No	**Multiplexed Address:** Provides multiplexed row and column address to memory. Provides the row address for Active commands and the column address and Auto Precharge bit for Read/Write commands to select one location out of the memory array in the respective bank. A10 is sampled during a Precharge command to determine whether the Precharge applies to one bank (A10 LOW) or all banks (A10 HIGH). If only one bank is to be precharged, the bank is selected by BA0 - BA2. The address inputs also provide the op-code during MRS or EMRS commands.
DDR1_MA14_WE_N	O	No	**DDR1_WE_N:** When DDR1_ACT_N_MA[15] signal is high, otherwise DDR1_MA[14]
DDR1_MA15_CAS_N	O	No	**DDR1_CAS_N:** When DDR1_ACT_N_MA[15] signal is high, otherwise DDR1_MA[15]
DDR1_MA16_RAS_N	O	No	**DDR1_CAS_N:** When DDR1_ACT_N_MA[15] signal is high, otherwise DDR1_MA[15]
DDR1_MA17	O	No	**Address Lines:** Provide the row address for ACTIVATE commands and column address for Read/Write commands. This address line is only defined for the x4 configuration.
DDR1_ACT_N_MA[15]	O	No	**Activation Command Input:** ACT_N defines the Activation command being entered along with CS_N
DDR1_CLK_DP[3:0] DDR1_CLK_DN[3:0]	O, Differential	No	**Differential DDR Clock:** All address and control input signals are sampled on the crossing of the positive edge of CK_P and negative edge of CK_N. Output (read) data is referenced to the crossings of CK_P and CK_N (both directions of crossing).

Table 9-2. Signal Names and Descriptions (Sheet 4 of 5)

Signal Name	Direction	Shared	Description
DDR1_CKE[3:0]	O	No	**Clock Enable:** (active high) CKE is used for power control of the DRAM devices. CKE HIGH activates and CKE LOW deactivates DRAM device internal clock signals and device input buffers and output drivers. These are output signals from the SoC.

Table 9-2. Signal Names and Descriptions (Sheet 5 of 5)

Signal Name	Direction	Shared	Description
Memory Channel 1 (continued)			
DDR1_CS_N[3:0]	O	No	**Chip Select:** (active low) These signals determine whether a command is valid in a given cycle for the devices connected to it. All commands are masked when CS_N is registered HIGH. CS_N provides for external rank selection on systems with multiple ranks. CS_N is considered part of the command code.
DDR1_C0	O	No	**Chip ID:** Not supported by the SoC. Board designs shall treat this pin as a No-Connect (NC).
DDR1_BA[0:1]	O	No	**Bank Address:** Defines the bank which is the destination for the current Activate, read, write or precharge command.
DDR1_BG0_BA[2]	O	No	Bank group address.
DDR1_BG1_MA[14]	O	No	Bank group address.
DDR1_ODT[3:0]	O	No	**On-Die Termination Enable:** (active high). ODT (registered HIGH) enables termination resistance internal to the DDR device SDRAM. When the ODT feature is enabled, it is dynamically enabled for the receiver of the data. The SoC does this internally for read data returning from the DRAM devices. For write data to the DRAM devices, the DDR1_ODT[] pins are asserted to enable ODT w/in the DRAM devices themselves. Because ODT consumes power, when the feature is enabled, it is controlled dynamically by the SoC. ODT impacts the DQ and DQS. The ODT pin will be ignored by the DDR devices if the EMR(1) is programmed to disable ODT. One pin per rank.
DDR1_PAR	O	No	Command and address parity.
DDR1_ALERT_N_PAR_ERR_N	I	No	**Alert:** Command and address parity error flag or write data CRC error flag (Note the SoC does not support CRC). There is no SoC-internal termination to this input signal. This SoC input is the receiver of the active-low DDR4 "ALERT_n" signal bus which is possibly driven by more than one system source. Board-level termination is required.
Signals Common to Both Memory Channels			
DDR01_DRAMRST_N	O	No	**DRAM Reset:** Active low Reset to the DDR DIMMs of both Memory Controllers.
DDR01_COMP	O	No	The platform board must provide a 1% resistor from this pin to VSS: • 392 Ω for DDR4
ADR_TRIGGER	I,O-OD	Yes	**Asynchronous DRAM Self-Refresh (ADR) Trigger:** Chapter 16, "Power Management Controller (PMC)"
ADR_COMPLETE	I,O	Yes	**Asynchronous DRAM Self-Refresh (ADR) Complete:** Chapter 16, "Power Management Controller (PMC)"

9.3 Feature List

- Up to two 32/40 bit [1] or 64/72 bit wide memory channels. Up to two DIMMs per channel
- Single-rank or dual-rank per DIMM module
- ECC [3] and non-ECC support
- DDR4 Low Voltage version operating at 1.2V
  - 1600, 1866 [2], 2133, and 2400 MT/s
  - x8 and x16 width for unbuffered memory (UDIMM, SO-DIMM & memory down)
  - x4 and x8 width devices for RDIMM
  - 4 Gb, 8 Gb, and 16 Gb technology devices
  - Minimum memory is:
    32 bit [1] wide memory channel: 1GB (4 Gb, 1 rank, x16 width)
    64 bit wide memory channel: 2GB (4 Gb, 1 rank, x16 width)
  - Maximum memory single channel is 128GB (16 Gb, x4n width, 4 ranks, 64 bit)
  - Both memory channels maximum is 256GB (128GB with two 64 bit channels)
- SoC memory population rules:
  - Both channels must be 32 bit [1] or 64 bits wide
  - At least 1 memory channel must be populated and enabled.
    Either channel 0 or channel 1 may be disabled
  - Both channels require either unbuffered memory (UDIMM, SO-DIMM or memory down), or registered memory (RDIMM and/or NVRDIMM). Technology mixing is not supported.
  - Rank mixing is allowed but can result in a speed bin loss.

To calculate the capacity of a DIMM, the type of DRAMs used must be understood. The width of the DRAM should be used to find the number of DRAMs needed to make up the data bus. The capacity per rank can then be calculated by multiplying the number of DRAMs by the size of the DRAM, and further divided by eight to convert bits into bytes. The total DIMM capacity is finally calculated by multiplying the rank capacity and the number of ranks on the DIMM.

Notes:
1. A0 and A1 step silicon only support 64/72-bit wide memory channels.
2. The silicon design supports 1866 MT/s but is not validated on Intel platforms. Customers are responsible for validation.
3. The ECC SDRAM device must be of the say type and width as the SDRAM devices used for the data bits. This limitation is driven by the DDR4 spec.
   - It is NOT alright to use x16 SDRAM devices for data and a x8 device for ECC.
   - It is NOT alright to use x8 SDRAM devices for data and a x4 device for ECC.
4. Memory based on 16 Gb dual rank technology (including maximum memory configuration of 256GB) is supported by silicon but not validated on Intel platforms.

9.4 Memory Controller Power Management Features

9.4.1 DRAM Running Average Power Limit (RAPL)

DRAM Running Average Power Limiting (RAPL) allows power limiting for the memory connected to the SoC.

DRAM RAPL provides a way to set power limits on your memory power consumption. This will allow the SoC to dynamically limit max average power, to match its expected power budget. DRAM RAPL Domain only includes the memory connected directly to the SoC. Implementing RAPL across multiple SoC must be implemented in a multi-node management RAPL solution. DRAM RAPL provides a way to set short term and longer term averaging windows for power limits for the SoC DRAM Memory.

9.4.2 Dynamic (HW autonomous) Self-refresh DDR4

The Self-Refresh command can be used to retain data in the DDR4 DRAM, even if the rest of the system is powered down. When in the Self-Refresh mode, the DDR4 SDRAM retains data without external clocking.The DDR4 DRAM device has a built-in timer to accommodate Self-Refresh operation. The Self-Refresh-Entry (SRE) Command is defined by having CS_n, RAS_n/A16, CAS_n/A15, and CKE held low with WE_n/A14 and ACT_n high at the rising edge of the clock.

Before issuing the Self-Refresh-Entry command, the DDR4 DRAM must be idle with all bank precharge state with tRP satisfied. 'Idlestate' is defined as all banks are closed (tRP, tDAL, etc. satisfied), no data bursts are in progress, CKE is high, and all timings from previous operations are satisfied (tMRD, tMOD, tRFC, tZQinit, tZQoper, tZQCS, etc.). Deselect command must be registered on last positive clock edge before issuing Self Refresh Entry command. Once the Self Refresh Entry command is registered, Deselect command must also be registered at the next positive clock edge. Once the Self-Refresh Entry command is registered, CKE must be held low to keep the device in Self-Refresh mode. DRAM automatically disables ODT termination and set Hi-Z as termination state regardless of ODT pin and RTT_PARK set when it enters in Self-Refresh mode.

Upon exiting Self-Refresh, DRAM automatically enables ODT termination and set RTT_PARK asynchronously during tXSDLL when RTT_PARK is enabled. During normal operation (DLL on) the DLL is automatically disabled upon entering Self-Refresh and is automatically enabled (including a DLL-Reset) upon exiting Self-Refresh.

When the DDR4 SDRAM has entered Self-Refresh mode, all of the external control signals, except CKE and RESET_n, are "don't care." For proper Self-Refresh operation, all power supply and reference pins (VDD, VDDQ, VSS, VSSQ, VPP, and VRefCA) must be at valid levels. DRAM internal VrefDQ generator circuitry may remain ON or turned OFF depending on DRAM design. If DRAM internal VrefDQ circuitry is turned OFF in self refresh, when DRAM exits from self refresh state, it ensures that VrefDQ generator circuitry is powered up and stable within tXS period. First Write operation or first Write Leveling Activity may not occur earlier than tXS after exit from Self Refresh. The DRAM initiates a minimum of one Refresh command internally within tCKE period once it enters Self-Refresh mode.

The clock is internally disabled during Self-Refresh Operation to save power. The minimum time that the DDR4 SDRAM must remain in Self-Refresh mode is tCKESR. The user may change the external clock frequency or halt the external clock tCKSRE after Self- Refresh entry is registered, however, the clock tCKESR must be restarted and stable before the device can exit Self-Refresh operation.

Note: Package C6 (PC6) only helps to save power when DDR dynamic self-refresh feature is on.

9.4.3 Unsupported Features and Restrictions

- DDR3 and DDR3L DRAM technology is not support on this product.
- Technology to minimize DDR pass-gate charge migration issues.
- DDR4 data bus widths other than 32/40 bits or 64/72 bits are not supported.
- 2-Gb Device Density (or lower).
- Dual Channel: Both channels do not have to be populated identically
  - Same voltage.
  - ECC versus non-ECC DIMMs; DIMMs must all be ECC or non-ECC; no mixing allowed.
  - DIMMs must be all either UDIMMs, RDIMMs or NVRDIMM. No DIMM type mixing is permitted.
  - Frequency – BIOS will set the overall Memory frequency to the lowest frequency that is detected during SPD discovery across both channels and all populated DIMMs.
- Partial Self Refresh is not supported.
- Memory mirroring is not supported.
- Memory lockstep is not supported.
- Memory sparing is not supported.
- Memory Hot-Swap is not supported.
- Suspend to Memory (S3) is not supported.
- Single Device Data Correction (SDDC) is not supported.

Note:

1. SPD setting impacts memory initialization during the system boot up. Please refer to the *SPD Annex L, Serial Presence Detect (SPD) for DDR4 SDRAM Modules* for details.

9.4.4 DDR4 DIMM Types and Population

Registered (RDIMM), unbuffered (UDIMM), or small-outline (SODIMM) ECC modules are supported. ECC RDIMMs and UDIMMs are supported. Single rank ("1R") and dual rank ("2R") DIMMs can be used.

Note: Contact your Intel representative for the Harrisonville Platform Snapshot document which contains the most up to date supported memory information.

9.4.4.1 DIMM Population Requirements

Either channel may be populated or both. There are no DIMM matching requirements between channels. Both channels, however, must run at the same interface frequency. Each channel may run at different DIMM timings (RAS latency, CAS latency, and so forth).

The platform does not support mixing of DIMM types. Sockets are populated with all RDIMMs, all UDIMMs, or all SODIMMs. All DIMMs must be DDR4 DIMMs.

DIMMs with different timing parameters can be installed on different slots within the same channel, but only timings that support the slowest DIMM will be applied, i.e., the faster DIMM in a channel will run at the lower speed.

No mixing of x4 and x8 RDIMMs is allowed within a channel. It is allowed when in different channels. Mixing of single rank (SR) and dual rank (DR) DIMMs is allowed but there may be a speed bin loss.

Each populated channel must be x4 or x8 or x16 only (no width mixing within a channel).

These are summarized in Table 9-3.

Regardless of RAS mode, the requirements for DIMM populating within a System and a channel provided in the System/Channel Level DIMM Population Requirements sections in the Product Design Guide must be met at all times.

Table 9-3. DIMM Configurations, Two DIMM Socket per Channel

Style	1N/2N	DIMM1	DIMM0
RDIMM	1N	empty [1]	SRx4, SRx8, DRx4, DRx8
	1N	SRx4	SRx4
	1N	SRx8	SRx8
	1N	DRx4	DRx4
	1N	DRx8	DRx8
UDIMM	2N	empty	SRx8, DRx8
	2N	SRx8	SRx8
	2N	DRx8	DRx8
SODIMM	2N	empty	SRx8, SRx16, DRx8
	2N	SRx8	SRx8
	2N	SRx16	SRx16
	2N	DRx8	DRx8

Notes:
1. For designs using the T-topology in a two socket configuration with only one DIMM slot being populated it is recommended to populate DIMM0 first, although either DIMM0 or DIMM1 may be populated but DIMM1 only population is not fully validated by Intel. For daisy chain designs customers need to populate the further connector to decrease the risk of reflections that impacts signal integrity.

9.5 Memory Controller RAS Features

9.5.1 Data Scrambler

Data scrambling is a general technique to reduce supply noise and improve signal integrity by XORing data and ECC with a pseudo random sequence. The pseudo random sequence has two important effects relative to power delivery. Across the 72 data/ECC bits of the bus, it drives very close to 50% "1's" and 50% "0's" in every cycle. This eliminates the previous worst case where all bits of the bus would simultaneously drive high or low.

9.5.2 Patrol Scrub

Patrol Scrubbing is a process that allows the SoC to correct correctable memory errors detected on a memory module and send the correction to the requester (the original source). When this item is set to Enabled, the SoC will analyze one cache line every 16K cycles, if there is no delay caused by internal processing. By using this method, roughly 64 GB of memory connected to the SoC will be scrubbed every 24 hours. This option can be enabled or disabled.

Note: The above feature requires ECC to be enabled.

9.5.3 Demand Scrub

Demand Scrubbing is a process that allows the SoC to correct correctable memory errors found on a memory module. When the SoC or I/O issues a demand-read command, and the read data from memory turns out to be a correctable error, the error is corrected and sent to the requester (the original source). Memory is updated as well. This option can be enabled or disabled.

Note: The above feature requires ECC to be enabled.

9.5.4 Asynchronous DRAM Refresh (ADR)

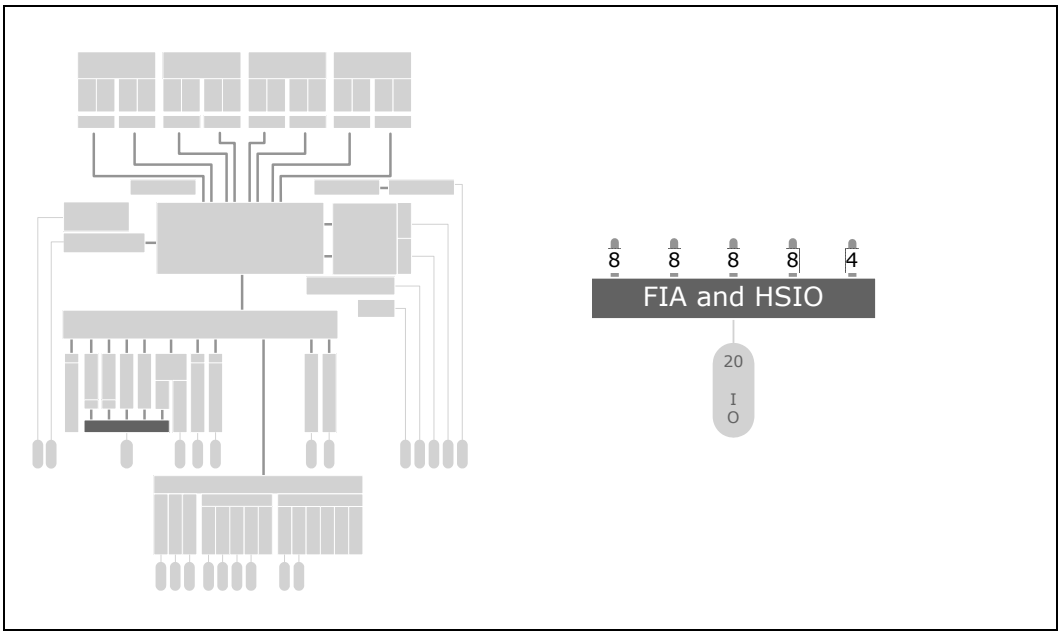
Asynchronous DRAM Refresh is a SoC feature that preserves context data to NVRDIMMs before data loss can occur in the event of an unexpected power loss. Once all inflight data is flushed including CPU cached data, the DRAMs must be placed into a self-refresh state before platform power is lost. Details about ADR are in Section 16.15, "Asynchronous DRAM Refresh (ADR)" on page 547.

§ §

10 Flexible I/O Adapter (FIA) Overview

The High Speed I/O (HSIO) lanes are configured by the SoC customer. The product SKU determines how many lanes of PCI Express* Root Ports, SATA ports, and USB 3.0 ports are available. The arrangement of the available lanes is up to the customer. BIOS, via the Intel® Management Engine (Intel® ME), along with Soft Straps and the bifurcation settings of the PCIe* Root Port clusters, configure the lanes.

Figure 10-1. What is Covered in This Chapter



10.1 Signal Descriptions

The signal descriptions are shown in Table 10-1. For additional signal information, including whether a signal is assigned to shared-function pin or can be used as a GPIO signal see Section 39.1, "Directory of Signal Names and Pin Names" on page 993. The Direction/Type column of Table 10-1 is interpreted as follows:

- I = Input signal. The SoC has receiver circuit.
- O = Output signal. The SoC has driver circuit.
- Differential = Differential signal pair. Two pins: Positive; Negative.

Note: The HSIO transmit and receive differential pairs for each lane have SoC-internal termination designed to conform to the PCIe*, SATA, or USB 3.0 industry specification for which the lane is configured.

Table 10-1. Signal Names and Descriptions

Signal Names	Direction	Shared	Description
HSIO_RX_DP[19:0] HSIO_RX_DN[19:0]	I, Differential	Yes	**High-Speed I/O Lane Read Data** - These 20 sets of differential receivers are configured by the customer as PCI Express Root Ports, SATA Ports, and/or USB 3.0 Ports.
HSIO_TX_DP[19:0] HSIO_TX_DN[19:0]	O, Differential	Yes	**High-Speed I/O Lane Write Data** - These 20 sets of differential drivers are configured by the customer as PCI Express Root Ports, SATA Ports, and/or USB 3.0 Ports.
HSIO_COMPREF_DP HSIO_COMPREF_DN	O, Differential	No	**High-Speed** I/O **Common Lane Compensation Pins** - The platform board must provide a 100 Ω, 1% resistor connected from the DP pin to the DN pin.
HSHV_IRCOMP	I,O	No	**HSHV_IRCOMP** - Special compensation resistor to support 3.3V shared by all of the High-Speed I/O Lane interfaces. The platform board must provide a 100-Ω, 1% resistor connected from this pin to VSS.

10.2 Feature List

- Customer-configurable high-speed lane patterns
- Controlled by BIOS, Soft Straps, Intel® ME, and the PCIe bifurcation settings

10.3 Architectural Overview

The Flexible I/O Adapter (FIA) is the mechanism that enables the customer to configure the High Speed I/O (HSIO) lanes to fit a particular system need.

Three controller types are involved to determine HSIO usage:

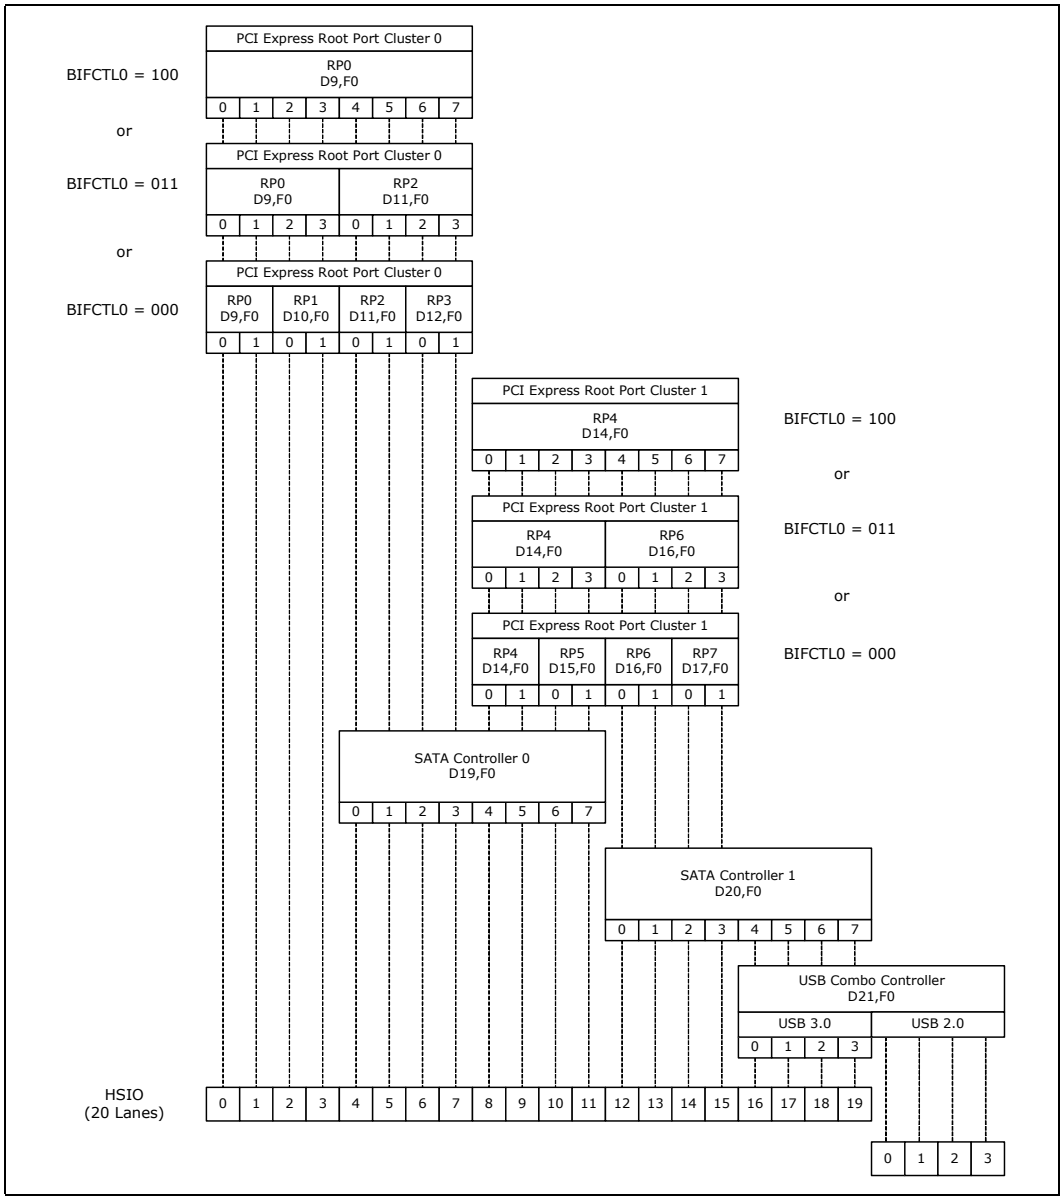
- PCI Express Root Ports
- SATA
- USB 3.0

See Figure 10-2, "FIA and HSIO Structure".

The FIA provides a high degree of configuration flexibility without increasing pin count by allowing a single PHY lane to be statically mapped to different controllers. This provides great flexibility to platform board designers as the number of PCIe, SATA and USB 3.0 ports and their mapping to SoC pin-out can be configured differently for different platforms.

The FIA supports shared clock-control logic that allows the integrated controllers to share a single master clock. The FIA also contributes to dynamic PHY power gating by managing the PHY common-lanes power gating, allowing power gating only when all the controllers permit. This further reduces the idle power of the PHY. The PHY data lanes power gating is managed by the respective controllers.

Figure 10-2. FIA and HSIO Structure



Note: The structures for PCIe RP bifurcation control BIFCTL0 = 001 and 010 are not shown here but are valid configurations. Most use cases are satisfied by what is shown in the figure.

10.4 USB 3.0 as a Debug Port

Depending on the product SKU, lanes 19:16 are set to be either SATA or USB 3.0. See Figure 10-2 on page 362. For the debug Intel® Direct Connect Interface (Intel® DCI) to work correctly, the Intel® ME programs the Intel® DCI registers to indicate which lanes are SATA and which are USB 3.0 for the particular SoC product SKU. See Chapter 38, "JTAG and Debug Ports" for Intel® DCI and the SoC JTAG port.

10.5 Lane Configuration

All product SKUs are shipped with all controllers enabled for the PCI Express Root Ports, SATA, and USB 3.0 interfaces. The product SKUs are shown in Section 1.1, "Overview." Each product SKU has a limit to the number of HSIO lanes that a customer can use, but this limitation does not specify which physical lanes can and cannot be used. The customer defines the Soft Strap settings (see Chapter 4, "Strapping and Configuration") to connect the I/O lanes of the PCIe Root Port, SATA and USB 3.0 controllers to individual HSIO lanes. Section 10-2, "FIA and HSIO Structure" shows the relationship of the controllers with the HSIO lane numbers. The Soft Straps must define controller connections to no more than the maximum number of HSIO lanes allowed for the particular product SKU. In addition, the PCI Express lane patterns are determined by the values programmed in the PCIe Bifurcation Control Registers described in Section 10.5.2, "PCI Express Lane Configuration."

If the SoC determines that there are more HSIO lanes connected by Soft Straps than allowed by the product SKU, the SoC will configure the HSIO lanes as only four USB 3.0 lanes. In this case, BIOS is still initiated but the system will have only the four USB 3.0 lanes active at the HSIO pins.

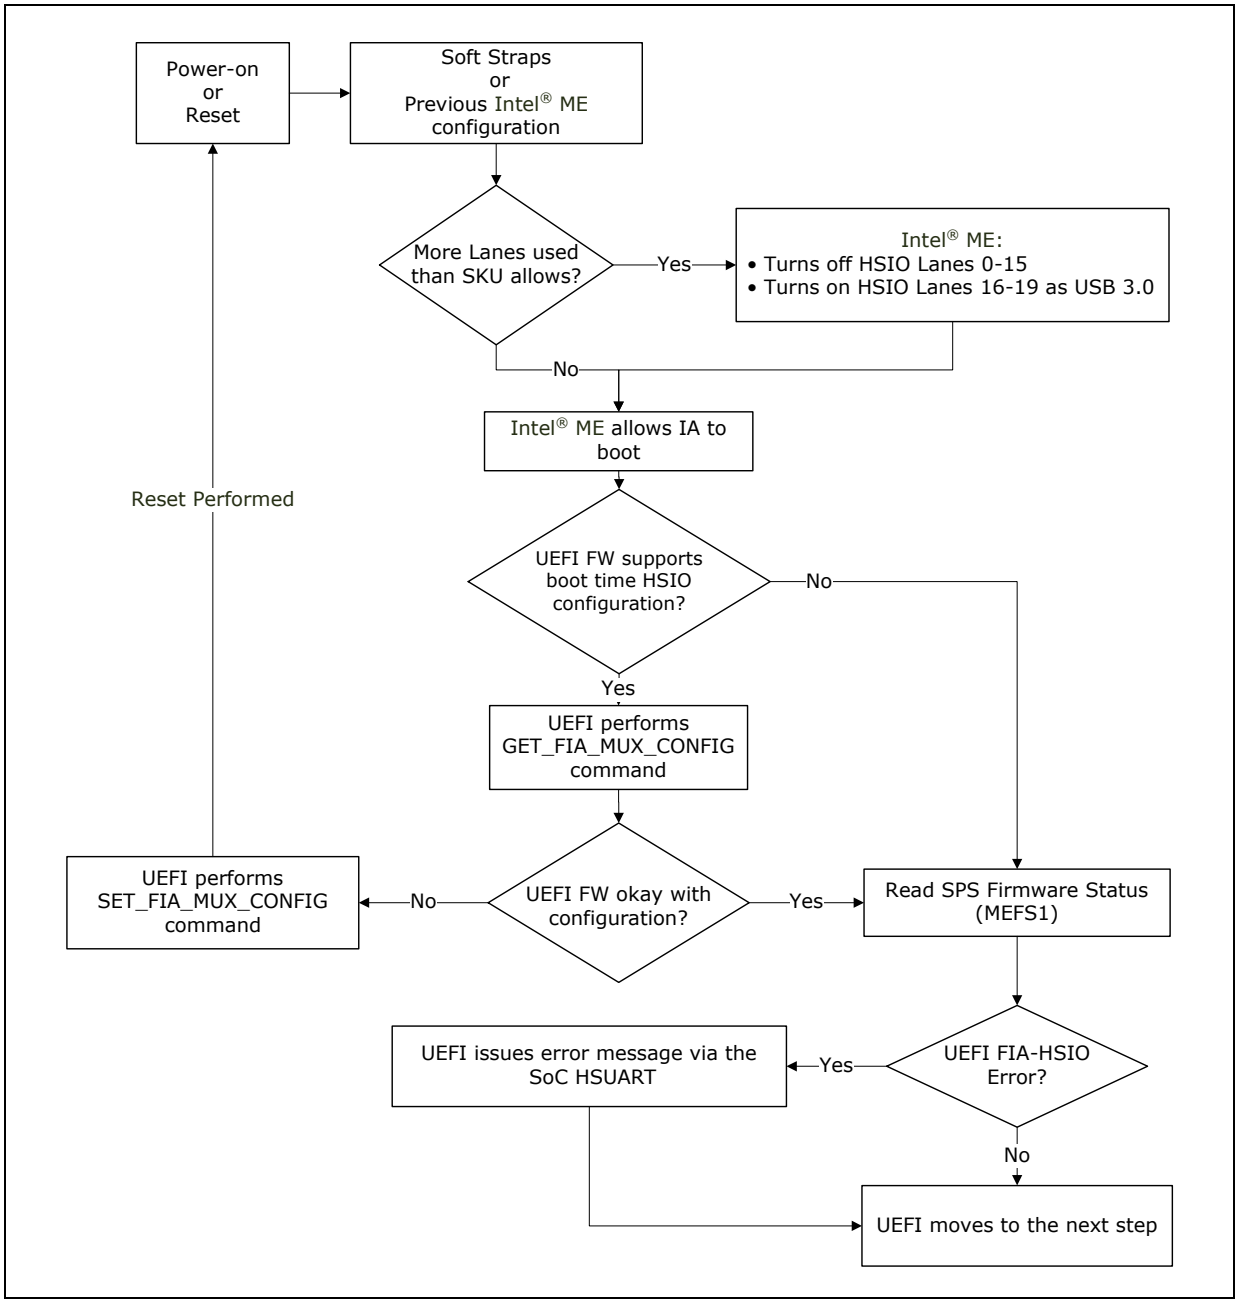
10.5.1 Intel® Management Engine and BIOS Roles in Lane Configuration

FIA lane configuration and management are part of the Intel® Server Platform Services (SPS) firmware.

The specification includes a flow diagram for systems with Intel® SPS firmware where the BIOS and Intel® ME determine the lane-assignment validity and confirm that the assignments are within the SoC product SKU definition. This flow is summarized in Figure 10-3, "Intel® ME-BIOS/UEFI Interactions in a System with Intel® SPS Firmware" and addresses three customer use cases:

- The resulting system has a unique integrated firmware image (IFWI) and product-SKU combination for each of the system's boards. This combination is custom-programmed in the SPI device during board manufacturing. Here the SoC Soft Straps provide the HSIO lane assignments.
- A single IFWI for a particular board design is programmed to the SPI device during board manufacturing. The board is designed to accommodate one of a number of SoC product SKUs. Here the SoC Soft Straps in the single IFWI provide the HSIO lane assignments and, if required, the BIOS/UEFI overrides the initial HSIO lane assignments based on the product SKU used on the board.
- A single IFWI for a particular board design is programmed to the SPI Flash memory at manufacturing similar to above, but the desired HSIO assignments cannot be determined until the board is plugged into the chassis and power applied. Here the BIOS/UEFI determines which system I/O cards/controllers are system-connected to the board and attempts to configure the HSIO lanes.

Figure 10-3. Intel® ME-BIOS/UEFI Interactions in a System with Intel® SPS Firmware



10.5.2 PCI Express Lane Configuration

In addition to lane disabling/enabling, the PCI Express lane patterns are determined by the values programmed in the three-bit Bifurcation Control 0 (BIFCTL0) field of the PCIe Port Bifurcation Control Register (PPBIFCTL_PRIV) registers. There is one physical PPBIFCTL_PRIV register for PCI Express Root Port (RP) Cluster 0 and one for RP Cluster 1. Each of the two 8-lane PCI Express RP Clusters has a PPBIFCTL_PRIV register. Bifurcation of the eight lanes is shown in Table 10-2. The effects of the three unshaded BIFCTL0 decodes are shown in Figure 10-2, "FIA and HSIO Structure." BIFCTL0 = 001 and 010, not shown in the figure, are also valid decodes.

Table 10-2. Bifurcation Control for PCIe RP Clusters 0 and 1

BIFCTL0 [2:0]	Port 0	Port 1	Port 2	Port 3
000	X2	X2	X2	X2
001	X4		X2	X2
010	X2	X2	X4	
011	X4		X4	
100	x8			
101	**Reserved**			
110				
111				

There are two access mechanisms for each of the two PCIe Port Bifurcation Control registers. When accessed as a Sideband Register, it is a Read-Write register where the value in BIFCTL0 can be locked once it is set. It can also be accessed through Configuration Space where it is a Read-Only register. The PCIe Port Bifurcation Control registers is called:

- PPBIFCTL_PRIV when accessed as a Sideband Register
- PPBIFCTL when accessed via Configuration Space

As a Sideband Register, PPBIFCTL_PRIV for PCIe RP Cluster 0 is at Sideband Port B4h offset 10h and at Port B3h offset 10 for RP Cluster 1. These Sideband Registers are accessed in Host Memory-Mapped Space using SBREG_BAR, offsets B4_0010h and B3_0010h respectively.

In Configuration Space, PPBIFCTL is a Device-Specific Register located at offset C0h from B0,D9,F0 for PCIe RP Cluster 0 and is aliased in Configuration Space at F0 for Devices 10, 11, and 12. It represents the lane arrangement of RP0, RP1, RP2, and RP3. PCIe RP Cluster 1 has its PPBIFCTL located at offset C0h in Configuration Space at B0,D14,F0 and is aliased in Configuration Space at F0 for Devices 15, 16, and 17. It represents the lane arrangement of RP4, RP5, RP6, and RP7.

10.5.3 Configuring PCIe Lane to x1 and SATA Ports

The FIA is flexible in its lane assignments and efficient. A PCIe Root Port that results as a x2 from the bifurcation setting, can give up its higher-numbered lane so that the HSIO lane can be configured to a SATA port. Soft Straps settings allow this PCIe x1 Root Port configuration. Figure 10-4 shows an example of this PCIe-SATA arrangement of lanes. The RP Enable and RP Width Soft Strap values shown in the example are for Root Ports 0, 1, 2, and 3 for PCIe Cluster 0 and for Root Ports 4, 5, 6, and Cluster 1.

§ §

11 PCI Express Root Ports (RP)

The SoC supports up to 16 PCI Express* lanes that comply with the PCI Express Base Specification Revision 3.0. The maximum data rate is 8.0 GT/s. The 16 lanes can be configured to a maximum of eight, independent PCIe* Root Ports (RP). The eight RPs are grouped in to two clusters, four RPs per cluster:

- Cluster 0 - RP0, RP1, RP2, RP3 are assigned Device Numbers 9, 10, 11, 12 decimal
- Cluster 1 - RP4, RP5, RP6, RP7 are assigned Device Numbers 14, 15, 16, 17

The number of available lanes and Root Ports depend on the product SKU.

Twelve of the 16 PCIe lanes share their SoC signal pins with the integrated SATA0 and SATA1 controllers. Each of the 12 shared lanes must be configured as either PCIe or SATA through Soft Straps and BIOS. See Chapter 10, "Flexible I/O Adapter (FIA) Overview." The Root Ports can be configured to support a diverse set of lane assignments.

11.1 Signal Descriptions

The signal descriptions are shown in Table 11-2, "Signal Names and Descriptions." For additional signal information, including whether a signal is assigned to shared-function pin or can be used as a Customer GPIO signals see Section 39.1, "Directory of Signal Names and Pin Names." Also, see Table 39-3, "Signals that Share the Twenty HSIO Lanes." The Direction/Type column of Table 11-2, "Signal Names and Descriptions" is interpreted as follows:

- I = Input signal. The SoC has receiver circuit.
- O = Output signal. The SoC has driver circuit.
- O-OD = Open-Drain Output. SoC output circuit uses an open-drain driver.
- Differential = Differential signal pair. Two pins: Positive; Negative.

Table 11-2. Signal Names and Descriptions

Signal Names	Direction	Shared	Description
PCI Express RP Cluster 0 - SoC Root Ports 0, 1, 2, and 3			
PCIE0_RP0_RP3_TX_DP[7:0] PCIE0_RP0_RP3_TX_DN[7:0]	O, Differential	Yes	**Transmit (Tx):** These differential output signals are internal to the SoC. The actual signal pins are determined by the FIA configuration.
PCIE0_RP0_RP3_RX_DP[7:0] PCIE0_RP0_RP3_RX_DN[7:0]	I, Differential	Yes	**Receive (Rx):** These differential input signals are internal to the SoC. The actual signal pins are determined by the FIA configuration.
PCIE_CLKREQ_N[3:0]	I,O-OD	Yes	**Reference Clock Control:** These active-low signals are used for reference clock control. See CLKREQ# signal in the PCIe Mini CEM specification.
PCI Express RP Cluster 1 - SoC Root Ports 4, 5, 6, and 7			
PCIE1_RP4_RP7_TX_DP[7:0] PCIE1_RP4_RP7_TX_DN[7:0]	O, Differential	Yes	**Transmit (Tx):** These differential output signals are internal to the SoC. The actual signal pins are determined by the FIA configuration.
PCIE1_RP4_RP7_RX_DP[7:0] PCIE1_RP4_RP7_RX_DN[7:0]	I, Differential	Yes	**Receive (Rx):** These differential input signals are internal to the SoC. The actual signal pins are determined by the FIA configuration.
PCIE_CLKREQ_N[7:4]	I,O-OD	Yes	**Reference Clock Control:** These active-low signals are used for reference clock control. See CLKREQ# signal in the PCIe Mini CEM specification.
Common to All Root Ports			
CLK_OUT_DP[4:0] CLK_OUT_DN[4:0]	O, Differential	No	**Differential Reference Clock:** These differential output signals can be used to provide a PCIe interface clock to external PCIe devices. These five sets of output signals enable the platform board design to have five PCIe devices without requiring a clock-buffer component. ***Note:*** While there are eight PCIE_CLKREQ_N signal pins, there are only five Differential Reference Clock pins provided. Clock buffering may be needed on some platform board designs.

11.2 Feature List

The following table lists PCI Express Root Port (RP) supported features:

Table 11-3. PCI Express Features (Sheet 1 of 2)

Feature	Root Port (RP)
Alternate Routing-ID Interpretation (ARI)	Supported
Link Speed	Gen3[1] (8 GT/s), Gen2 (5 GT/s), Gen1 (2.5 GT/s)
Port Configuration	2 RP of x8 each (16 lanes)
Maximum Payload Size	256 bytes (default). 128 bytes also supported.
Lane reversal	Inferred during Link training rather than strapped
PME logging with interrupt for WAKE support	Supported
NP request Splitting	Supported on 64/128/256 bytes boundary
Posted Transaction Splitting	Supported on 64 byte boundary
PLL Shutdown/Standby	Supported
PCI Express Card Hot-Plug* In-band Hot Plug	Supported
Full Hot-Plug (PCIe Cards + SHPC)	Supported
Routing of AtomicOps	Not supported
Revise ASPM	Supported
Latency Tolerance Reporting (LTR)	Not Supported
Project Specific Messages	Supported
Dynamic Link Width	Supported (as Slave, Controlled by CSR when port is Master)
Completion Combining	Supported
Windows Hardware Error Architecture (WHEA)	Supported
Completion Time Out (CTO)	Supported
End-to-End CRC (ECRC)	Supported
Stop and Scream (S&S)	Supported
Enhanced Downstream Port Containment (eDPC)	Not supported
Enhanced Live Error Recovery (eLER)	Not supported
Single Root I/O virtualization (SR-IOV)	Supported
Swizzle In-bound INTx into INTA	Supported
Separate Refclk Independent SSC Architecture (SRIS)	Supported
Continuous Time Linear Equalizers (CTLE)	Supported
Initial FoM Search Algorithm/Modified F0M Search Algorithm for WMP	Supported
Squelch Dynamic Enable	Supported
Resizable BAR	Not Supported
Optimized Buffer Flush/Fill Mechanism with WAKE# (OBFF)	Not Supported
Thermal Throttle	Not Supported
SATA Over PCIe	Not Supported
Programmable Device Idle Duration	Not Supported

Table 11-3. PCI Express Features (Sheet 2 of 2)

Feature	Root Port (RP)
Address Translation Services (ATS)	Not Supported
TLP Processing Hints (TLP)	Not Supported
Dynamic Power Allocation (DPA) Capability	Not Supported

1. SKU dependent.

11.3 Architectural Overview

The SoC supports two sets of PCIe* Root Port (RP) clusters. Each cluster consists of four Root Ports. Each cluster can be configured to provide up to eight lanes. RP[3:0] are assigned Device Numbers 12, 11, 10, and 9 while RP[7:4] are assigned 17, 16, 15, and 14. Each can operate at speeds up to 8.0 GT/s.

The internal bus of these root ports is Bus 0 and consists of secondary PCIe buses of specific link width. BIOS and/or OS can assign any logical bus number to the secondary PCIe ports.

Each of the eight RP controllers has three regions in Configuration Space. The contents of these regions and their offset values are:

1. Standard PCI Header:
   — Type 1 = PCI-to-PCI bridge
2. PCI Device Dependent Region:
   — PCI Express Capability
   — PCI Power Management Capability
   — SVID/SID Capability
   — Message Signaled Interrupts (MSI) Capability
   — Various implementation-specific and Intel-reserved registers
3. PCI Express Extended Configuration Space:
   — Advanced Error Reporting (AER) Capability
   — Access Control Services (ACS) Capability
   — Windows* Hardware Error Architecture (WHEA) Capability
   — Latency Tolerance Reporting (LTR) Capability
   — L1 Power Management Substates Capability

Note: The Multicast and Secondary PCI Express Extended Capabilities are not supported.

The PCIe Architecture also includes:

- PCIe Transaction Layer Registers
  — Performance Monitor
  — Local Event Triggers
  — Error Injection
  — Debug Registers
  — Test and High-Volume Manufacturing Registers
- PCIe Link Layer Registers
- PCIe Physical (PHY) Layer Registers

The vendor-specific extended capabilities in Configuration Space are primarily for Intel debug and testing purposes.

Note: The SoC does not support peer-to-peer transactions between RPs.

11.3.1 PCI Bridge Subsystem Identification Capability

The PCI Bridge Subsystem Vendor ID (Intel® Corporation) and additional identification information are read by the software.

11.3.2 Message Signaled Interrupt (MSI) Capability

Supported by the root ports:

- Per-vector masking capable (PVM)

Not Supported by the root ports:

- Address 64-Bit Capable - The root ports are not capable of generating a 64-bit message address
- Multiple Message Capable - No, only one message is supported

Supported by the root ports when enabled by the software [Default]:

- MSI Enable (MSIE) - When set, MSI is enabled and traditional interrupt pins are not used to generate interrupts. Default is 0 (not set)
- Trigger Mode (TM) - Either Edge-Triggered or Level-Triggered. Default is Edge-Triggered
- Level- or edge-triggered messages are always treated as assert messages. For level-triggered interrupts, the Level bit reflects the interrupt input state if TM (above) specifies the level-triggered mode as follows:
  - 0: Deassert messages
  - 1: Assert messages

11.3.3 Advanced Error Reporting (AER) Capability

PCI Express* defines two error reporting paradigms:

- Baseline capability
- Advanced Error Reporting (AER) capability

The baseline error reporting capabilities are required of all PCI Express devices and define the minimum error reporting requirements. The root ports provide the optional Advanced Error Reporting Capability which is defined for more robust error reporting and is implemented with a specific PCI Express Capability structure. PCIe* baseline error handling does not support severity programming.

The Advanced Error Reporting Capability provides each of the root ports the Uncorrectable Error Severity register which allows each uncorrectable error to be programmed to fatal or non-fatal. Uncorrectable errors are not recoverable using defined PCI Express mechanisms. However, the SoC considers a particular error fatal to a link or device or possibly considers that error non-fatal. The Uncorrectable Error Severity register (ERRUNCSEV) default value is re-programmed if the device driver or platform software requires more robust error handling.

11.3.4 PCIe Extended Capability and Other Supported Technology

11.3.4.1 Access Control Services (ACS) Capability

ACS prevents various forms of silent data corruption by preventing PCI Express Requests from being incorrectly routed to a peer Endpoint below a switch. ACS is also used to validate that every request transaction between two downstream components is allowed. Also, ACS allows some robustness checks by checking for the ReqID from a function to be a valid ReqID at a coarse granularity. When ACS is enabled, the PCIe Root Port does loopback memory transactions (reads and writes) to the same port if the address map check matched.

11.3.4.2 Windows Hardware Error Architecture (WHEA)

WHEA is an error-injection methodology that allows the software stack to test how it handles an error. WHEA is a Windows* hardware-enabling specification that requests one correctable and one uncorrectable error to be injected in the SoC.

WHEA is implemented in the PCIe Root Ports controllers as a vendor-specific error-injection capability structure, defined for software recognition in Configuration Space. The Intel-defined Vendor Specific ID is 3h.

It is a programmatic way to inject a correctable and an uncorrectable error. Two bits are provided to allow software to inject correctable and uncorrectable errors. Errors are injected when software sets one of the bits. Software must clear the error injection bit before setting again to generate another error. The bit will not be cleared by the hardware.

This will cause normal error logging and interrupt trigger. The error handler code is expected to be invoked. Error injection software should not preclude the invocation of the error handler. The appropriate status registers are set so that the operating system handler can go through its flows.

As a security feature, a write-once bit is provided to disable the error injection mechanism. BIOS sets this bit in every boot to prevent a denial-of-service (DOS) attack. BIOS keeps this disable bit clear only when error injection is being tested.

The error-injection mechanism does not require dependency on any external component.

The selected correctable error is the Receiver Error. The uncorrectable error is the Completion Timeout Error. Neither of these have header logs associated with them.

11.3.4.3 Dynamic Link Width

The capability allows either end of a link to initiate a dynamic link width change by going through Recovery and Configuration back to L0. This can be used by devices to adjust the link width based on dynamically changing bandwidth requirements. The UPCFGCSR register, located at offset AB8h in the Root Port's Configuration Space, allows the device to advertise up configure capability in the TS2 training set, so the other end can dynamically adjust the link width as needed.

11.3.4.4 Alternative Routing-ID Interpretation (ARI)

ARI enables next generation I/O implementations to support an increased number of concurrent users of an Endpoint, while providing the same level of isolation and controls found in existing implementations. While ARI obviously benefits the virtualized operating environments where each Requester ID can be uniquely assigned to a guest OS, ARI also benefits non-virtualized environments where (due to increased process improvements) a large number of I/O Functions can be integrated into a single Endpoint.

Routing IDs, Requester IDs, and Completer IDs are 16-bit identifiers traditionally composed of three fields:

- an 8-bit Bus Number
- a 5-bit Device Number
- a 3-bit Function Number

With ARI, the 16-bit field is interpreted as two fields instead of three:

- an 8-bit Bus Number
- an 8-bit Function Number

The Device Number field is eliminated.

This new interpretation enables an ARI Device to support up to 256 Functions. ARI is controlled by a new set of capability and control register bits defined in the PCIe registers.

11.4 Physical Layer

11.4.1 PCI Express Speed Support

The PCI Express (PCIe) physical layer implements high-speed, low-voltage differential signaling that is described in detail in the PCI Local Bus Specification, Revision 3.0. The integrated root ports support 2.5 GT/s, 5 GT/s and 8 GT/s (SKU dependent) PCI Express speeds. The Root Port controllers negotiate the speed using the in-band signaling mechanism, Link Initialization and Training, of the specification.

The PCI Express Root Ports use 8b/10b encoding when the data rate is 2.5 GT/s or 5 GT/s. For data rates greater than or equal to 8 GT/s, the encoding mechanism used is a link-wide physical layer packeting along with a per-lane encoding scheme that uses 2-bits of sync header with a payload of 128 bits.

11.4.2 Separate Refclk with Independent SSC Architecture (SRIS)

SRIS can be utilized to enable a PCI Express application involving an inexpensive cabling solution such as for PCIe-attached Solid-State Storage Devices (SSD) with a new cabling form factor that supports non-common clock mode with Spread-Spectrum Clocking (SSC) architecture. The reference clock is not needed to be delivered through cable. However, the new clock mode requires both sides of a link to tolerate a much higher ppm tolerance of 5600 ppm compared to the PCIe Base Specification defined as 600 ppm. For more details, please refer to PCI-SIG Engineering Change Notice (ECN) "Separate Refclk Independent SSC Architecture (SRIS)."

- The SoC has Soft Straps to enable SRIS on each of the eight Root Ports. See Table 4-3, "Flash Descriptor Soft Straps."
- The SoC Root Ports only support Separate Refclk with no SSC (SRNS) and do not support SRIS for 8-GT/s speeds. Both SRIS and SRNS are supported for PCIe 2.5-GT/s and 5-GT/s speeds.

11.4.3 Form Factor Support

The PCIe controllers support card-edge-connector and Server I/O Module (SIOM) form-factors. Form-factor-specific differences that exist for Hot-Plug* and power management are captured in their individual sections elsewhere in this chapter.

The root ports have enough buffering to provide full performance using up to a 20-inch trace of FR4 with two connectors. They do not provide any additional buffering for cable/repeater latencies and are not able to achieve full bandwidth on PCI Express using these topologies. But functionally, they are able to support cables.

11.4.4 Configuration of the PCI Express Ports and Link Widths

While there are up to two, eight-lane (Maximum Link Width = 8) PCI Express Root Port clusters, each can be configured to provide one, two, three or four Root Ports. Each of the two controllers has a PCI Express Port Bifurcation Control (PPBIFCTL_PRIV) register that determines the number of Root Port Links per controller and the number of Lanes per Link. The SoC also provides flexibility in the number of High-Speed I/O interface signals that can be made available on the SoC. Details of the PCI Express Root Port and Lane-configuration possibilities are explained in Section 10.5.2, "PCI Express Lane Configuration" of the Flexible I/O Adapter (FIA) chapter of this document.

The PPD0.ILINKTRN0 bit, located in Host Configuration Space for each of the eight possible Root Ports, controls the PCIe Express port Link Training for the associated port. A value of '1' initiates Link Training. After writing this bit to a '1', software can poll the Data Link Layer Link Active (DLLLA) bit in the LINKSTS register, which is also located in Host Configuration Space for each Root Port. Polling this bit allows software to determine if a port is up and running. Root ports do not automatically initiate Link Training after reset unless the default value of '0' of the ILINKTRN0 bit is changed to a '1'. A write of '0' to a default register-setting has no effect.

A Capability Lock (CL) bit is provided for each PPD0 register and each PPBIFCTL_PRIV register. A write of '1' locks-down the associated register for security purposes. Refer to the register-description chapters of this document for details.

There is a dedicated Soft Strap for port enable on a per-port basis to enable/disable the port. When certain PCI Express lanes within a port are disabled, via Soft Straps or through the Host Configuration-Space Registers, then the Link-Training and Status State Machine (LTSSM) associated with those lanes must be put in the "disabled" state (which disables receiver detect sequence on those lanes). In addition, strap of slot width, per port basis, can be utilized for constraining the port operation at a particular width. This is instant and the behavior is an undefined post, allowing the link to train. The SoC Soft Straps are described in Chapter 4, "Strapping and Configuration."

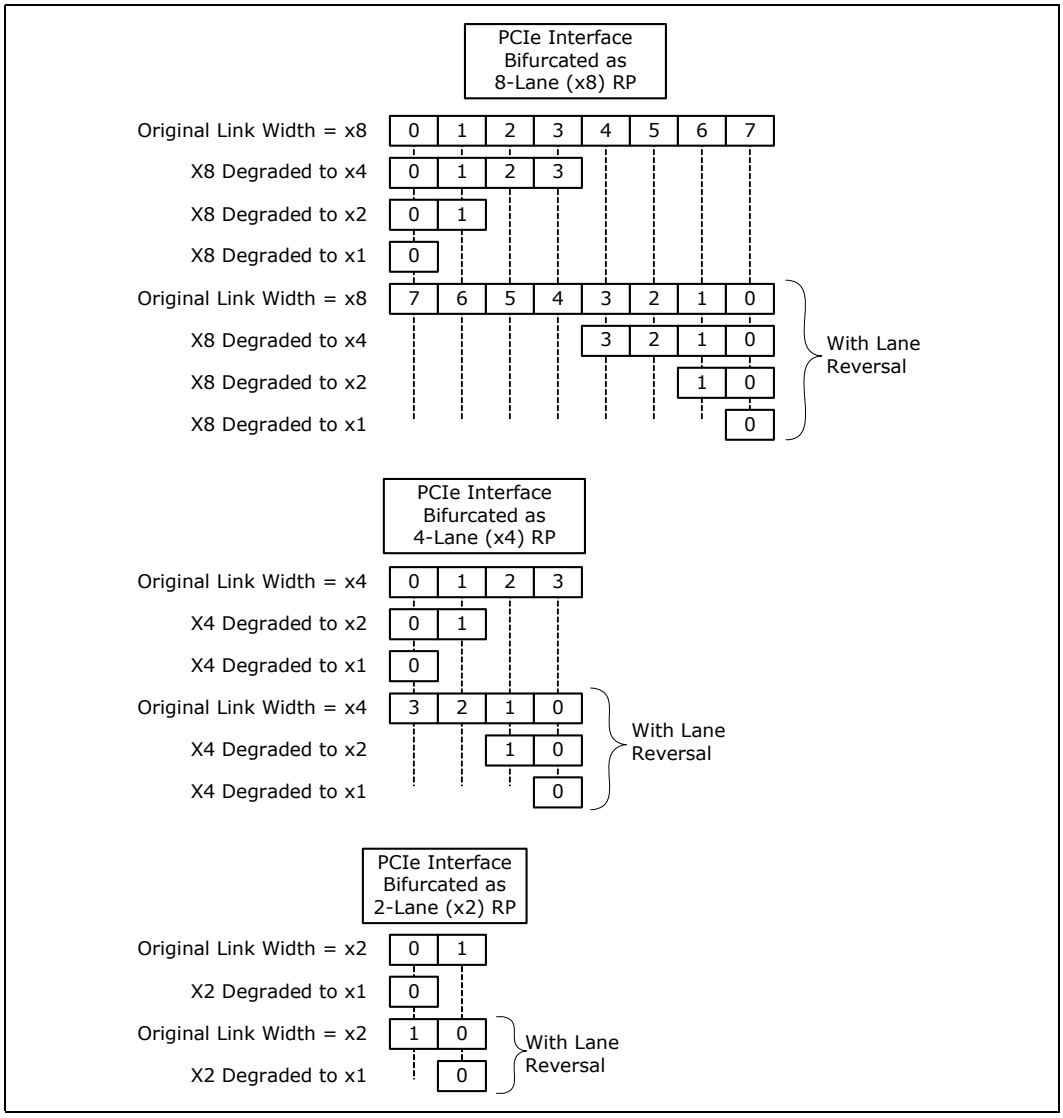
11.4.5 Degraded Mode

Degraded-Mode Link Widths a PCI Express negotiation behavior supported by the SoC and is automatically attempted every time the PCI Express link is trained. To maximize performance, the SoC first attempts Degraded Mode of a higher Link Width before trying any of the lower-Link-Width Degraded Modes. The x1 is the smallest Link Width supported by the SoC in the PCIe Degraded Mode operation. Link-Width degradation is always be anchored to a slot edge.

Lane-degradation remapping occurs in the Physical Layer. The Link Layer and Transaction Layer are transparent to the Link-Width change.

See Figure 11-2, "PCIe Bifurcation and Physical Ports."

Figure 11-2. PCIe Bifurcation and Physical Ports



11.4.5.1 Dynamic Lane Reversal

Lane Reversal is a Link negotiation behavior that creates a condition where if a Link fails to train, the Link is then forced to train again with its Lanes re-ordered in the opposite order. For an 8x situation with a Link wired as Lanes 0 through 7, Lane Reversal tries the training again with the Link physically wired as Lanes 7 through 0. See Figure 11-2, "PCIe Bifurcation and Physical Ports."

If a Link encounters a "bad Lane" during its initial training, the Link then chooses a "subset" of Lanes. It does this either on the reversed order, anchored to physical Lane N-1, or on the non-reversed order, anchored to physical Lane 0.

If the device connected to the Root Port does not support Lane Reversal, Link training may fail (no possible Lane-0 match).

This Lane Reversal negotiation is only enabled when the Link falls back to the Detect State from the Configuration.Lanenum.Wait or Configuration.Lanenum.Accept state prior to when the Physical Layer reports Physical LinkUp = 1b. Once the link reaches the Configuration.Complete substate, the Lane Reversal negotiation is turned off.

11.4.5.2 Lane Polarity Inversion

Lane Polarity Inversion is a Link negotiation behavior that is supported by the SoC. Polarity inversion allows the board designer to connect the D+ and D- lines to the Rx- and Rx+ pins of the chip respectively.

11.5 Transaction Layer

PCI Local Bus Specification, Revision 3.0 defines a field in the header called the Transaction Descriptor. This descriptor comprises three sub-fields:

- Transaction ID
- Attributes
- Traffic Class

11.5.1 Transaction ID

The Transaction ID uniquely identifies every transaction outstanding on the PCI Express interface. The Transaction ID comprises four sub-fields described in Table 11-4, "PCI Express Transaction ID Handling."

Table 11-4, "PCI Express Transaction ID Handling" provides details on how this field in the PCI Express header is populated by the SoC on the requests it issues on PCI Express (requests issued by core) and the completions it sends back on PCI Express.

Note: The SoC does not support Peer-to-Peer transactions between PCIe Root Ports.

Table 11-4. PCI Express Transaction ID Handling

Field	Definition	SoC as Requester	SoC as Completer
Bus Number	Specifies the Bus Number on which the Requester resides.	The SoC fills this field with its internal Bus Number that the PCI Express cluster resides on.	This field from the request is preserved and copied into the completion.
Device Number	Specifies the Device Number of the Requester.	The SoC fills this field with the Device Number that the root port owns.	
Function Number	Specifies the Function Number of the Requester.	The SoC fills this field with the Function Number that the root port owns.	
Tag	Identifies a unique identifier for every transaction that requires a Completion. Since the PCI Express ordering rules allow read requests to pass other read requests, this field reorders separate completions if they return from the target out-of-order.	• NP Tx: The SoC fills this field with a value such that every pending request carries a unique Tag. • NP Tag[7:5]=Note that bits 7:5 can be non-zero only when 8-bit tag usage is enabled. Otherwise, the SoC always zeros out 7:5. • NP Tag[4:0]=Any algorithm that guarantees uniqueness across all pending NP requests from the port. • P Tx: No uniqueness guaranteed. Forward from source port to destination for p2p posteds.	

11.5.2 Attributes

The Attributes field is used to provide additional information that allows modification of the default-handling of Transactions. Attributes are hints that allow for optimizations in the handling of traffic. PCI Express supports two attributes:

Table 11-5. PCI Express Attribute Handling

Attribute	Definition	PCIe SIP as Requester	PCIe SIP as Completer
Relaxed Ordering	Allows the system to relax some of the standard PCI ordering rules.	This bit is not applicable and set to zero for transactions that the PCIe SIP generates on PCIe on behalf of a request.	The PCIe SIP preserves this field from the request and copies it into the completion.
Snoop Not Respond	This attribute is set when an I/O device controls coherency through software mechanisms. This attribute is an optimization design to preserve processor snoop bandwidth		

For relaxed ordering, PCIe ports implements Downstream CPL relaxed ordering. For the cases where the No-Snoop attribute is set in the inbound TLP, it should be passed to the upstream block or root port and the request should be treated as non-coherent in the UnCore.

The PCI express ports support the “No Snoop Attribute” but there is no isochronous support.

11.5.3 Traffic Class

The SoC does not support any PCI Express Virtual Channels (VC) except for the default channel VC0. There is no Traffic Class (TC)-to-VC mapping capability structure. However, as per the PCI Express Base Specification, a completer must accept requests with a TC label other than TC0, and must preserve the TC label.

The SoC accepts inbound transactions with zero/non-zero TC, but it treats the non-zero TC as mapped to VC0 for inbound requests destined for memory. For completions heading upstream, the Root Port copies the TC value received into the completion packet. If the SoC receives a non-zero TC for any I/O or Configuration transaction, it is treated as a malformed TLP and the error-logged appropriately.

11.5.4 Completer ID

The CompleterID field is used in PCI Express completion packets to identify the completer of the transaction. The CompleterID comprises three sub-fields which are populated on a completion sent back on PCI Express, as described in Table below.

Table 11-6. PCI Express CompleterID Handling

Field	Definition	PCIe RP as Completer
Bus Number	Specifies the bus number om which the completer resides on.	PCIe RP fills this field with its internal Bus Number on which the port resides.
Device Number	Specifies the device number of the completer.	PCIe RP fills this field with its Internal Device Number.
Function Number	Specifies the function number of the completer.	PCIe RP fills this field with its Internal Function Number.

11.5.5 Transaction Ordering

Table 11-7 lists the combined set of ordering rules in the PCIe inbound paths of the root port.

Table 11-7. Transaction Ordering on PCIe Block

Row Pass Column	Message or Posted Wr (PR)	Rd or Configure Write or I/O Req (NPR)	Rd Completion	I/O or Configure Write Completion
Message or Posted Wr (PR)	No	Yes	Yes	Yes
Rd or Configure Write or I/O Req (NPR)	No	No	Yes[1]	Yes
Rd Completion	No	Yes	No	No
I/O or Configure Write Completion	No	Yes	No	No

1. When a completion is stalled, a subsequent read can be allowed to pass it.

11.5.6 PCI Express Port Arbitration

The SoC provides a normal, weighted (based on port width), round-robin method of arbitration amongst the eligible sources.

11.5.7 Request Splitting

The Transaction Layer Packet (TLP) Maximum Payload size is defined as 256 bytes for the PCI Express* Root Ports.

Each SoC Root Port splits Non-Posted Requests greater than 256 bytes at the 256-byte address boundary. This maximum-byte size of 256 is without regard to the target address. The expectation is, that for better performance, the target agent will provide the maximum payload-size completions. The Root Port implements completion tracking to assure that multiple completions for a greater-than 256-byte read are sent to the requester in addressed order.

Posted Requests in the Root Port have a length of up to the defined Maximum Payload Size of 256 bytes and are handled as normal TLPs.

11.5.8 Read Prefetching Policies

The Root Ports do not perform any outbound-read prefetching. They also do not perform any autonomous, speculative Prefetch on their inbound interfaces.

11.5.9 Read Completion Combining

The PCI Local Bus Specification, Revision 3.0 allows a single request to be satisfied with multiple "sub-completions" as long as the sub-completions return in linearly-increasing address order. Therefore, since the Root Ports must split requests into cacheline quantities before issuing them to the coherent interface, the Root Ports often complete a large request in cacheline-sized sub-completions.

As a performance optimization, the Root Port implements an opportunistic read-completion combining algorithm. When the downstream PCI Express* interface is busy (for example, with another transaction) and multiple cachelines have returned before completion on PCI Express is possible, the PCI Express interface combines the cacheline sub-completions into larger quantities up to defined Maximum Payload size.

11.5.10 Write Combining

The Root Ports do not support any outbound write combining.

Potentially, inbound memory writes to the system DDR SDRAM could be combining in the Root Port Write of the coherent interface.

11.6 Interrupt Support

The PCIe Root Port supports both Message Signaled Interrupt (MSI) and in-band legacy interrupt mechanisms. The PCIe Root Port can generate an in-band legacy interrupt request on PCI Express for boot devices and for systems that do not support MSI.

11.6.1 Legacy Interrupt Sharing

PCI Express provides interrupt messages that emulate the legacy wired mechanism.

This feature allows I/O devices to signal PCI-style interrupts using a pair of ASSERT and DEASSERT messages. This message pairing preserves the level-sensitive semantics of the PCI interrupts on PCI Express.

The four virtual wire interrupts (INTA–INTD) correspond to the four interrupt wires defined in the PCI Local Bus Specification, Revision 3.0. The switch routes its interrupts messages from the downstream ports to the upstream ports interrupts as shown in Table below.

Table 11-8. Bridge Mapping for Interrupt Virtual Wires

Device #	Interrupt Message on Port	Interrupt Message on the Upstream Port
0, 4, 8, 12, 16, 20, 24, 28	INTA#	INTA#
	INTB#	INTB#
	INTC#	INTC#
	INTD#	INTD#
1, 5, 9, 13, 17, 21, 25, 29	INTA#	INTB#
	INTB#	INTC#
	INTC#	INTD#
	INTD#	INTA#
2, 6, 10, 14, 18, 22, 26, 30	INTA#	INTC#
	INTB#	INTD#
	INTC#	INTA#
	INTD#	INTB#
3, 7, 11, 15, 19, 23, 27, 31	INTA#	INTD#
	INTB#	INTA#
	INTC#	INTB#
	INTD#	INTC#

The switch tracks the INTx messages from each port independently and presents a collapsed INTx message on the upstream port. For example, each INTx message from the downstream ports are ORed together and presented upstream as a single INTx message. The switch uses its upstream port primary bus number and device number in the Requester ID field for the PCI Express INTx messages. As stated in the PCI Local Bus Specification, Revision 3.0, the function number is reserved for interrupt messages and is always 0.

11.7 Power Management

11.7.1 Hardware Controlled Active Power Management

PCI Express Base Specification defines a HW-initiated power management of the PCIe link called the active state power management (ASPM). Under hardware control, the link can be put into a low-power L0s state or an even lower power L1 link state. Latency to recover from L0s back to L0 (active link state) is smaller than that of recovery from L1 to L0. The PCIe Root Port supports both ASPM link states L0s and L1. ASPM is totally traffic dependent and is not initiated by software. But the software could either enable or disable the active state management via the PCIe Express capability structure.

11.7.2 PCI-PM 1.2 Support

The PCI Express Root Port supports PCI Express link states required to implement PCI_PM 1.2 compatible device states (D0, $D3_{HOT}$, $D3_{COLD}$). These states correspond to PCI Express link states L0, L1, and L3. When all the root ports and the IOxAPIC are programmed to $D3_{HOT}$ state, the upstream link of the switch automatically transitions to the link state L1. The switch also supports the PME_Turn_Off/PME_TO_Ack handshake protocol to enter the $D3_{COLD}$/L3 device/link states.

Each function (upstream port, downstream ports, and IOxAPIC) behaves as follows when in the $D3_{HOT}$ state:

- The function responds to Configuration cycles on UpStream PCIe ports
- The function does not respond to Memory Cycles on UpStream PCIe ports except for completions
- The function does not respond to I/O cycles on UpStream PCIe ports except for completions
- The function does not initiate UpStream PCIe port transactions
- The function does not reset its registers when programmed from D0 to $D3_{HOT}$

Note: When a downstream port is in the $D3_{HOT}$ state, a Hot-Plug event on that port must generate a PME event since the port is unable to generate an interrupt. Software needs to setup the Hot-Plug to generate a wake event instead of interrupts when the port is in $D3_{HOT}$ state.

11.7.3 Power Management Event Signaling

PCIe Root Port supports Active State Power Management (ASPM) transitions into L0s and L1 state. L0p state is not supported by the SoC.

Also, the PCIe Root Port supports the D0 and D3hot power management states per PCI Express port and also supports a wake event from these states on a PCI Express Hot-Plug event. In D3hot, the root port will master abort all configuration transactions targeting the PCI Express link.

PME signaling in PCI-Express accomplishes two distinct functions:

- Firstly, it provides a signaling mechanism for devices requiring service to propagate a wake-up request to the power management controller.
- Secondly, it provides a messaging mechanism for devices requesting a power state change to pass their unique location within the PCI Express hierarchy to the power management controller.

The combination of these two functions provides great flexibility and controllability for the power manager.

11.7.4 Beacon and WAKE# Signaling

At the link level, the PCI Local Bus Specification, Revision 3.0 describes two optional mechanisms used by components to request the reapplication of main power (transition to the fully-operative L0 state) when in the low-power L2 Link state:

- Beacon (using in-band signaling):
  - — Not supported by the Root Ports.
- WAKE# (using sideband signaling):
  - — Supported by the Root Ports through the signal pin WAKE_B.

11.7.5 Non-D0 State PM Handling

The Non-D0 and Bus Master Enable (BME) state requirements are as follows:

11.7.5.1 Non-D0 Behavior for Transmit (Tx) Transactions

- Memory and I/O requests are treated as Unsupported Request (UR) completions
- Memory or I/O requests that require response get a UR response (internally generated)
- Type0 Cfg requests proceed normally for Downstream Port (of an Upstream Component)
- Type0 Cfg requests are treated as URs (completion w/ UR response) for Upstream Port (of an Downstream Component)
- Type1 Cfg are treated as URs (completion w/ UR response)
- Messages and completions are unaffected by device states

11.7.5.2 Non-D0 Behavior for Receive (Rx) Transactions

- Memory and I/O requests are treated as URs
- Memory or I/O requests that require response get an UR response (internally generated)
- Type0 Cfg request is treated as URs (completion w/ UR response) for Downstream Port (of an Upstream Component)
- Type0 Cfg request proceeds normally for Upstream Port (of an Downstream Component)
- Type1 Cfg is treated as URs (completion w/ UR response)
- Messages and completions are unaffected by device states

When the Upstream port is programmed to the non-D0 state, it should initiate its Upstream PCIe link to the transition to PCI-PM L1 state when all conditions are met.

The transition of a PCIe of a Virtual Bridge (such as a root port) from D3hot state to D0 because of a powerstate command will not cause an internal soft reset and this is indicated by setting the No_Soft_Reset bit3 (RO) of PMCSR register.

11.7.6 BME Clear State Handling

In BME (=1) set state, all transactions are treated as normal.

11.7.6.1 BME (=0) Clear State Behavior for Transmit (Tx) Transactions

- Downstream Port (of an Upstream Component)
  - All transmit transactions are treated as normal and behavior is unaffected by BME bit state
- Upstream Port (Downstream Component)
  - Memory, I/O requests are treated as URs
  - Configuration, Messages and completions are treated as normal and behavior is unaffected by BME bit state
  - All requests that require response get an UR response (internally generated)

11.7.6.2 BME (=0) Clear State Behavior for Receive (Rx) Transactions

- Downstream Port (of an Upstream Component)
  - Memory, I/O requests are treated as URs
  - Configuration, Messages and completions are treated as normal and behavior is unaffected by BME bit state
  - All requests that require response get an UR response (internally generated)
- Upstream Port (of an Downstream Component)
  - All transmit transactions are treated as normal and behavior is unaffected by BME bit state

11.7.6.3 Internal MSI/Error Messages During Non-D0/BME (clear)

- MSIs generated internally are blocked when in non-D0 and BME (clear).
- MSIs generated internally in non-D0 with BME = 1 (for example, a completion timeout or an MSI due to PME event) should be allowed to propagate but after the port is reinitialized back to D0. There should be no loss of interrupts.
- MSIs received at the root port or in the switch port from external sources should be blocked (UR) when non-D0.
  Assumption: PCI configuration software should place the downstream component in non-D0 first and then the upstream components. There should be no MSI writes received at the upstream component under these conditions and if any spurious MSIs do arrive, they will be master aborted.
- INTx, VLW and ERR messages should not be blocked.

11.7.6.4 L1 PM Substates

PCIe supports the optional PM L1 Substates including L1.1 and L1.2,where L1.1 is hardware autonomous without Software intervention and L1.2 may require Software not to access device for longer period, which allow for dramatically lower idle power, including near complete removal of power for high speed circuits. The L1 PM Substates are applicable in both the ASPM and PCI-PM L1 Link states and the entrance and depth is constrained by aggregated PCIe LTR.

11.8 PCI Express RAS Features

The PCI Local Bus Specification, Revision 3.0 supports PCI Express Advanced Error Reporting (AER) capability.

11.8.1 End-to-End CRC (ECRC) Support

PCIe End to End CRC (ECRC) is the CRC field generated by a device and is appended to the TLP to protect the data through layers of switches and bridges.

For inbound traffics, PCIe Root Ports support ECRC checking and will strip the ECRC if no error is detected. The corresponding TLP will be dropped and logged UC if an error is detected. ECRC error severity should be set to non-fatal in the Uncorrectable Error Severity Register during initialization.

For outbound traffic, PCIe Root Ports will generate ECRC based on AER Capabilities and Control Register (AERCAPCTL), and insert ECRC to the packet prior to forwarding to the PCIe link. Refer to PCI Local Bus Specification, Revision 3.0 for more details of ECRC generation rules.

11.8.2 Completion Timeout

For all non-posted requests that the PCIe Root Port issues, the PCIe maintains a timer that times the max completion time for that request.

The PCIe Root Port follows the timeout mechanism as defined in the PCI Express Base Specification. The spec provides a way for the OS to select a coarse range for the timeout value. The PCIe root port chooses a final value of the timeout within each coarse range. The timeout value is programmable from 50 ms all the way up to 64s.

Refer to Chapter 6, "Reliability, Availability and Serviceability (RAS)" for details of responses returned by the PCIe Root port to various interfaces on a completion timeout event. AER-required error logging and escalation happen as well.

11.8.3 Data Poisoning

The PCI Express Root Ports support forwarding poisoned information between the coherent interface and the PCIe link, and vice-versa. Also, forwarding poisoned data between peer PCIe ports is supported. The PCIe has a mode where poisoned data is never sent out on PCI Express, in other words, any packet with poisoned data is dropped internally in the root port and an error escalation done.

11.8.4 Role-based Error Reporting

The PCIe Root Port supports the new role-based error reporting that is specified in the PCI Local Bus Specification, Revision 3.0.

When the PCIe Root Port times out or receives a UR/CA response on a request outstanding on PCI Express, it does not attempt recovery in hardware. The UR/CA received does not cause any error escalation via AER mechanism and causes error escalation only via the IO module-specific mechanism. The PCIe Root Port would forward those to the ultimate destination. Also, the PCIe Root Port would treat the completion timeout condition as a normal non-fatal error condition (and not as an advisory condition).

The PCIe Root Port also treats an unexpected completion it receives from PCI Express port as an advisory non-fatal error if the severity of it is set to non-fatal. If the severity is set to fatal, then unexpected completions are NOT treated as advisory but as fatal.

When the PCIe Root Port detects a UR/CA condition on a non-posted request it received from PCIe link, it treats the error as advisory error if the severity of UR/CA is set to non-fatal, and send a UR/CA completion back to the device. Note that a UR/CA condition detected on a posted request that the PCIe Root Port received from the PCIe link is treated as normal non-fatal error with the appropriate escalation/logging.

11.9 PCI Express Hot-Plug Surprise

PCIe Root Port Hot-Plug slot capability is supported mainly through software stacks by setting Hot-Plug related CSRs for handling Hot-Plug events such as in-band presence detect. It does not utilize any mechanical or electromechanical features such as MRL/sensor/EM interlock/ Attention button, etc.

The Hot-Plug Surprise slot capability involves a device that is inserted into or removed from a running system without prior notification to the system. It is not an orderly operation and could cause undesirable effects to the running system. The general expectation from hardware and software is to avoid Hot-Plug error event propagating into a catastrophic system event.

In general, all outstanding Non-posted request should synthesize a Master Abort to avoid completion timeout and suppress catastrophic AER storm whenever applicable. En-queued inbound traffic at the port upstream to the device must complete normally in the event of a Surprise Removal. PME_Turn_Off handshake and VDM should be terminated appropriately plus discarding all other posted & completion requests.

The Hot-Plug Surprise event is limited to the link transitions back to L0, in other words, software may need to wake up periodically during low power states accordingly. To handle the L1 inband Hot-Plug Surprise case, the link will not be allowed to train until the SLOTSTS.PDCS has been cleared by software to avoid hot-add interrupt from being merged with the hot-removal interrupt.

11.9.1 PCI Express Hot-Plug Interrupts and Events

11.9.1.1 Presence Detect

When a module is plugged in and power is supplied, the physical layer will detect the presence of the device, and the downstream port sets SLOTSTS.PDS and SLOTSTS.PDCS. If SLOTCTL.PDCIE and SLOTCTL.HPIE are both set, the downstream port will also generate an interrupt. When a module is removed through physical layer detection, the downstream port clears SLOTSTS.PDS and sets SLOTSTS.PDCS. If SLOTCTL.PDCIE and SLOTCTL.HPIE are both set then the downstream port will also generate an interrupt. The interrupt is generated on an edge-event. For example, if SLOTSTS.PDCS is already set, a change in SLOTSTS.PDS will not generate a new interrupt. Only SLOTSTS.PDCS going from `0 to `1 will cause an interrupt to be generated.

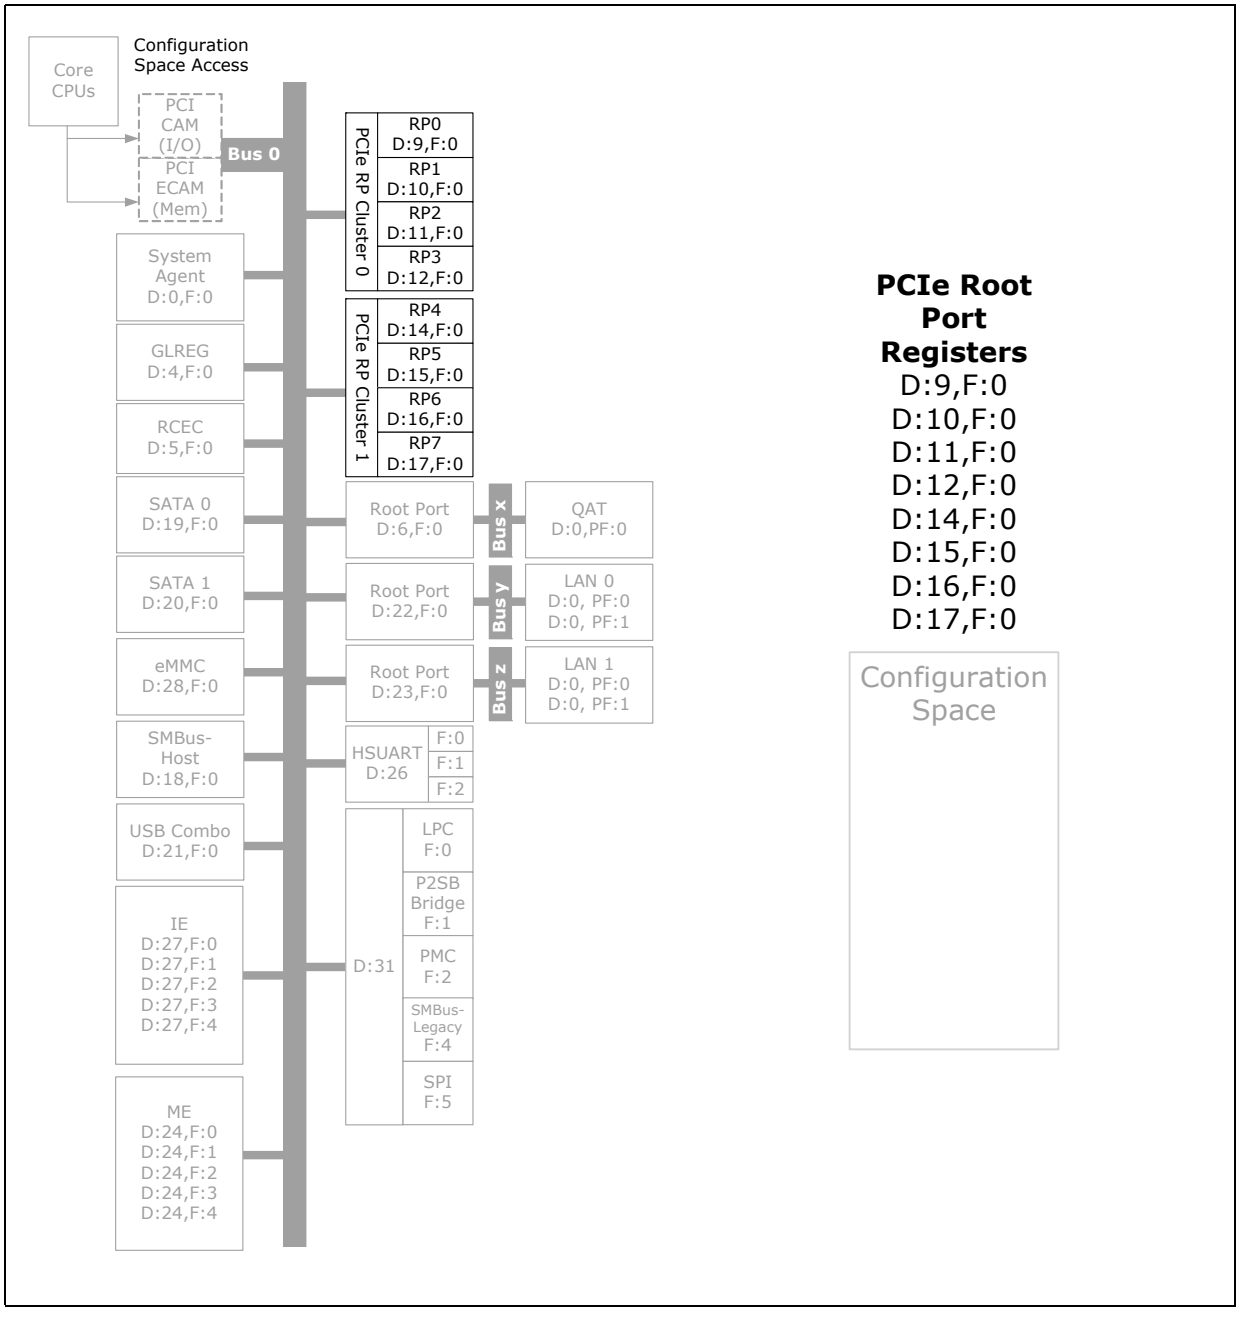
11.9.1.2 SCI/SMI Generation

When a module is plugged in and power is supplied, the physical layer will detect the presence of the device, and the downstream port sets SLOTSTS.PDS and SLOTSTS.PDCS. If SLOTCTL.PDCIE and SLOTCTL.HPIE are both set, the downstream port will also generate an interrupt. Similarly, PCIe Root Port could generate SCI/SMI based on PM_PME message received from downstream PCIe devices.

11.10 Register Map

Figure 11-3, "Register Map" shows the associated registers from a system software viewpoint.

Figure 11-3. Register Map



§ §

12 SATA Controller

The SoC has two independent integrated SATA 3.1 host controllers (SKU dependent). Each controller supports DMA operation on up to eight ports and supports data transfer rates of up to 6 Gbps (600 MBps). Legacy data transfer rates of 3 Gbps and 1.5 Gbps are supported as well. Serial General Purpose Input Output (SGPIO) support is added in this generation and support is per the SFF 8485 specification.

Note: Legacy and Native IDE are not supported in this generation.

Figure 12-1. What is Covered in This Chapter

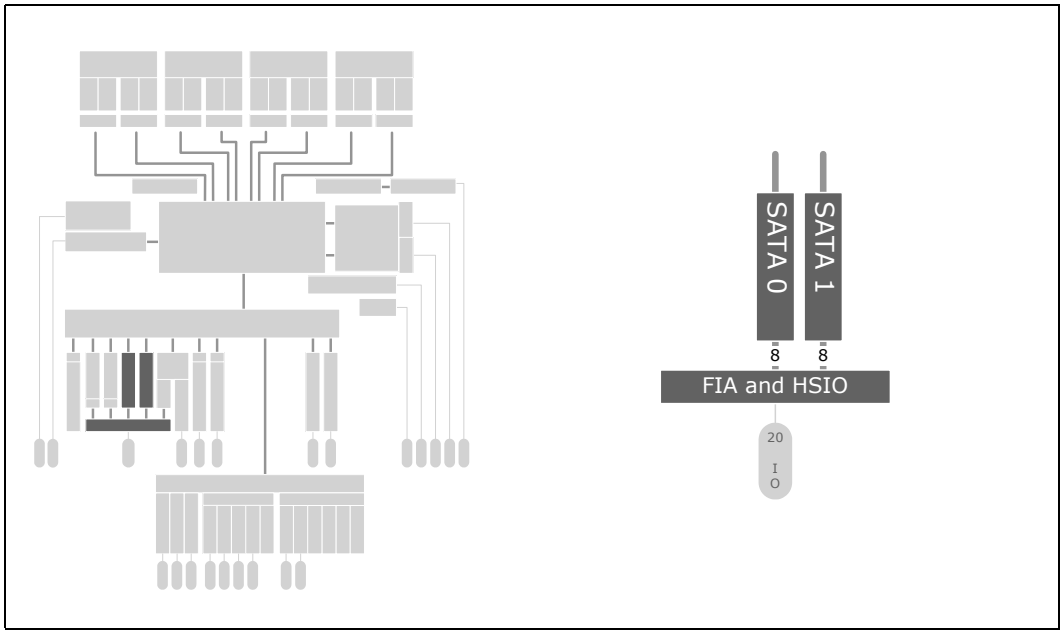


Table 12-1. References

Reference	Revision	Date	Document Title

AHCI Specification	1.3.1	June 2008	*Serial ATA Advanced Host Controller Interface (AHCI) Specification, Rev 1.3.1*
SFF-8485	0.7	Feb. 1, 2006	*SFF-8485 Specification for Serial GPIO (SGPIO) Bus*, Revision 0.7

12.1 Signal Descriptions

The signal descriptions are shown in Table 12-2. For additional signal information, including whether a signal is assigned to shared-function pin or can be used as a Customer GPIO signals see Section 39.1, "Directory of Signal Names and Pin Names" on page 993. Also, see Table 39-3, "Signals that Share the Twenty HSIO Lanes" on page 1028. The Direction/Type column of Table 12-2 is interpreted as follows:

- I = Input signal. The SoC has receiver circuit.
- O = Output signal. The SoC has driver circuit.
- O-OD = Open-Drain Output. SoC output circuit uses an open-drain driver.
- Differential = Differential signal pair. Two pins: Positive; Negative.

Table 12-2. Signal Names and Descriptions

Signal Names	Direction	Shared	Description
SATA Controller 0			
SATA0_TX_DP[7:0] SATA0_TX_DN[7:0]	O, Differential	Yes	SATA0 Transmitter: These differential output signals are internal to the SoC. They are at the SATA0 controller interface with the FIA circuitry.
SATA0_RX_DP[7:0] SATA0_RX_DN[7:0]	I, Differential	Yes	SATA0 Receiver: These differential input signals are internal to the SoC. They are at the SATA0 controller interface with the FIA circuitry.
SATA0_SLD	O-OD	Yes	SATA0 SGPIO Load: This is the SGPIO SLoad signal. During power-up and reset, this pin is 1 (high impedance). When using the SGPIO bus but purposely not exchanging a bit stream, the SoC sets SLoad to 0. This lets the target know that the initiator (the SoC) is still present and has not been removed.
SATA0_SCLK	O-OD	Yes	SATA0 SGPIO Clock: This is the 32-kHz SGPIO SClock signal. During power-up and reset, this pin is 1 (high impedance). When using the SGPIO bus but purposely not exchanging a bit stream, the SoC sets SClock to 0.
SATA0_SDOUT	O-OD	Yes	SATA0 SGPIO Data Out: This is the SGPIO SDataOut signal. During power-up and reset, this pin is 1 (high impedance).
SATA0_LED_N	O-OD	Yes	Open drain output pin driven during SATA command activity. It is to be connected to external circuitry that can provide the current to drive platform LED. When active, the LED is on. When inactive, the LED is off. An external pull-up resistor is required.
SATA_PDETECT[1:0]	I	Yes	Mechanical Presence Detect: This input signal is called Mechanical Presence Switch in the AHCI Specification: • SATA_PDETECT[0] - SATA Controller 0, Port 0 (FIA/HSIO Lane 4) • SATA_PDETECT[1] - SATA Controller 0, Port 1 (FIA/HSIO Lane 5)
SATA Controller 1			
SATA1_TX_DP[7:0] SATA1_TX_DN[7:0]	O, Differential	Yes	SATA1 Transmitter: These differential output signals are internal to the SoC. They are at the SATA1 controller interface with the FIA circuitry.
SATA1_RX_DP[7:0] SATA1_RX_DN[7:0]	I, Differential	Yes	SATA1 Receiver: These differential input signals are internal to the SoC. They are at the SATA1 controller interface with the FIA circuitry.
SATA1_SLD	O-OD	Yes	SATA1 SGPIO Load: This is the SGPIO SLoad signal. During power-up and reset, this pin is 1 (high impedance). When using the SGPIO bus but purposely not exchanging a bit stream, the SoC sets SLoad to 0. This lets the target know that the initiator (the SoC) is still present and has not been removed.
SATA1_SCLK	O-OD	Yes	SATA1 SGPIO Clock: This is the 32-kHz SGPIO SClock signal. During power-up and reset, this pin is 1 (high impedance). When using the SGPIO bus but purposely not exchanging a bit stream, the SoC sets SClock to 0.
SATA1_SDOUT	O-OD	Yes	SATA1 SGPIO Data Out: This is the SGPIO SDataOut signal. During power-up and reset, this pin is 1 (high impedance).
SATA1_LED_N	O-OD	Yes	Open drain output pin driven during SATA command activity. It is to be connected to external circuitry that can provide the current to drive platform LED. When active, the LED is on. When inactive, the LED is off. An external pull-up resistor is required.

12.2 Feature List

- Complies to SATA specification rev 3.1
- Complies AHCI specification rev 1.3.1
- Supports Native Command Queuing. Up to 32 commands can be queued
- Supports Staggered Spin-up
- Supports Aggressive Link Power Management
- Activity LED support via SGPIO
- Enclosure Management support
- Supports Command based Port Multiplier
- Supports Hot-Plug operation
- Supports MSI and MSI-X interrupts.

12.3 Architectural Overview

There are two independent SATA controllers. Both controllers support up to SATA Gen3 (SKU dependent) traffic speeds of 6 Gbps and are backward compatible to Gen2 and Gen1 speeds. Software mode is supported; this mode requires specific OS device driver support. IDE support is not available. The SoC enables SGPIO support, this is to enable and manage target device LED control. Enclosure management support is also available. SoC also has two dedicated pins for LED activity. SATA0_LED_N and SATA1_LED_N can be employed if a single drive is populated on SATA controller 0 and 1.

Each SATA controller has the following PCI capabilities:

- PCI Power Management Interface Capability
- Message Signaled Interrupts (MSI) Capability
- Extended MSI (MSI-X) Capability
- Serial ATA Capability

Note: The SATA controller configuration registers have default values that do not include the MSI-X Capability in the Capabilities List. BIOS must alter the Capabilities List links to include the MSI-X Capability which is located at offset D0h of each controller Configuration Space.

Note: If your design uses the SoC SATA then one of the following has to be met:

1. HSIO lane 16, 17, 18 or 19 must be assigned to the xHCI controller and the xHCI controller must be enabled and visible as a PCI device.

   OR

2. A PCIe Root Port Cluster must be enabled and visible as a PCI device. There is no requirement to assign any HSIO lanes to the PCIe Root Port.

12.4 AHCI Operation

Each controller supports up to 8 ports and each port can support up to 32 commands. A total of 256 commands can be pending at an instance per controller, a total 512 commands across controllers.

For AHCI operation details, refer to the *Serial ATA Advanced Host Controller Interface (AHCI) Specification, Rev 1.3.1*.

12.4.1 Staggered Spin Up Support

A staggered spin up feature enables a controller to individually spin up attached devices. This mechanism is useful to avoid having a power supply, needing to apply power to all the devices, while handling maximum current draw from all devices at the same time. In order for a system to support staggered spin up, the SATA controller, BIOS and device driver must all support staggered spin up.

Staggered spin-up is controlled by software via sequencing of COMRESET signaling. The table below summarizes the operations of SATA controller in AHCI mode. Refer to the *Serial ATA Advanced Host Controller Interface (AHCI) Specification, Rev 1.3.1* for more details on AHCI staggered spin up.

Table 12-3. SATA Controller Operations Summary

PCS.PxE	CAP.SSS	PxCMD.SUD	Result
0	X	X	No COMRESET and no spin up
1	X	X	COMRESET and spin up
0	X	X	No COMRESET and no spin up
1	0	0	This is not a valid combination. When CAP.SSS is 0, PxCMD.SUD must be 1
1	0	1	COMRESET and spin up
1	1	0	No COMRESET and no spin up
1	1	1	COMRESET and spin up

12.4.2 Staggered Spin-up Operation in AHCI Mode

Device Driver/BIOS to perform following actions

1. Programming ABAR.
2. Configure controller in AHCI mode by setting AHCI GHC.AE bit.
3. Set AHCI CAP.SSS to indicate staggered spin up support.
4. Set PCS.PxE bits.
5. Set PxCMD.SUD bits, this will result in COMRESET to be issued to the all the enabled ports.

12.4.3 Interrupts

12.4.3.1 Interaction Between INTx# and MSI/MSI-X

When MSI is enabled via MMC.MSIE=1, INTx# interrupt is disabled regardless of the setting of the PCI CMD.ID bit. The state of the CMD.ID bit does not affect MSI and MSI-X generation. This is shown the table below.

Table 12-4. Interaction Between INTx# and MSI

CMD.ID	MMC.MSIE/MXC.MXE	INTX# Assertion	MSI/MSI-X Generation
0	0	Yes	No
0	1	No	Yes
1	0	No	No
1	1	No	Yes

12.4.4 Power Management

The SATA Host Controller supports the PCI specification and the SATA PCI specification defined power states. See section 8 of the *Serial ATA Advanced Host Controller Interface (AHCI) Specification, Rev 1.3.1*. This controller also implements specific power management like clock and power gating.

Once BIOS enables the clock gating during the boot process, this is fully hardware autonomous and requires no software intervention.

12.4.5 Automatic Transition of Partial to Slumber

This feature is supported per the AHCI specification.

12.4.6 Enclosure Management and Activity LED

The Enclosure management is supported per the *Serial ATA Advanced Host Controller Interface (AHCI) Specification, Rev 1.3.1*. LED support is per the SFF 8485 specification.

The SAF-TE, SES-2 and SGPIO message formats are defined in the corresponding specifications.

Note: When SGPIO is enabled it will always send 8 ports worth of messages.

12.5 Register Map

Figure 12-2 shows the associated registers from a system software viewpoint.

§ §

13 LAN Controllers

There are two SoC LAN controllers (LAN0 and LAN1) with two ports each, providing a total of four ports. Each port contains an independent LAN Media Access Control (MAC) that supports a XGMII-like interface link to an internal PHY (see Figure 13-1).

The internal MAC/PHY combine to support 1GbE (KX and SGMII), 2.5GbE and 10GbE operation through various modes of operation.

Refer to Section 13.2, "Supported Modes of Operation" on page 415 for all supported modes of Ethernet for use with internal PHYs (native support) and external PHYs.

13.1 Signal Descriptions

The signal descriptions are shown in Table 13-2, "Signal Names and Descriptions". For additional signal information, including whether a signal is assigned to a shared-function pin or can be used as a Customer GPIO signal see Section 39.1, "Directory of Signal Names and Pin Names". The Direction/Type column of Table 13-2, "Signal Names and Descriptions" is interpreted as follows:

- I = Input signal. The SoC has receiver circuit.
- O = Output signal. The SoC has driver circuit.
- O-OD = Open-Drain Output. SoC output circuit uses an open-drain driver.
- Differential = Differential signal pair. Two pins: Positive; Negative.

Table 13-2. Signal Names and Descriptions (Sheet 1 of 3)

Signal Names	Direction	Shared	Description
LAN Ports 0 and 1 - LAN Controller 0			
LAN0_PORT0_I2C_CLK	I,O-OD	Yes	**I^2C Clock:** The 2-wire management interface Clock used to access the management registers of an external optical module of port n. One clock pulse is generated for each data bit transferred.
LAN0_PORT0_I2C_DATA	I,O-OD	Yes	**I^2C Data:** The Data of the 2-wire management interface used to access the management registers of an external optical module of port n. Stable during the clock high period (unless it is a start or stop condition).
LAN0_PORT0_LED[3:0]	O-OD	Yes	**LED Drivers:** Four LED drivers for this LAN Port.
LAN0_PORT0_SDP[3:0]	I,O	Yes	**Software Defined Pins:** Four general-purpose SDPs for this LAN Port, can be used to support IEEE1588 auxiliary devices or input for external interrupts.
LAN0_PORT0_RX_DP LAN0_PORT0_RX_DN	I, Differential	No	**PHY Differential Input:** This lane is used in 10GBASE-KR, 1000BASE-KX, 2.5G and SFI.
LAN0_PORT0_TX_DP LAN0_PORT0_TX_DN	O, Differential	No	**PHY Differential Output:** This lane is used in 10GBASE-KR, 1000BASE-KX, 2.5G and SFI.
LAN0_PORT1_I2C_CLK	I,O-OD	Yes	**I^2C Clock:** The 2-wire management interface Clock used to access the management registers of an external optical module of port n. One clock pulse is generated for each data bit transferred.
LAN0_PORT1_I2C_DATA	I,O-OD	Yes	**I^2C Data:** The Data of the 2-wire management interface used to access the management registers of an external optical module of port n. Stable during the high period of the clock (unless it is a start or stop condition).
LAN0_PORT1_LED[1:0]	O-OD	Yes	**LED Drivers:** Two LED drivers for this LAN Port.
LAN0_PORT1_SDP[3:0]	I,O	Yes	**Software Defined Pins:** Four general-purpose SDPs for this LAN Port. Can be used to support IEEE1588 auxiliary devices or input for external interrupts.
LAN0_PORT1_RX_DP LAN0_PORT1_RX_DN	I	No	**PHY Differential Input:** This lane is used in 10GBASE-KR, 1000BASE-KX, 2.5G,100 Mb/s full duplex, 10 Mb/s full duplex, and SFI.
LAN0_PORT1_TX_DP LAN0_PORT1_TX_DN	O	No	**PHY Differential Output:** This lane is used in 10GBASE-KR, 1000BASE-KX, 2.5G,100 Mb/s full duplex, 10 Mb/s full duplex, and SFI.
LAN0_RBIAS	I,O	No	**Bias Resistor:** External resistor bias input. The platform board must provide a 1000 Ω, 0.10% resistor connected from this pin to VCCKR0LCPLL_LV. Intel recommends shielding the trace to this pin.

Table 13-2. Signal Names and Descriptions (Sheet 2 of 3)

Signal Names	Direction	Shared	Description
LAN Ports 0 and 1 - LAN Controller 1			
LAN1_PORT0_I2C_CLK	I,O-OD	Yes	**I²C Clock:** The Clock of the 2-wire management interface used to access the management registers of an external optical module of port n. One clock pulse is generated for each data bit transferred.
LAN1_PORT0_I2C_DATA	I,O-OD	Yes	**I²C Data:** The Data of the 2-wire management interface used to access the management registers of an external optical module of port n. Stable during the high period of the clock (unless it is a start or stop condition).
LAN1_PORT0_LED[1:0]	O-OD	Yes	**LED Drivers:** Two LED drivers for this LAN Port.
LAN1_PORT0_SDP[1:0]	I,O	Yes	**Software Defined Pins:** Two general-purpose SDPs for this LAN Port. Can be used to support IEEE1588 auxiliary devices or input for external interrupts.
LAN1_PORT0_RX_DP LAN1_PORT0_RX_DN	I, Differential	No	**PHY Differential Input:** This lane is used in 10GBASE-KR, 1000BASE-KX, 2.5G and SFI.
LAN1_PORT0_TX_DP LAN1_PORT0_TX_DN	O, Differential	No	**PHY Differential Output:** This lane is used in 10GBASE-KR, 1000BASE-KX, 2.5G and SFI.
LAN1_PORT1_I2C_CLK	I,O-OD	Yes	**I²C Clock:** The Clock of the 2-wire management interface used to access the management registers of an external optical module of port n. One clock pulse is generated for each data bit transferred.
LAN1_PORT1_I2C_DATA	I,O-OD	Yes	**I²C Data:** 2-wire management interface data used to access the management registers of an external optical module of port n. Stable during high period of clock (unless it is a start or stop condition).
LAN1_PORT1_LED[1:0]	O-OD	Yes	**LED Drivers:** Two LED drivers for this LAN Port.
LAN1_PORT1_SDP[1:0]	I,O	Yes	**Software Defined Pins:** Two general-purpose SDPs for this LAN Port, can be used to support IEEE1588 auxiliary devices or input for external interrupts.
LAN1_PORT1_RX_DP LAN1_PORT1_RX_DN	I, Differential	No	**PHY Differential Input:** This lane is used in 10GBASE-KR, 1000BASE-KX, 2.5G and SFI.
LAN1_PORT1_TX_DP LAN1_PORT1_TX_DN	O, Differential	No	**PHY Differential Output:** This lane is used in 10GBASE-KR, 1000BASE-KX, 2.5G and SFI.
LAN1_RBIAS	I,O	No	**Bias Resistor:** External resistor bias input. The platform board must provide a 1000 Ω, 0.10% resistor connected from this pin to VCCKR1LCPLL_LV. Intel recommends shielding the trace to this pin.
Signals Common to LAN Controllers 0 and 1			
LAN_MDC	O	Yes	**Management Clock:** Clock output for accessing the external PHYs management registers.
LAN_MDIO	I,O-OD	Yes	**Management Data:** Bi-directional signal for serial data transfers between MAC and the external PHY.
SMB_LAN_DATA	I,O-OD	Yes	**SMBus Data:** Stable during the high period of the clock (unless it is a start or stop condition).
SMB_LAN_CLK	I,O-OD	Yes	**SMBus Clock:** One clock pulse is generated per data bit transferred.
SMB_LAN_ALRT_N	I,O-OD	Yes	**SMBus Alert:** Acts as an interrupt pin of a slave device on the SMBus.
NCSI_ARB_IN	I	Yes	**NC-SI Arbitration In:** Along with NCSI_ARB_OUT, this signal provides hardware-based arbitration when multiple Network Controllers are used. The SoC provides an internal 20-kΩ pull-down resistor.
NCSI_ARB_OUT	O	Yes	**NC-SI Arbitration Out:** Along with NCSI_ARB_IN, this signal provides hardware-based arbitration when multiple Network Controllers are used.

Table 13-2. Signal Names and Descriptions (Sheet 3 of 3)

Signal Names	Direction	Shared	Description
Signals Common to LAN Controllers 0 and 1 (continued)			
NCSI_CLK_IN	I	Yes	**NC-SI Reference Clock Input:** Synchronous clock reference for receive, transmit, and control interface. It is a 50 MHz clock ±100 ppm. The SoC provides an internal 20-kΩ pull-up resistor.
NCSI_CRS_DV	O-Tri	Yes	**Carrier Sense/Receive Data Valid:** Tri-state output signal to the MC. Indicates that the data transmitted from the SoC to the MC is valid. If this signal is used, the platform board must provide a pull-up resistor when the output signal is in the high-impedance state.
NCSI_RXD[1:0]	O-Tri	Yes	**MC Receive Data:** Tri-state output data signals from the SoC LAN controllers to the MC. The SoC provides an internal 20-kΩ pull-up resistor for each output signal.
NCSI_TX_EN	I	Yes	**MC Transmit Enable:** Indicates received data from the MC is valid.
NCSI_TXD[1:0]	I	Yes	**MC Transmit Data:** Data signals from the MC to the SoC LAN controllers.

Note: The SoC LAN controllers only have one SMBus and one NC-SI bus associated with all LAN ports. Both the SMBus and NC-SI can be used simultaneously by the platform board design provided that both sets of signals are configured.

13.2 Supported Modes of Operation

The SoC LAN controllers support speeds of 2.5 GbE[1], 1 GbE, and 10 GbE, as well as 10/100 Mb/s in only full-duplex mode.

There are two SoC LAN controllers (LAN0 and LAN1) with two ports each, providing a total of four ports.

LAN Controller 0 will be enabled for product SKU that only has two ports.

For product SKU with LAN controller 0 and LAN controller 1 if SOC Ethernet is used LAN controller 0 must be enabled.

For each port, there are options to use internal PHYs supporting:

- 10GBASE-KR
- SFI
- 1000BASE-KX
- 2500BASE-X

There are also options to connect to external PHYs via:

- 10GBASE-KR
- 1000BASE-KX
- SGMII is supported for Full Duplex 10 Mb/s, 100 Mb/s and 1 GbE

Each integrated I/O interface block provides the following physical interfaces and electrical modes:

- 10GbE PHY supports:
  - 10GBASE-KR for backplane applications (IEEE802.3 clause 72)
  - 10GBASE-KR FEC (IEEE 802.3 Clause 74)
  - 1000BASE-KX for backplane applications (IEEE802.3 clause 70)
  - Auto-negotiation for backplane Ethernet (IEEE 802.3 Clause 73)
  - SFI compatible interface to: SFP+[2] (SFF8431)
  - KR to 10GBASE-T PHY (Intel® X557-AT2/AT4 LAN PHY)

Note: No support for BASE-T SFP modules.

Note: No support for half duplex at 10 Mb/s, 100 Mb/s, 1 GbE, 2.5 GbE or 10 GbE.

Note: LAN port topologies must be the same for each respective LAN, for example, Ports 0 and 1 of LAN0 must be the same Ethernet mode. However, LAN 0 and LAN 1 can support different topologies as long as care is given to the trace layout. Due to the cross-talk requirements, there is no mixing of DAC (Direct-Attached-Cable) and Optical modules on ports 0 and 1 of the same LAN when using an SFI (native) design.

1. Auto-negotiation is not supported in 2.5 GbE. Auto-negotiate is supported in all other modes.
2. Some system designs might require adding a InPhi* CS4227(dual port)/CS4223 (quad port) re-timer PHY between the SoC and the SFP+ module see Table 13-3, "Supported System Configurations".

Table 13-3, "Supported System Configurations" lists all the supported system configurations, operating modes, and link partners for the LAN controllers. Selecting the desired PHY and system configuration is determined at power on through the use of the shared SPI Flash configuration.

Table 13-3. Supported System Configurations

Connection	Speed	Electrical Interface	Third Party PHYs/Switches[4]
Backplane	1 GbE	1000BASE-KX	Intel® FM4000/FM5000/FM6000 Ethernet switches Broadcom* BCM5684x-series switches
Backplane	10 GbE	10GBASE-KR	Intel FM5000/FM6000 Ethernet switches Broadcom* BCM5684x-series switches
Backplane	2.5 GbE	2500BASE-X [1]	Intel FM4000/FM5000/FM6000 Ethernet switches Broadcom* BCM5684x-series switches
10BASE-T 100BASE-TX 1000BASE-T	10 Mb/s 100 Mb/s 1 GbE	SGMII (no half duplex support)	Marvell* 88E1514/88E1512 [5] Marvell 88E1543
10GBASE-T [7]	10 GbE	KR	Intel® X557-AT2/AT4 10 GbE PHY
1000BASE-T [7]	1 GbE	KX	Intel® X557-AT2/AT4 10 GbE PHY
SFP+ [7]	10 GbE	SFI	Native SFI support
SFP+ [7]	10 GbE	KR [3]	Inphi CS4227 (2 port) [6] Inphi CS4223 (4 port) [6]

Notes:
1. 2500BASE-X is not an IEEE standard. The SoC supports 2.5G rate only.
2. No support for half duplex.
3. Inphi devices required for long reach support in KR mode.
4. XFP+ devices are not supported and should not be used as they may impact the reliability of the LAN port.
5. The 88E1512 and 88E1514 only supports two MDIO addresses (0 or 1) therefore a maximum of 2 of these PHY devices can be used with each SoC.
6. CS422X devices include integrated Rx CAPS. DO NOT include 100nF for Rx traces close to the devices.
7. Supported only in 10G capable LAN controller SKU.

13.3 Feature List

Table 13-4. Network Features

Feature	SoC LAN Controllers	82599
Compliant with the 1 Gb/s Ethernet/802.3 (KX) Specification	Y	Y
Compliant with the 10 Gb/s 802.3 (KR) specification	Y	Y
Support of 10GBASE-KR FEC	Y	Y
Full-Duplex Operation at all Supported Speeds	Y	N
802.3az Energy Efficient Ethernet (EEE) Support	N	N
Support Jumbo Frames of up to 15.5 KB	Y [1]	Y [1]
MDIO Interface Clause 45	Y	N
Flow Control Support: Send/Receive Pause Frames and Receive FIFO Thresholds	Y	Y
Statistics for Management and RMON	Y	Y
802.1q VLAN Support	Y	Y
Double VLAN	Y	Y

1. The SoC LAN controllers support full-size 15.5 KB jumbo packets while in a basic mode of operation. When virtualization is enabled, or OS2BMC is enabled, then the SoC LAN controllers supports 9.5 KB jumbo packets. Packets to/from the MC longer than 2 KB are filtered out.

Table 13-5. Host Interface Features

Feature	SoC LAN Controllers	82599
Integrated I/O	Y	N
64-bit Address Support for Systems Using More Than 4 GB of Physical Memory	Y	Y
Outstanding Requests for Tx Data Buffers	16	16
Outstanding Requests for Tx Descriptors	8	8
Outstanding Requests for Rx Descriptors	8	8
Credits for P-H/P-D/NP-H/NP-D (shared for the two ports)	4/255/4/255 [1]	16/16/4/4
Credits for C-H/C-D (shared for the two ports)	4/255	N
Max Payload Size Supported	64 - 512 bytes	512 bytes
Max Request Size Supported	64B	2 KB
Vital Product Data (VPD)	Y	Y
End to End CRC (ECRC)	N/A	Y
Latency Tolerance Reporting (LTR)	N	N
ID-Based Ordering (IDO)	Y	N
Access Control Services (ACS)	Y	N
PCIe Functions Off through BIOS Control While LAN Ports Are On	Y	N

1. Each data credit accounts for 16 bytes.

Table 13-6. Miscellaneous Features

Feature	SoC LAN Controllers	82599
Serial Flash Interface	N [1]	Y
Configurable LED Operation for Software or OEM Customization of LED Displays	Y	Y
Shared SPI Flash Space for Private Configuration	Y	Y
Device Disable Capability	Y	Y
Watchdog Timer	Y	Y
Time Sync (IEEE 1588 v2)	Y	Y

1. Serial Flash interface is available at the SoC level and is shared among all the integrated devices.

Table 13-7. LAN Functions Features

Feature	SoC LAN Controllers	82599
Programmable Host Memory Receive Buffers	Y	Y
Descriptor Ring Management Hardware for Transmit and Receive	Y	Y
ACPI Register Set and Power Down Functionality Supporting D0 and D3 States	Y	Y
Software-Controlled Global Reset Bit (Resets Everything Except the Configuration Registers)	Y	Y
Software-Definable Pins (SDP) (per port)	2 [1]	8
SDP Pins Can Be Configured as General Purpose Interrupts	Y	Y
Wake on LAN (WoL)	Y	Y
IPv6 Wake-up Filters	Y	Y
Configurable (through shared SPI Flash update) Wake-up Flexible Filters	Y	Y
Default Configuration by shared SPI Flash update for all LEDs for Pre-Driver Functionality	Y	Y
LAN Function Disable Capability	Y	Y
Programmable Memory Transmit Buffers	160 KB / port	160 KB / port
Programmable Memory Receive Buffers	384 KB / port	512 KB / port

1. Available number is dependent on I/O MUXing and selected functionality.

Table 13-8. LAN Performance Features

Feature	SoC LAN Controllers	82599
TCP/UDP Segmentation Offload	256 KB in all modes	256 KB in all modes
TSO Interleaving for Reduced Latency	Y	Y
TCP Receive Side Coalescing (RSC)	32 flows / port	32 flows / port
Rate Limit VM Tx Traffic per TC (i.e. per TxQ)	Y	N
IPv6 Support for IP/TCP and IP/UDP Receive Checksum Offload	Y	Y
Fragmented UDP Checksum Offload for Packet Reassembly	Y	Y
Message Signaled Interrupts (MSI)	Y	Y
Message Signaled Interrupts (MSI-X)	Y	Y
Interrupt Throttling Control to Limit Maximum Interrupt Rate and Improve CPU Use	Y	Y
Rx Packet Split Header	Y	Y
Multiple Rx Queues (RSS)	Y (multiple modes)	Y (multiple modes)
Flexible RSS	N	N
Flow Director Filters: up to 32 KB Flows by Hash Filters or up to 8 KB Perfect Match Filters	Y	Y
Number of Rx Queues (per port)	128	128
Number of Tx Queues (per port)	128	128
TCP Timer Interrupts Relax Ordering	Y Y	Y Y
DMA Coalescing	Y	N

Table 13-9. Virtualization Features

Feature	SoC LAN Controllers	82599
Support for Virtual Machine Device Queues (VMDq1 and Next Generation VMDq)	64	64
L2 Ethernet MAC Address Filters (Unicast and Multicast)	128	128
L2 VLAN Filters	64	64
PCI-SIG SR IOV	Y	Y
Multicast and Broadcast Packet Replication	Y	Y
Packet Mirroring	Y	Y
Packet Loopback	Y	Y
Traffic Shaping	Y	Y
Anti Spoof	MAC, VLAN, Ethertype	N
Forwarding Modes	MAC, VLAN E-tag	N
VEB Support	Y	N

Table 13-10. Manageability Features

Feature	SoC LAN Controllers	82599
Advanced Pass Through-compatible Management Packet Transmit/Receive Support	Y	Y
SMBus Interface to an External MC	Y	Y
New Management Protocol Standards Support (NC-SI) Interface to an External MC	Y	Y
L2 Address Filters	4	4
VLAN L2 Filters	8	8
Flex L3 Port Filters	16	16
Flexible TCO Filters	1	4
L3 Address Filters (IPv4)	4	4
L3 Address Filters (IPv6)	4	4
Host-Based Application-to-BMC Network Communication Patch (OS2BMC)	Y	N
Flexible MAC Address	Y	N
MC Inventory of LOM Device Information	Y	N
iSCSI Boot Configuration Parameters via MC	Y	N
MC Monitoring	Y	N
NC-SI to MC	Y	N
NC-SI Arbitration	Y	N
NC-SI Package ID Via SDP Pins	Y	N
NC-SI Flow Control	Y	N
MCTP over SMBus (pass through and control)	Y	N

13.4 Programmers Reference Manual

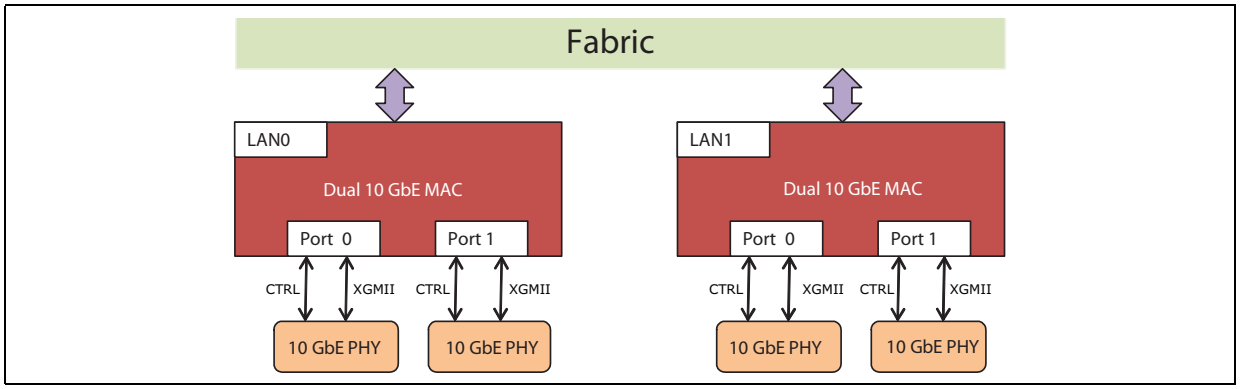
Much of the programming-related information and register descriptions for the SoC LAN controllers are in a separate document.

The descriptions of the MMIO registers and MSI-X registers located in memory space, the registers in I/O space, and the contents of the Shared NVM are described in the PRM. The SoC LAN controller registers located in PCI configuration space are provided in both the PRM and this document.

13.5 Architectural Overview

The SoC LAN controllers are a derivative of Intel® Ethernet Controller 82599 and largely supports most feature sets of this document.

Figure 13-2. System Architecture and Interface



Note: 10GbE PHY shown in Figure 13-2, "System Architecture and Interface" are internal to the SoC package.

13.5.1 PCIe Integrated Endpoint

From a systems view, the SoC LAN controllers are a PCIe* integrated endpoint consisting of two devices with two functions. Two independent controllers (LAN0 and LAN1), are connected to PCI Root Port with separate device and function numbers. LAN0 is connected to RP (D:22 F:0) 22 decimal while LAN1 is connected to RP (D:23 F:0) 23 decimal. Both ports on each controller are addressable by function 0 and 1.

SoC LAN controllers are highly configurable. Device IDs for each of the four functions are assigned, and its capabilities are enabled/disabled by data contained in the shared SPI Flash device. Configurable PCI and PCIe capabilities, and their offsets from the start of each capability location in PCI configuration space are listed in Table 13-11, "PCI and PCIe Capabilities Supported".

The LAN controllers are not connected through a standard PCIe bus. Though the LAN controllers appear as PCIe endpoints, and reports Gen1 speed and x1 width, the internal connection is not standard, and has much higher performance.

Table 13-11. PCI and PCIe Capabilities Supported

Offset in Configuration Space (hexadecimal)	Type of Capability	Capability
40	PCI	PCI Power Management Interface (PMI)
50	PCI	Message Signaled Interrupts (MSI)
70	PCI	Message Signaled Interrupts, extended (MSI-X)
A0	PCI	PCI Express Capability
E0	PCI	Vital Product Data (VPD)
100	PCI Express Extended	Advanced Error Reporting (AER)
140	PCI Express Extended	Device Serial Number
1B0	PCI Express Extended	Access Control Services (ACS)

Note: The dummy function device ID that is available on some Intel LAN components is not supported by the SoC.

Each of the four functions has six Base Address Registers (BARs) that are assigned address values during PCI bus enumeration. See Table 13-12, "Base Address Registers".

Table 13-12. Base Address Registers

Offset in Configuration Space (hexadecimal)	32-bit Register Name	Capability	Data Bytes Accessible in Given Space
10	BASE_ADDR_0	64-bit BAR for Memory Space for Memory-Mapped I/O (MMIOs)	128 K
14	BASE_ADDR_1		
18	BASE_ADDR_2	32-bit BAR for I/O Space	32
1C	BASE_ADDR_3	Reserved	
20	BASE_ADDR_4	64-bit BAR for Memory Space for Message Signaled Interrupts, extended (MSI-X)	16 K
24	BASE_ADDR_5		

There are two device-specific registers located in configuration space for each function. They provide one of the two possible methods for accessing the SoC LAN controller internal command and status registers. This first method uses PCI configuration space of each of the four functions:

- 0x98 - IOADDR (32 bits)
- 0x9C - IODATA (32 bits)

The other method uses the system I/O space. Once the BASE_ADDR_2 BAR is enumerated for a particular function, it can be used to access the IOADDR and IODATA registers:

- BASE_ADDR_2 (I/O base address) plus 0 - IOADDR (32 bits)
- BASE_ADDR_2 (I/O base address) plus 4 - IODATA (32 bits)

Note: There are many configuration options that affect the parameter assignments and operation of the SoC LAN controllers. This document only provides an overview and does not show all possibilities available to the SoC customer.

13.5.2 Interconnect Interfaces

The following interconnect interfaces are described in Section 13.7, "Interconnects":

- LED
- Software-Defined Pins (SDP)
- Shared SPI Flash
- MDIO
- I^2C
- SMBus
- NC-SI
- Memory-mapped I/O (MMIO)

13.6 Basic Operation

13.6.1 Transmit (Tx) Data Flow

Tx data flow provides a high-level description of all data/control transformation steps needed for sending Ethernet packets over the wire.

Table 13-13. Tx Data Flow

Step	Description
1	The host creates a descriptor ring and configures one of the LAN controllers transmit queues with the address location, length, head, and tail pointers of the ring (one of 128 available Tx queues).
2	The host is requested by the TCP/IP stack to transmit a packet, it gets the packet data within one or more data buffers.
3	The host initializes the descriptor(s) that point to the data buffer(s) and have additional control parameters that describes the needed hardware functionality. The host places that descriptor in the correct location at the appropriate Tx ring.
4	The host updates the appropriate Queue Tail Pointer (TDT).
5	The LAN controllers DMA senses a change of a specific TDT and as a result sends a PCIe request, over the primary integrated I/O interface bus, to fetch the descriptor(s) from host memory.
6	The descriptor(s) content is received in a PCIe read completion, over the primary integrated I/O interface bus, and is written to the appropriate location in the descriptor queue.
7	The DMA fetches the next descriptor and processes its content. As a result, the DMA sends PCIe requests, over the primary integrated I/O interface bus, to fetch the packet data from system memory.
8	The packet data is being received from PCIe completions, over the primary integrated I/O interface bus, and passes through the transmit DMA that performs all programmed data manipulations (various CPU offloading tasks as checksum offload, TSO offload, etc.) on the packet data on the fly.
9	While the packet is passing through the DMA, it is stored into the transmit FIFO. After the entire packet is stored in the transmit FIFO, it is then forwarded to transmit switch module.
10	The transmit switch arbitrates between host and management packets and eventually forwards the packet to the MAC
11	The MAC appends the L2 CRC to the packet and delivers the packet to the integrated PHY.
12	The PHY performs the PCS encoding, scrambling and the other manipulations required to deliver the packet over the physical interface at the selected speed.
13	When all the PCIe completions for a given packet are complete, the DMA updates the appropriate descriptor(s).
14	The descriptors are written back to host memory, over the primary integrated I/O interface bus, using PCIe posted writes. The head pointer is updated in host memory as well.
15	An interrupt is generated to notify the host driver that the specific packet has been read to the LAN controllers and the driver can then release the buffer(s).

13.6.2 Receive (Rx) Data Flow

Rx data flow provides a high-level description of all data/control transformation steps needed for receiving Ethernet packets.

Table 13-14. Rx Data Flow

Step	Description
1	The host creates a descriptor ring and configures one of the LAN controllers receive queues with the address location, length, head, and tail pointers of the ring (one of 128 available Rx queues).
2	The host initializes descriptor(s) that point to empty data buffer(s). The host places these descriptor(s) in the correct location at the appropriate Rx ring.
3	The host updates the appropriate Queue Tail Pointer (RDT).
4	A packet enters the PHY through the physical interface.
5	The PHY performs the required manipulations on the incoming signal de-scrambling, PCS decoding, etc.
6	The PHY delivers the packet to the Rx MAC.
7	The MAC forwards the packet to the Rx filter.
8	If the packet matches the pre-programmed criteria of the Rx filtering, it is forwarded to an Rx FIFO.
9	The receive DMA fetches the next descriptor from the appropriate host memory ring to be used for the next received packet.
10	After the entire packet is placed into an Rx FIFO, the receive DMA posts the packet data to the location indicated by the descriptor through the primary integrated I/O interface bus. If the packet size is greater than the buffer size, more descriptor(s) are fetched and their buffers are used for the received packet.
11	When the packet is placed into host memory, the receive DMA updates all the descriptor(s) that were used by the packet data.
12	The receive DMA writes back the descriptor content along with status bits that indicate the packet information including what offloads were done on that packet.
13	The LAN controllers initiates an interrupt to the host to indicate that a new received packet is ready in host memory.
14	The host reads the packet data and sends it to the TCP/IP stack for further processing. The host releases the associated buffer(s) and descriptor(s) once they are no longer in use.

13.7 Interconnects

13.7.1 Setting Up PCI Device Presence and Non-presence

PCI device and function presence or non-presence must be established before PCI enumeration and before the LAN controllers are released from PCI reset. Soft straps for the LAN controllers are provided for this purpose.

13.7.1.1 LAN Controllers Soft Straps

There are six soft straps that affect the four LAN ports. By default, all LAN ports and PCI functions of a particular product SKU are enabled. The six soft straps related to Ethernet ports/functions are:

1. LAN Controller 0 – Power in S5 enable.
2. LAN Controller 1 – Power in S5 enable.
3. LAN Controller 0 – Disable.
4. LAN Controller 1 – Disable.
5. LAN Controller 0, Port 1 Disable.
6. LAN Controller 1, Port 1 Disable.

Note: LAN0 Port 0 and LAN1 Port 0 cannot be disabled.

The definition of these soft straps can be found in Table 4-3, "Flash Descriptor Soft Straps". These soft strap settings are defined in the flash descriptor (region 0) of the SPI.

13.7.2 Disabling PCI Functions by BIOS

The BIOS can disable the LAN controller PCI functions. The memory mapped Function Disable (FUNC_DIS) register of the Power Management Controller (PMC) portion of the Platform Control Cluster (PCC) contains four bits to disable for PCI functions in LAN0 (ports 0 and 1) and LAN1 (ports 0 and 1).

Note: LAN port 0 must be enabled if a LAN controller is enabled.

13.7.3 LAN Port Interface

The LAN ports, each with its own MAC and set of transmit and receive queues, performs all of the functions required for transmission, reception, and collision handling called out in the standards.

The default link mode is set via the 2-bit *Link Mode* field (bits [5:4]) of the Initialization Control 3 word, located at 16-bit word offset 0x24 of the particular LAN-port base address of the shared SPI Flash. The link modes are listed in Table 13-15, "Link Modes".

Table 13-15. Link Modes

Link Mode	Device ID	Branding String
Default (10Gbps SKU)	0x1306	Intel® Ethernet Connection X553
Default (1Gbps SKU)	0x1307	Intel® Ethernet Connection X553
VF (Hyper-V)	0x15B4	Intel® X553 Virtual Function
KR/KX to Backplane	0x15C2 [1]	Intel® Ethernet Connection X553 Backplane
KX (2.5GbE)	0x15C3 [2], 0x15C2 [1]	Intel® Ethernet Connection X553 Backplane
SFI (Native) [3]	0x15C4	Intel® Ethernet Connection X553 10 GbE SFP+
VF	0x15C5	Intel® X553 Virtual Function
SGMII Backplane	0x15C6 [1], 0x15C7 [2]	Intel® Ethernet Connection X553 1GbE
SGMII	0x15E4 [1], 0x15E5 [2]	Intel® Ethernet Connection X553 1GbE
KR/KX to 10GBASE-T, 1GBASE-T (X557) [3]	0x15C8	Intel® Ethernet Connection X553 10GBASE-T
KR to SFP+ (InPhi) [3]	0x15CE	Intel® Ethernet Connection X553 10 GbE SFP+

Notes:
1. This device ID represents a 10G LAN controller SKU for the particular link mode.
2. This device ID represents a non-10G LAN controller SKU for the particular link mode.
3. Supported only on 10G capable LAN controller SKU.

LAN port features:

- Device power management and power states
- DMA coalescing
- Broadcast Wake Up
- IPv4/IPv6 packet-detect support
- Magic Packet detection and operation
- Packet pattern flexible filters

13.7.4 Reference Clock Input

The LAN controllers require a differential, non spread-spectrum reference clock for most of its MAC operation. The source of the clock is the 25-MHz crystal attached to pins CLK_X1_PAD and CLK_X2_PAD of the SoC. See Chapter 7, "Clock Architecture". Routing of this clock signal from the 25-MHz crystal to pins is critical and the Product Design Guide should be followed very carefully.

13.7.5 Pin Straps

There are no pin straps associated with the integrated LAN controllers in this SoC generation.

13.8 Shared SPI Flash for Use with LAN0 and LAN1

Unlike previous SoC generations, there is not a dedicated external NVM device that stores the Ethernet configuration parameters. LAN0 and LAN1 use two sections of the shared system SPI Flash to configure parameters for all LAN ports and PCI functions including MAC addresses, LED behaviors, receive packet filters for manageability, wake-up capability, etc.

The contents of the shared SPI Flash are always addressed as 16-bit words. When an offset value is shown, it is always in terms of 16-bit words.

Some of the shared SPI Flash 16-bit words are used to specify hardware parameters that affect all four LAN interfaces such as those affecting circuit behavior. Other words are associated with a specific LAN port. Both LAN0 and LAN1 interfaces access the shared SPI Flash to obtain their respective configuration settings.

13.8.1 Shared SPI Flash Starter Images

Intel provides a number of NVM flash images for LAN functionality that SoC customers can use with their designs. Please refer to the NVM flash image documentation with the images regarding the descriptions and use of these NVM images. These files are considered starter images and to some extent can be altered for a customer particular usage. Intel provides tools for customers to program images to the system for various operating systems. Contact your local Intel sales representative for details. If Intel needs to provide updates to customers, it provides the necessary software tools to do this.

13.8.2 Shared SPI Flash Map Related to LAN0 and LAN1

The shared SPI Flash related to LAN0 and LAN1 is divided into five major regions and a number of sub-regions as listed in Section 4.0 of the “Programmer’s Reference Manual” show a list of words of customer interest. Shared SPI Flash words defined for exclusive use by Intel are not listed.

13.8.3 Unique MAC Address

The SoC customer assigns their own unique six-byte MAC address for each LAN port. The shared SPI Flash has three 16-bit word locations defined for each of the four LAN ports. The six-byte MAC address is programmed to the shared SPI Flash as shown in this example, where the desired MAC address for LAN port 2 is 00-A0-C9-00-00-03:

- Word 0xC0 = 0xA000
- Word 0xC1 = 0x00C9
- Word 0xC2 = 0x0300

13.8.4 VLAN Support

Two basic types of VLANs are supported:

- Tagged VLANs are based on the IEEE 802.1Q specification. Each packet has a 4-byte tag added to the packet header. The switch must support IEEE 802.1Q tagging and be properly configured. Check the switch documentation for the correct switch configuration.
- Untagged or port-based VLANs are statically configured on the switch and are transparent to connected devices.

13.9 MMIO and Software Interface

The MMIO register descriptions for each of the PCI functions of the LAN controllers are not described in this document.

13.10 Host Primary Interface

The LAN controllers communicate with the host CPUs and host memories over an internal fabric.

13.10.1 Host Interface Architecture, Transaction and Link Layer Properties

- All PCI functions are native PCIe functions
- Credit-based flow control
- Packet sizes/formats:
  - Maximum upstream (write) payload size of 512 bytes
    Configurable sizes are: 128 bytes through 512 bytes
  - Maximum downstream (read) payload size of 2 KB
    Configurable sizes are: 128 bytes through 2 KB
- Reset/initialization:
  - Credit negotiation performed by hardware
- Transaction layer mechanisms
  - 64-bit memory address spaces
  - Removal of I/O BAR (optional)
  - Relaxed ordering
  - Flow control update time out mechanism
  - ID-based ordering (IDO)
  - Function-Level Reset (FLR)
  - Reliability
  - Advanced Error Reporting (AER)
- Power management
  - Wake capability
  - Latency Tolerance Reporting (LTR)
- The LAN controllers support the following extended capabilities:
  - Device serial number
  - Alternative Routing-ID Interpretation (ARI)
  - Single Root I/O Virtualization (SR-IOV)
  - Access Control Services (ACS)
- Software configuration mechanism:
  - Uses PCI configuration and bus enumeration model
  - PCIe-specific configuration registers mapped via PCI extended capability mechanism

13.10.2 PCIe Transaction Layer

13.10.2.1 Transaction Types Accepted by the LAN Controllers

Table 13-16, "Transaction Types Accepted by the Transaction Layer" lists the transactions accepted by the device and their attributes.

Table 13-16. Transaction Types Accepted by the Transaction Layer

Transaction Type	Tx Layer Reaction	Hardware Should Keep Data From Original Packet
Configuration Read Request	CPLH + CPLD	Requester ID, TAG, attribute
Configuration Write Request	CPLH	Requester ID, TAG, attribute
Memory Read Request	CPLH + CPLD	Requester ID, TAG, attribute
Memory Write Request	-	-
I/O Read Request	CPLH + CPLD	Requester ID, TAG, attribute
I/O Write Request	CPLH	Requester ID, TAG, attribute
Read Completions	-	-
Message	-	-

13.10.2.1.1 Size of Target Accesses

Memory Accesses

Rules for accesses to the CSR space (both memory BAR and MSI-X BAR):

- Write accesses
  - Zero-length writes have no internal impact (nothing written, no effect such as clear-by-write). The transaction is treated as a successful operation (no error event).
- CSR writes are 32-bit or 64-bit only. Larger or partial CSR writes are handled as completer abort - data is dropped and an error is generated per PCIe rules read accesses
  - Partial reads with at least one byte disabled are handled as a full read. Any side effect of the full read (such as clear by read) is also applicable to partial reads. The completion on PCIe follows the specification rules regarding the number of bytes reported in the completion.
  - Zero-length reads generate a completion, but the register is not accessed and undefined data is returned.
  - CSR reads are 32-bit or 64-bit only. Larger CSR read requests are handled as completer abort - the completion includes a CA status and an error is generated per PCIe rules.
  - Some 64-bit reads are handled atomically (such as not interleaved with any other requests). This applies mainly to reading counters, where all 64 bits need to be read simultaneously. Such registers are explicitly marked in their description.

Rules for accessing the shared SPI Flash space in the memory BAR:

- Write accesses
  - Writes to the shared SPI Flash are 16-bit wide only
  - Any larger write accesses are handled as completer abort - data is dropped and an error is generated per PCIe rules
- Read accesses
  - Reads to shared SPI Flash are 16-bit wide
  - Partial reads with at least one byte disabled are handled internally as a full read. That is, any side effect of the full read (such as clear by read) is also applicable to partial reads. The completion on PCIe follows the specification rules regarding the number of bytes reported in the completion.
  - Larger CSR read requests are handled as completer abort; the completion includes a CA status and an error is generated per PCIe rules

I/O Accesses

Rules for accesses to the I/O BAR:

- Write accesses
  - Write accesses are 32-bit wide
  - Zero-length writes have no internal impact (nothing written, no effect such as clear-by-write). The transaction is treated as a successful operation (no error event).
  - Other accesses (partial writes, larger writes) are handled as completer abort - data is dropped and an error is generated per PCIe rules
- Read accesses
  - Reads to the I/O BAR are 32-bit wide
  - Partial reads with at least one byte disabled are handled internally as a full read. That is, any side effect of the full read (such as clear by read) is also applicable to partial reads. The completion on PCIe follows the specification rules regarding the number of bytes reported in the completion.
  - Larger CSR read requests are handled as completer abort - the completion includes a CA status and an error is generated per PCIe rules

13.10.2.1.2 Support for Dynamic Changes

The LAN controllers capture the bus number and device number per each configuration write request. However, a dynamic change of the bus number or device number is not supported. Rather, the PCIe link should be quiescent prior to such a change, including reception of all completion for previous requests.

13.10.2.2 Transaction Types Initiated by the LAN Controllers

Table 13-17. Transaction Types Initiated by the Transaction Layer

Transaction Type	Payload Size	Tx Layer Reaction
Configuration Read Request Completion	Dword	CPLH + CPLD
Configuration Write Request Completion	-	CPLH
I/O Read Request Completion	Dword	CPLH + CPLD
I/O Write Request Completion	-	CPLH
Read Request Completion	Dword/Qword	CPLH + CPLD
Memory Read Request	-	NPH
Memory Write Request	<= MAX_PAYLOAD_SIZE	PH + PD
Message	64 bytes	PH

Configuration values:

- Max Payload Size - The value of the Max_Payload_Size Supported field in the Device Capabilities register is loaded from the shared SPI Flash.
  - Hardware default is 512 bytes.
  - System software then programs the actual value into the Max_Payload_Size field of the Device Control register.

    Non-ARI mode: If not all functions are programmed with the same value, the max payload size used for all functions is the minimum value programmed among all functions.

    ARI mode: Max_Payload_Size is determined solely by the setting in Function 0
- Max_Read_Request_Size - The SoC LAN controllers support read requests of up to 2 KB.
  - The actual maximum size of a read request is defined as the minimum (2 KB, Max_Read_Request_Size field in the Device Control register).

The number of outstanding memory read requests is bounded by the following:

- The total number of outstanding requests is not more than 32 requests. These are shared by all sources for memory reads.

13.10.2.2.1 Data Alignment

Requests must never specify an address/length combination that causes a memory space access to cross a 4 KB boundary. The LAN controllers therefore break requests into 4 KB-aligned requests (if needed). This does not place any requirement on software. However, if software allocates a buffer across a 4 KB boundary, hardware issues multiple requests for the buffer. Software should consider aligning buffers to a 4 KB boundary in cases where it improves performance. The maximum size of a read request is defined as the minimum (2 KB bytes, Max_Read_Request_Size).

The general rules for packet alignment are as follows. Note that these apply to all LAN controller requests (read/write):

- The length of a single request does not exceed the PCIe limit of MAX_PAYLOAD_SIZE(512B) for write and MAX_READ_REQ (2KB) for read.
- The length of a single request does not exceed the LAN controller internal limitations.
- A single request does not span across different memory pages as noted by the 4 KB boundary alignment previously mentioned.

If a request can be sent as a single packet and still meet the general rules for packet alignment, then it is not broken at the cache line boundary but rather sent as a single packet. However, if any of the three general rules require that the request is broken into two or more packets, then the request is broken at the cache line boundary.

For requests with data payload, if the payload size is larger than (MAX_PAYLOAD_SIZE - CACHELINE_SIZE), then the request is broken into multiple TLPs starting at the first cache line boundary following the (MAX_PAYLOAD_SIZE - CACHELINE_SIZE) bytes. For example, if MAX_PAYLOAD_SIZE = 256 bytes and CACHELINE_SIZE = 64 bytes, a 1 KB request starting at address 0x...10 is broken into TLPs such that the first TLP contains 240bytes of payload (since 240 bytes + 0x10 = 256 bytes is on cache line boundary).

The system cache line size is controlled by the *PCI_CNF2.CACHELINE_SIZE* bit, loaded from the shared SPI Flash update.

Note: The Cache Line Size register in the PCI configuration space is not related to the *PCI_CNF2.CACHELINE_SIZE* and is solely for software use.

13.10.2.3 Messages

13.10.2.3.1 Received Messages

Message packets are special packets that carry a message code. The upstream device transmits special messages to the LAN controllers by using this mechanism. The transaction layer decodes the message code and responds to the message accordingly.

Table 13-18. Supported Message in the LAN Controllers (as a Receiver)

Message Code [7:0]	Routing	Message	LAN Controller Later Response
0x40, 0x41, 0x43, 0x44, 0x45, 0x47, 0x48	100b	Ignored messages (used to be hot-plug messages)	Silently drop.
0x50	100b	Slot power limit support (has one Dword data)	Silently drop.
0x7E	000b, 010b, 011b, 100b	Vendor defined type 0	Drop and handle as an Unsupported request
0x7F	100b	Vendor defined type 1	Silently drop.
0x7F	010b, 011b, 000b	Vendor defined type 1	Silently drop.
0x00	011b	Unlock	Silently drop.

13.10.2.3.2 Transmitted Messages

The transaction layer is also responsible for transmitting specific messages to report internal/external events (such as interrupts and PMEs).

13.10.2.4 Transaction Attributes

13.10.2.4.1 Traffic Class (TC) and Virtual Channels (VC)

The LAN controllers only supports TC = 0b and VC = 0b (default).

13.10.2.5 Ordering Rules

The LAN controllers meet the PCIe ordering rules by following the PCI simple device model:

1. Deadlock Avoidance – The LAN controllers meets the PCIe ordering rules that prevent deadlocks:
   a. Posted writes overtake stalled read requests. This applies to both target and master directions. For example, if master read requests are stalled due to lack of credits, master posted writes are allowed to proceed. On the target side, it is acceptable to timeout on stalled read requests in order to allow later posted writes to proceed.
   b. Target posted writes overtake stalled target configuration writes.
   c. Completions overtake stalled read requests. This applies to both target and master directions. For example, if master read requests are stalled due to lack of credits, completions generated by the LAN controllers are allowed to proceed.
2. Descriptor/Data Ordering — The LAN controllers ensure that a Rx descriptor is written back on PCIe only after the data that the descriptor relates to is written to the PCIe link.
3. MSI and MSI-X Ordering Rules — System software might change the MSI or MSI-X tables during run-time. Software expects that interrupt messages issued after the table has been updated are using the updated contents of the tables.
   a. Since software doesn't know when the tables are actually updated in the LAN controllers, a common scheme is to issue a read request to the MSI or MSI-X table (a PCI configuration read for MSI and a memory read for MSI-X). Software expects that any message issued following the completion of the read request, is using the updated contents of the tables.
   b. Once an MSI or MSI-X message is issued using the updated contents of the interrupt tables, any consecutive MSI or MSI-X message does not use the contents of the tables prior to the change.
4. The LAN controllers meet the rules relating to independence between target and master accesses:
   a. The acceptance of a target posted request does not depend upon the transmission of any TLP.
   b. The acceptance of a target non-posted request does not depend upon the transmission of a non-posted request.
   c. Accepting a completion does not depend upon the transmission of any TLP.

13.10.2.5.1 Relaxed Ordering

The LAN controllers take advantage of the relaxed ordering rules in PCIe. By setting the relaxed ordering bit in the packet header, the LAN controllers enable the system to optimize performance in the following cases:

1. Relaxed ordering for descriptor and data reads — When the LAN controller masters a read transaction, its split completion has no ordering relationship with the writes from the CPUs (same direction). It should be allowed to bypass the writes from the CPUs.
2. Relaxed ordering for receiving data writes — When the LAN controllers master receive data writes, it also enables them to bypass each other in the path to system memory because software does not process this data until their associated descriptor writes are done.
3. The LAN controllers cannot relax ordering for receive descriptor writes or an MSI write.

Relaxed ordering is enabled in the LAN controllers by clearing the *CTRL_EXT.RO_DIS* bit. Relaxed ordering is further controlled through the *Enable Relaxed Ordering* bit in the PCIe Device Control register.

13.10.2.5.2 ID-based Ordering (IDO)

IDO was introduced in the PCIe rev. 2.1 specification. When enabled, The LAN controllers set IDO in all applicable TLPs defined in the PCIe specification.

This capability enables a supporting root complex to relax ordering rules for TLPs sent by different requesters.

IDO is enabled when all of the following conditions are met:

- The shared SPI Flash update *PCI_CAPSUP.IDO* Enable bit is set
- The PCIe *IDO Request Enable* bit (for requests) or the *IDO Completion Enable* bit (for completions) in Device Control 2 register is set

13.10.3 Error Events and Error Reporting

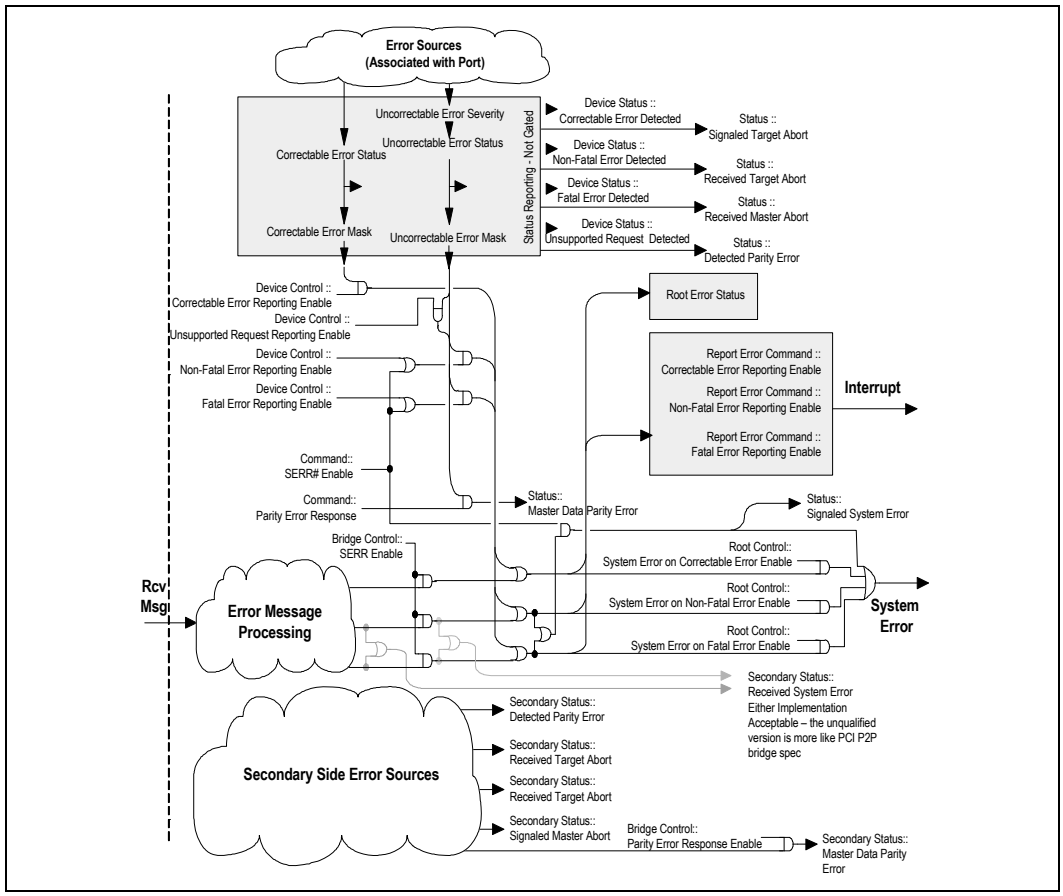
13.10.3.1 General Description

PCIe defines three error reporting paradigms: the baseline capability, the Advanced Error Reporting (AER) capability, and a proprietary mechanism. The baseline error reporting capabilities are required of all PCIe devices and define the minimum error reporting requirements. The AER capability is defined for more robust error reporting and is implemented with a specific PCIe capability structure. Both mechanisms are supported by the LAN controllers. The proprietary error reporting mechanism used for error is better handled by the software device driver using internal CSRs.

The *SERR# Enable* and the *Parity Error* bits from the Legacy Command register also take part in the error reporting and logging mechanism.

In a multi-function device, PCIe errors that are not related to any specific function within the device are logged in the corresponding status and logging registers of all functions in that device. Figure 13-3, "Error Reporting Mechanism" shows, in detail, the flow of error reporting in the LAN controllers.

Figure 13-3. Error Reporting Mechanism



13.10.3.2 Error Events

Table 13-19, "Response and Reporting of PCIe Error Events" lists the error events identified by the LAN controller and the response in terms of logging, reporting, and actions taken. Refer to the *PCI Express Base Specification Revision 3.0* for the effect on the PCI Status register.

Table 13-19. Response and Reporting of PCIe Error Events

Error Name	Error Events	Default Severity	Action
TLP Errors			
Poisoned TLP Received	• TLP With Error Forwarding (EP = 1b) • Data Parity	Uncorrectable ERR_NONFATAL Log Header	If completion TLP: Error is non-fatal (default case) • Send error message if advisory • Retry the request once and send advisory error message on each failure • If fails, send uncorrectable error message Error is defined as fatal • Send uncorrectable error message
Unsupported Request (UR)	• Receipt of TLP with unsupported Request Type • Receipt of an Unsupported Vendor Defined Type 0 Message • Invalid Message Code • Wrong Function Number • Received TLP Outside BAR Address Range • Receipt of a Request TLP during D3hot, other than Configuration and Message requests	Uncorrectable ERR_NONFATAL Log header	Send Completion With UR
Completion Timeout	Completion Timeout Timer Expired	Uncorrectable ERR_NONFATAL	Error is non-fatal (default case) • Send error message if advisory • Error is defined as fatal • Send uncorrectable error message
Completer Abort	Received Target Access With illegal data size per Section 13.10.2.1.1, "Size of Target Accesses"	Uncorrectable. ERR_NONFATAL Log header	Send completion with CA
Unexpected Completion	Received Completion Without a Request For It (Tag, ID, etc.)	Uncorrectable ERR_NONFATAL Log Header	Discard TLP
Malformed TLP (MP)	• Data Payload Exceed Max_Payload_Size Received • TD field value does not correspond with the observed size • PM Messages That Don't Use TC0 • Usage of Unsupported VC • Target request crosses a 4KB boundary	Uncorrectable ERR_FATAL Log Header	Drop the Packet, Free FC Credits
Completion with Unsuccessful Completion Status		No Action (already done by originator of completion)	Free FC Credits
Command Parity	Parity error is detected on the command	Uncorrectable ERR FATAL	

13.10.3.3 Completion Timeout Mechanism

- The LAN controllers support completion time out as defined in the PCIe specification.
- The LAN controllers control the following aspects of completion time out:
- Disabling or enabling completion timeout
  - The PCIe *Completion Timeout Disable Supported* bit in the Device Capabilities 2 register is hard wired to 1b to indicate that disabling completion timeout is supported
  - The PCIe *Completion Timeout Disable* bit in Device Control 2 register controls whether completion timeout is enabled
- A programmable range of timeout values
  - The LAN controllers support all four ranges as programmed in the *Completion Time out Ranges Supported* field of the Device Capabilities 2 register. The actual completion time out value is written in the *Completion Time out Value* field of Device Control 2 register.

The following sequence takes place when completion timeout is detected:

- The appropriate message is sent on PCIe as listed in Table 13-19, "Response and Reporting of PCIe Error Events"
- The affected queue or client takes action based on the nature of the original request.
- An interrupt is issued to the respective PF.

13.10.3.4 Error Forwarding (TLP Poisoning)

If a TLP is received with an error-forwarding trailer, the packet is dropped and is not delivered to its destination, the LAN controller then reacts as listed in Table 13-19.

The following sequence takes place when a poisoned TLP is received:

- The appropriate message is sent on PCIe as listed in Table 13-19, "Response and Reporting of PCIe Error Events".
- An interrupt is issued.
- If the TLP is a completion, a completion time out follows at some later time. Processing continues as described in Section 13.10.2.3, "Messages".

System logic is expected to trigger a system-level interrupt to signal the operating system of the problem. Operating systems can then stop the process associated with the transaction, re-allocate memory to a different area instead of the faulty area, etc.

13.10.3.5 Completion With Unsuccessful Completion Status

A completion arriving with an unsuccessful completion status (either UR or CA) is dropped and not delivered to its destination. A completion time out follows at some later time. Processing continues as described in Section 13.10.2.3, "Messages".

13.10.3.6 Blocking on Upper Address

The PCI_UPADD register blocks master accesses from being sent out on PCIe if the TLP address exceeds some upper limit. Bits [31:1] correspond to bits [63:33] in the PCIe address space, respectively.

When a bit is set in GLPCI_UPADD[31:1], any transaction, in which the corresponding bit in its address is set, is blocked and not sent over PCIe. If all register bits are cleared, there is no effect (such as no TLPs are blocked by this mechanism).

The PCI_UPADD register is loaded from the shared SPI Flash update with a value allowing all addresses to pass. The software device driver should override this value with a system dependent value.

Processing a blocked transaction:

  — Write transaction:

  — The transaction is dropped.

  — Set the Exceeded upper address limit (write requests) event in the PCIe errors register (see Section 13.10.3.7).

  — An interrupt is issued as described in Section 13.10.3.7.

- Read transaction:

  — The transaction is dropped.

  — Set the Exceeded upper address limit (read requests) event in the PCIe errors register (see Section 13.10.3.7).

  — The originating internal client is notified.

  — The affected queue or client takes action based on the nature of the original request. An interrupt is issued to the respective PF.

13.10.3.7 Proprietary Error Reporting

The PCIe specification defines how to report errors to system software. There are, however, error events that the software device driver should be aware of or that the software device driver is in better position to handle and recover from. This section describes the mechanism to report PCIe related errors to software device drivers.

Several CSRs are dedicated to this functionality, with a separate bit allocated per error type (see Table 13-20):

- The PCIe Errors Reported register (PCI_PCIERR - RO) indicates which errors are reported using this mechanism. It is shared by all PFs. It is loaded from the shared SPI Flash update. All non-reserved errors are enabled.
- The PCIe Interrupt Cause register (PCI_ICAUSE - RW1C) indicates pending errors for errors set in the PCIe Errors Reported register. It is dedicated per PF.
- The PCIe Interrupt Enable register (PCI_IENA - RW) determines if an interrupt should be issued to the respective PCI function on an error event. It is dedicated per PF.

Reporting an error to the PF driver involves the following steps:

- The Auto-Negotiate (AN) controllers check if the respective bit is set in the PCIe Errors Reported register. If cleared, done. Else, continue.
- The respective bit is set in the PCIe Interrupt Cause register.
- If the respective bit is set in the PCIe Interrupt Enable register, an interrupt is issued to the PCI function. The PCI_EXCEPTION cause is used (see the EICR register described in the PRM).

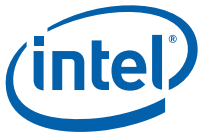


Table 13-20. PCIe Errors Reported to Device Software

Error Event	Index	Description and Comments	Function Association
Exceeded upper address limit (read requests)	00	See Section 13.10.3.6, "Blocking on Upper Address"	Sent to PF
Exceeded upper address limit (write requests)	01	See Section 13.10.3.6, "Blocking on Upper Address"	Sent to PF
Reserved	02	Reserved entries	N/A
Poisoned TLP received	03	See Section 13.10.3.4, "Error Forwarding (TLP Poisoning)"	Sent to PF
Reserved	04-05	Reserved entries	N/A
Unsupported Request - Request Type	07	Request causes an Unsupported Request due to receipt of TLP with unsupported Request Type	Sent to PF
Unsupported Request - Vendor Message	08	Request causes an Unsupported Request due to receipt of an Unsupported Vendor Defined Type 0 Message	Sent to PF unless r[2:0] = *Broadcast from Root Complex,* in which case sent to all PFs
Reserved	09	Reserved entries	N/A
Unsupported Request - Function Number	10	Request causes an Unsupported Request due to receipt of a not-supported Function Number	Sent to all PFs
Reserved	12 - 11	Reserved entries	N/A
Completer abort - target size	13	Received Target Access with illegal data size per Section 13.10.2.1.1, "Size of Target Accesses" (CA)	Sent to PF
Reserved	14 - 31	Reserved entries	N/A

13.11 Management Interfaces

The LAN controllers contain three possible interfaces to an external BMC.

- SMBus
- NC-SI (over RMII)
- MCTP (over SMBus)

LAN0 and LAN1 can support SMBus and NCSI independently. This is done through configuration in the shared NVM section for LAN0 and LAN1. Sideband management is typically off by default.

13.11.1 SMBus

SMBus is an optional interface for pass-through and/or configuration traffic between an external BMC and the LAN controllers. The SMBus channel behavior and the commands used to configure or read status from the LAN controllers are described in the PRM.

The LAN controllers also enable reporting and controlling the device using the MCTP protocol over SMBus. The MCTP interface is used by the BMC to control the port and for pass-through traffic. All network ports are mapped to a single MCTP endpoint on SMBus.

13.11.1.1 Channel Behavior

The SMBus specification defines a maximum frequency of 100 KHz. However, when acting as a slave, the LAN controllers can receive transactions with a clock running at up to 1 MHz. When acting as a master, they can toggle the clock at 100 KHz, 400 KHz or 1 MHz. The speed used is set by the *SMBus Connection Speed* field in the SMBus Notification Time out and Flags shared SPI Flash word as described in the PRM.

13.11.2 NC-SI Transactions

The NC-SI link supports both pass-through traffic between the BMC and the LAN controller LAN functions, as well as configuration traffic between the BMC and the SoC LAN controller internal units as defined in the NC-SI protocol.

13.11.3 MCTP (over SMBus)

The LAN controllers support MCTP protocol for management. MCTP runs over the SMBus. The LAN controller also implements MCTP over NC-SI for command and pass-through traffic.

13.12 Sideband Interface (NC-SI)

The NC-SI interface in the LAN controllers is a connection to an external MC. It operates as a single interface with an external BMC, where all traffic between the LAN controllers and the BMC flow through the interface.

The LAN controller NC-SI interface meets the NC-SI version 1.0.0 specification as a PHY-side device.

13.12.1 Electrical Characteristics

The LAN controllers comply with the electrical characteristics defined in the NC-SI specification.

13.13 Shared SPI Flash

13.13.1 General Overview

Enablement, configuration and addressing are configured in the sections of the system shared SPI Flash specific to LAN0 and LAN1. All management interfaces related to LAN0 and LAN1 are disabled by default and they must be enabled via the shared SPI Flash.

The LAN controllers (LAN0 and LAN1) use sections of the system shared SPI Flash specific to LAN0 and LAN1 to enable, configure and personalize each port. The shared SPI Flash section is divided into a few general regions:

- Hardware Accessed — Loaded by the LAN controller hardware after power up, PCI reset deassertion, D3 to D0 transition, or software reset. Different hardware sections in the shared SPI Flash are loaded at different events.
- Firmware Area — Includes firmware code and structures used by the firmware for management configuration in its different modes.
- Software Accessed — This region is used by software entities such as LAN drivers, option ROM software and tools, PCIe bus drivers, VPD software, etc.

13.13.2 Shared SPI Flash Protection

The contents of several shared SPI Flash update modules must be protected via authentication.

The shared SPI Flash protection method implemented in the LAN controllers rely on an authenticate on update concept. It means that protected modules are not authenticated after initialization, but prior to committing a module update operation only. Shared SPI Flash protection is guaranteed by an inductive authentication chain, that assumes an initial secured shared SPI Flash image, and requires that any shared SPI Flash update must be secure as well. This method mandates the following limitations and restricting working assumptions:

1. An initial good image is loaded into the shared SPI Flash at the manufacturing site, which is assumed to be safe.
   a. It assumes customers (OEM and end-user) know the source of the installed components, the supply chain producing these components is not compromised during manufacturing, and that the SoC is physically protected from modification after deployment.
   b. The possibility exists that unauthorized firmware might be loaded into the shared SPI Flash via physical modification post manufacturing, as well as through supply chain vulnerabilities. However, firmware updates via programmatic (software) methods are enhanced to require authentication prior to updating shared SPI Flash settings. Furthermore, host software can independently detect whether the firmware image has an invalid digital signature.
2. In a normal operating mode, shared SPI Flash write accesses are controlled by the device (firmware) and cannot be directly performed by the host. Memory mapped shared SPI Flash access remains available for shared SPI Flash read accesses only. For simplicity and flexibility reasons, shared SPI Flash write accesses from the host can be initiated via *S*oftware Host Interface commands, VPD write interface, or via a BMC command, which are all handled by firmware. All other direct access write modes are blocked by hardware when the shared SPI Flash is protected.

13.13.3 Shadow RAM

The first eight 4 KB sectors of the LAN controller shared SPI Flash are allocated to create two 16 KB sections (section 0 and section 1), for the configuration content. At least one of these two sections must be valid at any given time; otherwise, the SoC LAN controllers are set based on its hardware default. Following a Power On Reset, the LAN controllers copy the valid section of the shared SPI Flash device into an internal shadow RAM. Any further read accesses by software or firmware to the lower 16 KB addresses of the shared SPI Flash (not through a Flash BAR) are directed to the internal shadow RAM. Modifications made to the shadow RAM contents are copied by the LAN controllers to the other 16 KB section of the shared SPI Flash, circularly flipping the valid section between sections 0 and 1 in the shared SPI Flash. This mechanism provides the following advantages:

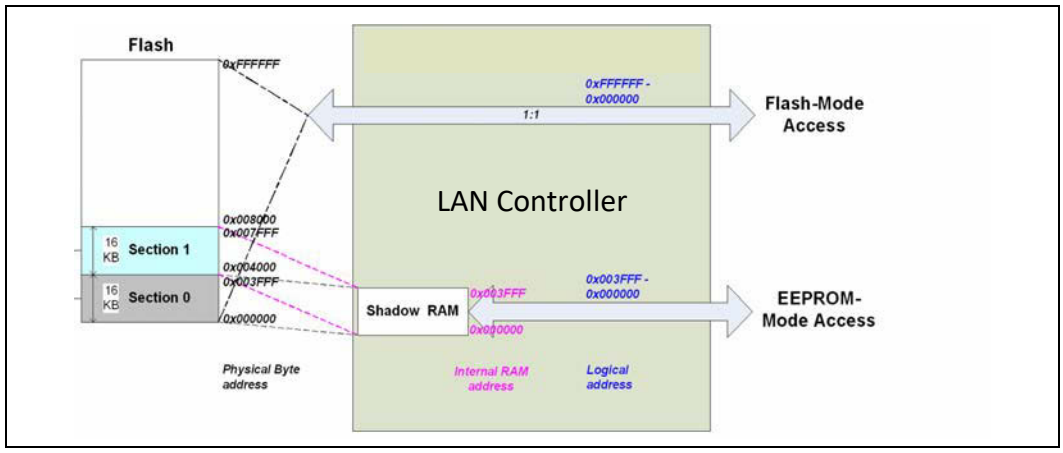
1. A seamless backward-compatible interface for software/firmware to access the first 16 KB of the shared SPI Flash as if an external EEPROM device was connected. This interface is referred as EEPROM-mode access to the shared SPI Flash.

Note: Write access to the physical shared SPI Flash is only available in blank Flash/ non-secure modes.

2. A way to protect the image-update procedure from power down events by establishing a double-image policy. See Section 13.13.8.9, "Software Flash Read Flow via the Flash-mode Interface" for a description of the double-image policy. It relies on having pointers to shared SPI Flash modules stored in the shared SPI Flash section mirrored in the internal shadow RAM.
3. A way to ensure hardware auto-load during a PCIe reset event can be completed within PCIe timing constraints (100 ms), even if the shared SPI Flash is busy performing an erase operation initiated prior to that reset event.

Figure 13-4 shows the shadow RAM mapping and interface.

Figure 13-4. Shared SPI Flash Shadow RAM



13.13.3.1 Shadow RAM Update Flow

1. Following a write access by the software device driver to update the shadow RAM, the data should be updated in the shared SPI Flash as well. The LAN controllers update the shared SPI Flash from the shadow RAM when software explicitly requests an update using the Shadow RAM Dump Host Interface command. To reduce shared SPI Flash update operations, software is expected to request a dump only once its last shadow RAM write access completes. The LAN controllers then copy the contents of the shadow RAM to the non-valid configuration section and makes it the valid one.
2. The software device driver should wait for the command completion to make sure the flow succeeded. Software should be aware that programming the shared SPI Flash might require a long time since the shared SPI Flash update sequence is handled by firmware. The sector erase command by itself can last hundreds of milliseconds. The regular timeout of the host interface commands should also be sufficient to cover this command also.

13.13.4 Shared SPI Flash Clients and Interfaces

There are different software clients that can access the shared SPI flash sections related to LAN0 and LAN1: driver, tools, BIOS, VPD, etc. Table 13-21, "Clients and Access Types to the Shared SPI Flash" lists the different shared SPI Flash access methods.

Table 13-21. Clients and Access Types to the Shared SPI Flash

Client	Shared SPI Flash Access Method (Data Width)	Shared SPI Flash Access Target	Logical Byte Address Range	Shared SPI Flash Access Interface	Protection and Enforcement
Host Software	Memory BAR (parallel 32-bit)	Flash	0x000000 - 0xFFFFFF	Memory mapped 32-bit read/write via BARs.	Write access is limited to a single byte and is allowed only if hardware protection is disabled. (FLA.LOCKED = 0b).
Host Software	FLA bit banging (serial 1-bit)	Flash	0x000000 - 0xFFFFFF	Software accesses to shared SPI Flash by toggling the SPI pins.	FLA interface access is available only if hardware protection is disabled (FLA.LOCKED = 0b).
Host Software	Host interface Shadow RAM Read/Write command	Shadow RAM	0x000000 - 0x003FFF	Access to shadow RAM through the Shadow RAM Read/Write command	Requires a valid firmware image. Write protection is enforced by firmware.
Host Software	Host interface Shared SPI Flash read command	Flash	0x000000 - 0xFFFFFF	Software read from the shared SPI Flash via Flash Read command.	Requires a valid firmware image.
Host Software	Host interface shared SPI Flash write command/shared SPI Flash sector erase command	Flash	0x008000 - 0xFFFFFF	Software writes and sector erase.	Requires a valid firmware image. Writes and erases to protected areas are dropped when firmware protection is enabled.
Host Software	VPD access (parallel 32-bit)	Shadow RAM	0x000000 - 0x0003FF	VPD Address and Data registers.	Write accesses are enabled to the R/W area of the VPD. If the VPD structure is not valid, the entire 1024 bytes area becomes RO to VPD accesses.

13.13.5 Memory Mapped Host Interface

The shared SPI Flash is accessed by the LAN controllers each time the host CPU performs a read operation to a memory location mapped to the shared SPI Flash address space, or upon boot via accesses to the space indicated by the Base Address register. Accesses to the shared SPI Flash is based on a direct decode of CPU accesses to a memory window defined in the Memory CSR + Flash Base Address register (PCIe Control register at offset 0x10).

The LAN controllers control accesses to the Flash when it decodes a valid access. Attempts to out of range read access, the PCIe expansion/option ROM module (according to shared SPI Flash size field in Shared SPI Flash Control Word 1) would return a value of 0xDEADBEEF. Attempts to memory-mapped write accesses to the shared SPI Flash when protection is enabled or via expansion ROM BAR are ignored.

13.13.6 Shared SPI Flash Access Contention

Shared SPI Flash accesses initiated through different LAN functions might occur concurrently. The LAN controllers do not synchronize between entities accessing the shared SPI Flash, so a contention caused from one entity reading and another modifying the same location is possible.

To avoid such contention between software LANs or between software and firmware accesses, these entities are required to make use of the semaphore registers. Any read or write access to the shared SPI Flash made by software/firmware must be preceded by acquiring ownership over the shared SPI Flash. This is also useful to avoid the time out of a PCIe transaction made to a memory-mapped shared SPI Flash address while the shared SPI Flash is busy performing a sector erase operation.

However, two software entities cannot use this semaphore mechanism: BIOS access through expansion ROM and VPD software.

- Since VPD software accesses only the VPD module, which is located in the configuration section of the shared SPI Flash, VPD accesses are always performed against the shadow RAM. Firmware must take shared SPI Flash ownership before dumping the VPD changes to the shared SPI Flash. The Shadow RAM dump sequence is described in Section 13.13.3.1, "Shadow RAM Update Flow".
- No contention can occur between the BIOS access through expansion ROM and other software entities (including VPD) as it accesses the shared SPI Flash while the operating system is down.
- Contentions between BIOS and firmware can however happen if a system reboot occurs while the MC is accessing the shared SPI Flash.
  - If a system reboot is caused by a user pressing the standby button, it is required to route the wake-up signal from the standby button to the MC and not to the chipset. The MC issues a system reboot signal to the chipset only after the shared SPI Flash write access completes. Firmware is responsible to respond with a busy error code to MC NC-SI commands while other shared SPI Flash update writes are in progress.

If a system reboot is issued by a local user on the host, there is no technical way to prevent shared SPI Flash access contentions between the BIOS and the MC.

Caution: It is the user responsibility when remotely accessing the shared SPI Flash via the MC, to make sure another user is not currently initiating a local host reboot.

Note: Other MAC auto-load events are performed from the internal shadow RAM and do not compete with memory mapped accesses to the shared SPI Flash device.

Note: Software and firmware should avoid holding shared SPI Flash ownership (via the dedicated semaphore bit) for more than 500 ms.

13.13.6.1 Flash Deadlock Avoidance

The Flash is a shared resource among the following clients:

1. Hardware auto-load of shadow RAM (at power up); the LAN controller.
2. LAN port 0 and LAN port 1 software accesses.
3. Manageability/firmware accesses.
4. Software tools.

All clients can access the shared SPI Flash using parallel access. Hardware implements the actual access to the shared SPI Flash. Hardware arbitrates among the different clients and schedules these accesses, avoiding starvation of any client.

However, in the LAN controllers, the software and firmware clients can access the shared SPI Flash using bit banging. In this case, there is a request/grant mechanism that locks the shared SPI Flash to the exclusive use of one client. If one client is stuck without releasing the lock, the other clients can no longer access the shared SPI Flash. To avoid this deadlock, the LAN controllers implement a time-out mechanism, which revokes the grant from a client that doesn't toggle the shared SPI Flash bit-bang interface (*FLA.FL_SCK* bit) for more than two seconds. If any client fails to release the shared SPI Flash interface, hardware clears its grant, enabling the other clients to use the interface.

The deadlock timeout mechanism is enabled by the *Deadlock Timeout Enable* bit in the Control Word 2 in the shared SPI Flash.

13.13.7 Signature Field

The only way the LAN controllers can tell if a shared SPI Flash is programmed, is by trying to read the shared SPI Flash. The LAN controllers first read the Control word at word address 0x0 and 0x2000. They then check the signature value at bits 7 and 6 in both addresses.

If bit 7 is 0b and bit 6 is 1b in (at least) one of the two addresses, it considers the shared SPI Flash to be present and valid. It then reads the additional shared SPI Flash words from that section and programs its internal registers based on the values read. Otherwise, it ignores the values read from that location and does not read additional words.

If the signature bits are valid at both addresses, the LAN controllers assume that the first section is the valid one.

13.13.8 VPD Support

The shared SPI Flash image can contain an area for VPD. This area is managed by the OEM vendor and does not influence the behavior of hardware. Word 0x2F of the shared SPI Flash image contains a pointer to the VPD area in the shared SPI Flash. A value of 0xFFFF means VPD is not supported and the *PCI_CAPCTRL.VPD_EN* bit should be cleared in the PCI shared SPI Flash section (described in the PRM), to prevent the VPD capability from appearing in the configuration space.

The maximum area size is 1024 bytes but can be smaller. The VPD block is built from a list of resources. A resource can be either large or small. The structure of these resources are listed in Table 13-22, "Small Resource Structure" and Table 13-23, "Large Resource Structure".

Table 13-22. Small Resource Structure

Offset	0	1 — n
Content	Tag = 0xxx,xyyyb (Type = Small(0), Item Name = xxxx, length = yy bytes)	Data

Table 13-23. Large Resource Structure

Offset	0	1 — 2	3 — n
Content	Tag = 1xxx,xxxxb (Type = Large(1), Item Name = xxxxxxxx)	Length	Data

The LAN controllers parse the VPD structure during the auto-load process following PCIe reset in order to detect the read only and read/write area boundaries. The LAN controllers assume the following VPD fields with the limitations listed.

Table 13-24. VPD Structure

Tag	Length (bytes)	Data	Resource Description
0x82	Length of identifier string	Identifier	Identifier string.
0x90	Length of RO area	RO data	VPD-R list containing one or more VPD keywords.
0x91	Length of RW area	RW data	VPD-W list containing one or more VPD keywords. This part is optional.
0x78	N/A	N/A	End tag.

VPD structure limitations:

- The structure must start with a Tag = 0x82. If the LAN controllers do not detect a value of 0x82 in the first byte of the VPD area or the structure does not follow the description of the VPD structure, they assume the area is not programmed and the entire 1024 bytes area is read only.
- The RO area and RW area are both optional and can appear in any order. A single area is supported per tag type. Refer to Appendix I in the PCI 3.0 specification for details of the different tags.
- If a VPD-W tag is found, the area defined by its size is writable via the VPD structure.
- The structure must end with a Tag = 0x78. The tag must be word aligned.
- The VPD area can be accessed through the PCIe configuration space VPD capability structure listed in the VPD structure. Write accesses to a read-only area or any access to an offset outside of the VPD area via this structure are ignored.
- VPD area must be mapped in the first 16 KB section of the shared SPI Flash mapped to the shadow RAM.
- VPD software does not check the semaphores before attempting to access the shared SPI Flash via dedicated VPD registers. Even if the shared SPI Flash is owned by another entity, VPD software read access to the VPD area in the shared SPI Flash might complete immediately since it is first performed against the shadow RAM. However, VPD software write access might not complete immediately since the VPD changes are committed to the shared SPI Flash device at the LAN controller initiative, once the other entity releases shared SPI Flash ownership, which can take up to several seconds.

13.13.8.1 VPD Access Flows

13.13.8.1.1 First VPD Area Programming

The VPD capability is exposed in the PCIe configuration space only if the *PCI_CAPCTRL.VPD_EN* bit is set, regardless to any other sanity check that is performed on the VPD area contents.

The VPD content and pointer can be written on a blank shared SPI Flash without any limitation, such as for any other shared SPI Flash module when in the blank shared SPI Flash programming mode. After protection is enabled, if *VPD Write Enable* bit in shared SPI Flash control word 1 is cleared, only the RW area of the VPD is writable and only via the VPD interface.

13.13.8.2 VPD Area Update Flows

1. The host initiates a VPD write by programming the offset and data fields of the VPD capability register set and then setting the capability's *Flag* bit. (bit 15 in VPD Address Register - 0xE2).
2. Firmware checks that the VPD write is allowed - it checks that the write offset falls within the VPD-RW area. If writing is not allowed, firmware clears the VPD flag in the configuration space to notify the host VPD software that the transaction completed. It then exits the flow.
3. Firmware indicates VPD access completion by clearing the VPD flag in the configuration space.

13.13.8.3 Shared SPI Flash Update Read, Write, and Erase Sequences

Refer to for the flow required to update secure shared SPI Flash modules.

Any software flow described in this section must be preceded by taking shared SPI Flash ownership via semaphores.

13.13.8.4 Software Flow to the Bit Banging Interface

To directly access the Flash when Flash is blank or not protected, software should follow these steps:

1. Write a 1b to the *Flash Request* bit (*FLA.FL_REQ*).
2. Poll the *Flash Grant* bit (*FLA.FL_GNT*) until it becomes 1b. It remains 0b as long as there are other accesses to the shared SPI Flash.
3. Write or read the shared SPI Flash using the direct access to the 4-wire interface as defined in the FLA register. The exact protocol used depends on the shared SPI Flash placed on the board.
4. Write a 0b to the *Flash Request* bit (*FLA.FL_REQ*).
5. Following a write or erase instruction, software should clear the *Request* bit only after it has checked that the cycles were completed by the shared SPI Flash. This can be checked by reading the *BUSY* bit in the shared SPI Flash device STATUS register. Refer to shared SPI Flash data sheet for the opcode to be used for reading the Status register.

Note: The bit banging interface is blocked during normal operation (protection enabled). Software should use the *FLSW* mode. Firmware can use this interface at all times.

13.13.8.5 Erase Flow Using the FLA Register

To directly erase a sector in the shared SPI Flash when the shared SPI Flash is blank or not protected, software should follow these steps:

1. Take ownership of shared SPI Flash update semaphore.
2. Set the *Flash Address* (*FLA.FL_ADDR*) to the index of the 4 KB sector to erase and *Sector Erase* bit (*FLA.FL_SER*) bit.
3. Read the FLA register until *Flash Busy* bit (*FLA.FL_BUSY*) is cleared.
4. Release ownership of shared SPI Flash update semaphore.

To directly erase the entire shared SPI Flash update when shared SPI Flash update is blank or not protected, software should follow these steps:

1. Take ownership of shared SPI Flash update semaphore.
2. Set *Device Erase* bit (*FLA.FL_DER*) bit.
3. Read the FLA register until *Flash Busy* bit (*FLA.FL_BUSY*) is cleared.
4. Release ownership of shared SPI Flash semaphore.

13.13.8.6 Software Access flow to Shadow RAM

13.13.8.6.1 Read Interface

Software can read from the shadow RAM using the following flow:

1. Send a Shadow RAM Read Host Interface command (described in the PRM) with the address and length to read.
2. Wait for the command to complete
3. Read the data from the response buffer.

13.13.8.6.2 Write Interface

Software can write to the shadow RAM using the following flow:

1. Send a Shadow RAM Write host Interface command (described in the PRM) with the address, length and data to write.
2. Wait for the command to complete

13.13.8.7 Flash Access Flow via the Memory Mapped Interface

13.13.8.7.1 Read Access

Software can always use the Flash BAR for read accesses.

Note: Software should take semaphore ownership before executing the flow.

13.13.8.7.2 Write Access

When the shared SPI Flash is blank or protection is disabled, software might initiate a write cycles via the Flash BAR as follows:

1. Take semaphore ownership before executing the flow.
2. Write the data byte to the shared SPI Flash through the Flash BAR.
3. Poll the *FL_BUSY* flag in the FLA register until cleared.
4. Repeat steps 2 and 3 to write additional bytes.
5. Release shared SPI Flash semaphore ownership.

As a response, hardware executes the following steps for each write access:

1. Set the *FL_BUSY* bit in the *FLA* register.
2. Initiate autonomous write enable instruction.
3. Initiate the program instruction right after the enable instruction.
4. Poll the Flash status until programming completes.
5. Clear the *FL_BUSY* bit in the *FLA* register.

Note: Software must erase the sector prior to programming it.

13.13.8.8 Software Flash/Shadow RAM Program Flow

Software must take semaphore ownership before executing the flow.

Software can write to non-write protected areas of the shared SPI Flash using the following flow:

1. Send a Flash Write Host Interface command (described in the PRM) with the address, length and data to write.
2. Wait for the command to complete.

13.13.8.9 Software Flash Read Flow via the Flash-mode Interface

Software must take semaphore ownership before executing the flow.

Software can read from the Flash using the following flow:

1. Send a Flash Read host Interface command (described in the PRM) with the address and length of the data to read.
2. Wait for the command to complete.
3. Read the data from the completion of the command.

13.13.9 Extended Shared SPI Flash Update Flows

13.13.9.1 Flow for Updating Secured Modules

This section describes the flow to use to update the firmware image.

In order to protect the shared SPI Flash update procedure from power-down events, a double image policy is used for each of the updated modules. The software flow to update a module is as follows:

1. Take ownership over the shared SPI Flash update via the semaphore bits. See PRM.
   a. If *SW_FW_SYNC.NVM_Update_Started* bit is read as clear, then set this bit together with setting the shared SPI Flash semaphore bit. It is used to notify other entities that a long shared SPI Flash update process that might take up to several minutes has started. During this time, other entities cannot perform a write access to the firmware module, but reading this module in between update write bursts is allowed using the shared SPI Flash memory mapping.
   b. Otherwise, release the shared SPI Flash semaphore ownership and restart the update process later on.
2. Read the pointer to the free provisioning area (shared SPI Flash word 0x40). Check that the free provisioning area size read from shared SPI Flash word 0x41 is greater or equal to the size of the new firmware image to be loaded in the shared SPI Flash.
   a. If not, release the shared SPI Flash semaphore ownership, clear the *SW_FW_SYNC.NVM_Update_Started* bit and exit the flow.
3. Initiate sector erase instructions (Section 13.13.8.3) to the entire free space provisioning segment.
   a. In order to guaranty shared SPI Flash semaphore ownership time does not exceed the one second timeout, it is recommended to perform at this step no more than four 4 KB sector erase operations at once in a burst, releasing semaphore ownership for 10 ms in between. This way, other entities can insert shared SPI Flash read accesses in between bursts without waiting for the entire update process completion, which might take minutes.
4. Write the new firmware/option ROM to the free provisioning area via Flash-mode access (Section 13.13.8.9)
   a. Same as step 3a, it is recommended to write at this step no more than four 4 KB sectors at once in a burst, releasing semaphore ownership for 10 ms in between.
5. Send a shared SPI Flash module update module ID of the section to update.The encoding of the modules is:

Table 13-25. SPI Flash Module Encoding

Module	ID	Reference
Firmware code	0x1	
Reserved	0x2	
Reserved	0x3	
Reserved	0x4	
Reserved	0x5	
Reserved	0x6:0xFD	
Reserved	0xFE	
Reserved (full shadow RAM)	0xFF	

6. Release the shared SPI Flash semaphore and clear the *SW_FW_SYNC.NVM_Update_Started* bit.
   a. Software must avoid taking the shared SPI Flash semaphore again until the firmware command has completed. Any attempt to write the shared SPI Flash until then is not performed by the device.
7. Firmware swaps between the free provisioning area pointer (word 0x40) and the firmware code module pointer, Network boot module pointer or the PHY pointer located at the shadow RAM word address 0x3A/0x5/0x4, respectively. Firmware dumps the shadow RAM into the shared SPI Flash.
8. Software waits for the command to complete.
   a. If the update process failed due to a security check failure or a shared SPI Flash write fault, an Authentication Error (0x80) or Data Error (0x6), respectively is returned. Software must then exit the flow, prior to attempting another update.

13.14 Configurable I/O Pins — Software-Definable Pins (SDPs)

The LAN controller has two software definable pins (SDP pins) per port that can be used for miscellaneous hardware or software-controllable purposes. Unless specified otherwise, these pins and their function are bound to a specific LAN device. The use, direction, and values of SDP pins are controlled and accessed by the Extended SDP Control (ESDP) register. To avoid signal contention, following power up, all SDP pins are defined as input pins.

Note: LAN0 has 4 SDP per port (total 8) and LAN1 has 2 SDP per port (total 4).

For the LAN controllers, the primary uses for the SDPs are:

- MOD_ABS connection pin for use in SFI supported designs where optics are used (SDP0 only)
- IEEE 1588 support
- Custom driver designs that require the use of an SDP for a desired use
- Creation of extended bus like I2C for LAN1 (created by MUXing pins)

Some SDP pins have specific functionality:

- The default direction of the SDP pins is loaded from the SDP Control word in the shared SPI Flash.
- The SDP pins can also be configured for use as External Interrupt Sources (GPI). To act as GPI pins, the desired pins must be configured as inputs and enabled by the GPIE register. The LAN controller can apply an inversion to the Rx data path via a programmable register. When detected, a corresponding GPI interrupt is indicated in the EICR register.

Note: An SDP configured as output can also generate interrupts, but this is not a recommended configuration.The bit mappings are listed in the following table for clarity.

Table 13-26. GPI to SDP Bit Mappings

SDP Pin To Be Used As GPI	ESDP Field Settings		Resulting EICR Bit (GPI)
	Directionality	Enable as GPI interrupt	
3	SDP3_IODIR	SDP3_GPIEN	28
2	SDP2_IODIR	SDP2_GPIEN	27
1	SDP1_IODIR	SDP1_GPIEN	26
0	SDIP_IODIR	SDP0_GPIEN	25

- The lowest SDP pins (SDP0_0) of port 0 can be used to encode the NC-SI package ID of the LAN controller. This ability is enabled by setting bit 15 in NC-SI Configuration 2 word (offset 0x07) of the shared SPI Flash. The 3-bit package ID is encoded as follows: Package ID = {0, SDP0_0, 0}.

When the SDP pins are used as IEEE1588 auxiliary signals they can generate an interrupt on any transition (rising or falling edge).

All SDP pins can be allocated to hardware functions. See more details on IEEE1588 auxiliary functionality in the PRM while I/O pin functionalities are programmed by the TimeSync Auxiliary Control (TSAUXC) register.

If mapping of these SDP pins to a specific hardware function is not required then the pins can be used as general purpose software defined I/Os. For any of the function-specific usages, the SDP I/O pins should be set to native mode by software setting of the SDPxxx_NATIVE bits in the ESDP register. Native mode in those SDP I/O pins, defines the pin functionality at inactive state (reset or power down) while behavior at active state is controlled by the software. The hardware functionality of these SDP I/O pins differ mainly by the active behavior controlled by software.

The following table lists the setup required to achieve each of the possible SDP configurations.

Table 13-27. SDP Settings

SDP	Usage	Shared SPI Flash Setting	ESDP		
			SDPx_NATIVE	SDPx_IODIR	SDP1_Function
0	SDP	N/A	0b	Input/Output	N/A
	MOD_ABS for SFI	bit 15 in NC-SI Configuration 2 shared SPI Flash word	0b	Input	
	1588 functionality as defined by the TSSDP register	N/A	1b	Input/Output	
1	SDP.	N/A	0b	Input/Output	
	XXXXXX	bit 2 in PCIe Control 3 word	N/A	Input	
	1588 functionality as defined by the TSSDP register	N/A	1b	Input/Output	0b

13.15 LEDs

The LAN controller implementation has two devices (LAN0 and LAN1) that provide two ports per device. LAN0 Port 0 has four and the other three ports have two output drivers intended for driving external LED circuits. Each of the LED outputs can be individually configured to select the particular event, state, or activity, indication on that output. In addition, each LED can be individually configured for output polarity as well as for blinking versus non-blinking (steady-state) indication.

The configuration for LED outputs is specified via the LEDCTL register. Furthermore, the hardware-default configuration for all LED outputs can be specified via shared SPI Flash fields thereby supporting LED displays configurable to a particular OEM preference.

Each of the LEDs can be configured to use one of a variety of sources for output indication. For more information on the MODE bits refer to the LEDCTL register description in the PRM.

The *IVRT* bits enable the LED source to be inverted before being output or observed by the blink-control logic. LED outputs are assumed to normally be connected to the negative side (cathode) of an external LED.

The *BLINK* bits control whether the LED should be blinked (on for 200 ms, then off for 200 ms) while the LED source is asserted. The blink control can be especially useful for ensuring that certain events, such as ACTIVITY indication, cause LED transitions, which are sufficiently visible by a human eye.

Note: The LINK/ACTIVITY mode ignores the BLINK value. The LED behavior in this mode is:

- Off if there is no LINK
- On if there is LINK and no ACTIVITY
- Blinks if there is LINK and ACTIVITY

The following mapping is used to specify the LED control source (MODE) for each LED output:

Table 13-28. LED Control Source (MODE) Mapping

Mode	Selected Mode	Source Indication
0000b	LINK_UP	Asserted or blinking according to the LEDx_BLINK setting when any speed link is established and maintained.
0001b	LINK_10G	Asserted or blinking according to the LEDx_BLINK setting when a 10 Gb/s link is established and maintained.
0010b	MAC_ACTIVITY	Active when link is established and packets are being transmitted or received. In this mode, the LEDx_BLINK must be set.
0011b	FILTER_ACTIVITY	Active when link is established and packets are being transmitted or received that passed MAC filtering. In this mode, the LEDx_BLINK must be set.
0100b	LINK/ACTIVITY	Asserted steady when link is established and there is no transmit or receive activity. Blinking when there is link and receive or transmit activity.
0101b	LINK_1G[1]	Asserted or blinking according to the LEDx_BLINK setting when a 1 Gb/s link is established and maintained.
0110b	Reserved[2]	Reserved.
0111b	LINK_2_5G	Asserted or blinking according to the LEDx_BLINK setting when a 2.5 Gb/s link is established and maintained.
1000b	Reserved	Reserved
1110b	LED_ON	Always asserted or blinking according to the LEDx_BLINK setting.
1111b	LED_OFF	Always deasserted.

Notes:
1. 10/100Mb operation will take same LED operation as 1G where applicable.
2. Undefined values are reserved.

13.16 Network Management Interface (MDIO or I^2C)

The LAN controllers support MDIO (Section 13.5.2, "Interconnect Interfaces") and/or I^2C (Section 13.5.2, "Interconnect Interfaces") interfaces, for control plane connection between the MAC (master side) and external PHY devices. The management interface enables both MAC and software access to the PHY for monitoring and controlling of the PHYs functionality and configurations. The LAN controllers are compliant with the IEEE Std 802.3 Clause 45 in LAN and 1 GbE operation. The LAN controllers also support IEEE Std 802.3 Clause 22 frame formats and register address space for accessing legacy PHY registers.

There are various connectivity options to external PHYs some use MDIO, such as Base-T PHYs, others might use I^2C, like SFP+ modules while in some special scenarios both might be needed such as when a device does not natively support SFI and requires the system designer to use both an external PHY for SFI translation, and an external SFP+ module. In such scenarios, the LAN controllers might need to use the MDIO to manage the external PHY and the I^2C to manage the external SFP+ module.

Make sure you select external devices that have been tested by Intel and that are supported in our native driver and tools. If an external device is selected that is not supported natively, it will be the customer's responsibility to change the driver, maintain updates to end users, and perform validation functions related to this added interface.

The list of supported devices can be found in Table 13-3, "Supported System Configurations".

13.16.1 I^2C or MDIO Selection

Since the LAN controller supports both MDC/MDIO and I^2C management interfaces, the final board and device setup must be communicated to the software device driver via a shared SPI Flash loaded configuration.

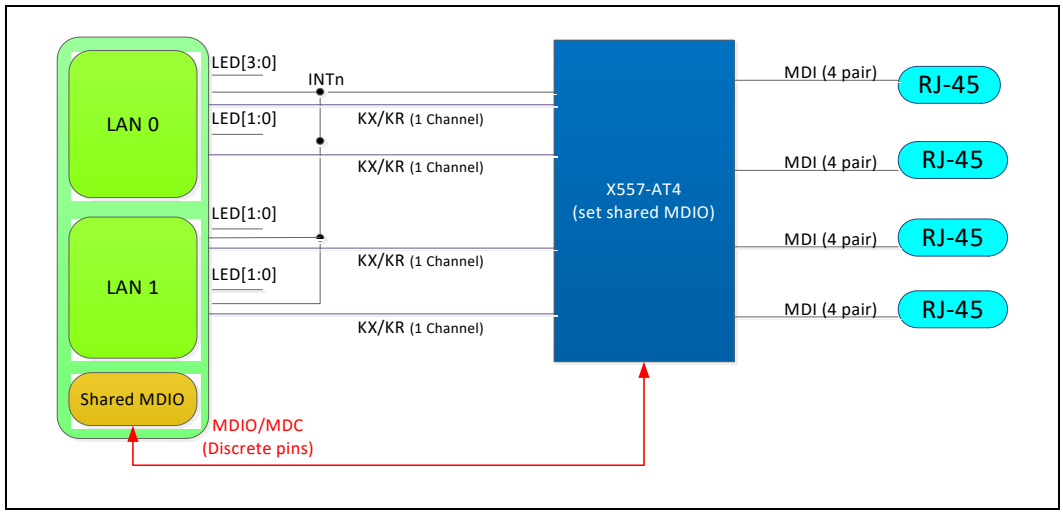
The following settings are provided in the NW Management Interface Select register for the software device driver to read. Based on these settings, the software device driver is able to understand if there is a companion device connected through either of the port's management interfaces. After power on, the software device driver reads the identity of the device connected through the interface and learns the physical topology.

Figure 13-5, "10GBASE-T Implementation" through Figure 13-8, "1G BASE-T Implementation" show the possible connectivity options.

13.16.2 Recommended Networking Topologies

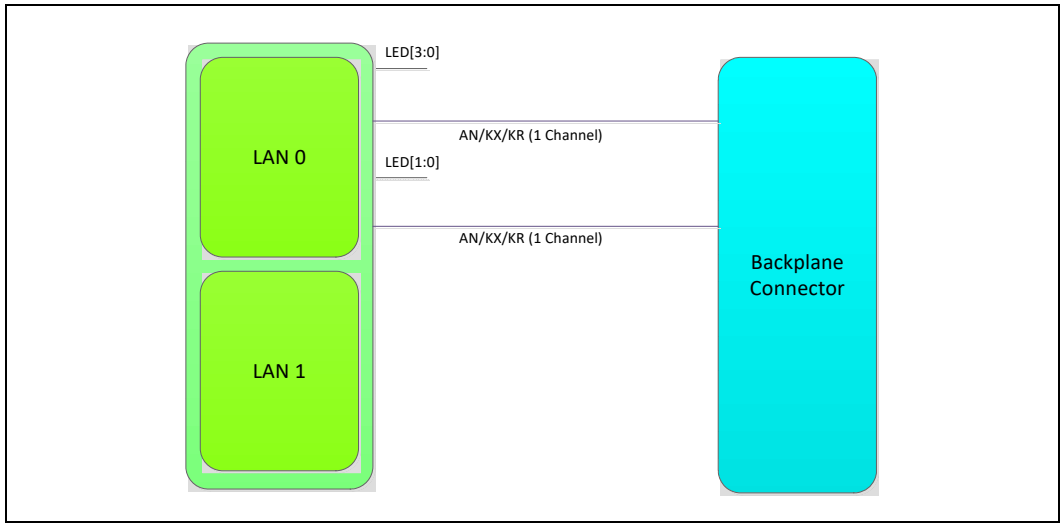
The following diagrams show various recommended options for LAN controllers support. Each of these implementations are described in detail in Table 13-3, "Supported System Configurations".

Figure 13-5. 10GBASE-T Implementation



This implementation uses a 10GBASE-T PHY to enable four ports of 10GBASE-T via the KR support found in the LAN controller LAN0 and LAN1. MDIO/MDC is used to configure the PHY at initialization for KR mode. Refer to the list of supported external PHYs in Table 13-3, "Supported System Configurations".

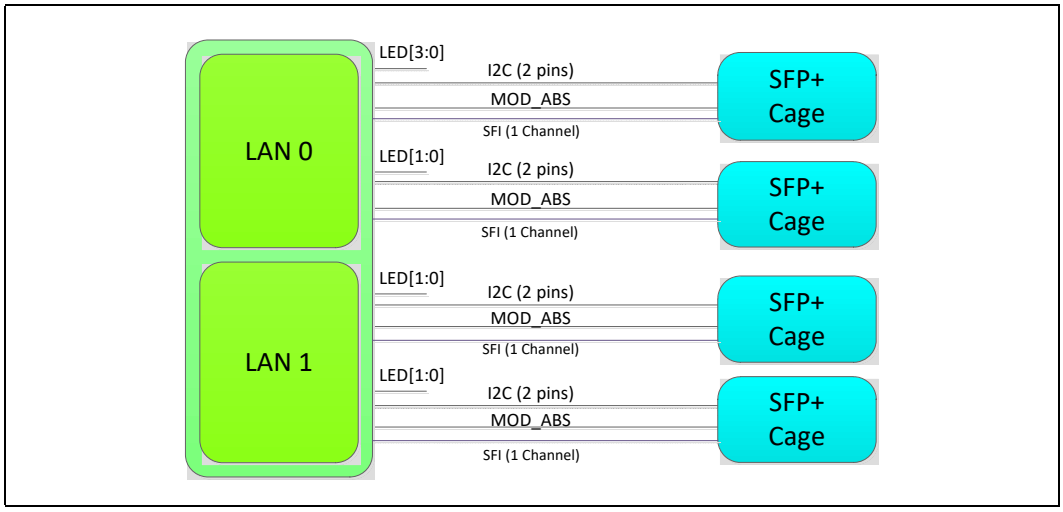
Figure 13-6. 10G Backplane Implementation Using KR to Backplane (Switch)



Note: Shown is LAN0 Ports 0 and 1 connected to the backplane. Similar connections would be made if LAN1 connectivity was desired.

This implementation uses the KR support found in the LAN controller LAN0 and LAN1 (all 4 ports) for connection to a supported backplane partner. Refer to the list of supported switches in Table 13-3, "Supported System Configurations".

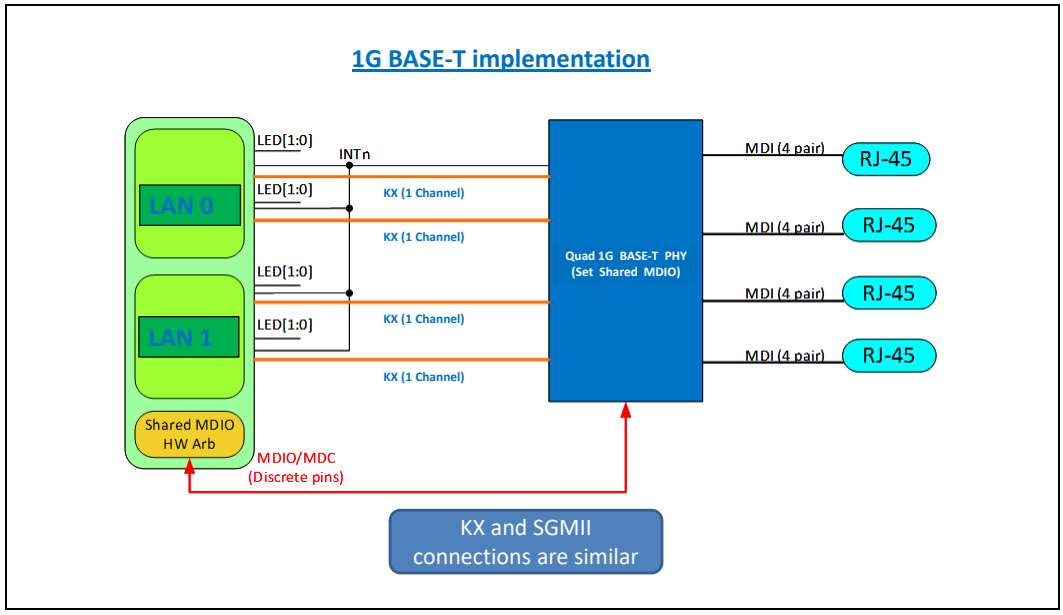
Figure 13-7. SFP+ Implementation



This implementation uses native SFI found in the LAN controller LAN0 and LAN1 for connection to a supported SFP+ optical modules. MOD_ABS (module absence) is provided via SDP support. I^2C connectivity is needed to ensure supported optical modules are populated.

13.16.3 Management Data I/O Interface (MDIO)

Figure 13-8. 1G BASE-T Implementation



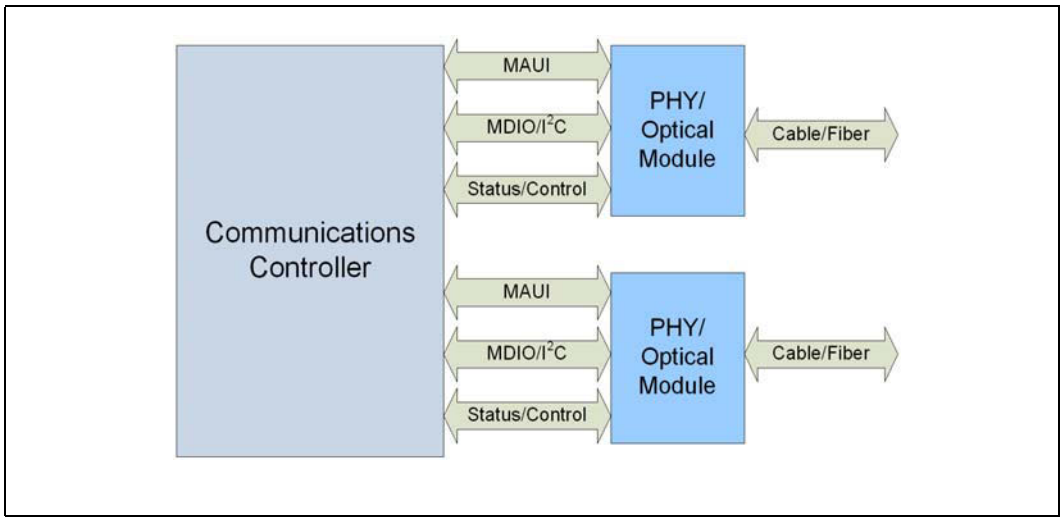
The LAN controllers support the MDIO interface for a control plane connection between the MAC (master side) and PHY devices. The MDIO interface enables both MAC and software access to the PHY for monitoring and controlling of the PHYs functionality and configurations. The LAN controllers are compliant with the IEEE802.3 clause 45 in both 10 GbE and 1 GbE operation. The LAN controllers also support IEEE 802.3 clause 22 frame formats and register address space for accessing legacy PHY registers. Note that these pins are shared with the LED pins and at a given time only one of them is functional based on an shared SPI Flash configuration.

Note: The MDIO interface uses LVTTL signaling as defined in Clause 22 of the IEEE802.3 standard. To access PHYs that support clause 45 1.2V electrical interface, level translators might be needed on board. The MDIO/MDC connection is not required for KX connectivity.

Figure 13-9 shows the basic connectivity between the PHY and MAC.

Note: The MAUI is defined as Medium Attachment Unit Interface.

Figure 13-9. Basic PHY/MAC Connectivity



The MDIO interface is a simple 2-wire serial interface between the MAC and PHY and is used to access Control and Status registers inside the PHY. The interface is implemented using two LVTTL I/O signals:

1. MDC — MDIO-interface clock signal driven by an external MAC (STA) device.
2. MDIO — Read/write data between an external MAC and PHY

13.16.3.1 MDIO Timing Relationship to MDC

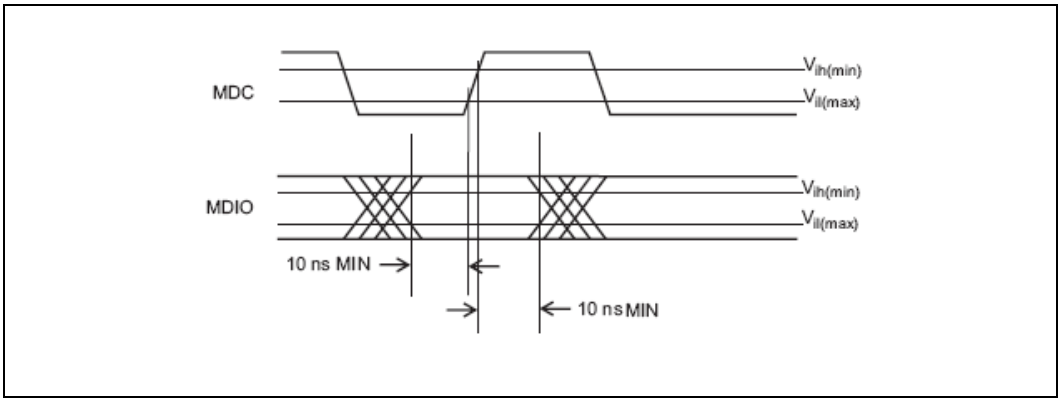
The MDC clock toggles during a read/write operation at a frequency of 2.4 MHz or 240 KHz depending on the link speed and register bit HLREG0.MDCSPD as listed in Table 13-29, "MDC Frequency as Function of Link Speed and MDC Speed Bit".

Table 13-29. MDC Frequency as Function of Link Speed and MDC Speed Bit

Link Speed	MDCSPD=1b	MDCSPD=0b
10 Gb/s	Reserved	2.4 MHz
1 Gb/s	2.4 MHz	240 KHz

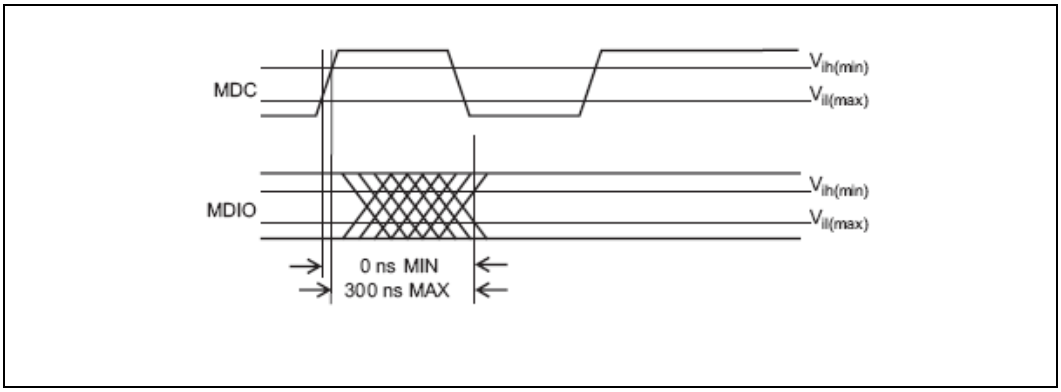
MDIO is a bidirectional signal that can be sourced by the Station Management Entity (STA) or the PHY. When the STA sources the MDIO signal, the STA must provide a minimum of 10 ns of setup time and a minimum of 10 ns of hold time referenced to the rising edge of MDC, as shown in Figure 13-10, "MDIO Timing Source by the MAC" (measured at the MII connector).

Figure 13-10. MDIO Timing Source by the MAC



When the MDIO signal is sourced by the PHY, it is sampled by the MAC (STA) synchronously with respect to the rising edge of MDC. The clock to output delay from the PHY, as measured at the MII connector, must be a minimum of 0 ns, and a maximum of 300 ns, as shown in Figure 13-11, "MDIO Timing Sourced by the PHY".

Figure 13-11. MDIO Timing Sourced by the PHY



13.16.3.2 IEEE802.3 Clause 22 and Clause 45 Differences

IEEE802.3 clause 45 provides the ability to access additional device registers while still retaining logical compatibility with interface defined in Clause 22. Clause 22 specifies the MDIO frame format and uses an ST code of 01 to access registers. In clause 45, additional registers are added to the address space by defining MDIO frames that use a ST code of 00.

Clause 45 (MDIO interface) major concepts:

- Preserve management frame structure defined in IEEE 802.3 Clause 22.
- Define mechanism to address more registers than specified in IEEE802.3 Clause 22.
- Define ST and OP codes to identify and control the extended access functions.

13.16.3.3 MDIO Management Frame Structure

The MDIO interface frame structure defined in IEEE802.3 clause 22 and Clause 45 are compatible so that the two systems supporting different formats can co-exist on the same MDIO bus. The SoC LAN controllers support both frame structures to enable interfacing PHYs that support either protocol.

The basic frame format as defined in IEEE802.3 clause 22 can optionally be used for accessing legacy PHY registers is listed in Table 13-30, "Clause 22 Basic MDIO Frame Format".

Table 13-30. Clause 22 Basic MDIO Frame Format

Function	Management Frame Fields							
Frame	Pre	ST	OP	PRTAD	REGAD	TA	Data	Idle
Read	1...1	01	10	PPPPP	RRRRR	Z0	DDDDDDDDDDDDDDDD	Z
Write	1...1	01	01	PPPPP	RRRRR	10	DDDDDDDDDDDDDDDD	Z

The MDIO interface defined in clause 45 uses indirect addressing to create an extended address space enabling access to a large number of registers within each MDIO Managed Device (MMD). The MDIO management frame format is listed in Table 13-31, "Clause 45 Indirect Addressing MDIO Frame Format".

Table 13-31. Clause 45 Indirect Addressing MDIO Frame Format

Function	Management Frame Fields							
Frame	Pre	ST	OP	PRTAD	DEVAD	TA	Address / Data	Idle
Address	1...1	00	00	PPPPP	EEEEE	10	AAAAAAAAAAAAAAAA	Z
Write	1...1	00	01	PPPPP	EEEEE	10	DDDDDDDDDDDDDDDD	Z
Read	1...1	00	11	PPPPP	EEEEE	Z0	DDDDDDDDDDDDDDDD	Z
Post-Read Increment Address	1...1	00	10	PPPPP	EEEEE	Z0	DDDDDDDDDDDDDDDD	Z

To support clause 45 indirect addressing each MMD (PHY — MDIO managed device) implements a 16-bit address register that stores the address of the register to be accessed by data transaction frames. The address register must be overwritten by address frames. At power up or device reset, the contents of the address register are undefined. Write, read, and post-read-increment-address frames must access the register whose address is stored in the address register. Write and read frames must not modify the contents of the address register. Upon receiving a post-read-increment-address frame and having completed the read operation, the MMD increments the Address register by one (up to a value of 0xFFFF). Each MMD supported implements a separate address register, so that the MMDs address registers operate independently of one another.

Idle Condition (IDLE) — The IDLE condition on MDIO is a high-impedance state. All three state drivers must be disabled and the PHYs pull-up resistor pulls the MDIO line to a logic one.

Preamble (PRE) — At the beginning of each transaction, the station management entity must send a sequence of 32 contiguous consecutive one bits on MDIO with 32 corresponding cycles on MDC to provide the PHY with a pattern that it can use to establish synchronization. A PHY must observe a sequence of 32 contiguous consecutive one bits on MDIO with 32 corresponding cycles on MDC before it responds to any transaction.

Start of Frame (ST) — The ST is indicated by:

- <00> pattern for clause 45 compatible frames for indirect access cycles.
- <01> pattern for clause 22 compatible frames for direct access cycles.

These patterns ensure a transition from the default value of one on the MDIO signal, and identifies the start of frame.

Operation Code (OP) — The *OP* field indicates the type of transaction being performed by the frame.

For Clause 45 compatible frames:

- A <00> pattern indicates that the frame payload contains the address of the register to access.
- A <01> pattern indicates that the frame payload contains data to be written to the register whose address was provided in the previous address frame.
- A <11> pattern indicates that the frame is an indirect read operation.
- A <10> pattern indicates that the frame is an indirect post-read-increment-address operation.

For Clause 22 compatible frames:

- A <10> pattern indicates a direct read transaction from a register.
- A <01> pattern indicates a direct write transaction to a register.

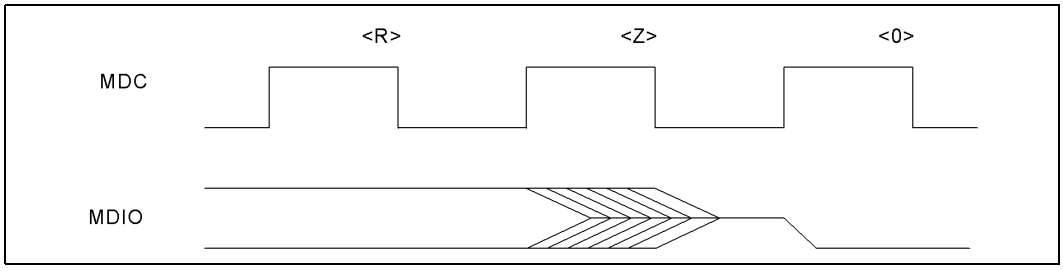
Port Address (PRTAD) — The PRTAD is five bits, allowing 32 unique PHY port addresses. The first *PRTAD* bit to be transmitted and received is the MSB of the address. A station management entity must have prior knowledge of the appropriate port address for each port to which it is attached, whether connected to a single port or to multiple ports.

Device Address (DEVAD) — The DEVAD is five bits, allowing 32 unique MMDs per port. The first *DEVAD* bit transmitted and received is the MSB of the address. This field is relevant only in clause 45 compatible frames (ST=<00>).

Register Address (REGAD) — The REGAD is five bits, allowing 32 individual registers to be addressed within each PHY. The first *REGAD* bit transmitted and received is the MSB of the address. This field is relevant only in clause 22 compatible frames (ST=<01>).

Turnaround (TA) — The TA time is a 2-bit time spacing between the *DEVAD* field and the *Data* field of a management frame. This is to avoid contention during a read transaction. For a read or post-read-increment-address transaction, both the STA and the PHY must remain in a high-impedance state for the first bit time of the TA. The PHY must drive a zero bit during the second bit time of the TA of a read or post-read-increment-address transaction. During a write or address transaction, the STA must drive a one bit for the first bit time of the TA and a zero bit for the second bit time of the TA. Figure 13-12, "Behavior of MDIO During TA Field of a Read Transaction" shows the behavior of the MDIO signal during the *TA* field of a read transaction.

Figure 13-12.Behavior of MDIO During TA Field of a Read Transaction



- Clause 45 compatible frames have 16-bit address/data fields. For an auto-negotiation address cycle, it contains the address of the register to be accessed on the next cycle. For the data cycle of a write frame, the field contains the data to be written to the register. For a read or post-read-increment-address frame, the field contains the contents of the register. The first bit transmitted and received must be bit 15.
- Clause 22 compatible frames have 16-bit data fields. The first data bit transmitted and received must be bit 15 of the register being addressed.

13.16.3.4 MDIO Direct Access

The MDI is accessed through registers MSCA and MSRWD. A single management frame is sent by setting bit MSCA.MDICMD to 1b after programming the appropriate fields in the MSCA and MSRWD registers. The MSCA.MDICMD bit is auto cleared after the read or write transaction completes. To execute clause 22 format write operations, the following steps should be done:

1. Data to be written is programmed in field MSRWD.MDIWRDATA.
2. Register MSCA is initialized with the appropriate control information (start, code, etc.) with bit MSCA.MDICMD set to 1b.
3. Wait for bit MSCA.MDICMD to reset to 0b when indicating that the transaction on the MDIO interface is complete.

The steps for clause 22 format read operations are identical to the write operation except that the data in field MSRWD.MDIWRDATA is ignored and the data read from the external device is stored in register field MSRWD.MDIRDDATA bits. Clause 45 format read/write operations must be performed in two steps. The address portion of the pair of frames is sent by setting register field MSCA.MDIADD to the desired address, field MSCA.STCODE to 00b (start code that identifies clause 45 format), and register field MSCA.OPCODE to 00b (clause 45 address register write operation). A second data frame must be sent after the address frame completes. This second frame executes the write or read operation to the address specified in the PHY address register.

13.16.4 I²C

The LAN controllers support 2-wire management interface (I^2C) for connectivity to external SFP+ modules. Optical and direct attached copper PHYs use 2-wire management interface (I^2C) as described in SFF8431 (SFP+) or SFF8636 (Direct attach Cu).

Note: Some external PHYs also support an I^2C management interface instead of MDIO. It is up to the board designer to choose which interface to use. See Section 13.16.1, "I^2C or MDIO Selection".

The I^2C interface operates via the I2CCMD and I2CPARAMS register set. Since this register set can be used by either software or firmware in alternation, its ownership must be acquired/released via the semaphore ownership taking/release flows described in the PRM.

The I^2C interface can be used in two methods, a hardware based access, where the device initiates a transaction following a software device driver request via the I2CCMD register or a software controlled bit banging using the I2CPARAMS register.

13.16.4.1 Hardware Based I^2C Access

The following flows should be used to access an I^2C register.

As part of device initialization, or anytime before the actual access, the following parameters should be set:

- *I2CPARAMS.PHYADD* - the address of the device to access.
- *I2CPARAMS.ACCESS_WIDTH* - the width of the data to read or write (byte or word).

To execute a write access, the following steps should be done:

1. Check that register is ready: Poll the *I2CCMD.R* bit until it is read as 1b.
2. Command - The I2CCMD register is initialized with the appropriate PHY register address in the *REGADD* field, the data to write in the *DATA* field and the operation (write) to the *OP* field (0b).
   a. If an interrupt is required, set the *I2CCMD.I* field
3. Check that command is done: Poll *I2CCMD.R* bit until it is read as 1b.
   a. Check that no error is indicated in the *I2CCMD.E* field.

To execute a read access, the following steps should be done:

1. Check that the register is ready: Poll *I2CCMD.R* bit until it is read as 1b.
2. Command - The I2CCMD register is initialized with the appropriate PHY register address in the *REGADD* field, and the operation (read) to the *OP* field (1b).
   a. If an interrupt is required, set the *I2CCMD.I* field
3. Check that command is done: Poll *I2CCMD.R* bit until it is read as 1b.
   a. Check that no error is indicated in the *I2CCMD.E* field.
4. Read the data returned from the *I2CCMD.DATA* field. If a byte access is done (*I2CPARAMS.ACCESS_WIDTH* = 0b), only *DATA[7:0]* is valid.

13.16.4.2 Bit Bang Based I²C Access

In this mode, the software device driver controls the I²C interface directly using the I2CPARAMS register according to the following table:

Table 13-32. Direct I²C Interface Control

Pad	Field Controlling The Output Value	Field Reflecting The Input Value	Field Controlling The Output Enable Value[1]
I2C clock	CLK_OUT	CLK_IN	CLK_OE_N
I2C data	DATA_OUT	DATA_IN	DATA_OE_N

1. 0b = Pad is output. 1b = Pad is input.

13.16.4.3 Supported Commands

The gray columns that follow denote cycles driven by the I²C device. White columns denote cycles driven by the SoC LAN controllers.

When a word Read command (*I2CPARAMS.ACCESS_WIDTH* = 1b, *I2CCMD.OP* =1b) is given, the following sequence is done by the SoC LAN controllers:

Table 13-33. I²C Read Transaction - Dummy Write

1	7	1	1	8	1
S	Device Address	Wr	A	Register Address	A
	From *I2CCMD.PHYADD*	0	0	From *I2CCMD.REGADD*	0

Table 13-34. I²C Read Transaction - Word Read

1	7	1	1	8	1	8	1	1
S	Device Address	Rd	A	Data	A	Data	A	P
	From *I2CPARAMS.PHYADD*	1	0	Stored in *I2CCMD.DATA[7:0]*	0	Stored in *I2CCMD.DATA[15:8]*	0	

When a byte read command (*I2CPARAMS.ACCESS_WIDTH* = 0b, *I2CCMD.OP* =1b) is given the following sequence is done by the SoC LAN controllers:

Table 13-35. I²C Read Transaction - Dummy Write

1	7	1	1	8	1
S	Device Address	Wr	A	Register Address	A
	From *I2CPARAMS.PHYADD*	0	0	From *I2CCMD.REGADD*	0

	From *I2CPARAMS.PHYADD*	0	From *I2CCMD.REGADD*	0		From in *I2CCMD.DATA[7:0]*	0

13.17 Network Interface

There are two LAN controllers (LAN0 and LAN1) with two ports each, providing a total of four ports. Each port contains an independent LAN Media Access Control (MAC) that supports a XGMII-like interface link to an internal PHY (see Figure 13-1, "What is Covered in This Chapter").

The internal MAC/PHY combine to support 1GbE (KX and SGMII), 2.5GbE and 10GbE operation through various modes of operation.

Refer to Section 13.2, "Supported Modes of Operation" for all supported modes of Ethernet for use with internal PHYs (native support) and external PHYs.

13.17.1 Companion Integrated PHY Register Access

The LAN controllers provide a set of registers, per port, to enable register access to the software device driver and firmware. The access is an indirect access. For example, the software agent writes the address and data into the pair of registers listed in Table 13-39, "PHY Access Registers" and then the LAN controllers translate this into an internal operation to the relevant PHY sub-section.

Table 13-39. PHY Access Registers

Register	Description
PHY Indirect Control	This register is used for: • Configuring the address to access. • Report a status at the end of the operation.
PHY Indirect Data	• When software writes the data to this register the write operation is triggered. • When software reads from this register the read operation is triggered.

13.17.1.1 PHY Register Addressing

The PHY registers are addressed using a 16-bit address. Further, the companion integrated PHY is a dual-port block and has its registers divided to three partitions.

Table 13-40. PHY Registers' Addressing

Partition	Address Decoding	Description
Common Registers	[15:14] - 11 [13:0] - register address	Holds global registers with information that is not per port.
Port-0 Registers	[15:14] - 01 [13:0] - register address	Holds port-0 configuration and status registers.
Port-1 Register	[15:14] - 10 [13:0] - register address	Holds port-1 configuration and status registers.

When software or firmware is programming the PHY Indirect Control register with a port register address, it must be aware of the physical port it needs to access and set bits [15:14] of the address accordingly.

In order to identify the port number, software should read the *LAN_ID* field in the LAN controller Device Status register (0x00000008).

13.17.1.2 PHY Indirect Read Operation

1. The software agent checks that the PHY *Indirect Control[Busy]*=0b.
2. The software agent writes the following fields:
   a. PHY Select — These are the three MSBs of the address used to select the PHY sub-section.
   b. Addr[15:0] — internal address of register to access.
3. Software performs a read operation from the PHY Indirect Data register (this triggers the read operation).
4. The LAN controllers issue a read message to the PHY.
5. The LAN controllers send a read completion to software. Software might read the PHY *Indirect Control RESP STAT* field as this indicates the status of the operation.

13.17.1.3 PHY Indirect Write Operation

1. The software agent checks that the PHY *Indirect Control[Busy]*=0b.
2. The software agent writes the following fields:
   a. PHY Select - these are the three MSBs of the address used to select the PHY sub-section.
   b. Addr[15:0] - Internal address of register to access.
3. The software agent writes the data into the PHY Indirect Data register.
4. The LAN controllers issue a write message.
5. The software agent polls the PHY *Indirect Control[Busy]* field until it is = 0b again.

13.17.2 Ethernet Flow Control (FC)

The LAN controllers support flow control as defined in 802.3x, as well as the specific operation of asymmetrical flow control defined by 802.3z.

Note: The LAN controllers can either be configured to receive regular FC packets or PFC packets. The LAN controllers do not support receiving both types of packets simultaneously.

FC is implemented to reduce receive buffer overflows, which result in the dropping of received packets. FC also allows for local controlling of network congestion levels. This can be accomplished by sending an indication to a transmitting station of a nearly full receive buffer condition at a receiving station.

The implementation of asymmetric FC allows for one link partner to send FC packets while being allowed to ignore their reception. For example, not required to respond to PAUSE frames.

The following registers are defined for implementing FC using index[0] of each register:

- MAC Flow Control Register (MFLCN) — Enables FC and passing of control packets to the host.
- Flow Control Configuration (FCCFG) — Determines mode for Tx FC (No FC vs. link-based vs. priority-based). Note that if Tx FC is enabled then Tx CRC by hardware should be enabled as well (*HLREG0.TXCRCEN* = 1b).
- Flow Control Source Address Low, High (RAL[0], RAH[0]).
- Flow Control Destination Address Low, High (*FCAMACL, FCAMACH)* — 6-byte FC multicast address.
- Priority Flow Control Type Opcode (PFCTOP) — Contains the type and OpCode values for PFC.
- Flow Control Receive Threshold Low (FCRTL[7:0]) — A set of 13-bit low watermarks indicating receive buffer emptiness. A single watermark is used in link FC mode.
- Flow Control Transmit Timer Value (FCTTV[3:0]) — A set of 16-bit timer values to include in transmitted PAUSE frame. A single timer is used in link FC mode.
- Flow Control Refresh Threshold Value (FCRTV) — 16-bit PAUSE refresh threshold value (in legacy FC FCRTV[0] must be smaller than FCTTV[0]).

13.17.2.1 MAC Control Frames and Reception of Flow Control Packets

13.17.2.1.1 MAC Control Frame — Other than FC

The IEEE specification reserved the Ethertype value of 0x8808 for MAC control frames, which are listed in Table 13-41, "MAC Control Frame Format".

Table 13-41. MAC Control Frame Format

DA	The *Destination Address* field can be an individual or multicast (including broadcast) address. Permitted values for the *Destination Address* field can be specified separately for a specific control OpCode such as FC packets.
SA	Port Ethernet MAC Address (six bytes).
Type	0x8808 (two bytes).
Opcode	The MAC control OpCode indicates the MAC control function.
Parameters	The MAC control *Parameters* field must contain MAC control OpCode-specific parameters. This field can contain none, one, or more parameters up to a maximum of minFrameSize = 20 bytes.
Reserved field = 0x00	The *Reserved* field is used when the MAC control parameters do not fill the fixed length MAC control frame.
CRC	Four bytes.

13.17.2.1.2 Structure of 802.3X FC Packets

802.3X FC packets are defined by the following three fields (see Table 13-42, "802.3X Packet Format"):

1. A match on the six-byte multicast address for MAC control frames or a match to the station address of the device (Receive Address register 0). The 802.3x standard defines the MAC control frame multicast address as 01-80-C2-00-00-01.
2. A match on the *Type* field. The *Type* field in the FC packet is compared against an IEEE reserved value of 0x8808.
3. A match of the MAC control Opcode field has a value of 0x0001.

Frame-based FC differentiates XOFF from XON based on the value of the PAUSE Timer field. Non-zero values constitute XOFF frames while a value of zero constitutes an XON frame. Values in the *Timer* field are in units of pause quanta (such as slot time). A pause quanta lasts 64 byte times, which is converted into an absolute time duration according to the line speed.

Note: XON frame signals the cancellation of the pause from that was initiated by an XOFF frame. Pause for zero pause quanta.

Table 13-42. 802.3X Packet Format

DA	01_80_C2_00_00_01 (6 bytes).
SA	Port Ethernet MAC Address (6 bytes).
Type	0x8808 (two bytes).
Opcode	0x0001 (two bytes).
Time	XXXX (two bytes).
Pad	42 bytes.
CRC	Four bytes.

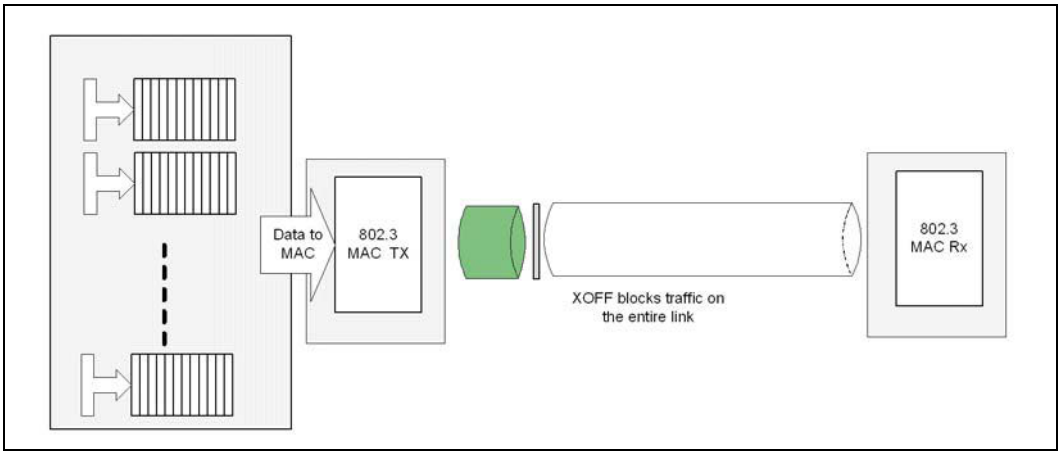
13.17.2.1.3 Priority Flow Control

Support is provided for multiple TCs assigning different priorities and bandwidth per TC. Link-level Flow Control (PAUSE) stops all the TCs. Priority Flow Control (PFC), known as Class Based Flow Control or CBFC, allows more granular Flow Control on the Ethernet link in a DCB environment as opposed to the PAUSE mechanism defined in 802.3X.

PFC is implemented to prevent the possibility of receive packet buffers overflow. Receive packet buffers overflow results in the dropping of received packets for a specific TC. Implement PFC by sending a timer indication to the transmitting station TC (XOFF) of a nearly full receive buffer condition at the LAN controllers. At this point the transmitter stops transmitting packets for that TC until the XOFF timer expires or a XON message is received for the stopped TC.

Similarly, once the LAN controllers receive a priority-based XOFF it stops transmitting packets for that specific TC until the XOFF timer expires or XON packet for that TC is received.

Figure 13-13.802.3X Link Flow Control (PAUSE)



13.17.2.1.4 Operation and Rules

The LAN controllers operate in either link FC or in PFC mode. Note that enabling both modes concurrently is not allowed:

- Link FC is enabled by the *RFCE* bit in the MFLCN register.
- PFC is enabled per UP by the corresponding *RPFCE* bit in the MFLCN register, and globally by *MFLCN.RPFCM* bit.

Note: Link FC capability must be negotiated between link partners via the auto-negotiation process. The PFC capability is negotiated via some higher level protocol and the resolution is usually provided to the software device driver by the DCB management agent. It is the software device driver responsibility to reconfigure the link FC settings (including RFCE and PRFCE) after the auto-negotiation process was resolved.

Note: Receiving a link FC frame while in PFC mode might be ignored or might pause TCs in an unpredictable manner. Receiving a PFC frame while in link FC mode is ignored. Flow control events that are ignored do not increment any flow control statistics counters.

Once the receiver has validated the reception of an XOFF, or PAUSE frame, the device performs the following:

- Increments the appropriate statistics register(s).
- Initialize the pause timer based on the packet's PAUSE *Timer* field (overwriting any current timer value).
  - For PFC, this is done per TC. If several UPs are associated with a TC, then the device sets the timer to the maximum value among all enabled *Timer* fields associated with the TC.
- Disable packet transmission or schedule the disabling of transmission after the current packet completes.
  - For PFC, this is done per paused TC.
  - Tx manageability traffic is bound to a specific TC as defined in the MNGTXMAP register, and is thus paused when its TC is paused.

Resumption of transmission can occur under the following conditions:

- Expiration of the PAUSE timer.
  - For PFC, this is done per TC.
- Receiving an XON frame (a frame with its PAUSE timer set to 0b).
  - For PFC, this is done per TC.

Both conditions clear the relevant TXOFF status bits in the Transmit Flow Control Status (TFCS) register and transmission can resume. Hardware records the number of received XON frames.

13.17.2.1.5 Timing Considerations

When operating at LAN line speed, the LAN controllers must not begin to transmit a (new) frame more than 74 pause quanta after receiving a valid Link XOFF frame, as measured at the wires (a pause quantum is 512 bit times).

When operating at 1 GbE line speed, the LAN controllers must not begin to transmit a (new) frame more than two pause quanta after receiving a valid Link XOFF frame, as measured at the wires.

The 802.1Qbb draft 2.3, proposes that the tolerated response time for priority XOFF frames are the same as Link XOFF frames with extra budget of 19360 bit times if MACSec is used, or of two pause quanta otherwise. This extra budget is aimed to compensate the fact that decision to stop new transmissions from a specific TC must be taken earlier in the transmit data path than for the link flow control case.

13.17.2.2 PAUSE and MAC Control Frames Forwarding

Two bits in the Receive Control register control transfer of PAUSE and MAC control frames to the host. These bits are *Discard PAUSE Frames* (*DPF*) and *Pass MAC Control Frames* (*PMCF*). Note also that any packet must pass the L2 filters as well.

- The *DPF* bit controls the transfer of PAUSE packets to the host. The same policy applies to both link FC and PFC packets as listed in Table 13-43, "Transfer of PAUSE Packet to Host (DPF Bit)". Note that any packet must pass the L2 filters as well.
- The Pass MAC Control Frames (PMCF) bit controls the transfer of non-PAUSE packets to the host. Note that when link FC frames are not enabled (RFCE = 0b) then link FC frames are considered as MAC control frames for this case. Similarly, when PFC frames are not enabled (RPFCM = 0b) then PFC frames are considered as MAC control frames as well.

Note: When virtualization is enabled, forwarded control packets are queued according to the regular switching procedure.

Table 13-43. Transfer of PAUSE Packet to Host (DPF Bit)

RFCE	RPFCM	DPF	Link FC Handling	PFC Handling
0b	0b	X	Treat as MAC control (according to *PMCF* setting).	Treat as MAC control (according to *PMCF* setting).
1b	0b	0b	Accept.	Treat as MAC control (according to *PMCF* setting).
1b	0b	1b	Reject.	Treat as MAC control (according to *PMCF* setting).
0b	1b	0b	Treat as MAC control (according to *PMCF* setting).	Accept.
0b	1b	1b	Treat as MAC control (according to *PMCF* setting).	Reject.
1b	1b	X	Unsupported setting.	Unsupported setting.

13.17.2.3 Transmitting PAUSE Frames

The LAN controllers generate PAUSE packets to ensure there is enough space in its receive packet buffers to avoid packet drop. The LAN controllers monitor the fullness of its receive FIFOs and compares it with the contents of a programmable threshold. When the threshold is reached, the LAN controllers send a PAUSE frame. The LAN controllers support both link FC and PFC — but not both concurrently. When DCB is enabled, it only sends PFC, and when DCB is disabled, it only sends link FC.

Note: Similar to receiving flow control packets previously mentioned, software can enable FC transmission by setting the *FCCFG.TFCE* field only after it is negotiated between the link partners (possibly by auto-negotiation).

13.17.2.3.1 Priority Flow Control (PFC)

The LAN controllers operate in either a link 802.3X compliant mode or in a PFC mode, but not in both at the same time.

The same watermarks mechanism is used for PFC and for 802.3X FC to determine when to send XOFF and XON packets. When PFC is used in the receive path, priority PAUSE packets are sent instead of 802.3X PAUSE packets. The format of priority PAUSE packets is described in Operation and Rules.

Specific considerations for generating PFC packets:

- When a PFC packet is sent, the packet sets all the UPs that are associated with the relevant TC (UP-to-TC association in receive is defined in RTRUP2TC register).

13.17.2.3.2 Operation and Rules

The *TFCE* field in the Flow Control Configuration (FCCFG) register enables transmission of PAUSE packets as well as selects between the link FC mode and the PFC mode.

The content of the Flow Control Receive Threshold High (FCRTH) register determines at what point the LAN controllers transmit the first PAUSE frame. The LAN controllers monitor the fullness of the receive FIFO and compares it with the contents of FCRTH. When the threshold is reached, the LAN controllers send a PAUSE frame with its pause time field equal to FCTTV.

At this time, the LAN controllers start counting an internal shadow counter (reflecting the pause time-out counter at the partner end). When the counter reaches the value indicated in FCRTV register, then, if the PAUSE condition is still valid (meaning that the buffer fullness is still above the low watermark), an XOFF message is sent again.

Once the receive buffer fullness reaches the low water mark, the LAN controllers send an XON message (a PAUSE frame with a timer value of zero). Software enables this capability with the XONE field of the FCRTL.

The LAN controllers send a PAUSE frame if it has previously sent one and the FIFO overflows. This is intended to minimize the amount of packets dropped if the first PAUSE frame did not reach its target.

13.17.2.3.3 Flow Control High Threshold — FCRTH

The LAN controllers send a PAUSE frame when the Rx packet buffer is full above the high threshold. The threshold should be large enough to overcome the worst case latency from the time that crossing the threshold is sensed until packets are not received from the link partner.

Referring to Annex O of IEEE802.1Qbb rev 2.3, worst case latency depends on three parameters:

1. Maximum frame size over the TC for which FCRTH is computed. It is referred as MaxFrame(TC).
2. Maximum frame size over the link (all TCs altogether). It is referred as MaxFrame(link).
3. Whether or not MACsec is enabled or disabled over the link.

Two values are envisaged for MaxFrame:

- 1.5 KB (Ethernet - jumbo disabled)
- 9.5 KB (jumbo enabled)

Worst case latency, which is referred as Standard Delay Value (Std DV), is given by:

Std DV = MaxFrame(TC) + MaxFrame(link) + PFC Frame + 2 x Cable Delay + 2 x Interface Delay + Higher Layer Delay + (MACSec enabled = yes) x Sec Y Transmit Delay

Std DV (bit time units) = MaxFrame(TC) + MaxFrame(link) + 672 + 2 x 5,556 + 2 x (25,600 + 8,192 + 2 x 2,048) + 6,144 + (MACSec enabled = yes) x (MaxFrame(link) + 3,200)

MaxFrame(TC) term and MaxFrame(link) term included in Sec Y Transmit Delay correspond to worst case scenarios issued by the link partner. All other terms in Std DV formula must take in account worst case incoming traffic pattern which would lead to worst case buffer utilization as per the internal architecture of Rx packet buffers in the LAN controllers.

Internal architecture of the Rx packet buffer has the following restrictions:

1. Any packet starts at 32 byte aligned address.
2. Any packet has an internal status of 32 bytes. As a result, the Rx packet buffer is used at worst conditions when the Rx packet includes 65 bytes that are posted to the host memory. Assuming that the CRC bytes are not posted to host memory then in the worst case the Rx packet buffer can be filled at 1.44 higher rate than the wire speed (69-byte packet including CRC + 8-byte preamble + 12-byte back-to-back IFS consumes 4 x 32 bytes = 128 bytes on the Rx packet buffer).
3. An additional packet from the concerned traffic class may be inserted into the Rx packet buffer due to the internal loopback switch just before it is decided to issue XOFF to the link partner.

FCRTH must be set to the size of the Rx packet buffer allocated to the TC minus the controller DV.

Table 13-44. LAN Controllers Delay Values (DV) Used For FCRTH

9.5 KB Jumbo Enabled	LAN Controllers DV
No	24 KB
No	25 KB
Yes	50 KB
Yes	35 KB
No	27 KB
No	27 KB
Yes	60 KB
Yes	45 KB

Note: 9.5 KB jumbo enabled/disabled is a global setting per port which concerns all TCs.

13.17.2.3.4 FC Low Threshold — FCRTL

The low threshold value is aimed to protect against wasted available host bandwidth. There is some latency from the time that the low threshold is crossed until the XON frame is sent and packets are received from the link partner. The low threshold must be set high enough so that the Rx packet buffer does not get empty before any new entire packets are received from the link partner. When considering data movement from the Rx packet buffer to host memory, then large packets represent the worst. Assuming the host bandwidth is about the bandwidth on the wire (when dual ports are active at a given time), and assuming a PCIe round trip is required to get the receive descriptors, we get the following formula for FCRTL:

FCRTL = 2 x MaxFrame(TC) + PCIe round trip delay

PCIe round trip delay is assumed to be ~1 μs and it must cover for worst case incoming traffic pattern (buffer utilization by 1.44 than wire rate):

FCRTL (bit time units) = 2 x MaxFrame(TC) + 1.44 x 10,000

Setting the FCRTL to lower values than expressed by the previous equation is permitted. It might simply result with potential sub-optimal use of the PCIe bus once bandwidth is available.

Table 13-45. LAN Controllers FCRTL

9.5 KB Jumbo Enabled	LAN Controllers DV
No	5 KB
No	7 KB
Yes	21 KB
Yes	7 KB

13.17.2.3.5 Packet Buffer Size

When FC is enabled, the total size of a TC packet buffer must be large enough for the Low and high thresholds. In order to avoid constant transmission of XOFF and XON frames it is recommended to add some space for hysteresis type of behavior. The difference between the two thresholds is recommended to be at least one frame size (when 9.5 KB jumbo frames are expected over the TC) and larger than a few frames in other cases (4.5 KB for instance). If the available Rx buffer is large enough, it is recommended to increase as much as possible the hysteresis budget. If the available Rx buffer is not large enough it might be required to cut both the low threshold as well as the hysteresis budget.

- For a PFC-enabled TC:
  - FCRTH = FCRTL + hysteresis budget = FCRTL + Max (MaxFrame(TC), 4.5 x 1024 B)
  - Rx packet buffer size = FCRTH + the LAN controller DV (see Section 13.17.2.3.3, "Flow Control High Threshold — FCRTH")
- For a best effort TC:
  - Rx packet buffer size = FCRTL, as the same considerations than described in Section 13.17.2.3.4, "FC Low Threshold — FCRTL" play here to avoid bubbles over PCIe

The total Rx packet buffer size available to a port for all its supported TCs is either 384 KB, 320 KB, or 256 KB, depending on the size allocated to the Flow Director table, 0 KB, 64 KB, or 128 KB, respectively.

The following table assumes four PFC-enabled TCs are defined over the port, of which two are allocated for loss less traffic types like iSCSI, etc. The table lists the recommended settings for the supported combinations. When less than 4 PFC-enabled TCs are defined, and/or when less than 8 TCs are defined, it is recommended to refer to the setting rules described in this section, in Section 13.17.2.3.3, "Flow Control High Threshold — FCRTH", and in Section 13.17.2.3.4, "FC Low Threshold — FCRTL". Note that reducing the number of TCs of a port to what is really needed, helps increasing the port throughput.

Table 13-46. Some Recommended Rx Packet Buffer Settings

Flow Director Table Size	9.5 KB Jumbo Enabled	Packet Buffer Size of Any of the 4 Best Effort TCs	Packet Buffer Size of Any of The Other 2 PFC-enabled TCs
No	No	33 KB	61 KB FCRTL = 6 KB FCRTH = 37 KB
No	Yes	27 KB	86 KB FCRTL = 21 KB FCRTH = 36 KB
No	No	32 KB	63 KB FCRTL = 6 KB FCRTH = 36 KB
No	Yes	22 KB	91 KB FCRTL = 21 KB FCRTH = 31 KB
64 KB	No	25 KB	53 KB FCRTL = 6 KB FCRTH = 29 KB
64 KB	Yes	19 KB	78 KB FCRTL = 20 KB FCRTH = 28 KB
64 KB	No	24 KB	55 KB FCRTL = 6 KB FCRTH = 28 KB
64 KB	Yes	14 KB	83 KB FCRTL = 18 KB FCRTH = 23 KB
128 KB	No	17 KB	45 KB FCRTL = 6 KB FCRTH = 21 KB
128 KB	No	16 KB	47 KB FCRTL = 6 KB FCRTH = 20 KB

Note: In some of the previous cases, it has been necessary to get compromised on the rules for hysteresis and FCRTL in order to fit the size available for Rx packet buffer.

Note: In some other cases, after having applied all the rules there was an exceeding available Rx packet buffer left that has been used to extend the hysteresis budgets.

Note: In all cases, FCRTH rule has been applied as is, since compromising on it is not allowed and extending it provides no performance benefits.

13.17.3 Inter Packet Gap (IPG) Control and Pacing

The LAN controllers support transmission pacing by extending the IPG (the gap between consecutive packets). The pacing mode enables the average data rate to be slowed in systems that cannot support the full link rate (10 GbE or 1 GbE). As listed in Table 13-47, "Pacing Speeds at 10 GbE Link Speed", the pacing modes work by stretching the IPG in proportion to the data sent. In this case the data sent is measured from the end of preamble to the last byte of the packet. No allowance is made for the preamble or default IPG when using pacing mode.

Example 13-1.

Consider a 64-byte frame. To achieve a 1 GbE data rate when link rate is LAN and packet length is 64 bytes (16 Dwords), add an additional IPG of 144 Dwords (nine times the packet size to reach 1 GbE). When added to the default IPG gives an IPG of 147 Dwords.

Example 13-2.

Consider a 65-byte frame. To achieve a 1 GbE data rate when link rate is LAN and packet length is 65 bytes (17 Dwords when rounded up) add an additional IPG of 153 Dwords (nine times the packet duration in Dwords). When added to the default IPG gives an IPG of 156 Dwords. Note that in this case, where the packet length counted in Dwords is not an integer, count any fraction of a Dword as an entire Dword for computing the additional IPG.

Table 13-47, "Pacing Speeds at 10 GbE Link Speed" lists the pacing configurations supported by the SoC LAN controller at link rates of 10 GbE. When operating at lower link speeds the pacing speed is proportional to the link speed.

Table 13-47. Pacing Speeds at 10 GbE Link Speed

Pacing Speeds (Gb/s)	Delay Inserted into IPG	Register Value
10 (10 GbE)	None	0000b
9.294196 (WAN)	1 byte for 13 transmitted	1111b
9.0	1 Dword for 9 transmitted	1001b
8.0	1 Dword for 4 transmitted	1000b
7.0	3 Dwords for 7 transmitted	0111b
6.0	2 Dwords for 3 transmitted	0110b
5.0	1 Dwords for 1 transmitted	0101b
4.0	3 Dwords for 2 transmitted	0100b
3.0	7 Dwords for 3 transmitted	0011b
2.0	4 Dwords for 1 transmitted	0010b
1.0	9 Dwords for 1 transmitted	0001b
10	None	Default

Note: Pacing is configured in the *PACE* field of the Pause and Pace (PAP) register.

13.18 Physical Functions (PF), Virtual Functions (VF) and ARI (Alternative RID Interpretation)

ATS and ARI are required to support PF and VF. Both ATS and ARI are required in order for PCIe configuration space to be able to address higher than 7 VFs PCIe configurations traditionally configures PF and VFs using 16 bits. ATS and ARI allow more (higher) than 7 functions to be addressed.

The number of VFs, in addition to the PFs, are indicated in the system shared SPI Flash section for the LAN controllers LAN0 and LAN1. A function in the shared SPI Flash image known as I/O Virtualization (IOV) is also need to be enabled. These newly created VF shows up in PCIe configuration space as base/device/function.

In short, to enable hardware based Single Root I/O Virtualization (SR-IOV) and benefit from use of VFs and the built-in Virtual Ethernet Bridge (VEB), you must have:

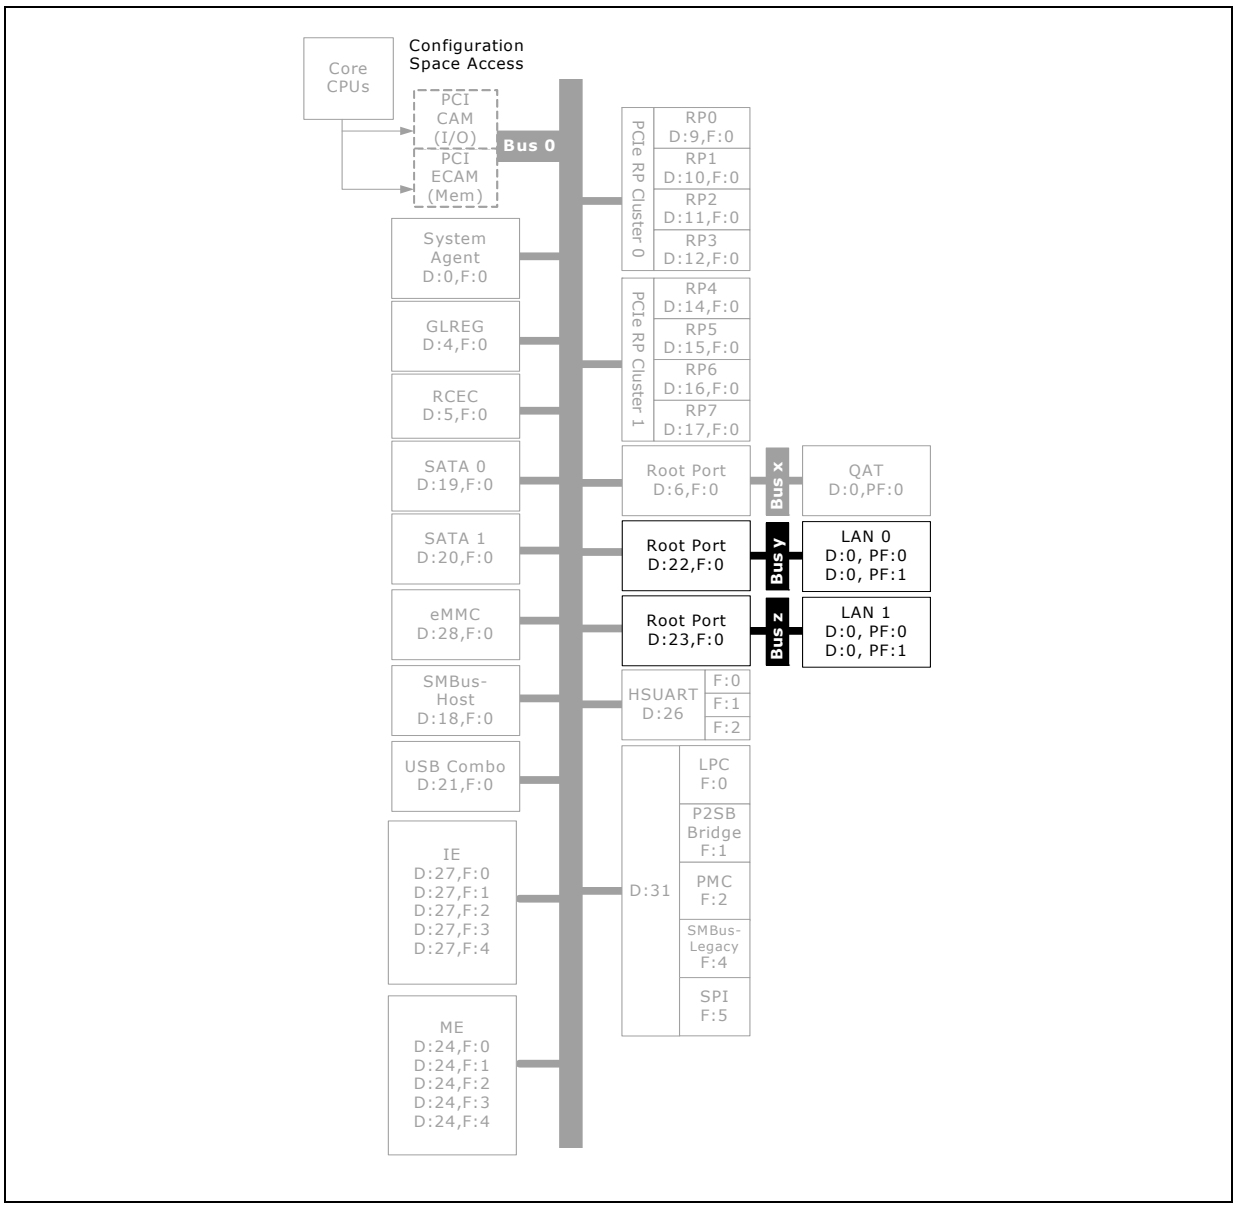
1. Ensure that ATS/ARI are supported in your version of BIOS.
2. Enable SR-IOV in your BIOS.
3. Use an OS that supports virtualization.
4. Enable IOV in the NVM section and indicated the # of VMs desired to create.

For further information regarding SR-IOV, refer to the published SR-IOV Primer titled *PCI-SIG* SR-IOV Primer: An Introduction to SR-IOV Technology*.

13.19 Register Map

The software-accessible registers are outlined in Table 13-12, "Base Address Registers" and are depicted here.
Figure 13-14, "Register Map" shows the associated registers from a system viewpoint.

Figure 13-14.Register Map



§ §

14 USB Combo Controller

This chapter describes the Universal Serial Bus (USB) Combo Controller. It provides USB 2.0 and USB 3.0 ports.

Figure 14-1. What is Covered in This Chapter

14.1 Signal Descriptions

The signal descriptions are shown in Table 14-2. For additional signal information, including whether a signal is assigned to shared-function pin or can be used as a Customer GPIO signals see Section 39.1, "Directory of Signal Names and Pin Names" on page 993. Also see Table 39-3.The Direction column of Table 39-3 on page 1028 is interpreted as follows:

- I = Input signal. The SoC has receiver circuit.
- O = Output signal. The SoC has driver circuit.
- Differential = Differential signal pair. Two pins: Positive; Negative.

Table 14-2. Signal Names and Descriptions

Signal Names	Direction	Shared	Description
USB3_TX_DP[3:0] USB3_TX_DN[3:0]	O, Differential	Yes	**USB 3.0 Transmit Data:** Differential output signals from the USB Combo Controller to the FIA/PHY.
USB3_RX_DP[3:0] USB3_RX_DN[3:0]	I, Differential	Yes	**USB 3.0 Receive Data:** Differential input signals to the USB Combo Controller from the FIA/PHY.
USB2_DP[3:0] USB2_DN[3:0]	I,O, Differential	No	**USB 2.0 Transceiver Data:** Differential bi-directional signal pins.
USB_OC_N	I	No	**USB Over Current.** Active low input signal from the platform board that alerts the SoC that a VBUS over-current condition exists.
USB2_COMP	I	No	**Compensation:** The platform board must provide a 113 Ω, 1% resistor connected from this pin to VSS.

14.2 Feature List

The SoC supports up to four USB 3.0 compliant ports depending on product SKU.

The SoC provides these ports through a USB 3/USB 2 Combo Controller which is an integrated PCI Express* function, Bus 0, Device 21 (decimal), Function 0.

All ports operate in Host Mode. The USB 2.0 operation supports USB 1.X devices and a Rate Matching Hub (RMH) is provided for USB 1.1 devices.

The controller contains one eXtensible Host Controller Interface (xHCI) with software, which complies to the *eXtensible Host Controller Interface for Universal Serial Bus (xHCI), Revision 1.1*.

Note: For a USB 3.0-compliant port design, one set of the controller USB 3.0 signals and one set of the USB 2.0 signals must be routed to the same port connector. Thus for USB 3.0 specification compliance, the USB Combo Controller (xHCI) can only support four devices.

Note: USB On-The-Go (OTG) not supported.

14.2.1 USB 3.0

The USB 3.0 Super Speed data interface is dual-simplex, four-wire differential signals (2-TX and 2-RX) which are separate from the USB 2.0 signals and supports simultaneous bi-directional (full Duplex) data flows. The interface supports a bit rate of 5 Gbps with a maximum data throughput of less than 4 Gbps due to usage of an 8b/10b symbol encoding scheme and additional protocol overhead.

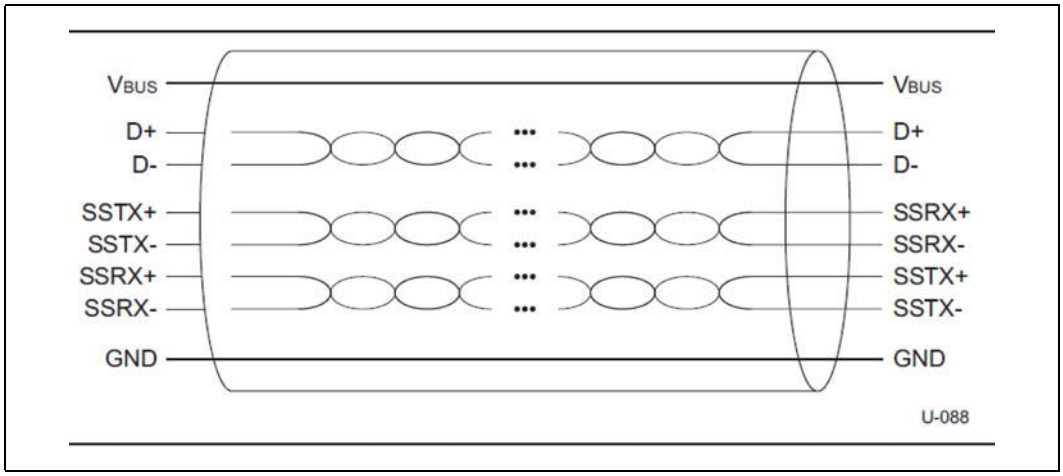
14.2.2 USB 2.0

The USB 2.0 data interface is half-duplex two-wire differential signals, which support unidirectional data flow with negotiated directional bus transitions. The USB 2.0 supports bit rates of:

- Low-speed (1.5 Mbps)
- Full-speed (12 Mbps)
- High-speed (480 Mbps)

For additional information refer to the *Universal Serial Bus Specification, Revision 2.0*.

Figure 14-2. USB 3.0 Cable



14.2.3 xHCI Interface

The USB 3.0 xHCI Host Controller (xHCI) supports the following features:

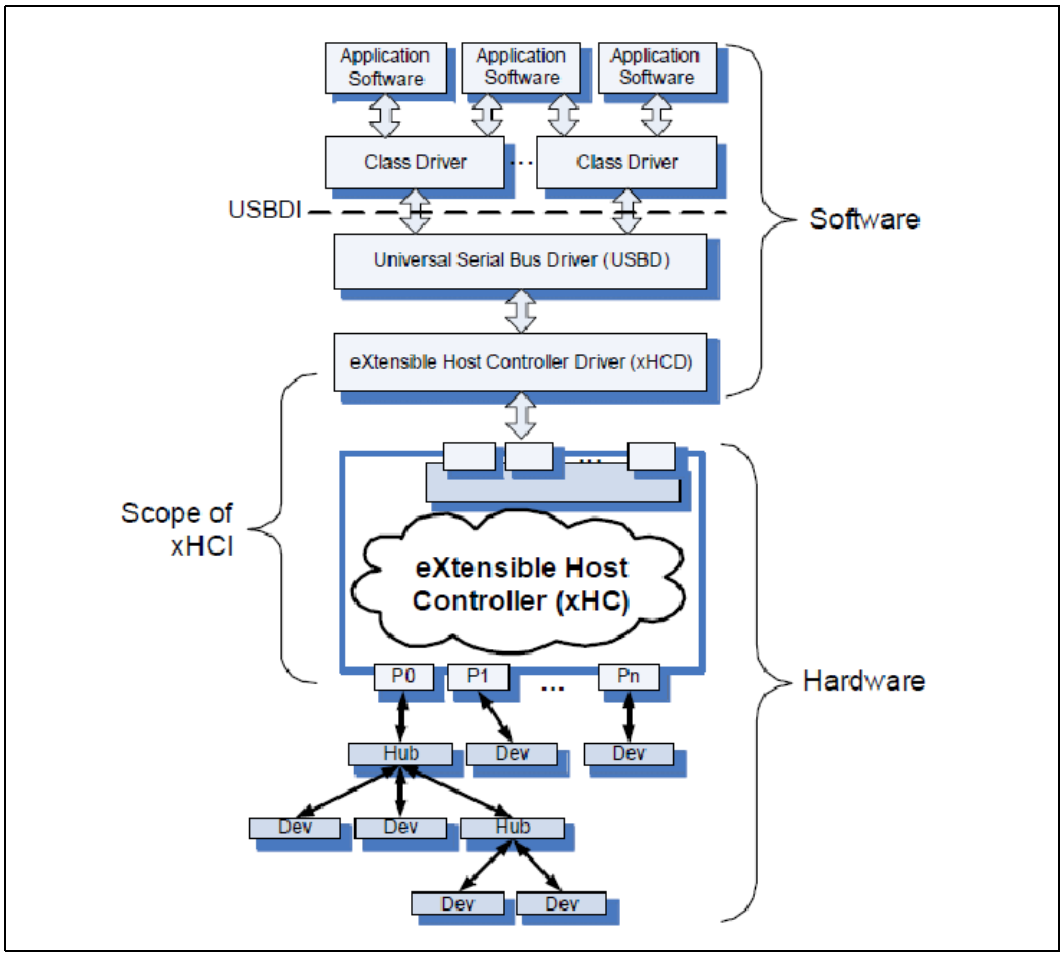
- Compliant with the specification for USB 1.x, 2.0 (1.5 Mbps, 12 Mbps, 480 Mbps) and USB 3.0 Super Speed (5 Gbps). Supports all USB transactions (bulk, isochronous, interrupt, control).
- USB ports support up to 32 slots and 96 end-points
- Supports xHCI software host controller interface
- Supports wakeup from suspend states S1-S5 and remote-suspend wakeup
- Per port USB disable
- Support prefetch-based pause feature
- Support of USB suspend mode including PLL turn off in S0/Sx
- Capability to use reduced Frame List Sizes
- 64-bit data and 36-bit address
- Downstream 1DW memory read and writes, upstream memory read and writes
- Intel® Direct Connect Interface (Intel® DCI) customer visible debug port
- Intel® Direct Connect Interface (Intel® DCI) over DbC
- Intel® Direct Connect Interface (Intel® DCI) over Intel® DCI OOB (Out of Band)
- xHCI Debug Capability
- EP Type based Port Lock Capability
- The following USB capabilities are not supported:
  - Port Disable Override capability
  - USB-R Capability

14.3 Architectural Overview

The following section is adopted from *eXtensible Host Controller Interface for Universal Serial Bus (xHCI), Revision 1.1*.

Table 14-3, "Universal Serial Bus, Revision 3.0 System Block Diagram" shows a conceptual block diagram of the building block layers in a USB host system that work in concert to support USB 3.0

Figure 14-3. Universal Serial Bus, Revision 3.0 System Block Diagram



The component layers are:

- **Application Software.** This software uses the services provided by one or more USB devices. Application software interfaces with USB devices through standardized interfaces provided by the Class Drivers.
- **Class Driver Software.** This software executes on the host PC corresponding to a particular "class" of USB device (Mass Storage, Human Interface, Audio, etc.). Class Driver software is typically part of the operating system or provided with the USB device.
- **USB Driver (USBD).** The USBD is a system software Bus Driver that abstracts the details of the particular Host Controller Driver for a particular operating system. The generic USB interface presented to the system by USBD is referred to as the *USB Driver Interface* or the **USBDI**.
- **eXtensible Host Controller Driver (xHCD).** xHCD provides the software layer between the Host Controller hardware and the USBD. The details of the host controller driver depend on the host controller hardware register interface definition.
- **eXtensible Host Controller (xHC).** The host controller is the specific hardware implementation of the host controller architecture. There is one host controller specification for the USB 3.0 host controller, which enables support for Low-, Full-, High- and SuperSpeed devices. The interface presented by the xHC to the system is referred to as the *eXtensible Host Controller Interface* or the **xHCI**.
- **USB Device.** This is a hardware device that expands the bus topology (hub) or performs a useful end-user function. Interactions with USB devices flow from the applications through the software and hardware layers to the USB devices.

A key feature of the USB architecture is the **Device Framework** that it presents. The Device Framework defines the interface between a USB device and a Class Driver, which is independent of the particular host controller interface that a system employs to communicate with the USB. This interface consists of a Default Pipe, and zero or more additional class defined Pipes. The Default Pipe (also referred to as the *Default Control Endpoint*) is used to enumerate and manage a USB device. It can also be used to provide access to application specific features of the device. The class defined Pipes provide specialized Quality-of-Service requirements to perform device class specific functions.

The Device Framework allows the USB architecture to separate the details of the "Bus" interface from that of the application specific ("Device") interface, resulting in a split driver model (xHCD/Class Driver). Note that in this context, Device Class refers to the portion of a USB device that performs some useful end user application specific function (e.g. Mass Storage, Audio, Human Interface, etc.).

The USB bus driver (USBD) provides a standard method of interfacing to the transport mechanisms (USB Framework) defined by the USB architecture (Isoch, Interrupt, Control, and Bulk Pipes) and the Device Class driver is where all the application specific knowledge resides. A Class Driver will also include any "value add" that a vendor may provide. As long as the USB Framework presented through the USBDI remains unchanged, the USB Class Drivers do not have to change because the USB bus driver does (e.g. to support the xHCI).

Working groups in the USB-IF have defined several standard USB Device Classes (Mass Storage, Audio, etc.). A USB device vendor may choose to define a proprietary Device Class for their product or utilize part or all of an appropriate USB-IF defined Device Class. The USB-IF defined Device Classes provide a baseline set of features, for their respective class. Several USB Device Classes are supported natively by today's Operating Systems.

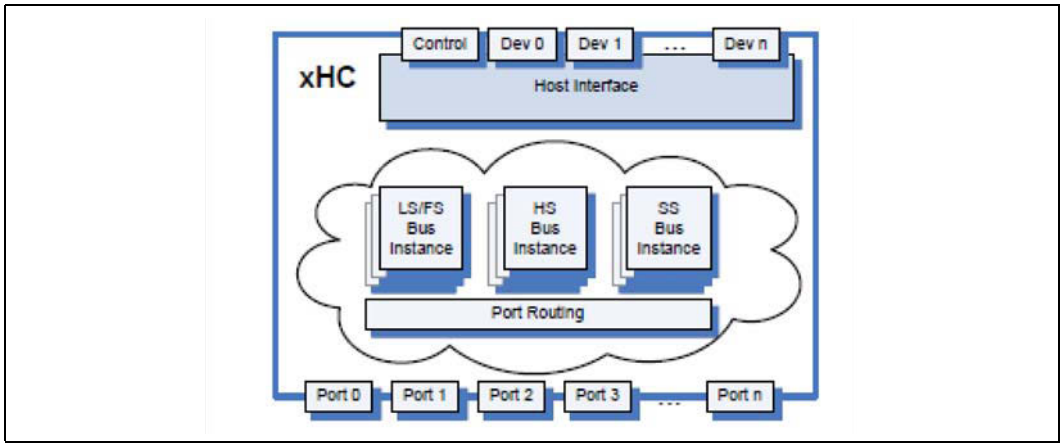
Native OS support for Device Classes allows a compliant device to provide a user with basic functionality if the vendor Device Class drivers are not available, however a vendor can define their own Class Driver to add value. Many commodity USB device vendors (mice, keyboard, etc.) take advantage of those provided by OS vendors and don't bother to offer their own Class Drivers. If a vendor offers a USB device that does not fall under one of the standard USB defined Device Classes supported by an OS then they shall offer their own Class Driver.

The xHCI is used for all communications to devices connected through the Root Hub ports of the USB 3.0 host controller.

The xHCI architecture allows the USB 3.0 host controller to provide USB functionality for all speed devices without requiring, as in previous generations, companion controllers along with the associated software support for their respective drivers. The enhanced features of the xHCI architecture are key to delivering this simplified operating environment.

Note that the Figure below does not imply a particular xHC implementation, however the functional partitioning that it illustrates is useful for this discussion. The Host Interface Logic manages the Registers and DMA associated with the xHC.

Figure 14-4. USB 3.0 eXtensible Host Controller



The xHC always manages the respective speed USB devices connected to its Root Hub ports. Depending on the implementation, the resources of a USB bus instance (bandwidth, device addressability, etc.) may be presented on each root hub port, shared across multiple root hub ports, or a combination of allocations.

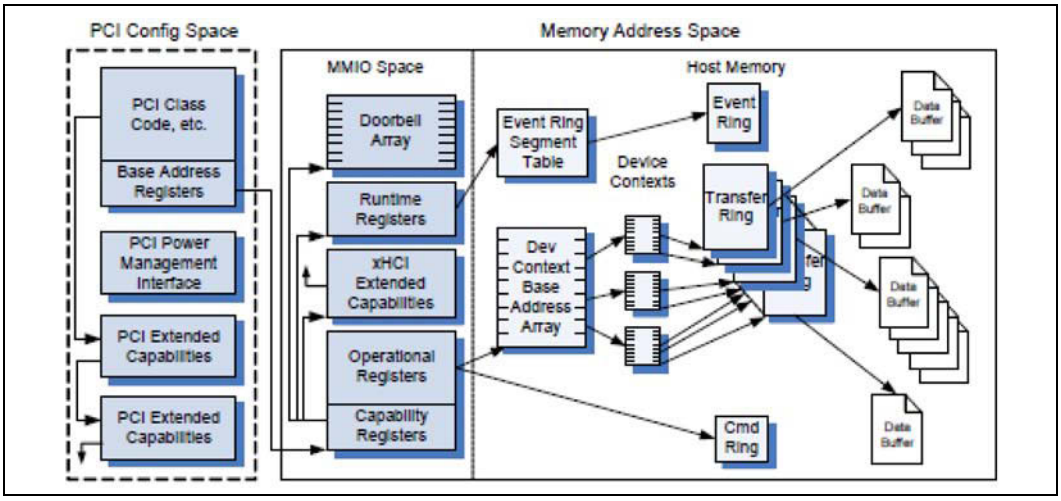
This specification defines the registers and interfaces for the eXtensible Host Controller Interface.

14.3.1 xHCI Interface Architecture

The xHCI interface defines three interface spaces (refer to in the Figure below):

- **Host Configuration Space.** Every xHC implementation shall include a means of identifying and enumerating the host controller by system software. This specification provides a PCI example of the Host Configuration Space, which is referred to as **PCI Config Space**. The PCI Config Space definition provides a working example of configuration space use for system xHC enumeration and resource (interrupt, power, virtualization, etc.) management.
- **MMIO Space.** The Register Space represents the hardware registers presented by the xHC to system software that reside in the Memory Address Space. The Register Space provides for the implementation-specific parameters defined in the xHCI normal and Extended Capabilities registers, the Operational and Runtime control and status registers, and the Doorbell Array used to flag accesses to individual USB devices. This space, normally referred to as I/O space, is implemented as Memory-Mapped I/O (**MMIO**) space.
- **Host Memory.** This space is defined by the control data structures (Device Context Base Address Array, Device Contexts, Transfer Rings, etc.) and data buffers that are allocated and managed by the xHC Driver to enable the endpoint traffic of individual devices. This space is allocated in the Kernel and User areas of the Memory Address Space.

Figure 14-5. General Architecture of the eXtensible Host Controller Interface



The xHCI provides support for two categories of USB transfer types: asynchronous and periodic. Isochronous and Interrupt transfers are Periodic transfer types. Asynchronous transfer types include Control and Bulk. Figure 3 illustrates that the xHCI provides a homogeneous mechanism (Transfer Rings) for each category of transfer type.

The USB Base Address Register (BAR) in the PCI Config Space points to the base address of the xHC register interface. The xHC register interface consists of 4 major components: Capability Registers, Operational Registers, Runtime Registers, and the Doorbell Array. The Operational and Capability Registers are concatenated in MMIO space. The Runtime Registers are actually just an extension of the Operational Registers. Their partitioning allows the xHC to better support virtualization, by allowing the Runtime Registers to reside on a separate page boundary. A xHCI Capabilities Pointer mechanism (similar to that defined by PCI) is presented in the Capability Registers to point to new or optional capabilities of an xHC implementation.

The ***Capability Registers*** specify read-only limits, restrictions and capabilities of the host controller implementation. These values are used as parameters to the host controller driver.

The ***Runtime*** and ***Operational Registers*** specify host controller configuration and runtime modifiable state, and are used by system software to control and monitor the operational state of the host controller. These registers are partitioned as a function of those that are heavily accessed during runtime and those that are accessed only at initialization time or only lightly during runtime to better support virtualization of the xHCI.

The ***xHCI Extended Capabilities*** specify optional features of an xHC implementation, as well as providing the ability to add new capabilities to implementations after the publication of this specification.

The ***Doorbell Array*** is an array of up to 256 Doorbell Registers, which supports up to 255 USB devices or hubs. Each ***Doorbell Register*** provides system software with a mechanism for notifying the xHC if it has Slot or Endpoint related work to perform. A *DB Target* field in the Doorbell Register is written with a value that identifies the reason for **"ringing"** the doorbell. Doorbell Register 0 is allocated to the Host Controller for Command Ring management.

The term ***Device Slot*** is used as a generic reference to a set of xHCI data structures associated with an individual USB device. Each device is represented by an entry in the *Device Context Base Address Array*, a register in the *Doorbell Array* register, and a device's *Device Context*. The term ***Slot ID*** refers to the index used to identify a specific *Device Slot*. For example the value of *Slot ID* will be used as an index to identify a specific entry in the *Device Context Base Address Array*.

The ***Device Context Base Address Array*** supports up to 255 USB devices or hubs, where each element in the array is a pointer to a *Device Context* data structure.

The **Command Ring** is used by software to pass device and host controller related commands to the xHC. The *Command Ring* shall be treated as read-only by the xHC. Refer to section 4.9.3 for a discussion of Command Ring Management.

The **Event Ring** is used by the xHC to pass command completion and asynchronous events to software. The *Event Ring* shall be treated as read-only by system software. Refer to section 4.9.4 for a discussion of Event Ring Management.

A ***Transfer Ring*** is used by software to schedule work items for a single USB Endpoint. A Transfer Ring is organized as a circular queue of ***Transfer Descriptor*** (TD) data structures, where each *Transfer Descriptor* defines one or more Data Buffers that will be moved to or from the USB. *Transfer Rings* are treated as read-only by the xHC. Refer to section 4.9.2 for a discussion of Transfer Ring Management.

All three types of rings support the ability for system software to grow or shrink them while they are active. Special TDs written to the Transfer and Command rings allow software to change their size, however since the Event Ring is read-only to software, the **Event Ring Segment Table** is provided so that software may modify its size.

14.4 xHCI Data Structures

The xHC is expected to run in virtual memory environments where the size of a contiguous block of physical memory will be limited by the Page size of the system. The data structures that the xHC uses to manage devices and endpoints are designed to accommodate this limitation, by either keeping the data structure under 4K Bytes (the minimum Page size supported), or providing mechanisms to link non-contiguous blocks of physical memory to form larger, logically contiguous data structures, e.g. circular queues of data structures that point to the data buffers used for transferring USB data to or from the host. The data buffers referenced by these data structures may be byte aligned and reference from 1 to 64K bytes of contiguous physical data.

Please refer to the xHCI Specification for further information.

14.5 Command Interface

To manage the xHC and the devices attached to it, the xHC provides an independent Command Ring interface. A work item on a Command Ring is called a *Command Descriptor* (CD). Command Ring operation is very similar to that of Transfer Rings, software issues a command to the xHC by placing a CD on the Command Ring then rings the Host Controller doorbell. The size of the Command Ring can be modified using the same Link TRB mechanism that Transfer Rings use. All commands result in a *Command Completion Event* being placed on the Event Ring, which reports the completion status of the command. Commands are executed by the xHC in the order that they are placed on the Command Ring. System software may add CDs to the Command Ring while it is running, however the execution of CDs should be stopped if software wants to delete or reorder (i.e. raise the priority of) scheduled CDs. Special Command Ring controls allow commands to be stopped or aborted.

Please refer to the *Enhanced Host Controller Interface Specification for Universal Serial Bus, Revision 1.0* for further information.

14.6 Root Hub Management

The host controller of a USB bus is required to implement Root Hub functionality. The Operational Register space contains port registers that provide the hardware status and control needed to manage each port within the USB Specification. An xHC Root Hub may provide USB 2.0 and USB 3.0 Root hub ports to support Low-, Full-, or High-Speed as well as SuperSpeed devices. The host controller traverses the Transfer Rings and encounters work items that result in the host controller executing USB transactions. These transactions are routed to the Root Hub port associated with the attached downstream USB device. The port registers provide system software with the control and status information required to manipulate the port in accordance with the USB Specification. The supported features include: detecting device connects, disconnects, performing device resets, manipulating port power and managing port power management capabilities. System software should provide an abstraction to the USB system software stack that allows the Root Hub ports to be manipulated by the system as if they were ports on an external hub.

14.7 Operational Model

Please refer to the xHCI Specification Chapter 4 “Operational Model” for information related to the eXtensible Host Controller Interface (xHCI) hardware and eXtensible Host Controller Driver (xHCD) (generally referred to as system software).

The chapter includes significant operational feature of the eXtensible Host Controller (xHC) and operational model requirements for the xHC hardware.

14.8 Supported Transaction Types

The controller is discovered as bus 0, device 21, function 0.

Table 14-3, "Transaction Type Supported by USB Block" shows the transaction types supported by the USB block:

Table 14-3. Transaction Type Supported by USB Block

Transaction Type	Upstream	Downstream
Memory Read (32/64 bits)	Yes	Yes
Memory Write (32/64 bits)	Yes	Yes
I/O Read	No	No
I/O Write	No	No
Configuration Read0	No	Yes
Configuration Write0	No	Yes
Configuration Read1	No	No
Configuration Write1	No	No
Message	No	No
MessageD	No	No
Completion	Yes	Yes
CompletionD	Yes	Yes

14.9 Reset Requirements

Table 14-4, "Reset Signal Information" shows the reset signal information used in the USB Controller.

Table 14-4. Reset Signal Information

Reset Signal	Power Well	Assertion	Description
AON Power Good Based Reset	SUS	Async Power Good Removal	Power Good based reset to be used for isolation
Reset	SUS	Async SoC Controlled conditions	Internally synchronous to SUS clock, after AON power is stable and reset sequence is complete.
VNN Power Good Based Reset	VNN/CORE	Async Power Good Removal	Power Good based reset to be used for isolation
SBI Reset	VNN/CORE	Async Fabric Reset	Internally Synchronous to Side Clock.
Fabric Reset	VNN/CORE	Async Host Partition Reset	Internally Synchronous to backbone clock.

14.10 USB Power Management – Link States

Table 14-5, "USB 2.0 Link States and Power Actions" explains the USB 2.0 link states and power actions. Each deeper link state includes actions from prior/shallower link states unless explicitly stated otherwise. So details are not repeated in each deeper link state.

Table 14-5. USB 2.0 Link States and Power Actions

Link State	Entry	Exit	Core Action	PHY Action
USB2				
U0 Idle	All scheduled transactions completed for BI. Minimum time left before next BI.	Start of new BI (early indication used to wake PLL).	Fabric Clock allowed to be trunkgated if other ports do not need it. Fabric PLL allowed to be shut down if no other port needs it. All RFpower gating.	x and Rx current sources and Bias circuits are actively managed. Tx shut down if Receiving. Rx shut down if Transmitting.
U2	L1 is enabled. Device on root port supports L1. Device on root port accepts L1 entry required.	Host DB ring. Device initiates exit from L1. Optional timer based wake for non-compliant devices.	Update LTR. Clock gate USB2 link clock at port level. Shut down USB2 PLL if all ports are in L1 or deeper. Indicate "suspend" to PHY.	Shut down HS clocks. Power gate core portion of PHY.
U3	SW places port in U3.	SW places port in U0.	Update LTR to "no requirement". Allow D3 based actions (implicit). Indicate L1 "suspend" to PHY.	Power gate core portion of PHY.
Disconnected			Update LTR to "no requirement". Allow D3 based actions (implicit). Indicate L1 "suspend" to PHY.	Power gate core portion of PHY.

Table 14-6, "USB 3.0 Link States and Power Actions" explains the USB 3.0 link states and power actions. Each deeper link state includes actions from prior/shallower link states unless explicitly stated otherwise. So details are not repeated in each deeper link state.

Table 14-6. USB 3.0 Link States and Power Actions

Link State	Entry	Exit	Core Action	PHY Action
USB3				
U0			Update LTR based on received BELT messages	
U0 Idle	All scheduled transactions completed for BI. Minimum time left before next BI.	Start of new BI (early indication used to wake PLL).	Fabric Clock allowed to be trunkgated if other ports do not need it. Fabric PLL allowed to be shut down if no other port needs it. All RFpower gating.	None.
U1	U1 idle time expires.	DB ring or Periodic transaction scheduled. Device initiated exit. U2 timer expires.	Link clocks gated at port level. PIPE state = PS1.	Tx OFF. Rx OFF. Maintain common mode.
U2	U2 idle timer expires.	DB ring or Periodic transaction scheduled. Device initiated exit.	Link clocks gated at port level. PIPE state = PS3. Indicate USB 3.0 link PLL can be shut off. Indicate Morhy port can be power gated. Aux clock gated at the partition level. Requires: Timer tick for RxDetect timers.	PLL off. Tx, Rx off. Common mode off. Power gate core well.
U3	SW initiated.	SW initiated.	Allow D3 actions similar to U2.	Similar to U2.
RxDetect.	NA	NA	PIPE state = PS3 (after first RxDetect). Similar to U3.	Similar to U3.

14.11 Error Condition and Handling

The USB 3.0 port Error handling is as per USB3 and xHCI Specifications.

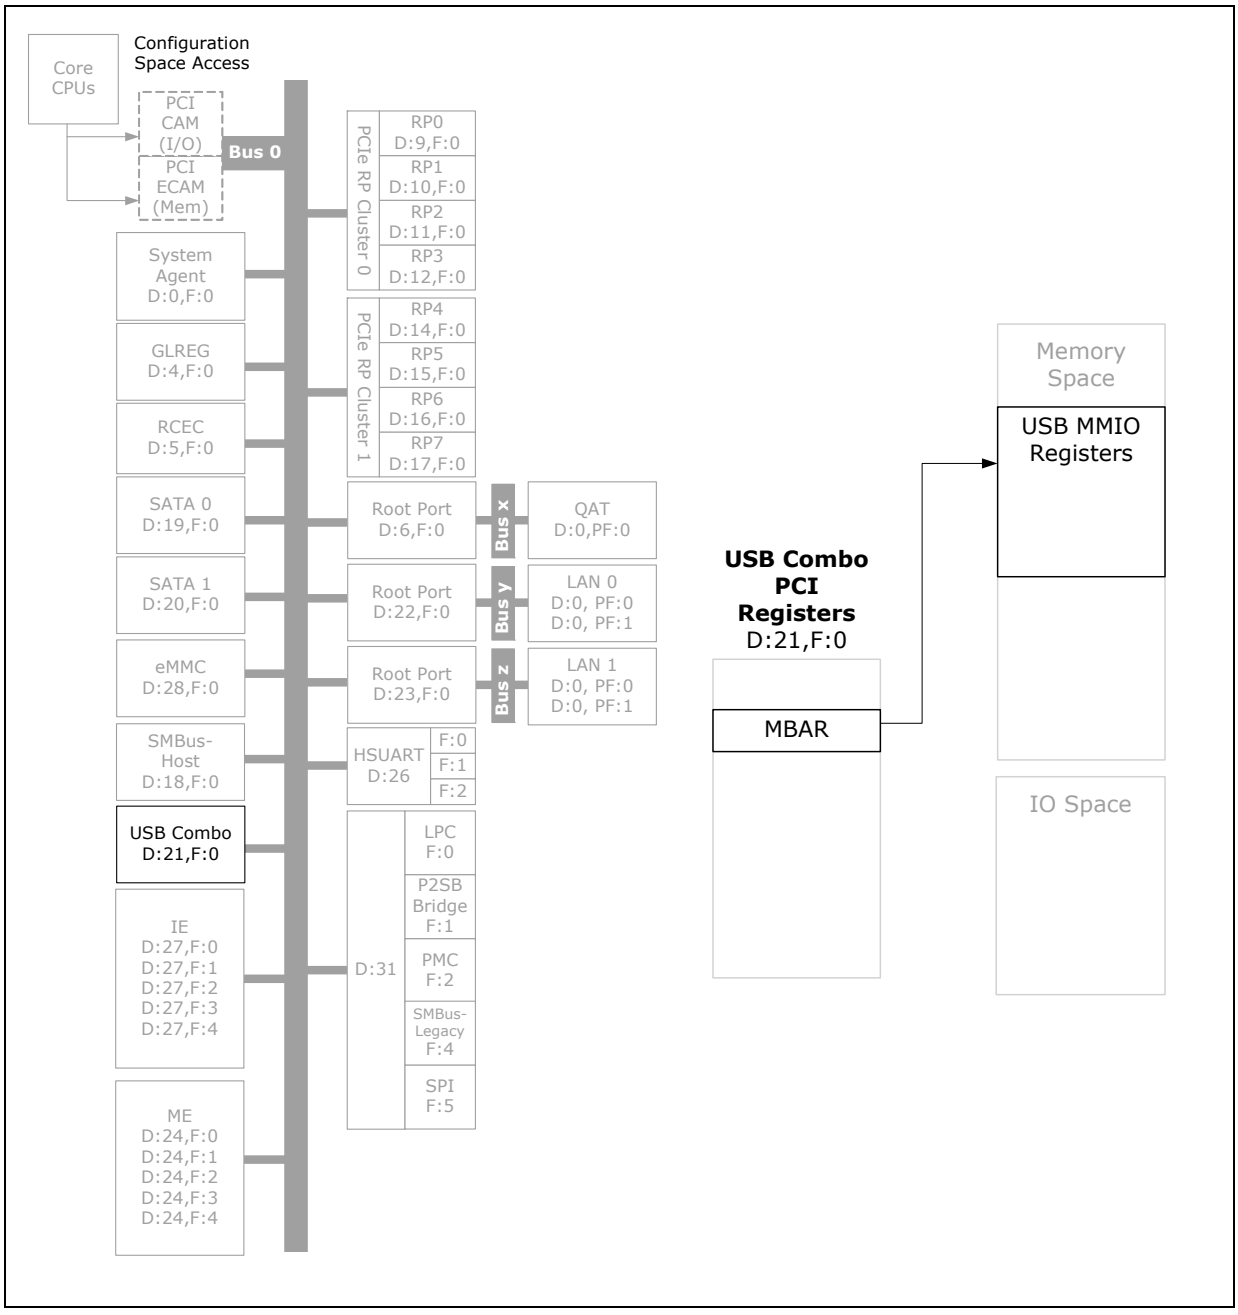
14.12 Debug Capability (DbC)

The USB Debug Capability (DbC) is provided by the SoC USB eXtensible Host Controller (xHC). DbC is an optional USB functionality that enables low-level system debug over USB. The xHC Interface (xHCI) debugging capability provides a means of connecting two systems where one system is a Debug Host and the other a Debug Target (System Under Test). See the section on DbC in the *eXtensible Host Controller Interface for Universal Serial Bus (xHCI), Revision 1.1*. Also see Section 38.4.1, "Debug Capability (DbC)" on page 988, in this document.

14.13 Register Map

Figure 14-6 shows the associated registers from a system software viewpoint.

Figure 14-6. Register Map



14.13.1 PCI Configuration and Capabilities

Table 14-7. Configuration and Capabilities Register Map (Sheet 1 of 2)

Offset from Configuration Space of B0:D21:F0 (hex)	Register Short Name	Description
Standard Type 0 PCI Configuration Registers		
0	VID	Vendor ID
2	DID	Device ID
4	CMD	Command
6	STS	Device Status
8	RID	Revision ID
9	PI	Programming Interface
A	SCC	Sub Class Code
B	BCC	Base Class Code
D	MLT	Master Latency Timer
E	HT	Header Type
10	MBAR	Memory Base Address
2C	SSVID	USB Subsystem Vendor ID
2E	SSID	USB Subsystem ID
34	CAP_PTR	Capabilities Pointer
3C	ILINE	Interrupt Line
3D	IPIN	Interrupt Pin
PCI Power Management Capability		
70	PM_CID	PCI Power Management Capability ID
71	PM_NEXT	Next Item Pointer #1
72	PM_CAP	Power Management Capabilities
74	PM_CS	Power Management Control/Status
Message Signaled Interrupt Capability		
80	MSI_CID	Message Signaled Interrupt CID
81	MSI_NEXT	Next item pointer
82	MSI_MCTL	Message Signaled Interrupt Message Control
84	MSI_MAD	Message Signaled Interrupt Message Address
88	MSI_MUAD	Message Signaled Interrupt Upper Address
8C	MSI_MD	Message Signaled Interrupt Message Data

Table 14-7. Configuration and Capabilities Register Map (Sheet 2 of 2)

Offset from Configuration Space of B0:D21:F0 (hex)	Register Short Name	Description
Device-Specific PCI Configuration Registers		
40	XHCC1	XHC System Bus Configuration 1
44	XHCC2	XHC System Bus Configuration 2
50	XHCLKGTEN	Clock Gatings
58	AUDSYNC	Audio Time Synchronization
60	SBRN	Serial Bus Release Number
61	FLADJ	Frame Length Adjustment
62	BESL	Best Effort Service Latency
90	DEVIDLE	Device Idle Capability
94	VSHDR	Vendor Specific Header
98	SWLTRPTR	SW LTR POINTER
9C	DEVIDLEPTR	Device Idle Pointer Register
A0	DEVIDLEPOL	Device Idle Power ON Latency
A4	HSCFG2	High Speed Configuration 2
B0	U2OCM1	XHCI USB2 Overcurrent Pin Mapping 1
D0	U3OCM1	XHCI USB3 Overcurrent Pin Mapping 1
FC	XHCC3	XHCC3

14.13.2 Memory-Mapped Registers

Table 14-8. Relocatable Memory-Mapped Registers (Sheet 1 of 11)

Base Address Register (BAR) Short Name	Offset from BAR (hex)	Register Short Name	Register Long Name
eXtensible Host Controller (xHCI) Capability Registers			
MBAR	0	CAPLENGTH	Capability Registers Length
MBAR	2	HCIVERSION	Host Controller Interface Version Number
MBAR	4	HCSPARAMS1	Structural Parameters 1
MBAR	8	HCSPARAMS2	Structural Parameters 2
MBAR	C	HCSPARAMS3	Structural Parameters 3
MBAR	10	HCCPARAMS	Capability Parameters
MBAR	14	DBOFF	Doorbell Offset
MBAR	18	RTSOFF	Runtime Register Space Offset
xHCI Operational Registers			
MBAR	80	USBCMD	USB Command
MBAR	84	USBSTS	USB Status
MBAR	88	PAGESIZE	Page Size
MBAR	94	DNCTRL	Device Notification Control
MBAR	98	CRCR_LO	Command Ring Low
MBAR	9C	CRCR_HI	Command Ring High
MBAR	B0	DCBAAP_LO	Device Context Base Address Array Pointer Low
MBAR	B4	DCBAAP_HI	Device Context Base Address Array Pointer High
MBAR	B8	CONFIG	Configure

Table 14-8. Relocatable Memory-Mapped Registers (Sheet 2 of 11)

Base Address Register (BAR) Short Name	Offset from BAR (hex)	Register Short Name	Register Long Name
xHCI USB Port Registers			
MBAR	480	PORTSC1	Port Status and Control USB2
MBAR	484	PORTPMSC1	Port Power Management Status and Control USB2
MBAR	48C	PORTHLPMC1	Port X Hardware LPM Control Register
MBAR	490	PORTSC2	Port Status and Control USB2
MBAR	494	PORTPMSC2	Port Power Management Status and Control USB2
MBAR	49C	PORTHLPMC2	Port X Hardware LPM Control Register
MBAR	4A0	PORTSC3	Port Status and Control USB2
MBAR	4A4	PORTPMSC3	Port Power Management Status and Control USB2
MBAR	4AC	PORTHLPMC3	Port X Hardware LPM Control Register
MBAR	4B0	PORTSC4	Port Status and Control USB2
MBAR	4B4	PORTPMSC4	Port Power Management Status and Control USB2
MBAR	4BC	PORTHLPMC4	Port X Hardware LPM Control Register
MBAR	4C0	PORTSC5	Port Status and Control USB3
MBAR	4C4	PORTPMSC5	Port Power Management Status and Control USB3
MBAR	4C8	PORTLI5	USB3 Port Link Info
MBAR	4D0	PORTSC6	Port Status and Control USB3
MBAR	4D4	PORTPMSC6	Port Power Management Status and Control USB3
MBAR	4D8	PORTLI6	USB3 Port Link Info
MBAR	4E0	PORTSC7	Port Status and Control USB3
MBAR	4E4	PORTPMSC7	Port Power Management Status and Control USB3
MBAR	4E8	PORTLI7	USB3 Port Link Info
MBAR	4F0	PORTSC8	Port Status and Control USB3
MBAR	4F4	PORTPMSC8	Port Power Management Status and Control USB3
MBAR	4F8	PORTLI8	USB3 Port Link Info

Table 14-8. Relocatable Memory-Mapped Registers (Sheet 3 of 11)

Base Address Register (BAR) Short Name	Offset from BAR (hex)	Register Short Name	Register Long Name
Host Controller Runtime Registers			
MBAR	2000	RTMFINDEX	Microframe Index
MBAR	2020	IMAN0	Interrupter 1 Management
MBAR	2024	IMOD0	Interrupter 1 Moderation
MBAR	2028	ERSTSZ0	Event Ring Segment Table Size 1
MBAR	2030	ERSTBA_LO0	Event Ring Segment Table Base Address Low 1
MBAR	2034	ERSTBA_HI0	Event Ring Segment Table Base Address High 1
MBAR	2038	ERDP_LO0	Event Ring Dequeue Pointer Low 1
MBAR	203C	ERDP_HI0	Event Ring Dequeue Pointer High 1
MBAR	2040	IMAN1	Interrupter 2 Management
MBAR	2044	IMOD1	Interrupter 2 Moderation
MBAR	2048	ERSTSZ1	Event Ring Segment Table Size 2

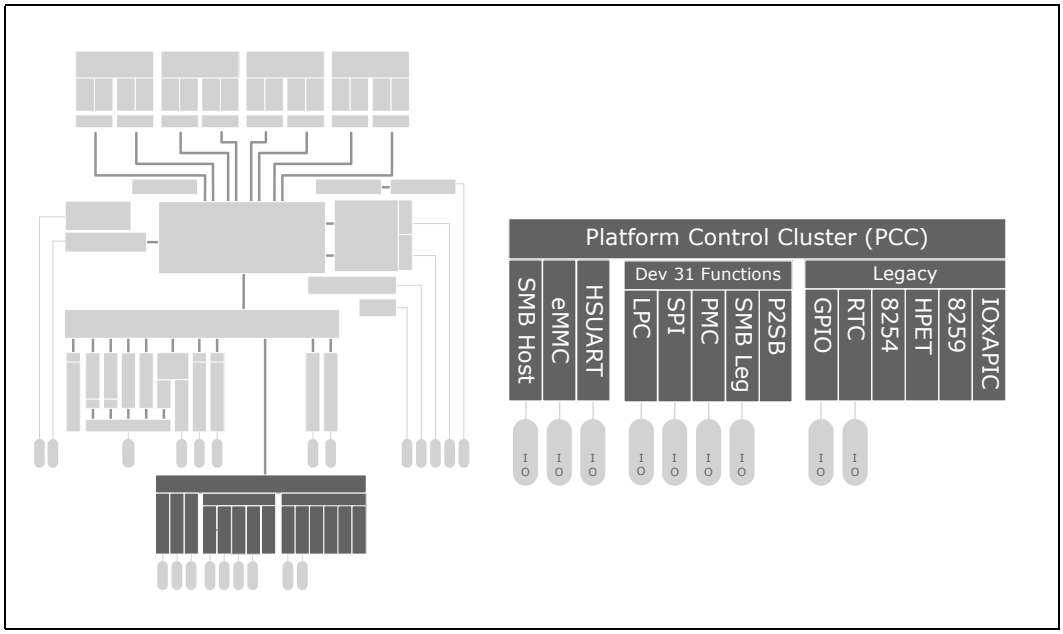
§ §

15 Platform Control Cluster (PCC)

This chapter describes the Platform Control Cluster (PCC).

Figure 15-1. What is Covered in This Chapter



15.1 Signal Descriptions

The signal pins and signal names associated with this chapter are described in the chapter of each PCC device.

15.2 Architectural Overview

The Platform Control Cluster (PCC) consists of the devices and controllers shown in Table 15-1. Details are in the Chapters shown in the table.

Table 15-1. Platform Control Cluster (PCC)

Device/Controller	Chapter
Integrated PCI devices	
SMBus - Host	See Chapter 29, "SMBus Controller - Host" for details.
Embedded Multimedia Card (eMMC)	See Chapter 17, "Embedded Multi-Media Card (eMMC)" for details.
High-Speed UART (HSUART)	See Chapter 18, "High-Speed UART Controller" for details.
Device 31 Functions	
LPC	See Chapter 20, "Low Pin Count (LPC) Controller" for details.
Serial Peripheral Interface (SPI)	See Chapter 19, "Serial Peripheral Interface (SPI)" for details.
Power Management Controller (PMC)	See Chapter 16, "Power Management Controller (PMC)" for details.
SMBus - Legacy	See Chapter 28, "SMBus Controller - Legacy" for details.
Primary to Sideband Bridge (P2SB)	See Chapter 22, "Primary to Side Band (P2SB) Bridge" for details.
Legacy controllers	
Customer GPIO	See Chapter 26, "Customer General-Purpose I/O (GPIO)" for details.
Real Time Clock (RTC)	See Chapter 24, "Real Time Clock (RTC)" for details.
8245 Programmable Interrupt Timer (PIT)	See Chapter 23, "Programmable Interval Timer (PIT)" for details.
High Performance Event Timer (HPET)	See Chapter 25, "High Precision Event Timer (HPET)" for details.
8259 Programmable Interrupt Controller (PIC)	See Chapter 21, "PIC and I/O APIC Controllers" for details.
IOxAPIC	See Chapter 21, "PIC and I/O APIC Controllers" for details.

15.2.1 Integrated PCI Devices

The PCC contains three integrated PCI devices which are accessible in Host Root Space:

- Device 18 (decimal), Function 0 - SMBus (Host) controller
- Device 26 (decimal), Functions 0, 1, and 2 - High-Speed UART (HSUART) controller
- Device 28 (decimal), Function 0 - Embedded Multimedia Card (eMMC) controller

Table 15-1 on page 523 provides a list of chapters for each controller.

15.2.2 Integrated PCI Device 31 Functions

Accessible in Host Root Space, the integrated, PCI Device 31 (decimal), has five PCI Functions:

- Function 0:
  - Low Pin Count (LPC) controller if the "Reserved for Intel" tied to pin (MCERR_N) SoC Hard Strap pin is 0.
- Function 1 - Primary to Sideband Bridge (P2SB) controller.
- Function 2 - Power Management Controller (PMC).
- Function 3 - SMBus (Legacy) controller.
- Function 4 - Serial Peripheral Interface (SPI) controller.

Table 15-1 on page 523 provides a list of chapters for each controller.

15.2.3 Legacy Controller Group

The Legacy group of controllers are the Customer General-Purpose I/O (GPIO) controller, Real-Time Clock, and the group of controllers that comprise the Interrupt Timer Sub System (ITSS). Table 15-1 on page 523 provides a list of chapters for each controller. The following section summarizes the ITSS group.

15.2.3.1 Interrupt Timer Sub System (ITSS)

The ITSS is a portion of the SoC internal circuitry consisting of the HPET, 8254 PIT, 8259 PIC, IOxAPIC and CPU interface components. It also provides the SoC interrupt routing control for the Host Root Space. The ITSS has its own clock and reset-control circuitry.

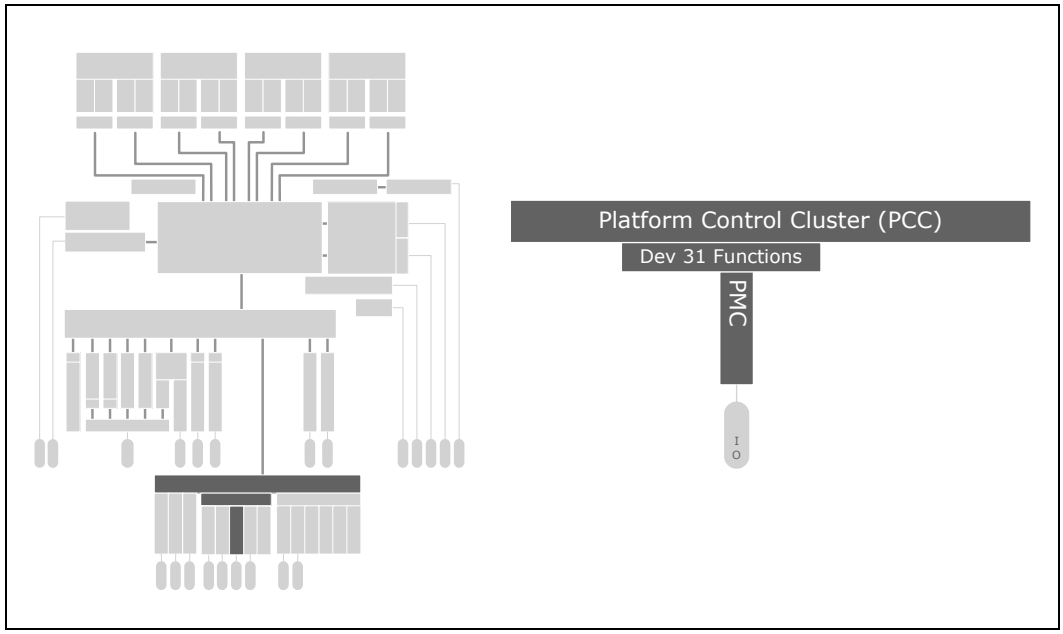
The Innovation Engine (IE) has a sideband connection to the ITSS components.

§ §

16 Power Management Controller (PMC)

This chapter describes the Power Management Controller (PMC) of the SoC.

Figure 16-1. What is Covered in This Chapter



16.1 Signal Descriptions

The signal descriptions are shown in Table 16-1, "Signal Names and Descriptions". For additional signal information, including whether a signal is assigned to shared-function pin or can be used as a Customer GPIO signals see Chapter 39, "Signal Pin Names and Signal MUXing". The Direction/Type column of Table 16-1, "Signal Names and Descriptions" is interpreted as follows:

- I = Input signal. The SoC has receiver circuit.
- O = Output signal. The SoC has driver circuit.
- O-OD = Open-Drain Output. SoC output circuit uses an open-drain driver.

Table 16-1. Signal Names and Descriptions (Sheet 1 of 2)

Signal Names	Direction	Shared	Description
ADR_TRIGGER	I,O-OD	Yes	**Asynchronous DRAM Refresh (ADR) Trigger:** This active-high input is driven by the platform board circuitry to start the SoC ADR flow of events. As an active-high, open-drain output, the SoC can also drive this signal high to trigger ADR when an enabled, internal ADR event occurs. The SoC drives this signal pin high as long as the internal, ADR-triggered event is valid. The platform board must connect a pull-down resistor to this pin. ***Note:*** The platform board must refrain from actively driving this signal before power loss (external qualified event) has happened. The internal SoC circuitry also drives this pin active when it detects and handles an internal qualified event.
ADR_COMPLETE	I,O	Yes	**Asynchronous DRAM Refresh (ADR) Complete:** This active-high output indicates that the SoC has completed the ADR flow of events. When power is invalid or removed from the SoC, this output signal is invalid. ***Note:*** Even though this signal pin is labeled as an input-output (I/O), the platform must use it as an output-only pin and must not drive it.
CPU_RESET_N	O	Yes	**CPU Reset:** This active-low output can be used by the platform board or debug tools to indicate that the SoC is in a reset state.
PMU_PLTRST_N	O	Yes	**Platform Reset:** This active-low signal is asynchronously driven by the SoC and can be used as the platform board's main reset. This signal can be used by the PCI Express interface as the Fundamental Reset signal (PERST#) as defined in the PCIe base specification.
PMU_PWRBTN_N	I	Yes	**Power Button:** This active-low signal is debounced (16 ms) by the SoC. It generates an SMI or SCI to request the system to go to a sleep state. If already in sleep state, it causes a Wake Event. When the signal is held asserted for 5.1 seconds or longer while the SoC is in the G0 or G1 state, a power-button override is generated. This causes an unconditional transition to the G2 soft-off state and is useful when the system is in a hung working state.
PMU_RESETBUTTON_N	I	Yes	**Reset Button:** This edge-triggered, active-low, input signal indicates that the system reset button is depressed. The SoC debounces this input signal and does nothing unless the signal is asserted for at least 16 ms, at which time the PMC begins reset-sequence actions. When this edge-triggered signal is asserted beyond the 16-ms period, no additional reset actions are taken (only one reset produced per asserted edge). ***Note:*** There is a SoC Soft Strap that can be set to either enable this 16-ms debounce period or disable the internal debounce circuitry on this pin. See Chapter 4, "Strapping and Configuration".

Table 16-1. Signal Names and Descriptions (Sheet 2 of 2)

Signal Names	Direction	Shared	Description
PMU_SLP_S3_N	O	Yes	**Sleep State 3:** This active-low signal indicates that the SoC is transitioning from S0 to S4 or S5, or transitioning back up to S0, and that the platform board can shut down power not needed in this state by the SoC and the rest of the system.
PMU_SLP_S45_N	O	Yes	**Sleep State 4 or 5:** This active-low signal indicates that the SoC has entered and is in either the Suspend-to-Disk (S4) or Soft-Off (S5) Sleep State and that the platform board can shut down power not needed in these states by the SoC and the rest of the system.
PMU_SUSCLK	O	Yes	**Suspend Mode Clock:** Output of the RTC circuit (32.768 kHz) that can be used by the platform board. The output has a duty cycle as low as 30% or as high as 70%.
PMU_WAKE_N	I	Yes	**Wake:** This active-low signal is the destination of the PCIe sideband WAKE# signals. All device WAKE# signals are open-drain output signals and are connected together as described in the PCIe base specification.
SUS_STAT_N	O	Yes	**Suspend Status:** This active-low signal indicates that the SoC will be entering a low power state soon. This can be monitored by devices with memory that need to switch from normal refresh to suspend refresh mode. It can also be used by other peripherals as an indication that they should isolate their outputs that may be going to powered-off state.
SUSPWRDNACK	O	Yes	**Suspend Power-Down Acknowledge:** This active-high signal is asserted by the SoC when it does not require its Suspend (SUS) power well to be powered.
COREPWROK	I	No	See Chapter 24, "Real Time Clock (RTC)" for details.
INTRUDER_N	I	No	See Chapter 24, "Real Time Clock (RTC)" for details.
RSMRST_N	I	No	See Chapter 24, "Real Time Clock (RTC)" for details.
RTEST_N	I	No	See Chapter 24, "Real Time Clock (RTC)" for details.
SRTCRST_N	I	No	See Chapter 24, "Real Time Clock (RTC)" for details.
THERMTRIP_N	O-OD	Yes	See Chapter 35, "Thermal Management" for details.

16.2 Feature List

- ACPI and general Power Management control
- Circuitry to lower the Total Cost of Ownership (TCO) of the system
- Interacts with the SoC Innovation Engine (IE)
- Interacts with the SoC Intel® Management Engine (Intel® ME)
- Asynchronous DRAM Refresh (ADR)

16.3 Architectural Overview

The SoC Power Management Controller (PMC) is circuitry that provides the power management interface to the SoC signal pins. These are listed in Table 16-1, "Signal Names and Descriptions". The controller is an internal micro-controller which is not directly accessible to the SoC customer.

The PMC appears as a PCI Bus 0, Device 31 (decimal), Function 2 to software.

A number of SoC power-control and status registers are located in relocatable Host Root I/O Space starting at the ACPI Base Address (ABASE). These I/O Space registers must be enabled by setting the ACPI Enable (EN), bit 7 of the ACPI Control (ACTL) register at offset 44h of the PMC Configuration Space.

There are also a number of PMC registers located in relocatable Host Root Memory Space starting at the PM Base Address (PWRMBASE). These Memory-Mapped registers must be enabled by setting the PWRM Enable (PWRM_EN), bit 8 of the ACPI Control (ACTL) register at offset 44h of the PMC Configuration Space.

Bits [2:0] of the aforementioned ACPI Control (ACTL) register specify to which IRQ the System Control Interrupt (SCI) is routed internal to the SoC. The default is IRQ9 and other options are programmable.

The PMC performs the software-generated reset when the Host software writes a value of 06h or 0Eh to the Reset Control (RST_CNT) Register located at address CF9h in I/O Space.

The Total Cost of Ownership (TCO) registers are accessible and are located in the SMBus-Legacy Controller that appears as a PCI Bus 0, Device 31 (decimal), Function 4 to software.

16.4 System Power States

See Section 34.8, "System Global Power States" on page 911.

16.5 SoC Internal Power Control

The required supply voltages for the SoC operation for each Global Power State are shown in Chapter 34, "Supply Voltage Rails". The PMC platform board must provide the SoC voltages, but the PMC circuitry controls the internal silicon voltage rails for its Power Wells, turning internal circuitry on and off as needed. Whether a platform board turns its voltage regulators on and off is up to the system designer, but the regulators must provide power during the power states shown in Chapter 34, "Supply Voltage Rails".

16.5.1 Internal Power Switching

The SoC internal circuitry required for a particular product SKU is fully powered-on during the ACPI G0 (S0) state. The internal SoC circuitry that is only powered-on during the G0 (S0) working state is in the Core Power Well. See Section 34.4.1, "Core Power Well" on page 906. Some internal functions of a product SKU can be programmed to be powered off.

When the system is in the G2 (S5) Soft Off state, the PMC turns off power to some of the internal circuitry. The internal circuitry that is powered-on during G0 (S0) and during the G2 (S5) state is in the SUS Power Well. See Section 34.4.2, "SUS Power Well" on page 906. Sometimes this is referred to as "Always On" circuitry. The integrated circuitry that is powered-on during G2 (S5) is shown Table 16-2, "SoC Circuitry Powered-On During the G2 (S5) Global Power State".

Table 16-2. SoC Circuitry Powered-On During the G2 (S5) Global Power State

SoC Internal Module	Circuitry Powered On	Power Usage
Power Management	All	Required for SoC state changes
USB Combo Controller	USB 2.0 PHY and portion of the USB controller	Required for debug interface and Wakeup
High-Speed IO (HSIO)	All (PCI Express, SATA, USB 3.0)	Required for Wakeup
LAN	PHY	Required for Wakeup (if enabled)
Customer General Purpose I/O (GPIO)	All	Required for Wakeup and operation in the G2 (S5) state
Intel® Management Engine	All	
Innovation Engine	All	
Intel® Trace Hub	All	

When all power supplied to the SoC is removed, the system is in the G3 Mechanical Off state. If the system design includes a functioning RTC battery, a number of SoC registers draw power from the battery and retain their information during the Mechanical-Off state. These registers are also powered-on during the G0 (S0) and G2 (S5) states and are in the SoC RTC Power Well. See Section 34.4.3, "RTC Power Well" on page 906. The integrated circuitry that is powered-on during G3 is shown Table 16-3, "SoC Circuitry Powered-On During the G3 Global Power State".

Table 16-3. SoC Circuitry Powered-On During the G3 Global Power State

SoC Internal Module	Circuitry Powered On	Power Usage
SoC RTC Circuitry	RTC Registers, 32.768 kHz clock, SRAM, time and calendar	Retain register and time information during G3
Power Management	Registers preserved by a functioning RTC battery	Saving system information when system power is off
Intel® Management Engine	Registers preserved by a functioning RTC battery	Saving system information when system power is off

16.6 Total Cost of Ownership (TCO)

The TCO system management functions are designed to allow the system to diagnose failing subsystems. The intent of this logic is that some of the system management functionality can be provided without the aid of an external micro-controller or a Baseboard Management Controller (BMC).

While the TCO circuitry and registers are located in the SoC SMBus-Legacy controller, the SoC does not provide SMBus connectivity to the TCO mechanism. The SoC does allow Operating System (OS) software to access the TCO registers. TCO provides various functions to make a system easier to manage and to lower the total cost of ownership of the system. TCO features supported by the SoC:

- First TCO Watchdog Timer timeout can generate SMI# after a programmable time
  - The programmable 10-bit timer is decremented approximately every 0.6 seconds and allows timeouts ranging from 1.2 seconds to 613.8 seconds. The timeout value is programmable in the TCO_TMR Register (TTMR).
  - OS software can periodically reload the SoC timer using the TCO_RLD Register (TRLD). The first TCO Watchdog Timer timeout causes an SMI# allowing SMM-based recovery from OS lockup.
- Second hard-coded TCO Watchdog Timer timeout to generate a system reboot by the SoC asserting the active low PMU_PLTRST_N signal
  - This second timer is used only after the first TCO Watchdog Timer timeout occurs.
  - The SMI# handler must reload the first timer within 2.4 seconds after it times out to prevent the second timer from causing a system reboot. A timeout here assumes to be from a CPU or hardware error and reason to generate a system reset and reboot.
  - Option to prevent the system from rebooting after the second timeout via the "No TCO Reboot Enable" Hard Pin Strap. See Table 4-1, "SoC Hard Straps/Pin Straps and Descriptions".
- Capability for the SMM handler to generate a TCO interrupt to the OS
- Capability for OS to generate an SMI# to alert the TCO code in the SMM handler
- Processor Present detection
  - Detects if the processor fails to fetch the first instruction after reset.
- Report various errors detected by the circuitry
  - Can generate an SMI# or TCO interrupt (SERR, SMI, SCI).
- Intruder-Detect input (INTRUDER_N):
  - Can generate a TCO interrupt or SMI# when the system cover is removed.
  - The IRQ interrupt routed per register
  - The INTRUDER_N input signal is allowed to go active in any power state, including G3.
- Illegal BIOS accesses through SPI Flash is tracked and enabled in local registers in SPI Flash.
- Detection of bad BIOS Flash programming:
  - Detects if data on first read is FFh (an indication that the BIOS flash device is not programmed).

16.6.1 Detecting a System Lockup

When the processor is reset, it is expected to fetch its first instruction. If the processor fails to fetch the first instruction after reset, the TCO Watchdog Timer times out twice and the SoC asserts the Platform Reset (PMU_PLTRST_N) SoC output signal.

The Platform Reset and subsequent re-boot does not occur if the "No TCO Reboot" SoC Hard Pin Strap is active when sampled when the Resume Reset RSMRST_N signal deasserts. See Table 4-1, "SoC Hard Straps/Pin Straps and Descriptions".

During every boot, BIOS must read the SECOND_TO_STS bit in the TCO2_STS Register (TSTS2) to see if this is normal boot or a reboot due to the timeout. This bit is only cleared by writing a 1 to this bit or by assertion of the active low RSMRST_N SoC input signal pin by the platform board. The BIOS may also check the OS_POLICY bits of the TCO2_CNT Register (TCTL2) to see if it should try another boot or shutdown.

16.6.2 Handling an Intruder

The SoC has an active-low input signal, INTRUDER_N, that can be wired to a switch that is activated by the system's case being open. The activation of this signal can be used to cause an SMI# and to send an interrupt to the Intel® Management Engine (Intel® ME). INTRUDER_N may go active in any power state.

This SoC input has a two RTC-clock de-bounce delay. If the INTRUDER_N signal is driven active (low), and after the de-bounce delay, the Soc sets the Intruder Detect (INTRD_DET) bit of the TCO2_STS Register (TSTS2). The INTRD_SEL bits in the TCO2_CNT Register (TCTL2) can be programmed to enable the SoC to cause:

- an interrupt as selected by the TCO IRQ Select (IS) bits of the TCO Configuration (TCOCFG) register, or
- an SMI#, or
- neither (default).

The BIOS or interrupt handler can then cause a transition to the S5 state by writing to the SLP_TYP and SLP_EN bit fields of the Power Management 1 Control (PM1_CNT) register.

If the INTRUDER_N signal goes inactive some point after the INTRD_DET bit is written as a 1, then the INTRD_DET bit will go to a 0 when INTRUDER_N input signal goes inactive.

The INTRUDER_N signal pin is not shared nor can it be assigned as a Customer GPIO. Even so, software can directly read the status of the INTRUDER_N signal (high or low) by clearing and then reading the INTRD_DET bit. This allows the INTRUDER_N signal pin to be used as a SoC general-purpose input (GPI) if the intruder function is not required.

Note: Refer to the register description shown for INTRD_DET for additional details about how software interfaces with this bit and the 65-µs recovery time involved. The bit is slightly different than a classic sticky bit, since most sticky bits remain active indefinitely when the signal goes active and immediately go inactive when a 1 is written to the bit.

16.6.3 SMM-to-OS and OS-to-SMM Calls

Two eight-bit data registers are provided by the SoC for interaction between an SMI handler and OS-related code.

1. The SMI handler can generate an interrupt to the OS by writing to the TCO_DAT_OUT register. Doing this sets the TCO_INT_STS bit in the TCO1_STS (TSTS1) register. It also causes an interrupt as selected by the TCO IRQ Select (IS) bits of the TCO Configuration (TCOCFG) register. The interrupt is cleared by writing a 1 to the TCO_INT_STS bit.
2. The OS (or driver) can generate an SMI# by writing to the TCO_DAT_IN Register. Doing this sets the OS_TCO_SMI bit in the TCO1_STS Register (TSTS1). The SMI# is cleared by writing a 1 to the OS_TCO_SMI bit.

Reads to the TCO_DAT_IN (TDI) and TCO_DAT_OUT (TDO) registers do not cause an SMI# or interrupt.

Writing a 1 to the NMI_NOW bit of the TCO1_CNT (TCTL1) register allows for an immediate NMI.

16.7 SMI#/SCI Generation

The SoC does not have an System Management Interrupt (SMI)# signal pin. Upon any enabled SMI event taking place while the End of SMI (EOS) bit of the SMI Control and Enable (SMI_EN) is set, the SoC clears the EOS bit and asserts an SMI internal signal to the processor. This causes the CPU to enter System Management Mode (SMM). The PMC takes no further action on behalf of active SMI events until the Host software sets the EOS bit again. At that point, if any SMI events are still active, the PMC sends another SMI internal signal to the processor.

The SoC must have SMI fully enabled when the SoC is enabled to trap cycles. If SMI is not enabled in conjunction with the trap enabling, then hardware behavior is undefined.

The System Control Interrupt (SCI) is a level-mode interrupt that is typically handled by an ACPI-aware operating system. The SCI IRQ Select (SCIS) bits of the ACPI Control (ACTL) register specify the IRQ to which the SCI is mapped.

In non-APIC systems (which is the default), the SCIS bits must be set to route the SCI IRQ to one of the 8259 interrupts IRQ9, IRQ10, or IRQ11. The integrated 8259 interrupt controller must be programmed to level mode for that interrupt. Here the selected IRQ cannot be shared with the SoC LPC Serialized Interrupt (LPC_SERIRQ pin) stream, but it can be shared with other PCI interrupts.

In systems using the APIC, the SCIS bits can routed the SCI to the 8259 interrupts IRQ9, IRQ10, IRQ11, and if APIC Mode is enabled, IRQ20, IRQ21, IRQ22, or IRQ23. The interrupt polarity changes depending on whether it is on an interrupt shareable with a PIRQ or not. The interrupt remains asserted until all SCI sources are removed.

For additional information see Section 8.4, “System Control Interrupt (SCI)” on page 339. Table 16-4, “Causes of SMI and SCI” shows which events can cause an SMI and SCI. The SCI_EN bit of the Power Management 1 Control (PM1_CNT) register and the GBL_SMI_EN bit of the GPE0_EN_127_96 register determine whether the interrupt is routed as an SCI (SCI_EN=1) or SMI (SCI_EN = 0 AND GBL_SMI_EN = 1).

Table 16-4. Causes of SMI and SCI (Sheet 1 of 2)

Cause	SCI	SMI	Additional Enables (Note 1)	Where Reported
PME_B0 *Internal PME-Capable Agents*	Yes	Yes	PME_B0_EN=1	PME_B0_STS
PCI Express* PME Messages *Each Root Port has two SCI enable bits in their SCICSR register in Host Configuration Space*	Yes	No	PCI_EXP_EN=1	PCI_EXP_STS
PCI Express* PME Messages *Each Root Port has two SMI enable bits in its SMICSR register in Host Configuration Space*	No	Yes	None	PCI_EXP_SMI_STS
Power Button Press	Yes	Yes	PWRBTN_EN=1	PWRBTN_STS
Power Button Override (Note 2)	Yes	No	None	PRBTNOR_STS
RTC Alarm	Yes	Yes	RTC_EN=1	RTC_STS
ACPI Timer overflow (2.34 seconds)	Yes	Yes	TMROF_EN=1	TMROF_STS
Any GPIO enabled for SCI/SMI (Note 3)	Yes	Yes		
TCO SCI Logic	Yes	No	TCOSCI_EN=1	TCOSCI_STS
TCO SMI Logic	No	Yes	TCO_EN=1	TCO_STS
TCO SMI – TCO TIMEROUT	No	Yes	None	TIMEOUT
TCO SMI – NMI occurred *and NMIs mapped to SMI*	No	Yes	NMI2SMI_EN=1	NMI2SMI_STS
TCO SMI – Write attempted to BIOS	No	Yes	BIOSWE=1	BIOSWR_STS
BIOS_RLS bit of the SMI_EN register is written to 1 by BIOS (Note 4)	Yes	No	GBL_EN=1	GBL_STS
GBL_RLS written to	No	Yes	BIOS_EN=1	BIOS_STS
Write to B2h register	No	Yes	APMC_EN = 1	APM_STS
Periodic timer expires	No	Yes	PERIODIC_EN=1	PERIODIC_STS
64 ms timer expires	No	Yes	SWSMI_TMR_EN=1	SWSMI_TMR_STS
Monitor Status	No	Yes	None	MONITOR_STS
Enhanced USB Legacy Support Event	No	Yes	LEGACY_USB2_EN = 1	LEGACY_USB2_STS
PMC instructed to generate an SCI	No	Yes	MCSMI_EN	MCSMI_STS
LPC SMI is trapped if trapping is enabled *for legacy USB keyboard emulation*	No	Yes	LEGACY_USB_EN	LEGACY_USB_SMI_EN
Serialized IRQ SMI reported	No	Yes	None	SERIRQ_SMI_STS
SPI Command Completed	No	Yes	None	SPI_STS
SPI Flash Controller asserted SMI	No	Yes	None	SPI_SMI_STS
Device monitors match address in its range	No	Yes	None	DEVTRAP_STS
SMBus Host Controller	No	Yes	SMB_SMI_EN *Host Controller Enabled*	SMBus Host Status Register
SMBus Slave SMI message	No	Yes	None	SMBUS_SMI_STS
SMBus SMBALERT# signal active	No	Yes	None	SMBUS_SMI_STS
SMBus Host Notify message received	No	Yes	HOST_NOTIFY_INTREN	SMBUS_SMI_STS HOST_NOTIFY_STS
SLP_EN bit written to 1	No	Yes	SMI_ON_SLP	SMI_ON_SLP_EN_STS
Software Generated GPE	Yes	Yes	SWGPE_EN=1	SWGPE_STS
Intel® Management Engine causes SCI	Yes	No	ME_SCI_EN=1	ME_SCI_STS

Table 16-4. Causes of SMI and SCI (Sheet 2 of 2)

Cause	SCI	SMI	Additional Enables (Note 1)	Where Reported
Intel® Management Engine causes SMI	No	Yes	ME_SMI_EN=1	ME_SMI_STS
Innovation Engine causes SCI	Yes	No	IE_SCI_EN=1	IE_SCI_STS
Innovation Engine causes SMI	No	Yes	IE_SMI_EN=1	IE_SMI_STS
RTC update-in-progress	No	Yes	If enabled in the I/O Trap Register Space	RTC_UIP_SMI_STS
USB3 (xHCI) SMI Event	No	Yes	XHCI_SMI_EN=1	XHCI_SMI_STS
Wake Alarm Device Timer	Yes	Yes	WADT_EN	WADT_STS
Internal Interrupt Error Handler (IEH) circuitry	No	Yes	IEH_SMI_EN	IEH_SMI_STS

Notes:
1. The SCI_EN bit of the PM1_CNT register must be 1 to enable SCI. When SCI_EN is 0 AND GBL_SMI_EN = 1, SMI is enabled except for when an SCI is generated when the BIOS_RLS bit of the SMI_EN register is written to a 1 by BIOS.
2. When a power button override first occurs, the system transitions immediately to S5. The SCI will only occur after the next wake to S0 if the residual PWRBTNOR_STS status bit of the PM1_EN_STS register is not cleared prior to setting SCI_EN.
3. Refer to Chapter 26, "Customer General-Purpose I/O (GPIO)" for specific Customer GPIOs enabled for SCIs and/or SMIs.
4. GBL_STS being set will cause an SCI, even if the SCI_EN bit of the PM1_CNT register is not set. Software and BIOS must take great care not to set the BIOS_RLS bit of the SMI_EN register (which causes GBL_STS to be set) if the SCI handler is not in place.

16.7.1 PCI Express* SCI

PCI Express ports and the processor have the ability to cause a Power Management Event (PME) using messages. When a PME message is received, the SoC sets the PCI Express Status (PCI_EXP_STS) bit of the GPE0_STS_127_96 register. If the SCI Enable (SCI_EN) bit of the Power Management 1 Control (PM1_CNT) register and the PCI Express Enable (PCI_EXP_EN) bit of the GPE0_EN_127_96 register are also set, the SoC generates cause an SCI.

16.8 C States

The SoC processor power management circuitry, rather than the PMC, controls the C States. See Section 34.9, "Processor Power States - C-States" on page 913.

16.9 Dynamic LPC 24-MHz Clock Control

See Section 20.3.10, "Dynamic LPC Clock Control" on page 629.

16.10 Sleep States

For an overview of the Global Power States and the associated Sleep States see Section 34.8, "System Global Power States" on page 911. Power-supply cycling requirements associated with state changes are described in Chapter 33, "Resets and Voltage Sequencing".

16.10.1 Initiating State Changes when in the G0 (S0) Working State

These initiate a Global Power State change:

- In the G0 (S0) Working State, the Operating System Power Management (OSPM) software initiates the state change by following these steps:
  a. Mask interrupts
  b. Turn-off all bus-master enable bits
  c. Enabling the appropriate wake events that will trigger the exit from the selected state
  d. Set the desired sleep type in the three-bit Sleep Type (SLP_TYP) field of the Power Management 1 Control (PM1_CNT) register located in Host I/O Space at ABASE plus offset 4h. The SLP_TYP bits are in the RTC power well and are retained during G3 if the system has a functioning RTC battery.
  e. Set the Sleep Enable (SLP_EN) bit of the PM1_CNT register

  The hardware then attempts to gracefully put the system into the sleep state designated by SLP_TYP. Once in the sleep state, whenever one of the wake events enabled in "step c" occurs, the hardware transitions the system back to the G0 (S0) Working State which requires rebooting the system.
  The G3 Mechanical Off Global Power State cannot be entered by any operating-software mechanism. If the platform power is removed while in the G2 (S5) state, the G3 state is entered.
- In the G0 (S0) Working State, the user initiates the state change:
  a. The user presses the system Power button for less than 5.1 seconds. The SoC provides the active-low PMU_PWRBTN_N input signal pin to sense the position of the system Power button.
  b. The SoC then generates a power-management event using either a System Management Interrupt (SMI) or System Control Interrupt (SCI), to request the system's power-button driver to go to a sleep state.
  c. The OSPM sequence described in the bullet above this one is then followed. This is a controlled transition that allows OSPM to bring the system down in an orderly fashion by unloading applications, closing files, etc.
- In the G0 (S0) Working State, a Power Button Override is initiated by the user by pressing the system's Power button (active-low PMU_PWRBTN_N input signal pin) for more than 5.1 seconds in order to turn-off a hung system. This causes an unconditional, less graceful transition to the G2 (S5) Soft-Off State. Here the SoC first transitions directly to the early-boot phase and then transitions to the S5 Soft-Off state. Subsequent situations that can trigger a Warm Reset or Cold Reset are ignored.
  — The Intel® Management Engine and Innovation Engine firmware each has a mechanism to turn off a hung system similar to the Power-Button Override by writing bits in their power-management control registers. Subsequent situations that can trigger a Warm Reset or Cold Reset are ignored.

- In the G0 (S0) Working State, the SoC detects a Catastrophic Thermal Trip situation that may damage the SoC component. See Chapter 35, "THERMTRIP_N". The SoC asserts the THERMTRIP_N output signal pin. Except for the V3P30 voltage group, all SoC rails must shut down immediately. Just like a Power Button Override, Catastrophic Thermal Trip causes an unconditional, less graceful transition to the G2 (S5) Soft-Off State. Subsequent situations that can trigger a Warm Reset or Cold Reset are ignored.
  - If all platform power-supply sources to the SoC are shutdown at this point, and the platform doesn't have a working coin-cell battery, the SoC is incapable of retaining the cause of the global reset or straight-to-S5 during the subsequent reboot.
- If a reset button is part of the platform board design, and the user presses the button, it causes the PMU_RESETBUTTON_N SoC input signal pin to go active after a 16-ms de-bounce period). The SoC asserts the active low PMU_PLTRST_N output signal pin, and enters, or remains in, the G0 (S0) Working State.
  - If I/O Port CF9h (RST_CNT) register bit 3=0 in Host I/O Space, a Warm Reset occurs where no power cycles occur, and the SoC performs a system boot.
  - If I/O Port CF9h bit 3=1 in Host I/O Space, a Cold Reset occurs where the Core Power Well is cycled, and the SoC performs a system boot.
- Whenever a write of 06h is performed to I/O Port CF9h (RST_CNT) register, the SoC reacts as if the user pushed the system reset button. The SoC asserts the active low PMU_PLTRST_N output signal pin, and enters, or remains in, the G0 (S0) Working State.
  - If I/O Port CF9h bit 3=0 in Host I/O Space, a Warm Reset occurs where no power cycles occur, and the SoC performs a system boot.
  - If I/O Port CF9h bit 3=1 in Host I/O Space, a Cold Reset occurs where the Core Power Well is cycled, and the SoC performs a system boot.
- Whenever the system is shutdown to G2 (S5) or G3 by integrated manageability functions like Alert Standard Format (ASF).
- Whenever the TCO Watchdog Timer timeout occurs a second time within the SoC. If directed by the hard pin strap "No TCO Reboot Enable," the SoC asserts the active low PMU_PLTRST_N output signal pin, enters (or remains in) the G0 (S0) Working State. There is no power cycle involved and the destination is the G0 (S0) Working State. This is considered a "Warm Reset" and performs a system reboot. See Table 4-1, "SoC Hard Straps/Pin Straps and Descriptions".
- Whenever SoC hardware detects internal errors and is enabled to generated some type of reset. The types of reset and what happens is shown in Table 16-7, "Causes of Host Reset and Global Reset".

16.10.2 Initiating State Changes when in the G3 Mechanical-Off State

- When the SoC is in the G3 Mechanical Off state and the main system power is turned on, the platform board cycles-on the voltages it supplies to the SoC while systematically de-asserting the active-low RTEST_N, SRTCRST_N, and RSMRST_N input signals of the SoC. This initiates what is called a Cold Boot sequence and is shown in Figure 33-1, "ACPI Cold Boot Sequence". The SoC is put in the G2 (S5) Soft-Off state.
  - The SoC has circuitry to determine if this is the first time the system leaves the G3 Mechanical Off state. For this first-boot situation, the SoC uses the "AG3E Boot Select" Soft-Strap setting (see Chapter 4, "SoC Soft Straps") to determine whether to immediately transition to the G0 (S0) Working state and perform a "Cold Boot" or whether to wait in the G2 (S5) Soft-Off state for the power button or some other enabled wake event to transition to the G0 (S0) Working state.
  - During the first-boot sequence, the SoC retains the "AG3E Boot Select" Soft-Strap value in the AFTERG3_EN (AG3E) bit of the General PM Configuration B (GEN_PMCON_B) register for subsequent boot cycles. It retains the AG3E value until the SoC RTC power well loses power. BIOS can alter the AG3E register bit for subsequent boot cycles so that they behave differently than the first boot. If the AG3E bit is still set when the SoC transitions out of the G3 state, it not considered the first-boot situation. The retained value of AG3E is used instead of the "AG3E Boot Select" Soft Strap.

16.10.3 Returning to the S0 State when in the G2 (S5) Soft-Off State

The S5 Soft-Off sleep state is exited based on wake events. Before S5 was entered via the SLP_EN bit setting, software enabled the appropriate wake events in the Power Management 1 Enables and Status (PM1_EN_STS) register. When an enabled wake event occurs in S5, it forces the system to a full-on G2 (S0) Working state. Some non-critical subsystems, like rotational hard drives, might still be shut off and have to be brought back on using some other system-design mechanism.

Upon exit from the S5 Soft-Off state, the WAK_STS bit is set by the SoC. This bit is not affected by hard resets caused by a write to the Host I/O Port CF9h (RST_CNT) register, and is reset by writing a one to this bit, or by an internal power-good reset. The PM1_EN_STS register contains the wake event that caused the exit from the S5 state.

The possible causes of wake events (and their restrictions) are shown in Table 16-5 on page 537.

Table 16-5. Power Management Wake Events (Sheet 1 of 2)

Cause of the Wake Event	How the Wake Event is Enabled	Wake Event Status Reported	Besides Wake from S5, can also Wake from Reset Types
RTC Alarm	RTC Alarm Enable (RTC_EN)	RTC Status (RTC_STS)	-
PMU_PWRBTN_N pin is active (Power Button)	Always enabled as a Wake Event. If an interrupt is desired, the Power Button Enable (PWRBTN_EN) bit must be set.	Power Button Status (PWRBTN_STS)	Notes 1, 2, 3
Any GPIO signal pin that is configured and enabled for triggering a Wake Event	GPI General Purpose Events Enable (GPI_GPE_EN_*signal pin name)* See Chapter 8, "GPIO and PMC General Purpose Event (GPE)".	GPI General Purpose Events Status (GPI_GPE_STS_*signal pin name)* See Chapter 8, "GPIO and PMC General Purpose Event (GPE)".	-

Table 16-5. Power Management Wake Events (Sheet 2 of 2)

Cause of the Wake Event	How the Wake Event is Enabled	Wake Event Status Reported	Besides Wake from S5, can also Wake from Reset Types
Integrated LAN Controllers	See Section 16.10.3.1, "LAN Power Management Wakeup" on page 539.	See Section 16.10.3.1, "LAN Power Management Wakeup" on page 539.	Notes 1, 2, 3
Power Management Event (PME) from SoC integrated devices (PME_B0_STS)	See Section 16.10.3.2, "Other Internal Power Management Events" on page 540.	See Section 16.10.3.2, "Other Internal Power Management Events" on page 540.	-
PMU_WAKE_N pin is active (PCI Express WAKE# signal)	PCI Express Wake Disable (PCIEXP_WAKE_DIS) is not set. Modification of this bit has no impact on the value of the PCIEXP_WAKE_STS bit.	PCI Express Wake Status (PCIEXP_WAKE_STS)	-
SMB_LEG_ALRT_N pin is active (SMBus SMBALERT# Signal)	GPI General Purpose Events Enable (GPI_GPE_EN_SMB0_LEG_ALRT_N)	GPI General Purpose Events Status (GPI_GPE_STS_SMB0_LEG_ALRT_N)	-
Intel® Management Engine (Intel® ME) Non-Maskable Wake	Always enabled as a wake event.	ME_HOST_WAKE_STS (ME_HOST_WAKE_STS)	Notes 1, 2, 3
Innovation Engine (IE) Non-Maskable Wake	Always enabled as a wake event.	IE Host Wake Status (IE_HOST_WAKE_STS)	Notes 1, 2, 3
Wake Alarm Device	Wake Alarm Device Timer Enable (WADT_EN)	Wake Alarm Device Timer Status (WADT_STS)	-

Notes:
1. Reset Type: The SoC transitions straight to the S5 Soft-Off state (not a gradual shutdown). Here the SoC first transitions to the beginning of the early-boot sequences and then transitions to the S5 Soft-Off state.
2. Reset Type: Host Reset with Power Down and the Host stays there when initiated by the Intel® ME.
3. Reset Type: Host Reset with Power Down and the Host stays there when initiated by the Innovation Engine.

16.10.3.1 LAN Power Management Wakeup

The integrated LAN controllers' advanced power management wakeup, or APM wakeup, was previously known as Wake on LAN (WoL). At power up, each SoC LAN controller reads the APM Enable bit from the LAN region of the SoC SPI Flash into the APM Enable (APME) bits of a controller register. This bit controls the enabling of LAN APM Wakeup. When APM Wakeup is enabled, the SoC LAN controller checks all incoming packets for Magic Packets. Each LAN controller can be configured to detect the APM Wakeup on one, both, or none if its two LAN ports. The LAN device driver has the ability to alter the APME bit after power up.

When all of its wakeup enables are in place the LAN controller sends a SoC-internal "enable" signal to the PMC. When the LAN controller detects a wake-up situation, it notifies the PMC through a SoC-internal "wakeup" signal. Before each time the PMC needs to transition from the G0 (S0) Working state to another sleep state, it senses the internal LAN enable signal to keep the LAN port powered-on during the new sleep state if LAN APM Wakeup is enabled. If for some reason the LAN controller is already powered-off during the G0 (S0) Working state, the internal enable signal has no effect on the LAN controller's power state.

If "WoL after SUS power loss" is configured in the LAN region of the SPI Flash, BIOS can use the WoL Enable Override (WOL_EN_OVRD) bit of the General PM Configuration B (GEN_PMCON_B) register to enable Wake-On-LAN regardless of the policies selected through the operating system. This bit is maintained in the RTC power well, therefore permitting WoL following a surprise power failure even in cases in which the system may have been running in S0 without the PME Enables set.

16.10.3.2 Other Internal Power Management Events

The SoC combines the LAN advanced power management enable and wakeup internal signals with the other SoC integrated PCI devices' power-management event enable and wakeup internal signals. The Power Management Event Bus 0 Status (PME_B0_STS) bit of the General Purpose Event 0 Status [127:96] (GPE0_STS_127_96) register is set to one by the SoC when any SoC-internal device with PCI Power Management capabilities on Host PCI Bus 0 asserts the equivalent of the PCI PME# signal. Additionally, if the PME_B0_EN bit of the GPE0_EN_127_96 register and SCI_EN bit in the PM1_CNT register are set, then the setting of the PME_B0_STS bit generates an SCI (or an SMI if SCI_EN is not set).

A Power Management Event (PME) from PM-enabled and powered-on SoC-internal devices that can set the PME_B0_STS bit are:

- Integrated LAN controllers (see Section 16.10.3.1, "LAN Power Management Wakeup" on page 539)
- Integrated SATA Controllers
- Integrated USB 2.0 Controllers
- Integrated USB 3.0 Controllers
- Intel® Management Engine (Intel® ME) Maskable Host Wake bit
- Innovation Engine (IE) Maskable Host Wake bit

If the PME_B0_EN bit is set, and the system is in the S3 or S4 state, or the S5 state due to SLP_TYP and SLP_EN, then the setting of the PME_B0_STS bit generates a wake event. If the system is in an S5 state due to power button override, then the PME_B0_STS bit does not cause a wake event or an SCI. PME_B0_STS is cleared by a software write of '1.'

Note: The S3 state for the SoC is not validated by Intel.

The truth table for situations when an integrated-device wakeup event is enable is shown in Table 16-6, "Power Management Event Enables". In the table:

— "Yes" indicated that the PME is enabled. Device power remains on during the S0-to-Sx transition.

— "No" indicates that the PME is not enabled. The power is turned off by the SoC to the affected devices during the S0-to-Sx transition. Exceptions to this are the Intel® ME and the IE in that they may stay powered-on (active) but the Sx PME wake might be disabled.

Table 16-6. Power Management Event Enables

PME_B0_EN bit	PME_B0_S5_DIS bit	Internal Wakeup Enable signal from LAN	Wakeup and provide wake event status in S4?	Wakeup and provide wake event status in S5?
0	0	0	No	No
0	1	0	No	No
0	X	1	No	Yes, LAN only
1	0	1	Yes, all PME B0 sources including LAN	Yes, all PME B0 sources including LAN
1	1	1	Yes, all PME B0 sources including LAN	Yes, LAN only
1	0	0	Yes, all PME B0 sources including LAN	Yes, all PME B0 sources including LAN
1	1	0	Yes, all PME B0 sources including LAN	No

16.10.4 Reset Triggers That Generate a State Change

Certain hardware situations generate a reset request to the PMC that can trigger the change of the Global Power State of the SoC. The SoC behavior after a reset trigger depends on the situation that generated the reset request.

See Section 16.13, "Reset Behavior" on page 543.

16.11 System Power Supplies, Planes, and Signals

All SoC power-control signal pins are described in Table 16-1, "Signal Names and Descriptions". The following is additional information about those signal pins that can be used for system power-supply control.

16.11.1 Platform Power Plane Control with PMU_SLP_S3_N and PMU_SLP_S45_N

When asserted, the active-low PMU_SLP_S3_N SoC output signal can be used to cut power to the system's VCC, VCCRAM, and VCCREF SoC power-supply pins. This same signal can be used to cut the termination voltage VTT to the DDR DIMMs. VTT is only delivered by the system to the DIMMs and not to the SoC.

When asserted, the active-low PMU_SLP_S45_N SoC output signal can be used to cut power to the system's VDDQ SoC power-supply pins. This is allowed because the SoC does not support the S3 sleep state.

Both of these pins can be configured as Customer GPIOs if not used in the system design.

16.11.2 COREPWROK SoC Input Signal

When asserted, the active-high COREPWROK signal is an indication to the SoC that the platform board Voltage Regulators (VRs) that supply the SoC Core Power Well rails have been stable for at least 10 ms. COREPWROK can be driven asynchronously. When COREPWROK is de-asserted, the SoC asynchronously asserts the active-low PMU_PLTRST_N signal. COREPWROK must not glitch, even if RSMRST_N is active (low)

The SoC output signal PMU_PLTRST_N de-asserts after the SoC input signal COREPWROK is asserted. Platforms which include a PCI Express* device may use the signal PMU_PLTRST_N to generate the PCI Express* signal PERST#. If the signal PMU_PLTRST_N is used to generate the PCI Express* signal PERST#, then the platform should not assert COREPWROK until at least 100ms after all the PCI Express power supplies and clocks have become stable and valid, as mandated within the PCIe Express* PCI Express* Card Electromechanical Specification.

16.11.3 SUSPWRDNACK SoC Output Signal

Suspend Power-Down Acknowledge (SUSPWRDNACK) is an active-high output signal that is asserted by the SoC when it does not require its Suspend (SUS) power well to be powered.

This pin can be configured as a Customer GPIO if not used in the system design.

16.12 Legacy Power Management Theory of Operation

Instead of relying on Advanced Configuration and Power Interface (ACPI) software, legacy power management uses BIOS and various hardware mechanisms. The scheme relies on the concept of detecting when individual subsystems are idle, detecting when the whole system is idle, and detecting when accesses are attempted to idle subsystems.

However, the operating system is assumed to be at least Advanced Power Management (APM) enabled. Without legacy APM calls, there is no quick way for the SoC to know when the system is idle (e.g., idle between keystrokes). The SoC does not support burst modes.

16.13 Reset Behavior

The SoC is divided into three reset partitions:

- Host Partition - The SoC hardware not including the Intel® Management Engine and the Innovation Engine.
- Intel® Management Engine Partition - Just the Intel® Management Engine portion of the SoC.
- Innovation Engine Partition - Just the Innovation Engine portion of the SoC.

The SoC can perform two main types of reset:

- Host Reset - Just the Host Partition hardware is reset. If a Host Reset is triggered and the PMC times out before receiving an internal acknowledge message from the processor, a Global Reset with power-cycle occurs.
- Global Reset - All three of the SoC partitions are reset and a power cycle is performed. During a Global Reset, all SoC functionality is reset except for information backed-up by the RTC Power Well or the SUS (Primary and DSW) Power Well. Also not reset are configuration information, and functional logic for controlling and reporting the reset. The Host, Intel® Management Engine, and Innovation Engine all power back up after the power cycle period.

16.13.1 Reset Request Conditions

Table 16-7, "Causes of Host Reset and Global Reset" shows the situations when the PMC is requested to perform a type of partition reset, possible power down/up cycle, or instead change (not gracefully) the Host sleep state to the G2 (S5) Soft-Off state and stay there until an enabled Wake Event occurs to return to the G0 (S0) Working state.

The latter is called "Straight to S5" and all SoC functionality is reset except for information backed-up by the RTC Power Well or the SUS Power Well. The terms "Primary" and "DSW" are used in the EDS register descriptions instead of "SUS." Also not reset are configuration information, and functional logic for controlling and reporting the reset. While Table 16-7, "Causes of Host Reset and Global Reset" shows Host Reset and Global Reset triggers, there are some situations where only the Intel® Management Engine Partition or Innovation Engine Partition is reset by the PMC.

Table 16-7. Causes of Host Reset and Global Reset (Sheet 1 of 3)

Reset Request and Condition	Host Reset Without Power Cycle (Note 1)	Host Reset With Power Cycle (Note 2)	Global Reset With Power Cycle (Note 3)	Straight to S5 and Host Stays in S5
From power management state-change software				
The CPU is reset when going to the G2 (S5) Soft-Off state. SoC functionality that needs to remain operational or retain status during the Host S5 sleep state does not get reset in this case	-	Yes see Note 4	see Note 5	-
From SoC input signal pins				
PMU_RESETBUTTON_N asserted and CF9h (RST_CNT Register) Bit 3 = 0	Yes	-	see Note 5	-
PMU_RESETBUTTON_N asserted and CF9h (RST_CNT Register) Bit 3 = 1	-	Yes	see Note 5	-
ADR_TRIGGER input signal is asserted when enabled to trigger a Global Reset. If the ADR flow is externally triggered, Global Reset will not be triggered.	-	-	Yes	-
Power Button (PMU_PWRBTN_N) 5.1-second override causes transition to S5 and reset asserts	-	-	-	Yes
From software reset (I/O Port CF9h)				
Write of 06h to CF9h (RST_CNT Register) when CF9h Global Reset (CF9GR) bit = 0 in the ETR3 register of the PMC	Yes	-	see Note 5	-
Write of 0Eh to CF9h (RST_CNT Register) when the SPD Reset (SPD_BIOS_RESET) bit = 1 in the PCH_PM_STS register	-	Yes see Note 6		-
Write of 0Eh to CF9h (RST_CNT Register) when CF9h Global Reset (CF9GR) bit = 0 in the ETR3 register of the PMC	-	Yes	see Note 5	-
Write of 0Eh to CF9h (RST_CNT Register) when CF9h Global Reset (CF9GR) bit = 1 in the ETR3 register of the PMC	-	-	Yes	-
From power failure and thermal alerts				
Power Failure: COREPWROK signal goes inactive in S0	-	-	Yes	-
Processor Thermal Trip (THERMTRIP_N) causes transition to S5 and reset asserts	-	-	-	Yes
SoC internal thermal sensors signals a catastrophic temperature condition	-	-	-	Yes

Table 16-7. Causes of Host Reset and Global Reset (Sheet 2 of 3)

Reset Request and Condition	Host Reset Without Power Cycle (Note 1)	Host Reset With Power Cycle (Note 2)	Global Reset With Power Cycle (Note 3)	Straight to S5 and Host Stays in S5
From detected hardware errors and interface time-out situations				
Total Cost of Ownership (TCO) Watchdog Timer reaches zero two times	Yes	-	see Note 5	-
Host Partition Reset Entry Timeout (see Note 7)	-	-	Yes	-
PMC hardware detects an uncorrectable parity error on a data read from one of its SUS (Primary) Power Well registers	-	-	Yes	-
Power Management Watchdog Timer	-	-	-	Yes
PMC hardware detects that the system has been running too long without Intel® Management Engine firmware acknowledgment	-	-	-	Yes
From shutdown cycles requested by the processor				
Special shutdown cycle from processor causes CF9h-like PMU_PLTRST_N when CF9h Global Reset (CF9GR) bit = 0 in the ETR3 register of the PMC and CF9h (RST_CNT Register) Bit 3 = 0	Yes	-	see Note 5	-
Special shutdown cycle from processor causes CF9h-like PMU_PLTRST_N when CF9h Global Reset (CF9GR) bit = 0 in the ETR3 register of the PMC and CF9h (RST_CNT Register) Bit 3 = 1	-	Yes	see Note 5	-
Special shutdown cycle from processor causes CF9h-like PMU_PLTRST_N when CF9h Global Reset (CF9GR) bit = 1 in the ETR3 register of the PMC	-	-	Yes	-
From the Intel® Management Engine				
Intel® Management Engine-Triggered Host Reset without Power-Cycle	Yes	-	see Note 5	-
Intel® Management Engine-Triggered Host Reset with Power-Cycle	-	Yes	see Note 5	-
Intel® Management Engine-Triggered Host Reset with power down (host stays there)	-	Yes see Note 4	see Note 5	-
Intel® Management Engine promotes a Host Partition Reset to a Global Reset	-	-	Yes	-
Intel® Management Engine-Triggered Global Reset	-	-	Yes	-
Intel® Management Engine detects an unexpected Minute IA (MIA) error	-	-	-	Yes see Note 8
Intel® Management Engine detects an unexpected Minute IA (MIA) shutdown error	-	-	-	Yes see Note 8
Intel® Management Engine Hardware Uncorrectable Error	-	-	-	Yes see Note 8
Intel® Management Engine Watchdog Timer Timeout	-	-	-	Yes see Note 8
Intel® Management Engine-Triggered Power Button Override	-	-	-	Yes
From the Innovation Engine				
Innovation Engine-Triggered Host Reset without Power-Cycle	Yes	-	see Note 5	-
Innovation Engine-Triggered Host Reset with Power-Cycle	-	Yes	see Note 5	-
Innovation Engine-Triggered Host Reset with power down (host stays there)	-	Yes see Note 4	see Note 5	-
Innovation Engine-Triggered Global Reset	-	-	Yes	-

Table 16-7. Causes of Host Reset and Global Reset (Sheet 3 of 3)

Reset Request and Condition	Host Reset Without Power Cycle (Note 1)	Host Reset With Power Cycle (Note 2)	Global Reset With Power Cycle (Note 3)	Straight to S5 and Host Stays in S5
Innovation Engine detects an unexpected Minute IA (MIA) error	-	-	-	Yes see Note 9
Innovation Engine detects an unexpected Minute IA (MIA) shutdown error	-	-	-	Yes see Note 9
Innovation Engine Hardware Uncorrectable Error	-	-	-	Yes see Note 9
Innovation Engine Watchdog Timer Timeout	-	-	-	Yes see Note 9
Innovation Engine-Triggered Power Button Override	-	-	-	Yes

Notes:
1. The SoC drops this type of reset request if received while the system is in the G2 (S5) Soft Off state.
2. The SoC does not drop this type of reset request if received while system is in a "software-entered" G2 (S5) Soft Off state. Here the SoC does perform the Host Reset with Power Cycle.
3. The SoC does not warn the processor. The Global Reset occurs without delay.
4. The PMC waits for an enabled Wake Event to occur before completing the Host Reset with Power Cycle.
5. If the PMC detects a problem while executing the Host Reset, the PMC promotes this request to be a Global Reset with Power Cycle.
6. SoC internal clocks are made ready for DIMM Serial Presence Detect (SPD) discovery.
7. Host Partition Reset Entry Timeout is automatically initiated if the hardware detects that the Platform Reset (PMU_PLTRST_N) sequence has not occurred within 5.1 seconds of being started.
8. Only the Intel® Management Engine is reset and not the Host or Innovation Engine
9. Only the Innovation Engine is reset and not the Host or Intel® Management Engine

16.14 Interaction with the Innovative Engine (IE)

The IE provides the fan control FAN_PWM[3:0] and FAN_TACH[3:0] signals that are listed in Chapter 37, "Innovation Engine".

A number of IE error conditions are reported internally to the PMC so that the PMC can take the appropriate action, typically a Global Reset. See Table 16-7, "Causes of Host Reset and Global Reset".

The IE and PMC also interact with the following:

- Power Up
- Power Down
- IE power control
- Expiration of the IE-based Anti-Theft Watchdog Timer

16.15 Asynchronous DRAM Refresh (ADR)

The ADR feature of the SoC provides a mechanism to enable preservation of key data in battery-backed DDR system memory, in the event of AC power-supply failure. For all processor cores of the product SKU, the SoC ADR sequence forces an L1 cache flush of "dirty write" data to the battery-backed, or supercapacitor-backed, DDR system memory DIMMs and then places DIMMs in the battery/supercapacitor-backed Self-Refresh Mode defined by JEDEC. Dirty writes located in the SoC internal memory data buffers are also flushed. For ADR to be successful, the platform board must sustain valid power levels to the SoC for a minimum of 50 µs once the SoC initiates and enters the ADR sequence.

As a configurable option, the SoC can also flush dirty-write data from the L2 caches to the battery-backed system-memory DIMMs. This adds a certain time to the process and the platform board must sustain valid power to the SoC during this period, too.

The SoC ADR_TRIGGER input signal is the early-warning alert asserted by the platform and system power supply indicating that AC power has been lost and that the platform voltage rails will soon be dropping. Before the platform-board circuitry asserts RSMRST_N or deasserts COREPWROK, the ADR_TRIGGER signal must be asserted and trigger the ADR flow of the SoC.

Typically, proper fencing protocol before ADR triggers is not needed if both L1 and L2 caches are flushed. This may not be true if the platform design contains external DMA subsystems or if multiple SoC nodes mirror data using an external Non-Transparent Bridge (NTB). The discussion of such fencing techniques is beyond the scope of this document.

Note: An SoC internal register bit is used to convey to BIOS that a successful ADR sequence occurred before the most-recent loss of power or Global Reset. For the ADR feature to function properly, a battery is required to keep the RTC power well powered when in the G3 state.

16.15.1 Configuring ADR

To provide imminent power loss as a condition to initiate ADR, BIOS ensures that the SoC pin-function MUXing is configured so that the SoC provides the ADR_TRIGGER and ADR_COMPLETE signal pins for communication with the platform board circuitry. By default, these signal pins are Customer GPIO output signals GPIO[81] and GPIO[0] respectively.

Note: The SoC ensures that the ADR_COMPLETE output signal is glitch-free, even during the SUS-Well power ramp.

The SoC ADR mechanism is configured and controlled by the 32-bit ADR Enable (ADR_EN) register. The register is one of the PMC Memory Mapped Registers located in Host Memory Space at the address specified by the Power Management Base (PWRMBASE) register, plus offset F0h. The PWRMBASE register is located in Configuration Space at Bus 0, Device 31 (decimal), Function 2, offset 48h.

Note: The PWRM Enable (PWRM_EN) bit must be set to enable the decode of the memory-mapped address range pointed by PWRMBASE. PWRM_EN is located in the 32-bit ACPI Control (ACTL) register which is located in Configuration Space at Bus 0, Device 31 (decimal), Function 2, offset 44h.

The ADR feature is enabled/disabled by the ADR Feature Enable (ADR_FEAT_EN) bit (bit 0) of the ADR_EN register. When the feature is enabled, the ADR_TRIGGER signal pin, indicating an impending power loss detected by the board, is used to start the ADR process. Any of a number of "Qualified Internal Events" can also start the ADR process provided they are enabled in the ADR_EN register.

Bit 29 of the ADR_EN register enables/disables whether a Global Reset is generated after the SoC internal-data flushing completes.

BIOS must indicate whether the L2 Cache is to be flushed or not flushed during the ADR process. BIOS does this by programming the L2_FLUSH bit (bit 0) of the P_CR_ADR_COMMAND_0_0_0_MCHBAR Register located in Host Root Memory Space at MCHBAR, offset 712Ch. MCHBAR is defined by the two 32-bit registers MCHBAR_LO_0_0_0_PCI and MCHBAR_HI_0_0_0_PCI located at offsets 48h and 4Ch in configuration space for the System Agent (Bus 0, Device 0, Function 0).

- L2_FLUSH bit = 0: The SoC does not flush L2 Cache during the ADR flow.
- L2_FLUSH bit = 1: The SoC flushes L2 Cache on all processor modules as part of the ADR flow when it is initiated by the ADR_TRIGGER signal pin.

16.15.1.1 Qualified Internal Events

There are a number of SoC-internal qualified events that can be enabled in the ADR_EN register to trigger the ADR sequence and generate a Global Reset after the internal cache-flush sequence completes. These are not associated with the Qualified External Event where the assertion of the ADR_TRIGGER signal pin by the platform board triggers the ADR sequence. The Qualified Internal Events include:

- Power Button Override
- Intel® ME-Initiated Power Button Override
- IE-Initiated Power Button Override
- SoC PMC Firmware Watchdog Timer
- Intel® ME Firmware Watchdog Timer
- IE Firmware Watchdog Timer
- SoC PMC Firmware-Initiated Global Reset
- Intel® ME-Initiated Global Reset
- IE-Initiated Global Reset
- SoC PMC SUS RAM Parity Error
- SYS_PWROK Failure
- Intel® ME Uncorrectable Error
- IE Uncorrectable Error

16.15.2 Configuring the Copy-to-Flash Extension

The Copy-to-Flash (C2F) extension to the ADR sequence is a special platform-level and BIOS sequence. It can extend the system's sequence of events when the SoC ADR sequence is triggered by the platform (ADR_TRIGGER signal for imminent power loss).

In some system designs, the information retained in the system memory after the ADR sequence (valid SDRAM power and SDRAMs in Self-Refresh Mode) is considered volatile. Such system designs require all or some of the system memory to also be written to persistent system memory such as a Solid-State Device (SSD).

To do this, the system platform needs to restore system power for a period of time, usually with some kind of backup power source or supercapacitor for the system, and have the SoC firmware/software write information to the persistent memory subsystem. Also, the platform may require special, on-board registers that are attached to the configured SoC Customer GPIO input signal pins, that later can be read by BIOS to determine a C2F situation.

Normally, when ADR_COMPLETE is asserted by the platform, the ADR sequence is not followed by a Global Reset. To facilitate C2F, the SoC can be configured to trigger a Global Reset once ADR_COMPLETE is asserted. To do so, these conditions must be met:

- ADR_GPIO_RST_EN bit of the ADR_EN register = 1, and
- ADR_FEAT_EN bit of the ADR_EN register = 1, and
- The product SKU supports the ADR feature, and
- The SoC internal ADR sequence has completed.

16.15.3 NVDIMM Copy-to-Flash

If NVDIMM is used for DRAM system memory by the platform design, the NVDIMMs integrated save-to-flash and restore-from-flash operations can be used once ADR_COMPLETE is asserted after an ADR sequence. NVDIMM has a SAVE# input pin, or a SAVE Serial Presence Detect (SPD) command via its SMBus interface, to instruct it to save its DRAM information (now in Self-Refresh Mode and powered by a resident supercapacitor) to its Flash memory. They also have a pin or SPD command to for the platform or BIOS to perform a RESTORE once the system returns to normal operation.

Note: At the time of publication of this document, there is no industry standard for NVDIMMs and for their SAVE and RESTORE pins and/or SPD commands. NVDIMM products typically follow the RDIMM JEDEC standards which has two reserved DIMM pins and reserved SPD registers. Platform designers and BIOS developers need to refer to NVDIMM technical information from NVDIMM manufactures for implementation details.

16.15.4 ADR Sequence of Events

1. BIOS has previously configured the SoC and has made necessary adjustments to the ADR_EN register and then sets the ADR_FEAT_EN bit. The ADR mechanism is armed and waiting.
2. The ADR_TRIGGER signal is asserted by the platform board indicating an imminent power failure has been detected or one of the enabled Qualified Internal Events (within the SoC) occurs. While the Global Reset triggers are captured in the GBLRST_CAUSE0 and GBLRST_CAUSE1 memory-mapped registers, the ADR sequence starts only if the particular trigger is enabled in the ADR_EN register.

Note: The active-high ADR_TRIGGER SoC pin is an open-drain output signal as well as an input signal. Not only can the board drive this signal pin, the SoC drives this pin high when one of the enabled Qualified Internal Events occurs. As long as the ADR-triggered event is valid, the ADR_TRIGGER remains asserted (logic high) by the SoC.

Warning: To indicate the deasserted state, the platform (and SoC) must float (High-Z state) the ADR_TRIGGER signal pin. The platform must have a pull-down resistor tied to this pin. The platform board must only drive this pin to logic 1, when it intends to assert ADR_TRIGGER. It must never drive this pin to a logic 0. The SoC drives this pin to a logic 1 only when one of the enabled, Qualified Internal Events occur. Otherwise the SoC floats (Hi-Z) this pin. The SoC never drives it to a logic 0.

3. The SoC closes all access paths to memory space.
4. All cores are put to sleep and L1 cache flushes are performed.
5. Internal data buffers holding dirty memory-write information are flushed.
6. Once all cores are idle, DRAM throttling is disabled.
7. If the SoC is configured to also flush the L2 caches during ADR, dirty writes in L2 cache are cleaned (written to DRAM). This could take some time to perform.
8. The SoC System Agent circuitry is made idle.
9. The SoC puts the SDRAM components in Self-Refresh Mode.
   - It is the platform's responsibility to maintain SDRAM/DIMM power and maintain the SDRAM components' Clock Enable input signals during Self-Refresh mode.
   - When the SDRAM is on an NVDIMM product, a supercapacitor, that is part of the NVDIMM product, powers the SDRAM while in Self-Refresh Mode.

Note: In order to continue the ADR sequence, the SoC internal timer for ADR completion must not have expired at this point. Ending the sequence at this point indicates that there was not enough time or power-level to complete the ADR sequence or that an internal error that prevented completion of the sequence. Nothing happens and the G3 state (mechanical off) is entered when power is finally lost.

10. The SoC sets ADR_RST_STS, bit 16 of the PCH Power Management Status (PCH_PM_STS) register located in memory space at PWRMBASE, offset 1Ch.
    — The ADR_RST_STS register bit is powered by the SoC RTC Power Well. The SoC must be provided power for the RTC well (VCCRTC_3P3_G3, pin AU48) for this register bit to be preserved during the G3 State (Mechanical Off).
11. The SoC asserts the ADR_COMPLETE output signal pin.
12. Depending on the information in the ADR_EN register, the SoC does one of the following:

- Initiates a Global Reset with an automatic power-up to the S0 state and start of BIOS execution. The platform-defined Copy-to-Flash extension relies on this reset and BIOS entry.
  — Before the SoC starts the power-up, it waits in the S5 state for about five seconds. No wake event is needed to exit S5.
  — Internal SoC registers are reset except for the RTC power-well registers and registers and functional logic in other SoC power wells needed to report this Global Reset.
- Transitions directly to the S5 State and waits for some kind of wake event.
  — The SoC output signal pins PMU_SLP_S3_N and PMU_SLP_S45_N are asserted.
  — Internal SoC registers are reset except for the RTC power-well registers and registers and functional logic in other SoC power wells needed to report this status.
  — Once the SoC asserts the ADR_COMPLETE output signal pin, and the "AG3E Boot Select" Soft Strap = 1 (see Section 4.2, "SoC Soft Straps" on page 199), the platform needs to drive the PMU_PWRBTN_N or PMU_WAKE_N SoC input signal, or configure and drive a wake-supported Customer GPIO (see Chapter 26, "Customer General-Purpose I/O (GPIO)") input to wake-up the SoC from the S5 state.
- Once awakened, the SoC powers-up and enters the S0 state where BIOS begins instruction execution.
  — If the "AG3E Boot Select" Soft Strap = 0, the SoC does not wait for a wake-up event to proceed. Here the SoC enters the S0 state and BIOS commences. For Soft Strap details, see Chapter 4, "Strapping and Configuration".

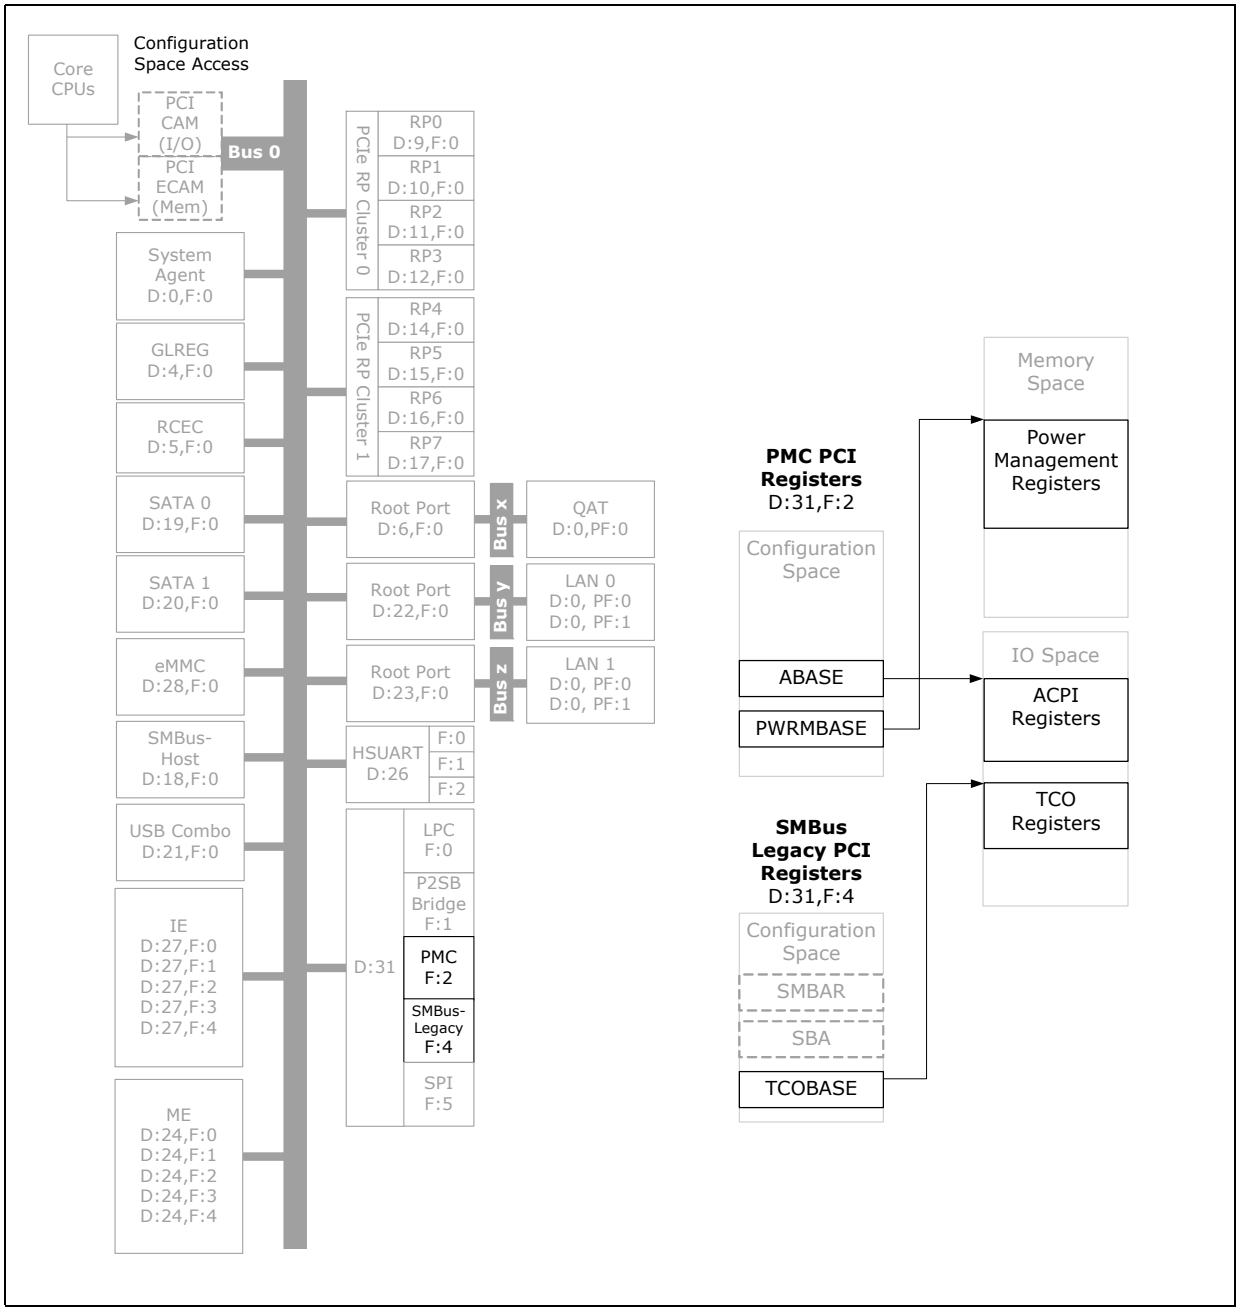
16.15.5 BIOS after Successful ADR

BIOS uses the ADR_RST_STS, bit 16 of the PCH Power Management Status (PCH_PM_STS) register to determine that a successful ADR sequence occurred before BIOS initiated. It also uses the SoC registers of the Customer GPIO input signals provided by the platform to signify a successful Copy-to-Flash (C2F). The BIOS sequences for ADR and C2F are not discussed in this document.

16.16 Register Map

Figure 16-2, "Register Map" shows the associated registers from a system software viewpoint.

Figure 16-2. Register Map



16.16.1 PCI Configuration and Capabilities

Table 16-8. Configuration and Capabilities Register Map

Offset from Configuration Space of B0:D31:F2 (hex)	Register Short Name	Description
00	PCIID	PCI Identifier
04	PCISTS_PCICMD	Device Status & Command
08	PCICC_PCIRID	Class Code & Revision ID
0C	PCIHTYPE_PCIMLT	Header Type and Master Latency Timer
10	PM_DATA_BAR	32-bit Power Management Data Base Address Register
2C	PCISID	Subsystem Identifiers
40	ABASE	ACPI Base Address
44	ACTL	ACPI Control
48	PWRMBASE	PM Base Address
A0	GEN_PMCON_A	General PM Configuration A
A4	GEN_PMCON_B	General PM Configuration B
A8	BM_CX_CNF	BM_BREAK_EN and Cx State Configuration Register

17 Embedded Multi-Media Card (eMMC)

The Embedded Multi-Media Controller (eMMC) is a high-speed Flash memory controller. The controller presents itself to the host as Bus 0, Device 28, and Function 0 during PCI bus enumeration process. This controller handles eMMC protocol at transmission, packing data, adding cyclic redundancy check (CRC), start/end bit, and checks for transaction format correctness.

Figure 17-1. What is Covered in This Chapter

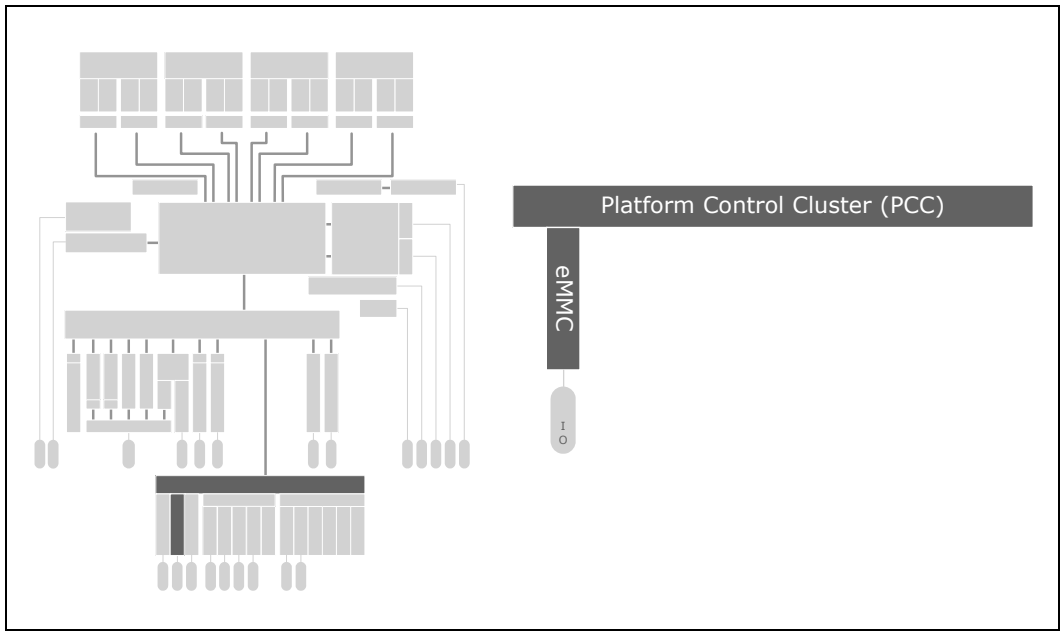

Table 17-1. References

Reference	Revision	Date	Document Title
eMMC Spec	5.0	Oct 2013	*Embedded Multi-Media Card (eMMC), Electrical Standard*

17.1 Signal Descriptions

The signal descriptions are shown in Table 17-2. For additional signal information, including whether a signal is assigned to shared-function pin or can be used as a Customer GPIO signals see Chapter 39, "Signal Pin Names and Signal MUXing". The Direction column of Table 17-2 is interpreted as follows:

- I = Input signal. The SoC has receiver circuit.
- O = Output signal. The SoC has driver circuit

Table 17-2. Signal Names and Descriptions

Signal Names	Direction	Shared	Description
EMMC_CLK	I,O	Yes	**Clock**
EMMC_CMD	I,O	Yes	**Command:** The platform requires a 20k Ohm pull-up resistor, tied to 1.8V for this signal.
EMMC_D[7:0]	I,O	Yes	**Data:** The platform requires a 20k Ohm pull-up resistor, tied to 1.8V for these signals.
EMMC_IRCOMP	I,O	No	**RCOMP for the eMMC interface**: The platform board must provide a 200 Ω, 1% resistor connected from this pin to VSS.
EMMC_STROBE	I	Yes	**Strobe for Rx Data**

17.2 Feature List

- Supports eMMC 5.0 and eMMC 4.5.
- 8-bit interface, maximum frequency of 200 MHz (data transfer rates of 400 MB/sec).
- Supports interrupt coalescing.
- Supports both DMA and non-DMA mode operation.
- Supports data transfers in 1-, 4- and 8-bit mode.
- Supports cyclic redundancy check CRC7 for command and CRC16 for data integrity.
- eMMC interface can be a boot interface to boot an Operating System.

17.3 Architectural Overview

There are two supported modes of operation, PCI and ACPI modes. Upon controller power-on this controller exposes itself as a PCI-compliant device to the host space. For details on how to configure this device as a ACPI device, see Section 17.4, "Address Map" on page 559.

17.3.1 eMMC Mass Storage Command and Data Flows

Host software is to manage data transfer to and from controller to the host memory.

Following steps describe data flows to and from the controller.

1. Host prepares the controller for data transfer by writing DMA descriptor(s) in the host memory.
2. Host write the controller registers to initiate the descriptor chain.
3. Controller moves data from the host memory to the device card.
4. Controller DMA notifies the IOxAPIC after the DMA is done.
5. IOxAPIC forwards the interrupt the host as MSI.

17.3.2 PCI Mode and ACPI Mode

The eMMC can be configured to work in either PCI Mode or ACPI Mode. The configuration is done via a write to the IOSF2OCP Sideband register. By default the eMMC is set to PCI Mode. To change the eMMC to ACPI Mode, it first needs to be enumerated and assigned a BAR. Once this is done, it is possible to configure the device to be an ACPI device (ACPI Mode). Its address shall be the configured BAR address.

17.4 Address Map

From the host point of view, the eMMC device has a 4KB BAR address space. The 4KB is divided into two regions

1. The device internal registers – a 2KB address space which maps the device internal registers.
2. Extended Configuration Registers – a 2KB address space which maps all the extended configuration.

17.5 Register Map

Figure 17-2 shows the associated registers from a system software viewpoint.

There are no I/O mapped registers.

§ §

18 High-Speed UART Controller

The SoC contains four[1] integrated High-Speed Universal Asynchronous Receiver/Transmitter (HSUART) serial ports. Each UART port signal may be shared and MUXed with other functional blocks (i.e., GPIO, SMBus, etc.).

Figure 18-1. What is Covered in This Chapter

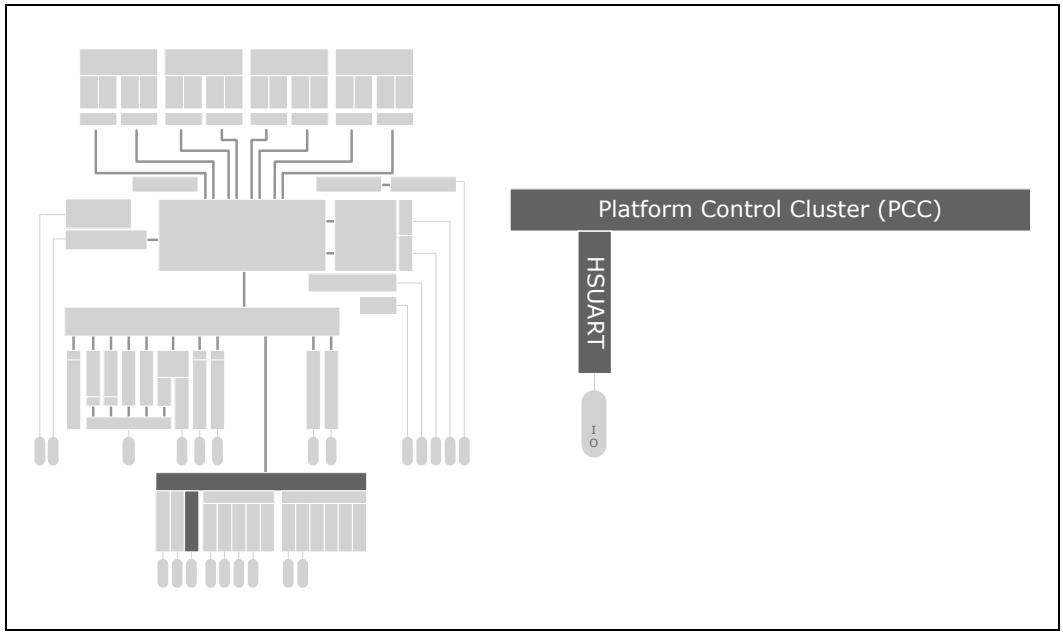

Table 18-1. References

Reference	Revision	Date	Document Title
PC16550D UART Specification	Rev C	May 2015	*PC16550D Universal Asynchronous Receiver/Transmitter With FIFOs (Rev. C)*

1. At most, three of the SoC four High Speed Universal Asynchronous Receiver/Transmitter (HSUART) controllers can be active. One set of the SoC HSUART pins is configurable to be either the Host Root HSUART or else the Innovation Engine (IE) HSUART.

18.1 Signal Descriptions

The signal descriptions are shown in Table 18-2. For additional signal information, including whether a signal is assigned to shared-function pin or can be used as a Customer GPIO signals see Section 39.1, "Directory of Signal Names and Pin Names" on page 993. The Direction/Type column of Table 18-2 is interpreted as follows:

- I = Input signal. The SoC has receiver circuit.
- O = Output signal. The SoC has driver circuit.

Table 18-2. Signal Names and Descriptions

Signal Names	Direction	Description
UART 0		
UART0_RXD	I	**UART0 Receive Data:** Active-high input
UART0_TXD	O	**UART0 Transmit Data:** Active-high output
UART0_CTS	I	**UART0 Clear to Send:** Active-high input
UART0_RTS	O	**UART0 Request to Send:** Active-high output
UART 1		
UART1_RXD	I	**UART1 Receive Data:** Active-high input

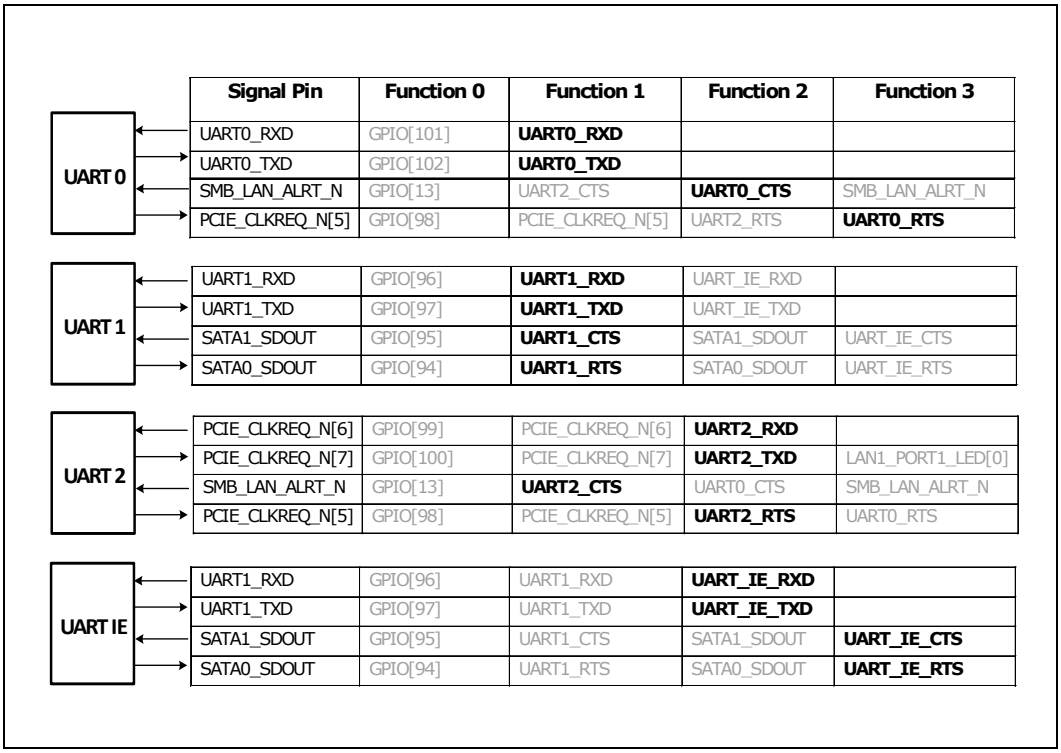
UART1_CTS	I	**UART1 Clear to Send:** Active-high input
UART1_RTS	O	**UART1 Request to Send:** Active-high output
UART 2		
UART2_RXD	I	**UART2 Receive Data:** Active-high input
UART2_TXD	O	**UART2 Transmit Data:** Active-high output
UART2_CTS	I	**UART2 Clear to Send:** Active-high input
UART2_RTS	O	**UART2 Request to Send:** Active-high output
UART Innovation Engine[1]		
UART_IE_RXD	I	**UART_IE Receive Data:** Active-high input
UART_IE_TXD	O	**UART_IE Transmit Data:** Active-high output
UART_IE_CTS	I	**UART_IE Clear to Send:** Active-high input
UART_IE_RTS	O	**UART_IE Request to Send:** Active-high output

1. All Innovation Engine (IE) related material described in this section can be reference to Chapter 37, "Innovation Engine".

Figure 18-2. UART MUXed Signals



18.2 Feature List

18.2.1 UART Features

- 16550 and 16750 compliant UART controllers
- 64-byte FIFO for each receiver and transmitter
- Programmable interrupt trigger levels for FIFOs
- Baud generation based on programmable multipliers and divisors
- Supports programmable baud rates from 300 bps to 3.6864 Mbps
- Data rate can be programmed using the multiplier and divisor of the direct digital synthesizer.
- Auto-baud rate detection capability
- Flow control by hardware (HW) or software (SW)
- Configurable data format
- Data bits: 5, 6, 7, or 8 bits
- Even, odd, or no parity generation
- 1, 1.5, 2 stop bits
- False start-bit detection
- Line break generation/detection
- Prioritized interrupt
- Supports DMA and non-DMA mode for data access
- Complete status report capabilities

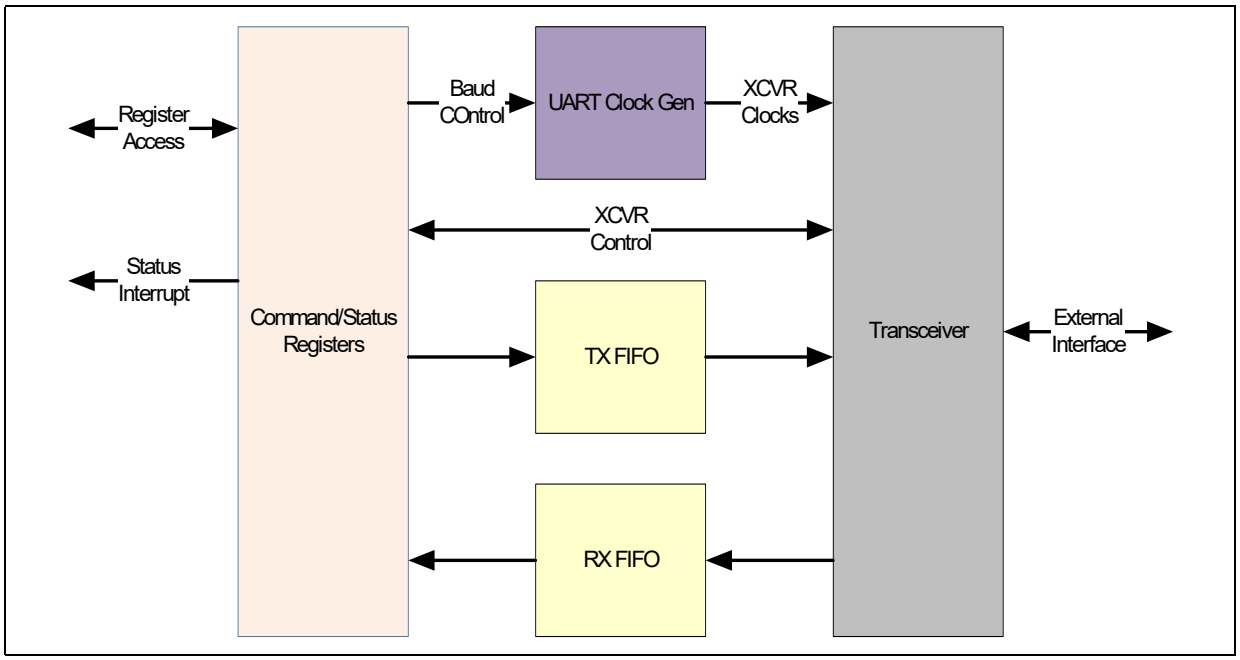
18.2.2 DMA Features

- Supports 32-bit data and addressing
- Dedicated TX and RX channel for each UART
- Each DMA channel has four descriptors
- Configurable interrupt generation for DMA operation
- Support for timeout
- Supports a single outstanding request at a time
- Uses round robin arbitration among active channels
- Support to generate non-DW aligned memory requests

18.3 Architectural Overview

The UART operates per the 16550 component specifications with optional DMA support. The UART can operate in legacy or enhanced mode. The first eight bytes of the 16550 register are set in addition to other registers for the enhanced UART mode.

Figure 18-3. UART Core Block Diagram Overview



18.3.1 UART Hiding and Locking

The 3 IA Host space UART devices are implemented as PCI devices that are discovered by PCI enumeration. The system BIOS always preforms PCI enumeration and the OS may re-enumerate the bus. This can cause the UART devices to move between BIOS and OS.

If your system does not use any or all of the UARTs the BIOS can hide them before preforming the PCI enumeration. The BIOS does this by writing to each UART PCI configuration space register FUNC_RDCFG_HIDE. UART devices must be hidden from UART 3, then UART 2, and lastly UART 1.

If your system requires the UART to be at a legacy COM 1, 2, 3 or 4 address then before PCI enumeration BIOS can assign the legacy I/O address and MMIO address space (if DMA is required). BIOS must also enabled the I/O address decoding by writing bit 0 of CMD_STAT_REG to 1'b1 and if used the MMIO address decoding by writing bit 1 to 1'b1. Then BIOS would hide the UART via PCI configuration space register FUNC_RDCFG_HIDE. In addition BIOS must setup the SoC to route the COM address to the UART and not to the LPC interface. See Table 3-3, “Host Fixed I/O Address Space” on page 176 for the COM address assigned on what additional registers need to be programmed.

If any of the UART devices are left as PCI enumerable (not hidden or put at a legacy COM address) they must be from low to high UART 1, then UART 2 then UART3.

Table 18-3. Legacy COM I/O Ports

COM Port	I/O Ports
COM1	3F8h – 3FFh
COM2	2F8h – 2FFh
COM3	3E8h – 3EFh
COM4	2E8h – 2EFh

18.3.2 Legacy Mode

In the legacy mode, the UART operates per the 16550 component specifications. The UART requests the eight bytes of I/O and 256 bytes of memory space using the corresponding PCI BAR0 (I/O Base Address Register, IOBA) and BAR1 (Memory Base Address Register, MEMBA). MEMBA is only required if your system uses the DMA feature.

The UART TX and RX FIFO depth can be configured to 64 bytes as opposed to only 16 bytes supported by 16550. This UART does not support DMA in legacy mode and does not comply with the DMA signaling mechanism outlined in the 16550 specifications.

18.3.3 Enhanced Mode

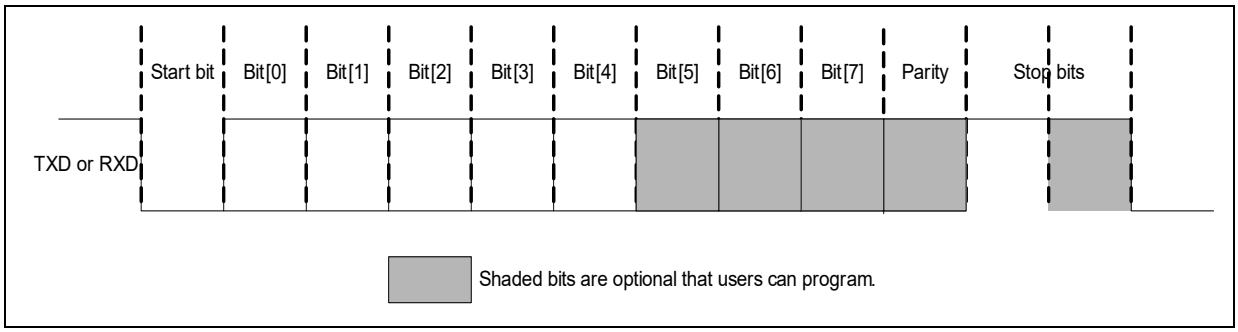
In the enhanced mode, the enhanced register set is available in addition to the legacy mode Command/Status Registers. The UART requests 256 bytes of the memory space per function using BAR1. In the enhanced mode, the memory space is required to be enabled. The UART supports the following additional features in the enhanced mode:

- Programmable UART base frequency using a clock multiplier and divisor
- FIFO size up to 64 bytes
- Baud rates higher than 115.2 kbps (see Table 18-4)
- Auto-baud detection capability
- Auto-flow mode
- DMA capability

18.3.4 UART Function

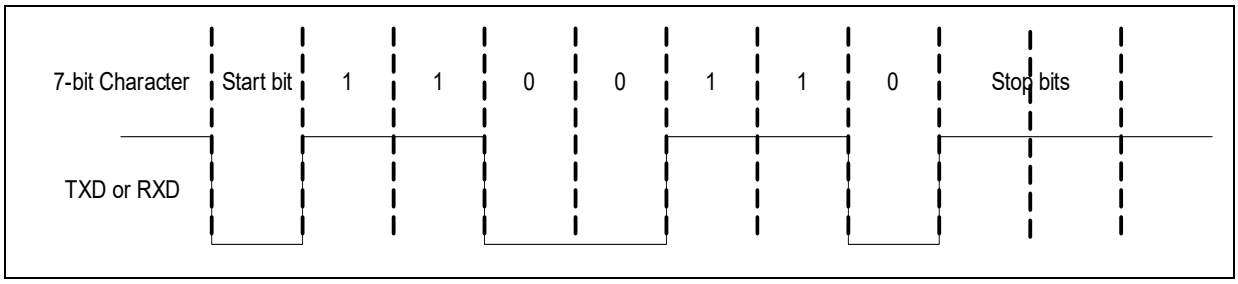
The UART transmits and receives data in bit frames. Each data frame is between 7 and 12 bits long, depending on the size of data programmed, whether parity is enabled or disabled, and the number of stop bits. The frame begins with a start bit that is represented by a high-to-low transition. Next, 5 to 8 bits of data are transmitted, beginning with the least significant bit. An optional parity bit follows, if enabled. The data frame ends with 1, 1.5, or 2 stop bits (as programmed), represented by 1 or 2 successive bit periods of a logic one.

Figure 18-4. UART Data Transfer Flow



The UART serial bit frames are encoded, where a 1 is represented by a line transition, and a 0 is represented by no line transition. Figure 18-5 shows the coded full 7-bit character 1100110 with no parity and 2 stop bits. The LSB of a byte is transmitted first.

Figure 18-5. 7-bit Character Encoding



Out of reset, the UART transceiver is enabled with the default register configuration. The UART transceiver can be disabled by clearing the UART Unit Enable (UUE) bit of the Auto-Baud Control register. When UUE is set, the receiver looks for the start bit of a frame and the transmitter sends data if data is available in the Transmit FIFO or Transmit Holding register. Disabling the transceiver with the UUE bit does not clear the data in the receive/transmit FIFO. Re-enabling the UART will continue transmission/reception with the original data.

Each UART has a transmit FIFO and a receive FIFO and each can store 64 characters of data. There are two separate methods for moving data into and out of the FIFOs: interrupts and polling. The UART also supports the full and half-auto flow control mode for transmission and receive. The UART baud rate can be configured or it also can support the auto-baud rate detection feature. Key UART modes and features are discussed in subsequent sections.

18.3.5 FIFO Interrupt Mode Operation

18.3.5.1 Receive Interrupt

When the receive FIFO (FCR [TRFIFOE] = 1) and the receiver interrupt (IER [RDA] = 1) are enabled, the following receiver interrupts can occur:

- The receive data available interrupt is asserted when the FIFO has reached its programmed trigger level. The interrupt is cleared when the FIFO drops below the programmed trigger level.
- The IIR [IID] receive data available indication also occurs when the FIFO trigger level is reached, and like the interrupt, the bits are cleared when the FIFO drops below the trigger level.
- The Data Ready bit (LSR [DR]) is set to 1 as soon as a character is transferred from the Shift register to the receive FIFO. This bit is reset to 0 when the FIFO is empty.

18.3.5.2 Timeout Interrupt

When the receive FIFO and receiver interrupt are enabled, a character timeout interrupt (IIR [TOD]) will occur to signal the presence of trailing bytes. The interrupt is cleared and the timer is reset when a character is read from the receiver FIFO. If a timeout interrupt has not occurred, then the timeout timer is reset after a new character is received or after the processor reads the receiver FIFO. Character timeout will occur when all the following conditions are true:

- At least one character is in the FIFO.
- A character has not been received for the amount of time it takes to receive four or more characters at the current baud rate.
- The FIFO has not been read for the amount of time it takes to receive four or more characters at the current baud rate.

18.3.5.3 Transmit Interrupt

A character has not been received for the amount of time it takes to receive four or more characters at the current baud rate.

The FIFO has not been read for the amount of time it takes to receive four or more characters at the current baud rate.

When the transmit FIFO (FCR [TRFIFOE] = 1) and the transmitter interrupt (IER [TDRQ] = 1) are enabled, the following receiver interrupts can occur:

- When FCR [TIL] = 0, the transmit data request interrupt occurs whenever the transmit FIFO is empty. The interrupt is cleared as soon as the Transmit Holding register is written or the IIR is read.
- When FCR [TIL] = 1, the transmit data request interrupt occurs when the transmit FIFO is empty or the FIFO level reaches the half empty mark from more than half full. The interrupt is cleared as soon as the Transmit Holding register is written or the IIR is read.

Users could cause the UART transmit FIFO to overflow if too many characters are written. FIFO underflow does not cause an error as the UART will wait for the transmit FIFO to be serviced.

18.3.6 FIFO Polled Mode Operation

With the FIFOs enabled (FCR [TRFIFOE] = 1), clearing IER puts the serial port in the FIFO polled operation mode. Because the receiver and the transmitter are controlled separately, either one or both can be in the polled operation mode. In this mode, software checks the receiver and transmitter status via the Line Status Register (LSR). The processor polls the following bits for receive and transmit data service.

Receive Data Service

Poll the data ready (LSR [DR]) bit that is set when 1 or more bytes remain in the receive FIFO or Receive Buffer Register (RBR).

Transmit Data Service

Poll the transmit data request LSR [TDRQ] bit that is set when the transmit FIFO or Transmit Holding Register (THR) is empty.

Poll the transmitter empty LSR [TEMT] bit that is set when the transmitter is empty.

18.3.7 Auto-flow Control Operation

Auto-flow control uses the Clear-to-Send (CTS) and Request-to-Send (RTS) signals to automatically control the flow of data between the UART and the external serial device. When auto-flow is enabled, the remote device is not allowed to send data unless the UART asserts RTS low. If the UART de-asserts RTS while the remote device is sending data, the remote device is allowed to send one additional byte after RTS is de-asserted. An overflow could occur if the remote device violates this rule. Likewise, the UART is not allowed to transmit data unless the remote device asserts CTS low. This feature increases system efficiency and eliminates the possibility of a receive FIFO overflow error due to long interrupt latency.

The auto-flow mode can be used in two ways: full auto-flow, automating both CTS and RTS; and half auto-flow, automating only CTS. Full auto-flow is enabled by writing a 1 to bits Modem Control Register (MCR) - MCR [AFE][1] and MCR [RTS] of the MCR. Auto-CTS-only mode is enabled by writing a 1 to MCR [AFE] and a 0 to MCR [RTS] of the MCR register.

The auto-flow mode can only be used in conjunction with the FIFO mode. During the auto flow mode, the modem interrupt should not be enabled.

The following are descriptions of RTS and CTS in both modes.

RTS (UART Output)

In full auto-flow mode, RTS is asserted when the UART FIFO is ready to receive data from the remote transmitter. This occurs when the amount of data in the receive FIFO is below the programmable threshold value. When the amount of data in the receive FIFO reaches the programmable threshold, RTS is de-asserted. It will be asserted once again when enough bytes are removed from the FIFO to lower the data level below the threshold.

CTS (UART Input)

In full or half auto-flow mode, CTS is asserted by the remote receiver when the receiver is ready to receive data from the UART. The UART transmitter checks CTS before reading the next byte from the FIFO and will not read the byte until CTS is low. If CTS goes high while the transfer of a byte is in progress or about to transfer a byte, the transmitter will complete the transmission of this byte.

1. Auto Flow Enable (AFE).

18.3.8 Loopback Operation

The loopback mode is on when MCR [LOOP] is set. During the loopback mode, the following will occur:

- The UART serial out TXD is set to an idle state. The UART serial input RXD is internally disconnected. The internal TX line is looped back into the internal RX line.
- The modem inputs are internally disconnected and modem outputs are connected to the disconnected inputs. The modem outputs are set to the idle state.

In the loopback mode, data that is transmitted is immediately received. This feature allows checking of the transmit and receive data paths of the UART.

In the loopback mode, receive and transmit interrupts are fully functional if enabled. The modem interrupts are also functional if enabled, but the sources of interrupt are the lower 4 bits of the MCR.

Note: Full auto-flow and loopback mode can be enabled simultaneously for efficient diagnostic testing. Half auto-flow and loopback mode should not be enabled simultaneously.

18.3.9 Auto-Baud Detection

Each UART supports auto-baud rate detection. This feature is only available in enhanced mode. When enabled, the UART counts the number of reference clock cycles within the receive start-bit pulse. The frequency of the reference clock is set when the UART clock gen is initialized. The default UART clock is 1.8432 MHz. The number of UART clock pulses in the start bit is written into the Auto-Baud Count Register (ACR) and is used to determine the baud rate. When the ACR is written, an auto-baud lock interrupt is generated (if enabled), and the UART can automatically program the Divisor Latch registers with the appropriate baud rate. If preferred, the processor can read the Auto-Baud Count register and use this information to program the Divisor Latch registers with a baud rate calculated by the processor. After the baud rate has been programmed, the host is responsible to verify that the predetermined characters (usually AT or at) are being received correctly.

If the UART is allowed to program the Divisor Latch registers in the auto-baud mode, users can choose between two methods for auto-baud calculation: table-based and formula-based. The method is selected via bit Auto-baud Table (ABT) of the Auto-Baud Control Register (ABR). When the formula-based method is used, the baud rate, based on the number of UART clock pulses in the start bit, can be programmed by the UART. This method works well for higher baud rates, but could possibly fail below 28.8 Kbps because of the fine resolution of the clock measuring the duration of the start bit, especially when the duration of the start bit is not exactly equal to the nominal due to the use of slow level translators. The actual baud rate may differ by more than one percent of its target.

Once the baud rate is detected the first time, the auto-baud circuitry will disarm itself by clearing bit ABE of the Auto-Baud Control Register (ABR). The Auto-Baud Enable (ABE) bit must be written as 1 by software to rearm the circuitry.

For the auto-baud rate detection circuit to work correctly, the first data bit transmitted after the start bit must be logic 1. If logic 0 is transmitted instead, the auto-baud circuit will count the 0 as part of the start bit, resulting in an incorrect baud rate being programmed into the Divisor Latch Low (DLL) and Divisor Latch High (DLH registers. The input signal with a baud rate less than 150 bps will result in undefined behavior of the auto-baud detection circuitry.

18.3.10 UART Clocking

The UART clock is derived from internal SoC clock system.

FUART = 44236800 Hz

18.3.11 UART Baud Rate Generation

The baud rates are generated from the UART base frequency (FUART) by programming the Divisor Latch Access Bit (DLAB) from Line Control Register (LCR.DLAB) and Pre-Scalar (PSR) registers.

FBAUD = FUART / (PSR/ DLAB)

To get the supported baud rates as mentioned in table below, use FUART = 44236800 Hz.

Table 18-4. Supported Baud Rates

FUART (Hz)	PSR	LCR.DLAB	FBAUD (bps)
44236800	0C	0001h	3686400
44236800	10C	0003h	921600
44236800	10C	0006h	460800
44236800	10C	0009h	307200
44236800	10C	000Ch	230400
44236800	10C	000Fh	184320
44236800	10C	0012h	153600
44236800	10C	0018h	115200
44236800	10C	0030h	57600
44236800	10C	0048h	38400
44236800	10C	0090h	19200
44236800	10C	0120h	9600
44236800	10C	0180h	7200
44236800	10C	0240h	4800
44236800	10C	0300h	3600
44236800	10C	0480h	2400
44236800	10C	0600h	1800
44236800	10C	0900h	1200
44236800	10C	1200h	600
44236800	10C	2400h	300

18.3.12 I/O and Memory Base Access Space

The UART supports 8 bytes of I/O space and 256 bytes of memory space to access registers of the UART. The lower 8 bytes are compliant to the 16550 UART. While addresses beyond 8 bytes give access to more advance features which include an auto-baud lock mechanism, DMA channel access, and higher baud rates.

Configure BAR0 (I/O Base Address Register, IOBA) by placing the device anywhere in the 16-bit I/O address space.

Configure BAR1 (Memory Base Address Register, MEMBA) by placing the device anywhere in the 32-bit memory address space.

18.3.13 Interrupt

The UART supports MSI messages to communicate interrupts.

In the event the MSIMC[MSIE] is set to 1, it is mandatory to configure the MSI address and MSI data properly in order to identify the MSI interrupt from this device.

Table 18-5. Interrupt Enabling

	CMD[ID] = 0	CMD[ID] = 1
MSIMC[MSIE] = 1	MSI sent via primary Interface	No interrupt to host

18.3.14 Memory Address MAP

The memory map is split between the UART Memory Mapped registers Table 18-10 and the DMA channel registers Table 18-11. The UART registers are mapped to the first 128 bytes in the memory map. Each DMA channel takes the next 64 bytes. The total memory requirement for a single function is shown in Table 18-6.

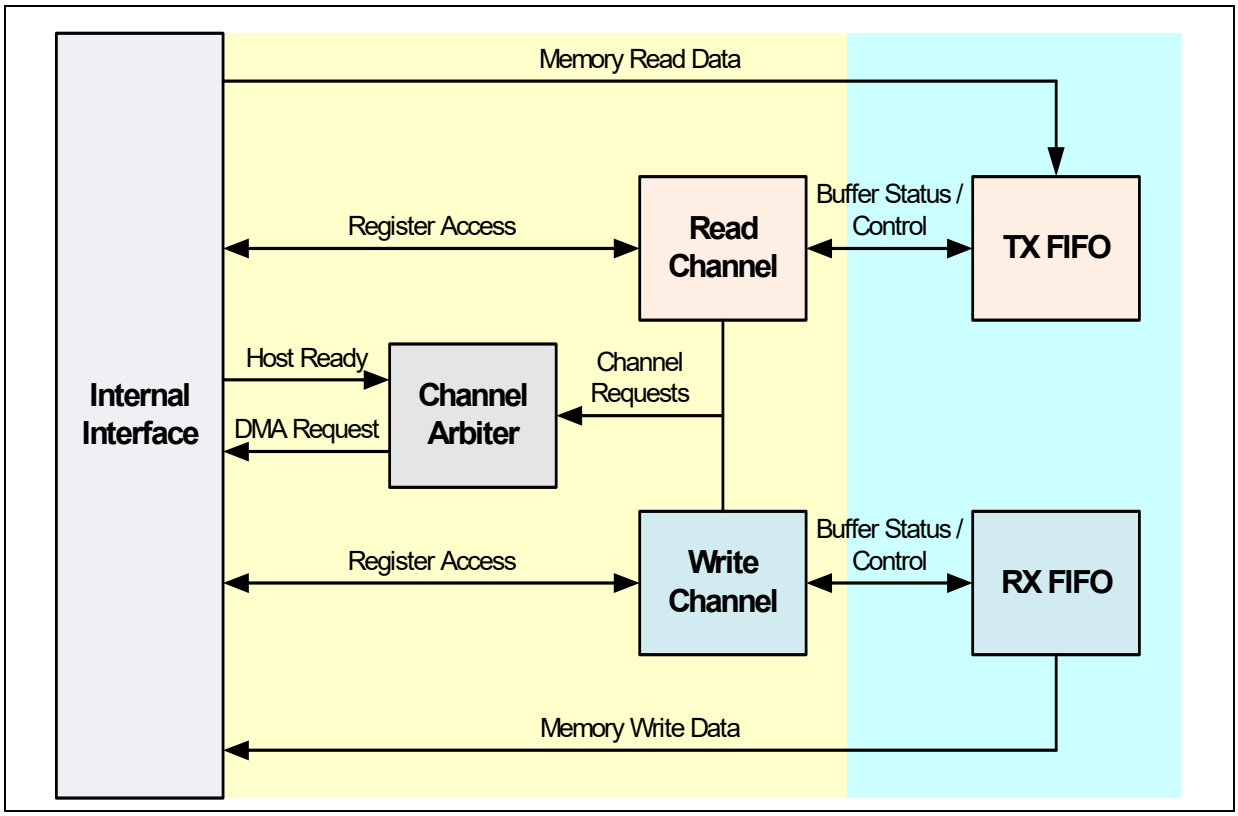
Table 18-6. UART Memory Space

Block	Memory Size	Base Address	Description
UART[n]	128 bytes per function	0x00	UART memory space requirement
DMA Channel[0]	64 bytes for read channel	0x80	DMA memory space read requirement
DMA Channel[1]	64 bytes for write channel	0xC0	DMA memory space write requirement

18.3.15 DMA

The UART provides optional support for direct memory access transactions that isolate the CPU from the need to deliver large chunks of data to or from the main memory to the UART FIFOs.

Figure 18-6. DMA Block Diagram



Each UART has a dedicated read and write channel that will handle read and writes to the host memory. DMA channels have around robin arbiter that arbitrates the requests from all the channels.

Each channel has four descriptor sets. Each has its own Start Address Register (SAR) and Transfer Size Register (TSR). The channel logic chases each descriptor on a round robin manner, i.e., once descriptor 0 is completely done, it moves to descriptor 1, and once descriptor 3 is done it goes back to descriptor 0.

Each descriptor that is active and selected for chasing, delivers the start address and the transfer size. The channel logic decides the actual transfer size, based on the availability of data/space in the buffer and based on the minimal/maximal transfer size programmed to that channel. The descriptor is described as following:

- Start address + actual transfer size -> start address
- Transfer size - actual transfer size -> transfer size
- The design ensures that actual transfer size <= transfer size.

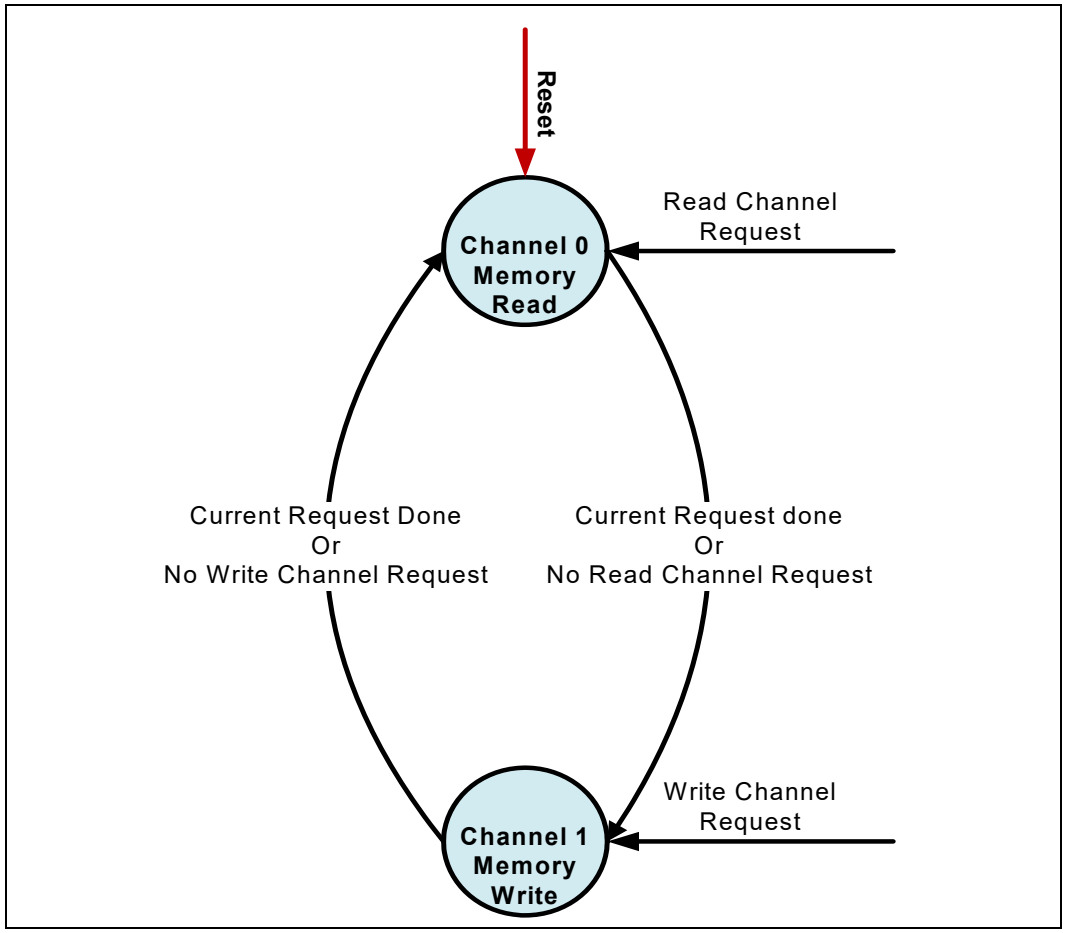
Once the descriptor transfer size reaches 0, the descriptor is considered to be completed and the channel logic can move to chasing the next descriptor.

18.3.15.1 Channel Arbitration

DMA channel arbitration has the following key functionality:

- Round robin arbitration scheme is used.
- The arbiter scans all the channels and whenever a channel has a valid request, the arbiter will send the request to the host interface if it is ready.
- Once the current request is done, the arbiter moves to the next channel, even if the current channel wishes to perform another transfer.

Figure 18-7. Logical Representation of Channel Arbitration



18.3.15.2 Descriptor Arbitration

The descriptor arbitration within each DMA channel has following key functionality:

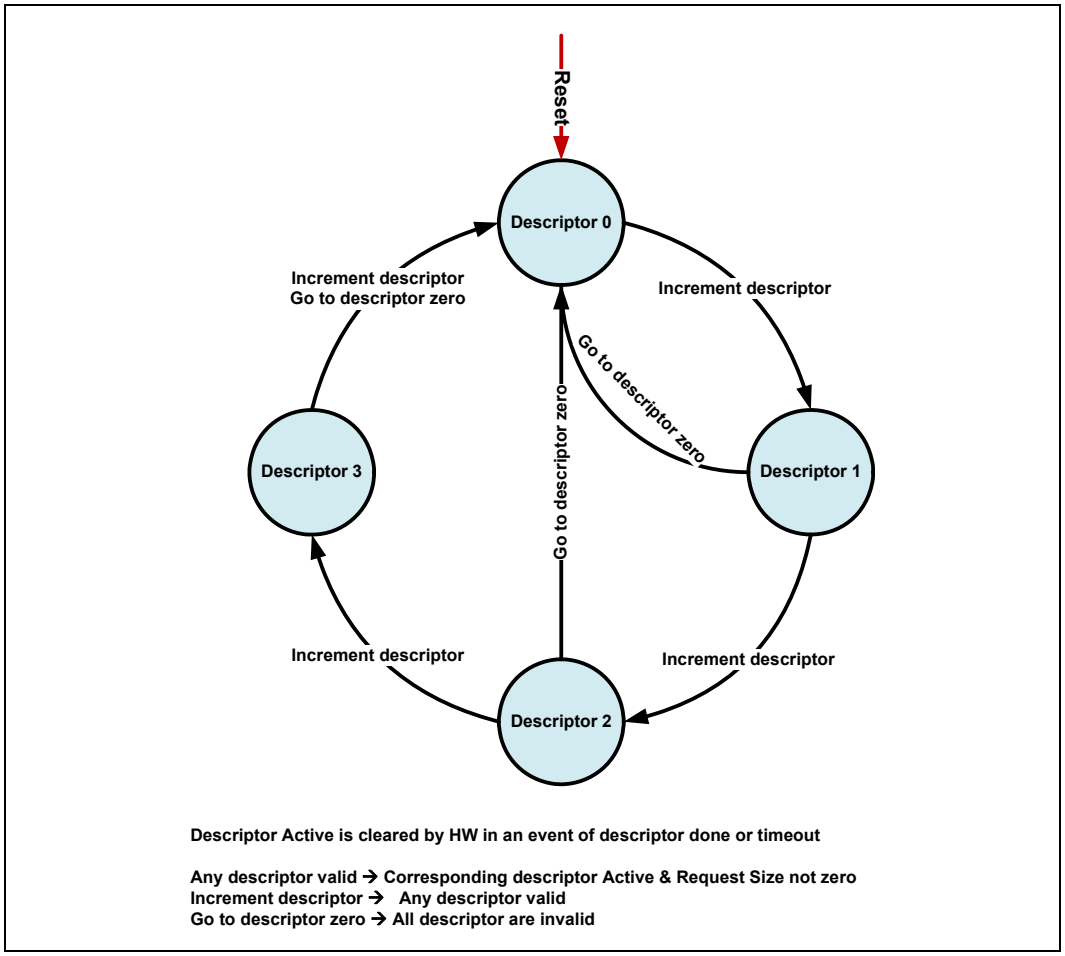
- Round Robin progresses 0 -> 1 -> 2 -> 3 -> 0 and so on.

On reset, the current descriptor points to descriptor 0. Descriptor arbitration is a function of the descriptor active, descriptor request size, and descriptor timeout for the corresponding descriptor. The descriptor select logic advances from one descriptor to the next once the transfer size on the current selected descriptor is down to 0 or a timeout condition is encountered during these events, the descriptor active bit will be cleared which results in an invalid descriptor.

When all descriptors are invalid, the current descriptor will immediately point to descriptor 0. The descriptor select logic starts with the first programmed valid descriptor. The current descriptor status is logged into the Channel Status register.

Any descriptor with a non-zero request size but an inactive descriptor active bit will not place the request to the channel arbiter.

Figure 18-8. Logical Representation of Descriptor Arbitration



18.3.16 MSI Generation

The UART has the capability to generate an MSI whenever the interrupt event happens within the UART or DMA units. The host needs to program the PCI MSI configuration registers to enable the MSI generation. The host needs to read the Capabilities Pointer (CP) PCI configuration register which points to the MSI Capability ID (MSICID) register. Then, the host needs to program the MSI Message Control (MSIMC) register, MSI Message Address (MSIMA) register, and MSI Message DATA (MSIMD) register to enable MSI generation for the UART. An MSI will be sent upstream as a posted write request to the address in MSIMA with the data value in MSIMD.

Once an MSI is enabled, legacy interrupt over sideband will be disabled. A single MSI is sent upstream whenever any of the interrupt is asserted. In the event of MSI software needs to read the relevant registers from all the three interrupt sources: UART, DMA read channel, and DMA write channel.

18.4 UART Programming Recommendation

This section is provided as recommendation steps for configuration sequencing for the UART programming.

18.4.1 Setup Access Space

The UART supports 8 bytes of the I/O space and 256 bytes of the MEM space to access registers of the UART. The lower 8 bytes are compliant to the 16550 UART. While addresses beyond 8 bytes give access to more advances features which includes the auto baud lock mechanism, DMA channel access, and higher baud rates.

Configure BAR0 (I/O Base Address Register, IOBA) by placing the device anywhere in the 16-bit I/O address space.

Configure BAR1 (Memory Base Address Register, MEMBA) by placing the device anywhere in the 32-bit memory address space.

18.4.2 Setup Interrupt

The UART supports MSI messages to communicate interrupts.

In the event that MSIMC[MSIE] is set to 1, it is mandatory to configure the MSI address and MSI data properly in order to identify an MSI interrupt from this device.

Table 18-7. Interrupt Enabling

	CMD[ID] = 0	CMD[ID] = 1
MSIMC[MSIE] = 1	MSI sent via primary interface	No interrupt to host

18.4.3 Space Enable

Once configuration of the PCI space is done, the host should enable the required space (Memory or I/O). Also, the host should allow the device to initiate a transaction as a master.

To enable memory space CMD[MSE] =1'b1 (1st bit, binary, set to 1)

To enable I/O space CMD[IOSE] = 1'b1

To enable device as a master CMD[BME] = 1'b1

18.4.4 DMA Programming

Even though the DMA channel number is fixed (i.e., Channel 0 is for DMA Rx and Channel 1 is for DMA Tx), it is mandatory to program CHnCR with the appropriate channel direction value. Note that "CHn" from register name represented to DMA Channel 0 and DMA Channel 1 for this chapter.

The UART has FIFO that holds 64 bytes in each direction (UART Tx and UART Rx). the same number must be configured to the Buffer Size register Channel n=channel number Status Register (CHnBSR).

The host has to enable the FIFO mode of the UART when needed to operate with DMA (FCR[TRIFIFOE]).

18.4.5 DMA Descriptor Use/Reuse

In the case when the DMA is enabled, every DMA channel supports four descriptors. Descriptor evaluation happens sequentially from 0 to 3 and then rolls over to 0 again.

It is important to know which descriptor to be evaluated first. Intel recommends to program the descriptor in a sequence rather than randomly.

Once the DMA indicates it is done with the transfer, the host must program the following registers in order for the DMA engine to chase the descriptors again. Failure in the sequence of this program may result in the DMA engine not working when the same descriptor is used again.

1. Deactivate the channel before modifying any descriptor values Channel n=channel number Control Register (CHnCR).
2. Disable all the descriptors (CHnDCR).
3. Program each descriptors of the respective channel with the appropriate value of SAR and TSR (CHnD0/1/2/3SAR, CHnD0/1/2/3TSR).
4. Change the minimum transfer size if required (CHnMOTSR).
5. Activate the channel (CHnCR).
6. Enable the required descriptors with the appropriate interrupt enable bits (CHnDCR).

18.4.6 Programming Optimization

18.4.6.1 Optimization Descriptor Programming Activities During DMA

Program TSR of each descriptor with a sufficient high value.

In the case of the DMA Rx, the host knows how many characters are required to be transferred. Therefore, it should use the full capacity of the TSR and SAR combination to transfer enough data at the UART Tx signals.

In the case of the DMA Tx, the host does not have the knowledge how much data is going to be received, but still the host can enable the timeout interrupt CHnDCR[27:24] for each descriptor. Also, program the fairly large value in TSR to minimize the descriptor programming cycles.

Note: The descriptors are still active when the DMA timeout happens, but the DMA done is not set. The DMA timeout acts as just a notification to the host that nothing is being received in last four character cycles. Also, the DMA engine empties the buffer towards the host with the appropriate address and length.

18.4.6.2 Optimization Access Time By UART During DMA

Channel minimum transfer size (CHnMTSR) instructs the DMA engine when to initiate a request towards the internal interface to the read/write data from the host memory. That means a smaller value shall initiate more requests with less payload size, and a higher value shall initiate less requests with a higher payload size.

This value must not increase the buffer size value in order to prevent overflow (in the case of DMA Tx) or deadlock (in the case of DMA Rx). For SoC I/O fabric UART, the maximum value that can be programmed is 64, and the minimum value that can be programmed is 1.

Intel recommends to program this register with value = 60 on the safe side and to optimize the Dword boundary access.

18.4.6.3 Optimization Interrupt Handling

The UART has two sources of interrupt and shares a common interrupt notification source to communicate an interrupt to the host. If an interrupting condition from the source is not cleared, a subsequent interrupt shall not be communicated. So it is very important to clear the interrupt source upon receipt by the host.

18.4.6.3.1 DMA Interrupt Handling

This section contains interrupt sources which can occur only when the UART is running in the DMA mode.

Descriptor Done Interrupt

When the DMA engine transfers the configured amount of characters (configured via TSR), the DMA engine asserts this interrupt to notify the host to reprogram the respective descriptor. In order to avoid more interrupts from this source, the host may chose to enable this interrupt only for the upper descriptor. For example, if three descriptors are programmed, counting from 0 -> 1 ->2, enable a done interrupt only for descriptor 2. This will skip an interrupt to the host when descriptor 0 and descriptor 1 are completed.

The cost that the host needs to pay is to keep track of which descriptors were programmed before.

This interrupt gets cleared upon reading the DMA interrupt status register.

Descriptor Timeout Interrupt

This interrupt acts as more of a notification of any action for the host. A timeout interrupt can never happen for the DMA Rx channel (Channel 0). Upon character timeout, the HSUART interrupts the host and then activates DMA Tx to flush the trailing bytes from the buffer.

This interrupt gets cleared upon reading the DMA interrupt status register.

18.4.6.3.2 UART Interrupt Handling

This section contains interrupt sources from the UART. The 16550 has the following five types of interrupts.

Receive Data Available Interrupt

This interrupt notifies the host that at least a configured number of characters are present in the buffer. The lower the number, the more frequent interrupts can be expected.

The threshold for this interrupt can be controlled through the FCR[ITL] value.

Note: In the DMA mode, this interrupt acts as a notification only. The DMA engine takes care of transferring the data to the host memory when the Rx buffer gets up to a minimum transfer size.

Programming this interrupt in the DMA mode may block any further interrupt communicated by the DMA or UART source if this interrupt is on. For instance, if FCR[ITL] is programmed to a value 00, upon every SoC I/O fabric transfer, which empties the Rx buffer, this interrupt gets de-asserted, and upon receiving the first character interrupt gets asserted.

Intel recommends to disable this interrupt when running with the DMA mode.

Transmit Data Request Interrupt

This interrupt notifies the host about availability for more characters in the transmit FIFO. The threshold for this interrupt can be controlled with the FCR[TIL] bit value.

Note: In the DMA mode, this interrupt acts as a notification only. The DMA engine takes care of transferring data from the host to the Tx buffer when a configured number of bytes are empty in the buffer.

Intel recommends to disable this interrupt while operating in the DMA mode.

Receiver Line Status Interrupt

This interrupt notifies the host that either error has been noticed in the UART reception or a break character is received. This interrupt notification is important for the host in order to receive error free characters.

Upon detection of line status interrupt, further decoding can be done by reading LSR.

Intel recommends to enable this interrupt.

Modem Interrupt

This interrupt notifies the host about modem-related information and updates.

If running with a modem signal, Intel recommends to enable an interrupt.

Receiver Timeout Interrupt

This interrupt only occurs in the FIFO mode.

If operating in the DMA mode, this interrupt acts as a notification only. The DMA engine takes care of transferring the trailing bytes to the host memory upon detection of a timeout.

If operating in the DMA mode, Intel recommends to disable this interrupt.

If operating in the FIFO mode but not in the DMA mode, Intel recommends to enable this interrupt.

Additional Interrupt

This set of interrupts are introduced in addition to the 16550 recommended interrupts from the UART module.

Auto Baud Lock Interrupt

When the auto baud lock feature (ABR[ABE]) and auto baud lock interrupt (ABR[ABLIE]) are enabled, upon getting locked on a receiving character, this interrupt gets generated.

This interrupt gets cleared when reading IIR.

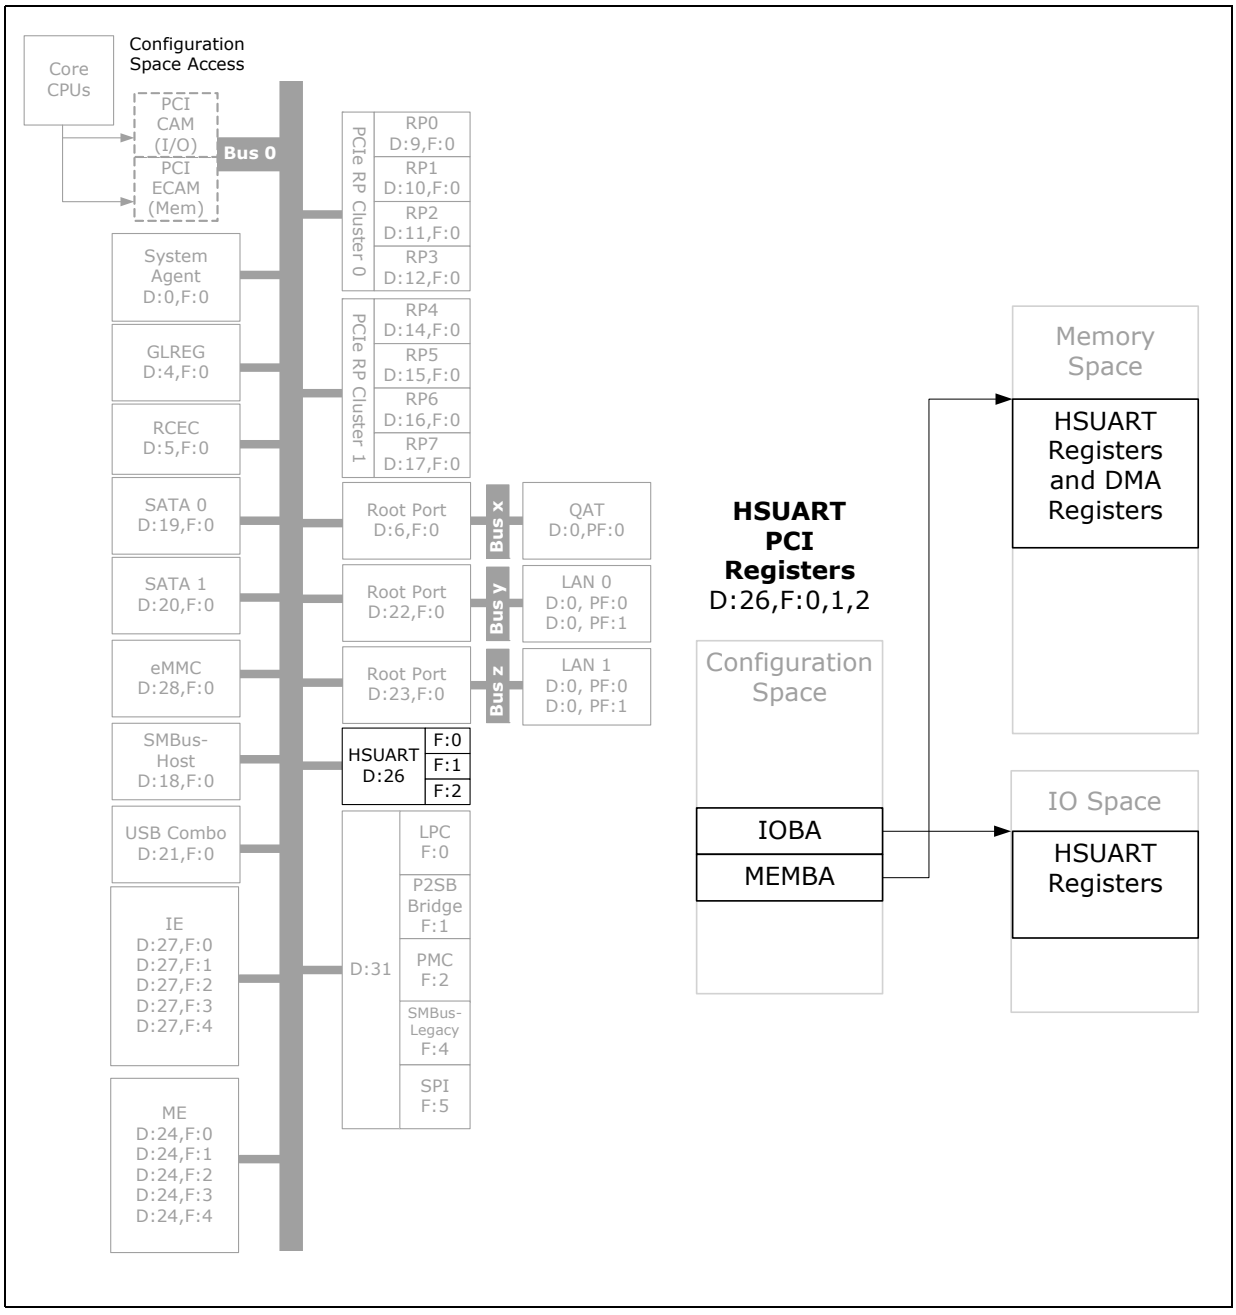
Intel recommends to enable this interrupt when operating with the auto baud lock feature. Also, Intel recommends not to transfer data unless the auto baud lock is achieved in the auto baud lock mode to ensure transfer integrity.

Enabling the auto baud lock interrupt when the auto baud lock feature is not enabled does not generate any interrupt to the host from the auto baud lock source.

18.5 Register Map

Figure 18-9 shows the associated registers from a system software viewpoint.

Figure 18-9. Register Map



18.5.1 PCI Configuration and Capabilities Registers

The UART PCI configuration registers:

- UART 0 = PCI Bus 0; Device 26 (decimal); Function 0
- UART 1 = PCI Bus 0; Device 26 (decimal); Function 1
- UART 2 = PCI Bus 0; Device 26 (decimal); Function 2

Table 18-8. PCI Configuration Registers (HSUART_REGS_PCI)

Offset from Configuration Space of B0:D26:Fn (n=0,1,2) (Decimal)	Register Name	Description
00h	VENDOR_DEVICE_ID	Vendor and Device ID Register
04h	CMD_STAT_REG	Command and Status Register
08h	REV_CLASS_CODE	Revision ID and Class Code Register
09h	CACHE	Header Type Register
10h	IOBA	I/O Base Address Register
14h	MEMBA	Memory Base Address Register
2Ch	SUBSYSTEM_VENDOR_ID	Subsystem Vendor ID Register
34h	CAP_PTR	Capability Pointer Register
3Ch	INTERRUPT	Interrupt Line Register
40h	MSIC	MSI Capability Register
44h	MSIA	MSI Message Address Register
48h	MSID	MSI Message Data Register
50h	PMC	Power Management Capability Register
54h	PMCSR	Power Management Control and Status Register
60h	DSC	Device Specific Control and Status Register
74h	FUNC_RDCFG_HIDE	Function-Hide Register

18.5.2 Memory Mapped Registers, BAR1 (Memory Base Address Register, MEMBA)

The memory map is split between the UART and DMA channel registers.

The UART registers are mapped to the first 128 bytes in the memory map. If the DMA is included in the design, each channel takes the next 64 bytes. The total memory requirement for a single function is shown in Table 18-9.

Table 18-9. UART and DMA Memory Space

Block	Memory Size	Description
UART	128 bytes per function	UART memory space requirement
DMA	128 bytes per function	DMA memory space requirement • 64-bytes for the read channel • 64-bytes for the write channel

18.5.2.1 UART Memory Mapped Registers

The UART is software compatible with 16650 and 16750 UART specifications. The first 8 bytes of the UART Command/Status Registers are a single byte register. These registers are DW wide.

Note: Software must not assume the existence of any Command/Status Registers which are not explicitly documented here.

Table 18-10. UART Memory Mapped Registers

Offset from MEM Base Address MEMBA (FFFFFF00h)	LCR.DLAB	Access	Register Name	Description
00h	0	RO	RBR	Receive Buffer Register
00h	0	WO	THR	Transmit Holding Register
00h	1	RW	DLL	Divisor Latch Low Byte Register
01h	1	RW	DLH	Divisor Latch High Byte Register

§ §

19 Serial Peripheral Interface (SPI)

The SoC implements a Serial Peripheral Interface (SPI) controller as the interface to the SPI Flash image storage. The SPI controller supports a maximum of two SPI NOR Flash devices and supports frequencies of 17 MHz (default), 30 MHz, and 48 MHz. The SPI controller also supports one discrete TPM device.

The SoC SPI NOR Flash controller allows the Flash component(s) to be shared by various masters including BIOS, Intel® ME, LAN Controllers (GbE), and Innovation Engine (IE). The Flash controller is accessed from either the host, IE, or Intel® ME root space. The GbE accesses to Flash (for both the controller and software driver) are via the GbE controller MMIO space.

Related reference material:

- LAN Controller (GbE) related material described in this section can be reference to Chapter 13, "LAN Controllers".
- Intel® ME related material described in this section can be reference to Chapter 36, "System Management".
- For Innovation Engine (IE) related material described in this chapter, see Chapter 37, "Innovation Engine", see Table 1-5, "Reference Documents" on page 127.

19.1 Signal Descriptions

The signal descriptions are shown in Table 19-2 For additional signal information, including whether a signal is assigned to shared-function pin or can be used as a Customer GPIO signals see Section 39.1, "Directory of Signal Names and Pin Names" on page 993. The Direction column of Table 19-2 is interpreted as follows:

- I = Input signal. The SoC has receiver circuit.
- O = Output signal. The SoC has driver circuit.

Table 19-2. Signal Names and Descriptions

Signal Names	Direction	Shared	Description
SPI_CLK	O	Yes	**SPI Clock:** The SPI clock signal during idle the bus owner will drive the clock signal low.
SPI_MOSI_IO[0]	I,O	Yes	**SPI Master OUT Slave IN:** Data output pin.
SPI_MISO_IO[1]	I,O	Yes	**SPI Master IN Slave OUT:** Data input pin.
SPI_IO[3:2]	I,O	Yes	**Extended SPI** I/O**:** to 4-bit data.
SPI_CS_N[0]	O	Yes	**SPI Chip Select 0:** Used as the SPI bus request signal for the Flash device.
SPI_CS_N[1]	O	Yes	**SPI Chip Select 1:** Used as the SPI bus request signal for the Flash device.
SPI_TPM_CS_N	O	Yes	**SPI Trusted Platform Module (TPM) Chip Select:** Used as the TPM dedicated request signal. ***Note:*** The "TPM Over SPI or LPC Select" Soft Strap much be set to SPI to use TPM on the SPI interface.
Boot BIOS Strap	I	Yes	See Chapter 4, "Strapping and Configuration."
LPC Select	I	Yes	See Chapter 4, "Strapping and Configuration."
Flash Security Override	I	Yes	See Chapter 4, "Strapping and Configuration."
Top Swap Override	I	Yes	See Chapter 4, "Strapping and Configuration."

19.2 Feature List

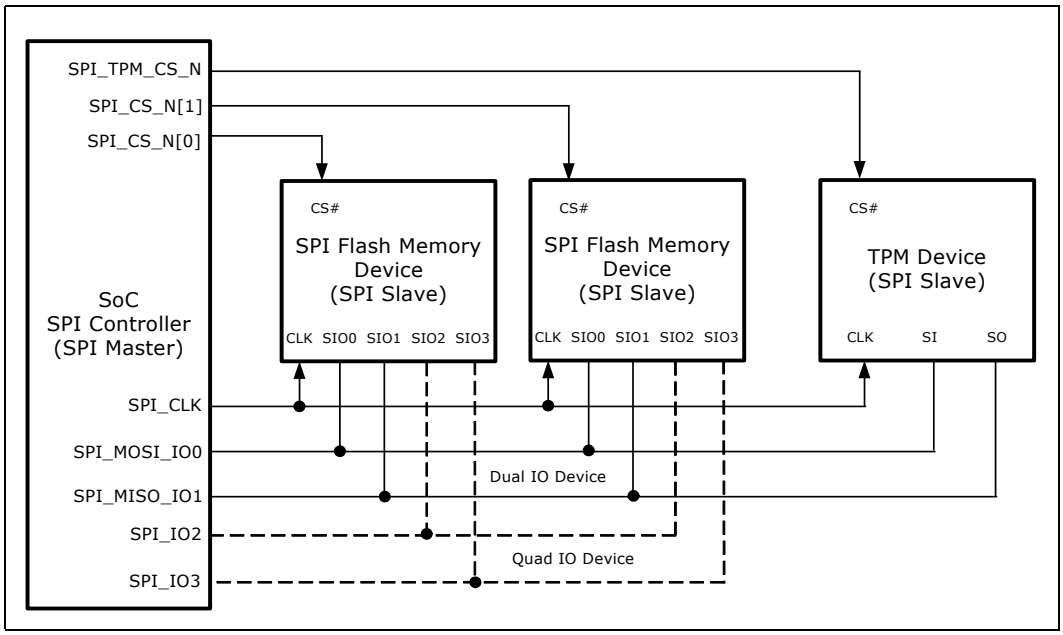
- Support for up to two SPI Flash devices
- The maximum size of each Flash device supported is determined by the SFDP-discovered addressing capability of each device.
  - Each component can be up to 16 MB (32 MB total addressable) using 3-byte addressing.
  - Each component can be up to 64 MB (128 MB total addressable) using 4-byte addressing
- Different size SPI Flash devices may be used on each chip select.
- Both SPI Flash devices must be from the same vendor and family.
- Supports five configurable protecting ranges.
- SoC soft-strap information is supported.
- 3.3V SPI I/O buffer VCC.
- Supports the SPI fast read instruction and frequencies 17 MHz (default), 30 MHz, and 48 MHz.
- Support for SPI attached TPM with one TPM chip select (SPI_TPM_CS_N).
- Supports up to quad mode.

19.3 Architectural Overview

Communication on the SPI bus is done with a master–slave protocol. See Figure 19-2 for the master-slave connection of the SPI devices. The Slave Output (SO) data is implemented through a tri-state bus.

The SPI Flash controller allows the Flash component(s) to be shared by various masters including the BIOS, Intel® ME, Innovation Engine (IE), and LAN Controllers. The Flash controller is accessed from either the host or Intel® ME or IE root space.

Figure 19-2. Connection to the SPI Devices



The chip select 0 (the SPI_CS_N[0] pin) Flash device must have a valid descriptor for SoC to boot.

19.3.1 Operation Mode

The SPI controller must operate in the descriptor mode with optional security access restrictions.

19.3.1.1 Descriptor Mode

The descriptor mode is required to enable many features:

- Supports Flash that is divided into regions and accessible by multiple masters.
  a. Regions are allowed to extend across multiple Flash components.
  b. Regions are aligned to 4K blocks/sectors.
- The soft strap region provides the ability to use Flash NVM as an alternative to hardware pull-up/pull-down resistors for the SoC.
- The Flash descriptor contains the Flash upper map.
  a. This is used by software to define Flash vendor specific capabilities.
- The top 256B of the Flash descriptor is reserved for use by the OEM.

19.3.1.2 Security

- Descriptor-based region restriction: Hardware enforced security restricting master accesses to different regions.
  a. Flash descriptor region settings define separate read/write access to each region per master.
  b. Flash security override SoC hard (pin) strap to remove all descriptor-based security (does not affect register-based protected ranges).
  c. Masters can grant other masters read/write access to their region.
- Protected range registers
  a. Five sets of lockable protected range registers that can restrict program register accesses.
  b. Can span multiple regions.
  c. Separate read and write protection.
- SMI write protection for the BIOS
  a. If enabled, will cause an SMI if a program register access occurs when enabled. The primary purpose of this requirement is to support SMI-based BIOS update utilities.
- Illegal instruction protection for instructions such as chip erase.
- Lockable software sequencing opcodes, disabled by default.

19.3.1.3 SPI Flash Access

- Direct read access
- Program register access
  a. Hardware sequencing: Sequencing uses hardware (HW) to provide the basic instructions of read, write, and erase.
  b. Software sequencing: Allows software (SW) to use only a legal opcode.
- Support for the boot BIOS on the SPI.
  a. SoC hard (pin) straps (BBS) determine the BIOS boot location.
- Pre-fetching/caching to improve performance
  a. Separate 64B pre-fetch/cache for the host.

19.3.1.4 Flash Component Requirements

- Serial Flash Discoverable Parameter (SFDP) support.
  Refer to *Serial Flash Discoverable Parameters (SFDP), JEDEC Specification JESD216B*

Notes:
1. SPI controller does not support legacy non-SFDP devices. SFDP support and an SFDP table are required for flash components.
2. SPI controller collects SFDP information for each chip select (CS0 and CS1) and will use the highest supported features for each chip select. CS0 and CS1 do not have to use the same modes.

- Supports two SPI Flash components using two separate chip select pins, SPI_CS_N[0] and SPI_CS_N[1].
- The Flash controller hardware allows selection of either 64k or 4k erase opcodes if the devices advertise these opcodes via SFDP.
- The maximum size of Flash supported is determined by the SFDP-discovered addressing capability of each device. Each component can be up to 16 MB (32 MB total addressable) using 3-byte addressing. Each component can be up to 64 MB (128 MB total addressable) using 4-byte addressing.
- 3.3V SPI I/O buffer VCC
- Supports frequencies 17 MHz (default), 30 MHz, and 48 MHz (48 MHz support requires components that meet 66 MHz timing).
- Supports the SPI fast read instruction.
- Supports the SPI dual output and dual I/O fast read instruction.
- Supports the SPI quad output and quad I/O fast read.
- Uses the standardized Flash instruction set.
- Supports Flash sizes which are not 2^N (where N is an integer), also known as non-power of 2, with the following restrictions:
  a. The Flash regions must be programmed to the actual size of the Flash component(s).
  b. If using two Flash components, the first Flash component (the one with the Flash descriptor) must be of size 2^N. The second Flash component can be a non-power of 2 size. If using only one Flash component, it can be of non-power of 2 size.
  c. The value programmed in the Flash descriptor component density must be set to the next power of 2 value larger than the non-power of 2 size.

Note:

If the SoC is configured to support "Flash dual output and dual I/O fast read" and/or the "quad output and quad I/O fast read" **and** The SPI flash device advertises via *Serial Flash Discoverable Parameters* (SFDP) the "dual output and dual I/O fast read instruction" and/or the "quad output and quad I/O fast read instruction".

Then: In addition to SFDP, the SPI flash device must also **enable** these SFDP advertised dual mode and/or quad mode at the SPI flash device power on. Check with your SPI flash vendor to determine if a specific device supports this requirement.

Else: The SoC will not boot

SoC	Dual (DORE/DIORE)		Quad (QORE/QIORE)	
Flash SFDP	Yes		Yes	
SPI Flash Enabled at power on	No	Yes	No	Yes
Boot	No	Yes	No	Yes

19.3.2 Flash Regions

The Flash is divided into regions. The following regions are assigned the following content.

Table 19-3. Flash Regions

Region	Name
0	**Descriptor**
1	**BIOS**
2	**Intel® ME**
3	Reserved
4	**Platform Data Region**
5	Reserved
6	Reserved
7	Reserved
8	Reserved
9	Reserved
10	**Innovation Engine (IE)**
11	**LAN Controller 0**
12	**LAN Controller 1**
13	Reserved
14	Reserved
15	Reserved

The regions have the following characteristics:

- Region 0, 1 (SPI boot only), and 2 are required to bring up the SoC. Other regions may be optional to include in the Flash, and depends on how the feature is used.
- Region 0 must be located in the first sector of component 0 and SPI_CS_N[0] and all other regions can be organized in any order.
- Region boundaries must be aligned to erasable sector boundaries, with a minimum granularity of 4 KB.
- Regions can extend across multiple components.

Figure 19-3. Flash Regions

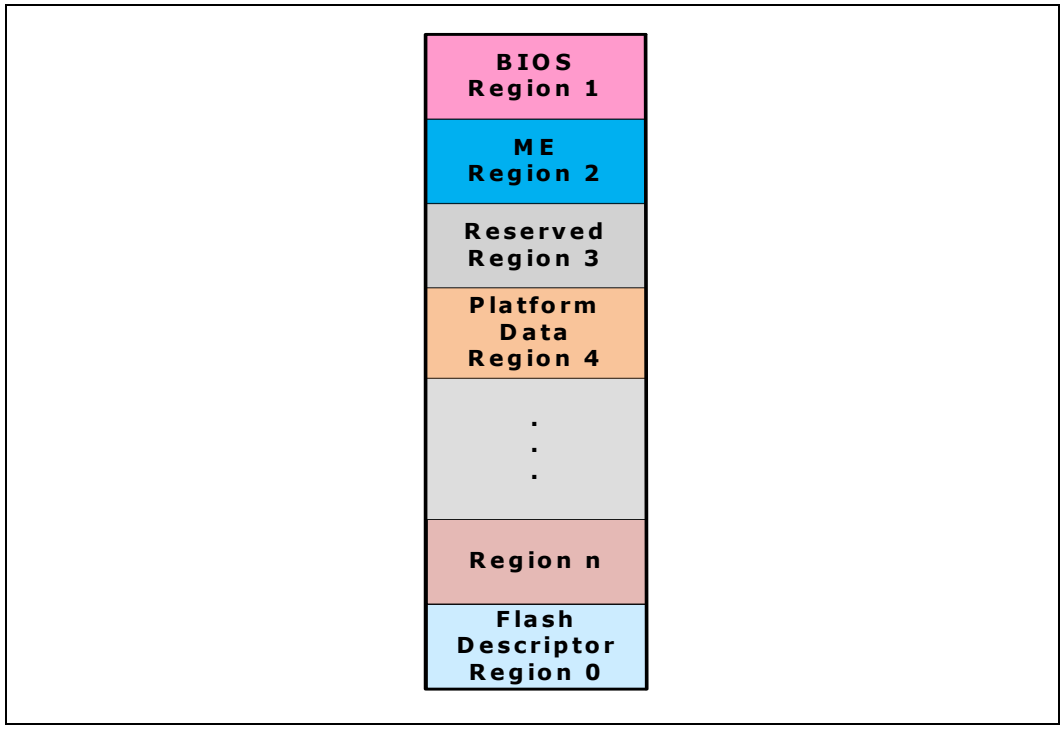


Figure 19-4. Organize Flash Region Single Flash vs. Dual-Flash Components

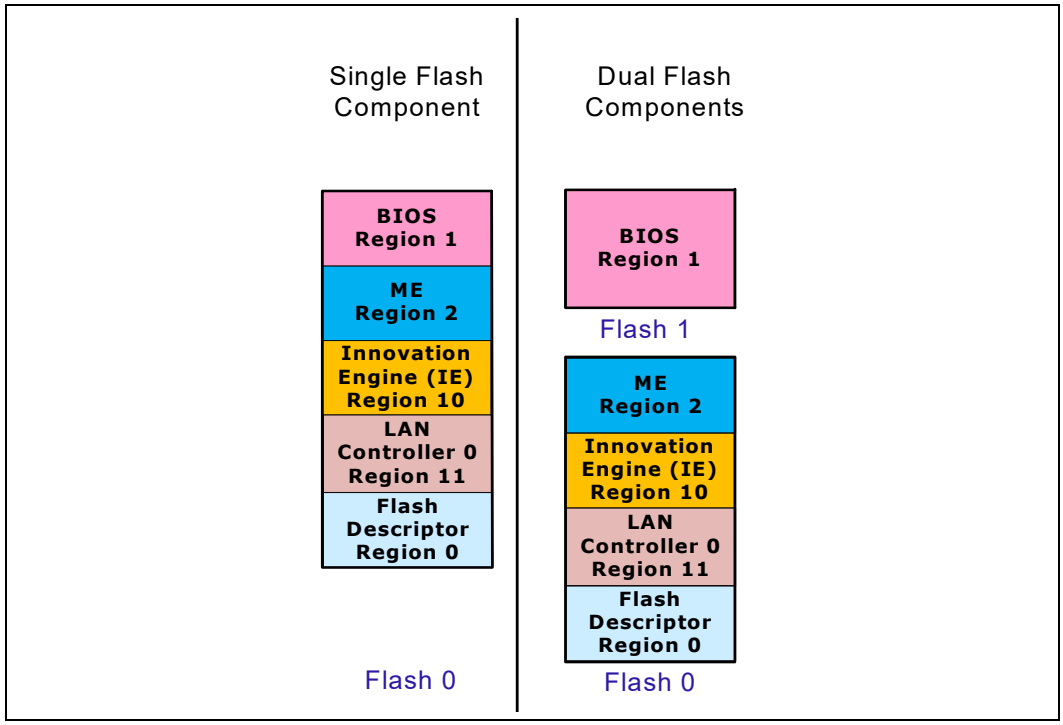


19.3.2.1 Flash Component Boundary

Flash regions are allowed to cross the component boundary, except for the LAN controller region.

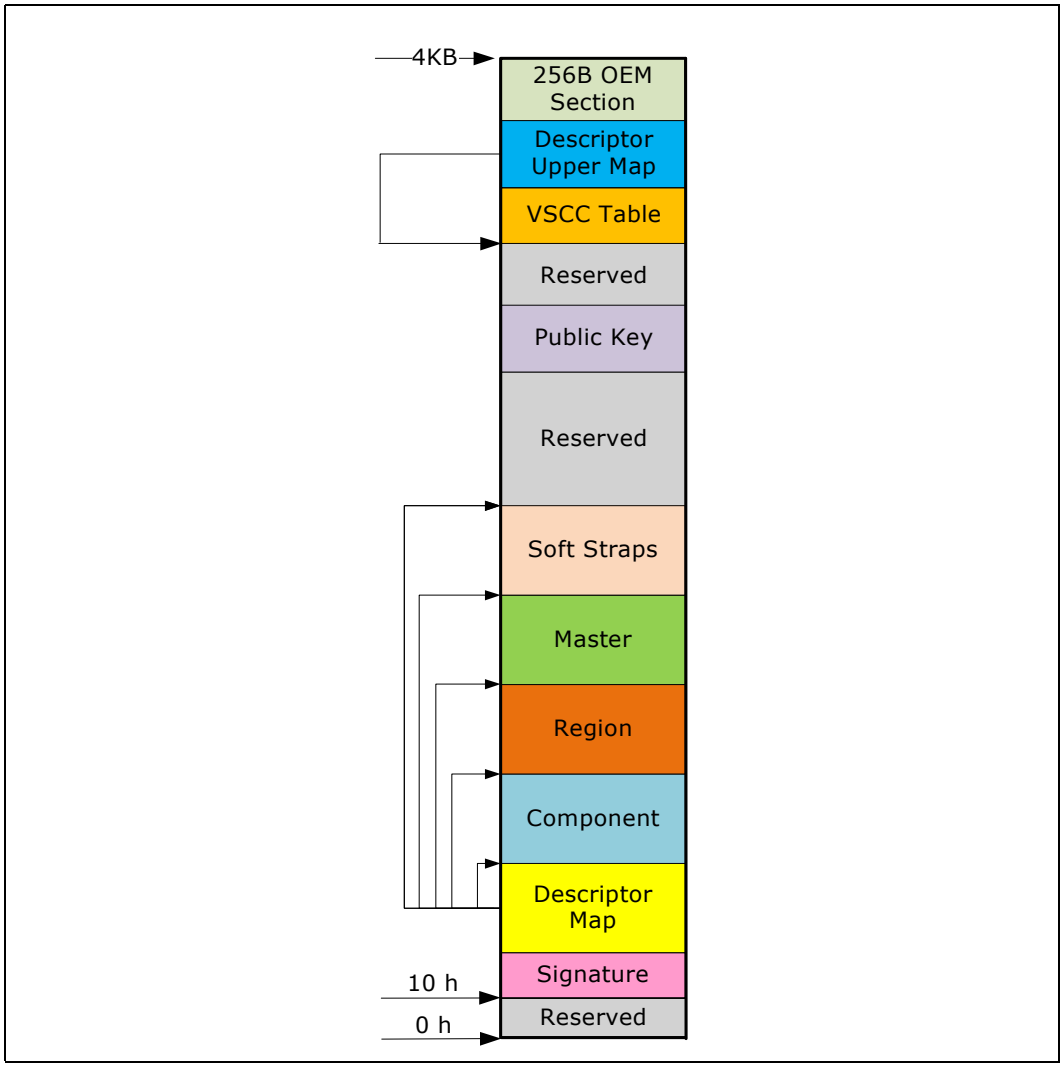
19.3.2.2 Flash Descriptor Region 0

The bottom sector of Flash component 0 contains the Flash Descriptor. The maximum size of the Flash Descriptor is 4K, even if the flash device's sector size is larger than 4K. (The hardware is not required to perform any checks to enforce this -- it's simply a descriptor programming error to configure it any other way.).

The information stored in the Flash descriptor is only written during the board-level manufacturing process. Intel requires the read/write permissions be set to read only when the system containing the SoC leaves the manufacturing floor.

The Flash descriptor is made up of the sections indicated in Figure 19-3.

Figure 19-5. Flash Descriptor Sections



- The **Reserved** sections are reserved.
- The **Signature** section selects the descriptor mode and verifies if the Flash is programmed and functioning. This signature is used to identify if the Flash is valid. The Flash signature is located at offset 10h.
- The **Descriptor Map** section defines the logical structure of the Flash in addition to the number of components used.
- The **Component** section has information about the SPI Flash in the system including:
  - Density of each component
  - Illegal instructions (such as chip erase)
  - Frequencies for read, fast read, and write/erase instructions
- The **Region** section points to the four other regions and the size of each region.
- The **Master** region contains the security settings for the Flash, grants read/write permissions for each region, and identifies each master by a requester ID.
- The **Soft Straps** section contains parameter bits that are used to configure the SoC features and/or behaviors.
- 1 KB is used for **Public Key** storage. The key programmed by the OEM.
- The **VSCC Table** section holds the JEDEC ID and the Vendor Specific Component Capabilities (VSCC) information of the entire SPI Flash supported by the NVM image.
- The **Descriptor Upper Map** section determines the length and base address of the **VSCC Table** section.
- The **OEM Section** is 256-bytes reserved at the top of the Flash descriptor for use by an OEM. The information stored by the OEM can only be written during the manufacturing process as the Flash descriptor read/write permissions must be set to read only when the computer leaves the manufacturing floor. The SoC Flash controller does not read this information. Security permissions in the Flash descriptor should be set to provide read access to both the SoC and for the Intel® ME so they read the OEM section and other Flash descriptor runtime as needed.

Note: It is the user's responsibility to allocate sufficient space in each descriptor region to hold the requested amount of data. Hardware does not check for overlaps in the descriptor map.

19.4 Flash Access

The two types of Flash accesses are:

- Direct access
- Program register access

19.4.1 Direct Access

- The SoC cores, Intel® ME, and IE are the only agents that can do direct read access. Access is limited to reading from their primary region.
- The SPI controller does not support direct writes to Flash, no master can do a direct write to the SPI Flash. Write accesses must take place through the Programmed Register interface.
- Direct write is supported to the SPI TPM when it is enabled.

19.4.1.1 BIOS Direct Read in Descriptor Mode

The SPI Flash controller only maps host direct reads to Flash. BIOS can issue Programmed Register accesses independent of the Boot BIOS Strap allowing BIOS to use the SPI Flash as NVM storage concurrently with LPC.

At Boot, BIOS can access the SPI Flash controller by doing a direct read to the 16MB address range just below 4GB, FF00_0000h to FFFF_FFFFh. BIOS can reduce the size of the 16MB of address space by writing to the BIOS Decode Enable (BDE) register. Independent of the settings of the BIOS Decode Enable Offset, the SPI Controller will not claim any direct reads that exceed the size of the active BIOS region. That is, the BIOS Decode Enable can reduce the memory space that is accessible via a direct read, but it cannot be used to address Flash exceeding the size of the active BIOS region.

When the SPI Flash controller sees a read request from the SoC Core to the BIOS Decode region it will claim the transaction. The read request will be a DW aligned address. The SPI Flash controller calculates the Flash Linear Address (FLA) from the BIOS address by subtracting the difference between the BIOS upper range (FFFF_FFFC) and the actual BIOS address, from the Flash Region Limit:

FLA[26:0] <= (Flash_Regionn_Limit[26:12] & "FFCh") - (FFFF_FFFCh - bios_address[31:2] & "00b") where n=1 if primary BIOS is enabled.

If the BIOS access is to the Legacy F segment (F0000h - FFFFFh) or Legacy E segment (E0000h - EFFFFh) which ranges must be aliased to just below 4GB, the SPI controller will calculate the FLA using the following arithmetic[1]:

FLA[26:0] <= (Flash_Regionn_Limit[26:12] & "FFCh") - (FFFF_FFFCh - "FFF" & bios_address[19:2] & "00b") where n=1 if primary BIOS is enabled.

The Flash Linear Address must be converted to a Flash Physical Address by the SPI Flash Controller prior to issuing on the SPI interface.

If the Top Swap (TS) bit is set when booting from SPI Flash, the SPI Controller will invert one of A16, A17, A18, A19 or A20 (note that LPC TS is only A16) depending on the value of the SPI - Boot Block Size soft strap. The inversion only occurs for the top most memory block, i.e. when all bits above the inverted bit are '1'. The inverted address is then used in the equation above to determine the Flash Linear Address. The Top Swap functionality does not apply to accesses generated to the holes below 1MB. The SPI Controller performs the address bit inversion on only the Direct Memory Read access method.

1. Intel is not validating legacy support.

19.4.1.2 Chip Select and Flash Linear Address (FLA)

The controller manages two chip select pins SPI_CS_N[0] and SPI_CS_N[1].

The 27-bit Flash Linear Addresses (FLA[26:0]) either calculated from the direct read address or as programmed in the Flash Linear Address program register must be converted into a 26 bit Flash Physical Address (FPA[25:0]) prior to being issued on the SPI pins according to the following algorithm.

The size of the Flash component is always taken from density field in the SFDP table. FLCOMP.C0DEN is no longer used by the SPI Controller.

If FLA <= Sizeof(Flash Component 0) then

FPA[25:0] = FLA[25:0];

Chip Select = 0

Else

FPA[25:0] = FLA[26:0] - Sizeof(Component 0)

Chip Select = 1

When a 3-byte address is issued the controller sends FPA[23:0] and truncates FPA[25:24].

19.4.2 Programmed Register Access

- Any master attempts to read or write the SPI programmed registers and SoC internal initiator logic check does not match that of the Primary Region master, an Unsupported Request will be returned.
- Program register access uses hardware or software sequencing. Section 19.10, “SPI Support for Trusted Platform Module (TPM)” on page 617.
- For programmed register accesses, the SPI controller implemented hardware security to ensure that the master never issues a read, write, or erase request to any region that it does not have proper access to by comparing the programmed FLA with the base and limit of each of the regions and verifying that master as read or write access to the specified address. Attempted access to addresses which do not fall within any defined region shall cause the access permission check to fail.
- Any attempt to access a region without proper access permissions will prevent the cycle from running and will cause the Flash Cycle Error (HSFSTS_CTL.FCERR) register error bit to be set.

19.5 Flash Security and Protection

The controller provides additional Flash protection mechanisms beyond the access restrictions defined in the Flash descriptor:

- Range write protection
- Intel® ME write protected range
- IE write protected range
- SMI-based global write protection (BIOS writes/erases to the BIOS regions)

The mechanisms are conceptually ORed together such that if any of the mechanisms indicate that the access should be blocked, then it is blocked.

The SoC provides these protections in hardware. It is critical that the hardware must not allow malicious software to modify the address or opcode pointers after determining that a cycle is allowed to run such that the actual cycle that runs on SPI should have been blocked.

If the command associated with an atomic cycle sequence is blocked according to the SoC configuration, the SPI controller must not run any of the sequence.

A blocked command will appear to software to finish, except that the FCERR status bit is set in this case.

Table 19-4. Flash Protection Mechanism Summary

Mechanism	Accesses Blocked[1]	Range Specific	Reset- Override or SMI-Override
BIOS Range Write Protection	Reads/Writes by Host	Yes	Reset Override
Intel® ME Write Protected Range	Writes by any Master	Yes	Reset Override
Intel® ME Protected Range	Reads/Writes by ME	Yes	Reset Override
IE Protected Range	Reads/Writes by IE	Yes	Reset Override
SMI Write Protect	Writes by Host	Applies to both BIOS regions	SMI Override

1. "Writes" implies both writes and erases

19.5.1 Flash Range Write and Read Protection

The SPI controller provides a method for blocking writes and reads to specific ranges in the SPI Flash when the protected ranges are enabled. This is achieved by checking the read or write cycle type and the address of the requested command against the base and limit fields of a read or write protected range. The protected range applies to all master-initiated Flash accesses except the BIOS. Therefore, those register protections do not apply to hardware-initiated descriptor reads. The BIOS protected range registers only apply to BIOS accesses, the IE protected range registers only apply to IE accesses, etc.

The range specified in the Flash Range registers are allowed to span any addresses, independent of whether that master has read or write access to the region(s) in, or partially in, the protected address range.

Note: Once software has locked down the BIOS or Host Protected Range registers, this mechanism remains in place until the next partition reset.

19.5.2 SMI Based Global Write Protection

The SPI controller blocks BIOS writes to the BIOS regions of the SPI Flash when the Write Protect Disable bit is cleared (i.e., protected). For software sequencing, this is achieved by checking the opcode type information (which can be locked down by the initial boot BIOS) of the requested command. Hardware sequencing write protection is triggered when attempting to issue a write or erase command.

The BIOS Write Protect bit does not apply to any other masters that have the write access permission to the BIOS regions. Host CPU accesses to the regions are not protected by the BIOS Write Protect bit. A blocked write may also generate an SMI. See Section 19.10, "SPI Support for Trusted Platform Module (TPM)" on page 617.

19.5.3 Flash Security Override Strap

The Flash descriptor security override strap is an SoC hard (pin) strap. The purpose of the SoC hard (pin) strap is to override all descriptor-based protections, including region definitions and master region permissions. It does not override register-based or software- programmable protections. It is typically used when an OEM wants to re-write a Flash image during manufacturing or board refurbishment. The effects of the override are limited to the following:

- The master region read access and master region write access permissions that were loaded from the Flash descriptor master section will be overridden giving every master read and write permissions to the entire Flash component(s) including areas outside the defined regions.
- The address checks to ensure that a linear address falls within the total size of the Flash components are not performed.
- No RequesterID security checks are performed

Note: The software programmable Protected Range registers, e.g., host PR0-PR4, GPR0, and IE PR0-PR4, are not affected by the Flash descriptor security override strap.

- The region boundaries for direct reads are still enforced.
- The Flash controller determines the size of the Flash devices from SFDP, not the descriptor. Therefore, cycles may be sent to SPI_CS_N[0] or SPI_CS_N[1] independent of the security override strap.

Note: Any access that exceeds the size of the device attached to SPI_CS_N[0] is sent to SPI_CS_N[1], independent of whether a Flash device is connected to SPI_CS_N[1].

- The SoC hard (pin) strap does not change the behavior of the BC.WPD register.

The Flash descriptor security override SoC hard (pin) strap resides in the resume power well. When the strap is enabled, security override will be performed by the Flash controller even though core power well may be down.

19.5.4 Illegal Instructions

Any attempt to execute an illegal instruction will prevent the cycle from running and will cause the FCERR register error bit to be set.

19.5.5 Error Status Table

Table 19-5 summarizes the status bits that are set under different error scenarios. The "cycle in progress" and "scenario" columns refer to the same master, i.e. it's only an error if Master A performs the scenario while Master A has a cycle in progress.

Table 19-5. Programmed Access Error Status

Cycle in Progress	Scenario	HW Seq FCERR	HW Seq DONE	SW Seq FCERR	SW Seq DONE
Hardware Sequence	Writes to HSFSTS_CTL byte_address 6h	1	N/A	N/A	N/A
	Writes to HSFLCTL.07h	1	N/A	N/A	N/A
	Writes to SSFLCTL.A1h (with SCGO =1)	N/A	N/A	1	
	Writes to SSFLCTL.A1h (with SCGO =0)	N/A	N/A	1	0
	Writes to SSFLCTL.A2h	N/A	N/A	1	0
	Writes to SSFLCTL.A3h	N/A	N/A	1	0
	Writes to FADDR or FDATAx	1	N/A	N/A	N/A
Software Sequence	Writes to HSFLCTL.06h (with FGO =1)	1	1	N/A	N/A
	Writes to HSFLCTL.06h (with FGO = 0)	1	0	N/A	N/A
	Writes to HSFLCTL.07h	1	0	N/A	N/A
	Writes to SSFLCTL.A1h	N/A	N/A	1	N/A
	Writes to SSFLCTL.A2h	N/A	N/A	1	N/A
	Writes to SSFLCTL.A3h	N/A	N/A	1	N/A
	Writes to SSFLCTL.A3h	N/A	N/A	1	N/A
	Writes to FADDR or FDATAx	N/A	N/A	1	N/A

19.5.6 Region Checks

Reads and writes are not allowed to cross 4k address boundaries in Flash. This implies they are not allowed to cross devices.

Region definitions must be contiguous, i.e., no unallocated Flash addresses between any two regions. Unallocated Flash addresses between the highest region limit and the end of Flash are allowed. It is a descriptor programming error to define a region that extends beyond the total size of Flash.

19.6 SMI Generation

19.6.1 Synchronous SMI

The SPI controller sends synchronous SMI assert/de-assert message pairs when the Write Protect Disable bit is written from 0 to 1 while the Lock Enable bit is set. Both bits are in the BIOS Control register in host root space PCI header. The SPI controller waits for the smi_ack message before sending the completion for the non-posted write which set the bit. The SPI controller sends the de-assert synchronous SMI message when software clears the SPI_SYNC_SS bit.

19.6.2 Asynchronous SMI

The SPI controller sends asynchronous SMI assert/de-assert message pairs when configured to generate an SMI for the hardware and software sequencing Flash cycle done. The SMI for Flash cycle done is enabled via HSFSTS_CTL.FSMIE for hardware sequencing and SSFSTS_CTL.SME for software sequencing. The BIOS Control(BC).SE_BWP bit does not control SMI for Flash cycle done. If the SMI is enabled, assert SMI is sent when the Flash cycle done transitions from 0 to 1. If the SMI is enabled, de-assert SMI is sent when the Flash cycle done transitions from 1 to 0 or when the SMI enable becomes false.

BIOS writes/erases may be blocked. When ASE_BWP = 1, such a blocked write or erase attempt by the host to the BIOS region(s) will cause an asynchronous SMI even if the transaction would also be blocked due to multiple causes. De-assert SMI is sent when the Flash cycle done transitions from 1 to 0 or when ASE_BWP becomes false.

19.7 Hardware vs. Software Sequencing

Hardware and software sequencing are the two methods used to communicate with the Flash via the programming registers.

Hardware sequencing is the safer method for communication with the flash. Since the SPI controller uses SFDP to determine the capabilities of each attached SPI flash, hardware sequencing will only use those supported capabilities. Software sequencing on the other hand might use capabilities that the SPI flash doesn’t support causing unpredictable result. Software sequencing is by default disabled in the SoC. To enable it please use SS9 bit [13] SPI - Host Software Sequencing Enable.

19.7.1 Hardware Sequencing

Hardware sequencing has a predefined list of opcodes with only the erase opcode being programmable. This mode is only available if the descriptor is present and valid.

Table 19-6 contains a list of commands and the associated opcodes that an SPI-based serial Flash device must support to be compatible with hardware sequencing.

Table 19-6. Hardware Sequencing Opcodes

Instruction Op-Code	Description
03h	Read data
05h	Read status
0Bh	Fast read
06h	Write enable
04h	Reserved
02h	Write data/program data
50h	Enable the Write Status register.
01h	Write Status register
3Bh/Discoverable	Dual output fast read Discoverable opcodes are obtained from each component SFDP table.
Discoverable	Dual I/O fast read
Discoverable	Quad output fast read
Discoverable	Quad I/O fast read
Discoverable	4k erase. Uses the value from SFDP (if available) or else the value from the VSSC.EO register. Industry standard is 20h.
Discoverable	64k erase. Industry standard is D8h.
Discoverable	RPMC Op1. Not supported via hardware sequencing in SPT. Industry standard is 9Bh.
Discoverable	RPMC Op2. Uses fast read timing with 8 wait states. Not supported via hardware sequencing in SPT. Industry standard is 96h.
5Ah	Read SFDP. Uses fast read timing with 8 wait states.
9Fh	Read JEDEC ID.
B7h	Enable 32-bit addressing mode.

If there is a Hardware Sequencing Cycle In Progress and an attempt is made to program any of the control, address, or data register the cycle is blocked and the FCERR bit is set.

If hardware sequencing allows selection of the Write Status opcode, then the Flash controller will insert a Write Enable (06h) opcode prior to issuing the Write Status. The two operations will be issued as an atomic sequence.

19.7.2 Software Sequencing

Any required command not supported by Hardware Sequencing must be programmed by the software in the Software Sequencing Control, Flash Address, Flash Data, and Opcode Configuration registers. The software must issue either a read ID or read JEDEC ID, or a combination of the two to determine what Flash component is attached. Based on the read ID, the software determines the appropriate opcode instruction sets to set in the program registers and at what SPI frequency to run the command.

The software must program the Flash linear address for all commands, even for those commands that do not require an address such as the read ID or read status. This is because the SPI controller uses the address to determine which chip select to use.

The opcode type and data byte count fields determine how many clocks to run before deasserting the chip enable. The Flash data is always shifted in for the number of bytes specified, and the Flash data out is always shifted out for the number of data bytes specified.

A status bit indicates when the cycle has completed on the SPI port allowing the host to know when read results are checked and/or when to initiate a new command.

The controller also provides the atomic cycle sequence for performing erases and writes to the SPI Flash. When this bit is 1 (and the Go bit is written to 1), a sequence of cycles is performed on the SPI interface without allowing other SPI devices to arbitrate and interleave cycles to the Flash device. In this case, the specified cycle is preceded by the Prefix command (8-bit programmable opcode) and followed by repeated reads to the Status register (opcode 05h) until bit 0 indicates the cycle has completed. The hardware does not attempt to check that the programmed cycle is a write or erase.

If a programmed access is initiated (Cycle Go written to 1) while the SPI controller is already busy with a direct memory read, then the SPI host hardware holds the new programmed access pending until the preceding SPI access completes.

Once the SPI controller has committed to running a programmed access, subsequent writes to the programmed cycle registers that occur before it has completed do not modify the original transaction and result in the assertion of the FCERR bit. The software never purposely behaves in this way and relies on this behavior. However, the FCERR bit provides basic error reporting in this situation. Writes to the following registers cause the FCERR bit assertion in this situation:

- Software Sequencing Control register
- Software Sequencing Address register
- SPI Data register

With the exception of illegal opcodes, the SPI controller does not police which opcodes are valid to be used in software sequencing. For example, if the software programs a dual-output-fast-read opcode, then the dual-output-fast-read cycle is issued, independent of whether the Dual-output Fast Read Enable bit was set in the component descriptor section. However, disabled opcodes for dual and quad reads will be run on the SPI pins as single-input, single-output commands, and will therefore return incorrect data to the requester and cause bus contention when the Flash device drives multiple pins of the SPI bus. Similarly, SPI controller does not use the device capabilities discovered via SFDP to alter any command programmed by software.

SW sequencing registers: HSFSTS_CTL, SSFSTS_CTL, PREOP_OPTYPE, OPMENU, FADDR, and FDATA. See Table 19-9, "BIOS Flash Program Register Address Map" on page 624.

- HSFSTS has the FLOCKDN bit which locks (prevents writing) most SW Sequencing opcode registers. Trusted firmware (BIOS or ME code) configures these registers, then sets FLOCKDN prior to handing control to operating system software.
- SSFSTS indicates when a transaction has completed and provides error status for the transaction. Software must write-to-clear the FCERR and Cycle Done Status bits prior to starting a transaction. Software polls this register, waiting for Cycle Done Status, before accessing read data or setting up a new transaction.
- SSFCTL contains all configuration data for a transaction, e.g., number of data bytes, which opcode(s), whether an atomic sequence of opcodes, and SPI_CLK frequency. Software sets the register SPI Cycle Go bit to initiate a transaction.
- PREOP is programmed with two Write Enable opcodes used by Flash devices. The selected PREOP opcode is sent to Flash prior to the selected OPMENU opcode when the atomic cycle sequence flag is set in the SSFCTL register. Flash devices require the Write Enable opcode be sent prior to Write and Erase instructions. Some devices also require Write Enable prior to a Write Status Register opcode. OPTYPE identifies whether each opcode in OPMENU is a read or a write cycle and whether an address must be sent following the opcode. For example, a Read Status opcode is a read instruction with no address, a Read SFDP opcode is a read instruction with an address, and a Write Status Register opcode is a write instruction with no address. Software must ensure that OPTYPE is programmed correctly for each opcode in OPMENU - hardware cannot detect or correct mismatches.
- OPMENU is programmed with the opcodes that are available for SW sequencing operations. Opcodes typically set in this register include Read SFDP (5Ah), Read JEDEC ID (9Fh), and Write Status Register (01h). Programming "read flash array" type instructions (e.g. Fast Read, Read Dual I/O, Read Quad I/O) is typically not required because the Flash controller will automatically select the most efficient read opcode when either HW Sequencing or direct reads are used.
- FADDR is programmed with the Flash Linear Address for the SW sequenced operation. FADDR must be programmed for every SW sequenced transaction because the Flash controller uses the address to determine which chip select to activate when running the transaction on the SPI bus.
- FDATA is programmed with data to be written to Flash. The Flash controller stores data read from Flash in FDATA.

Example: Read 16 bytes of SFDP from component 1 using SW sequencing

- Verify that HSFSTS.FLOCKDN=0, i.e. the SW sequencing registers are unlocked
- Write to SSFSTS to clear FCERR and Cycle Done Status
- Program OPTYPE 0 to "address required; read cycle type"
- Program OPMENU 0 to 5Ah
- PREOP is not required prior to Read SFDP; no need to touch this register
- Program FADDR to component 1, address offset zero. The size of the Flash component is always taken from density field in the SFDP table. FLCOMP.C0DEN is no longer used by the SPI Controller.
- Program SSFCTL to select opcode and start transaction. SSFCTL fields: SCF=100b, SME=0, DS=1, DBC=0xF, COP=0, SPOP=don't care, ACS=0, SCGO=1
- Poll SSFSTS, waiting for SCIP=0 to show completed SW Sequenced transaction
- Check error status in SSFSTS.FCERR
- Read 16 bytes from FDATA[3:0]

19.8 Serial Flash Device Compatibility Requirements

A variety of serial Flash devices exist in the market. For a serial Flash device to be compatible with the SPI bus, it must meet the minimum requirements.

19.8.1 BIOS SPI Flash Requirements

The SPI Flash device must meet the following minimum requirements when used explicitly for the system BIOS storage. Refer to Section 19.3.1.4, "Flash Component Requirements" on page 597.

- The erase size has at least one of the following: 64 Kbytes, or 4 Kbytes.
- The device must support multiple writes to a page without requiring a preceding erase cycle (refer to Section 19.5.1, "Flash Range Write and Read Protection" on page 605).
- The Serial Flash device must ignore the upper address bits such that an address of FF_FFFFh aliases to the top of the Flash memory for 3-byte addressing support.
- SPI compatible mode 0 support (the clock phase is 0 and data is latched on the rising edge of the clock).
- If the device receives a command that is not supported or incomplete (less than 8 bits), the device must complete the cycle gracefully without any impact on the Flash content.
- An Erase command (page, sector, block, chip, etc.) must set all bits inside the designated area (page, sector, block, chip, etc.) to 1 (Fh).
- Status register bit 0 must be set to 1 when a write, erase, or write to a status register is in progress and cleared to 0 when a write or erase is NOT in progress.
- Devices requiring the Write Enable command must automatically clear the write enable latch at the end of data program instructions.
- Byte write must be supported. The flexibility to perform a write between 1 byte to 64 bytes is recommended.

19.9 SPI Flash Interface

Communication on the SPI bus is done with a Master - Slave protocol. Typical bus topologies call for a single SPI Master with a single SPI Slave. The basic SPI interface consists of a four wire interface: clock (CLK), master data out (Master Out Slave In (MOSI)), master data in (Master In Slave Out (MISO)) and active low chip selects (CS0#).

The SoC SPI Flash controller supports 3 chip selects, SPI_CS_N[0], SPI_CS_N[1], and SPI_TPM_CS_N. The SPI_TPM_CS_N is dedicated to support TPM on SPI. The Flash controller supports up to 4 I/O pins, i.e. SPI_MOSI_IO[0], SPI_MISO_IO[1], SPI_IO[2] and SPI_IO[3] to comprehend the support for the Dual I/O and Quad I/O operation. The Flash controller does not support use of two or four wires for the opcode phase of a Flash transaction, e.g. 2-2-2 or 4-4-4 mode reads.

19.9.1 Single-Input, Dual-Output Fast Read

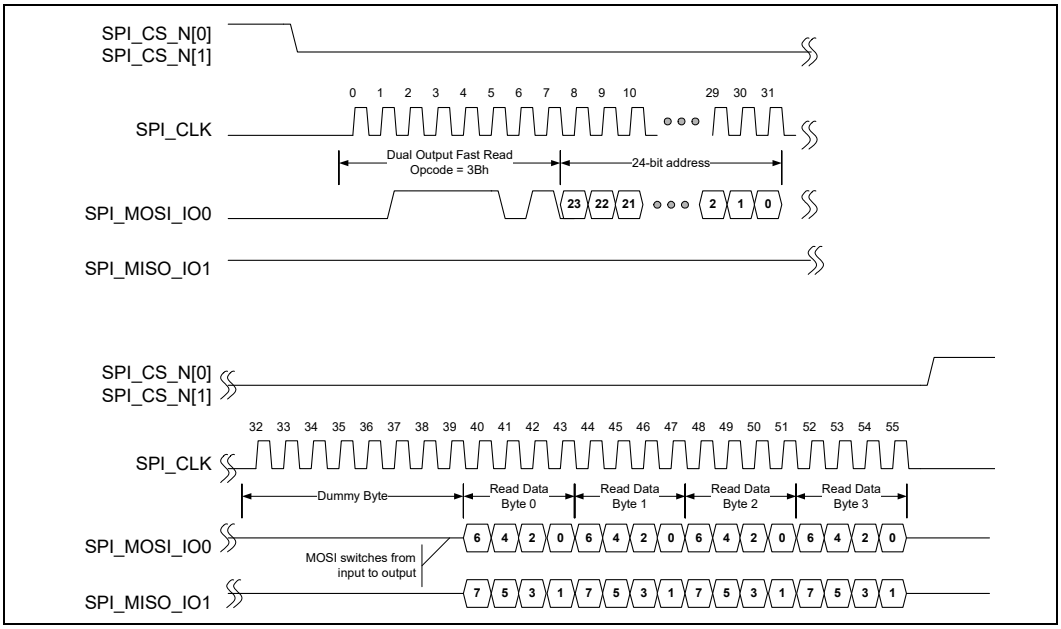
The SPI controller supports the functionality of a single-input, dual-output fast read: opcode 3Bh. This instruction has the same timing (including a dummy byte) and the same frequencies as the fast read instruction, with the difference that the read data from the Flash is presented on both the MISO and MOSI pins. During a dual-read instruction, the odd data bits are on the MISO pin and the even data bits are on the MOSI pin.

Note: When the dual-output-fast-read support is enabled the fast-read support must be enabled as well.

Note: The Micronix* SPI Flash uses a different opcode for dual-fast read and requires during the address phase the address bits are sent on both MOSI and MISO. The SoC does not support this implementation of the protocol.

Note: When in the 32-bit addressing mode, the address bits in the waveform in Figure 19-6 will be extended to 32 bits (i.e., 4 bytes) instead of 24 bits.

Figure 19-6. Dual-Output-Fast-Read Timing

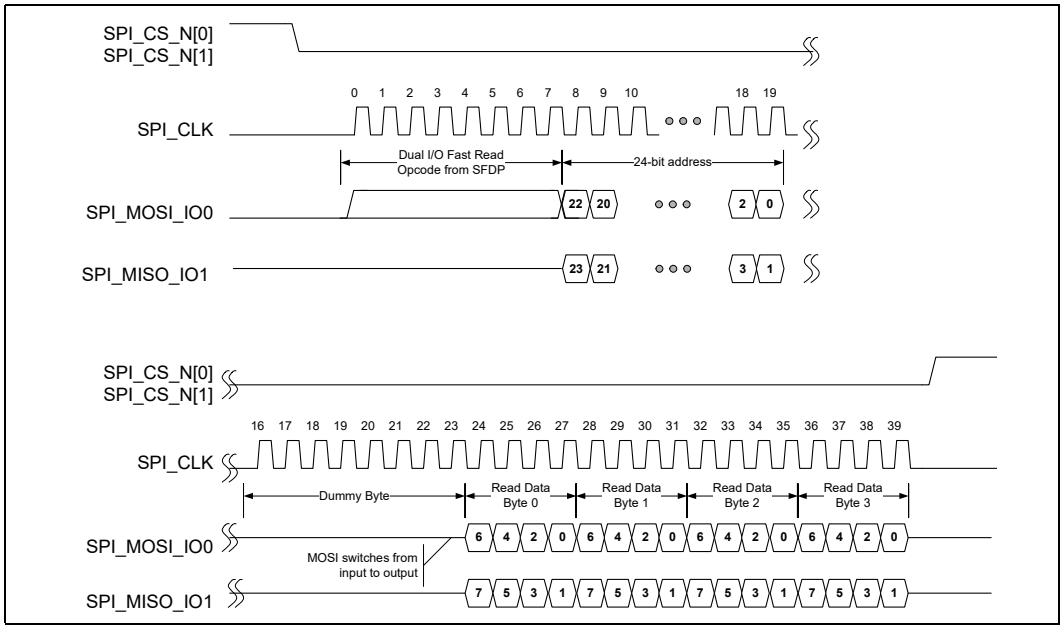


19.9.2 Dual-I/O Fast Read

Besides having the read data be presented on both the MOSI and MISO pins, dual-I/O fast read allows the address bits to be sent on both MOSI and MISO as well. Odd address bits are on the MISO pin and the even address bits are on the MOSI pin. The dummy byte is also on both the MOSI and MISO pins.

Note: When in the 32-bit addressing mode, the address bits in the waveform in Figure 19-7 will be extended to 32 bits (i.e. 4 bytes) instead of 24 bits.

Figure 19-7. Dual-I/O-Fast-Read Timing

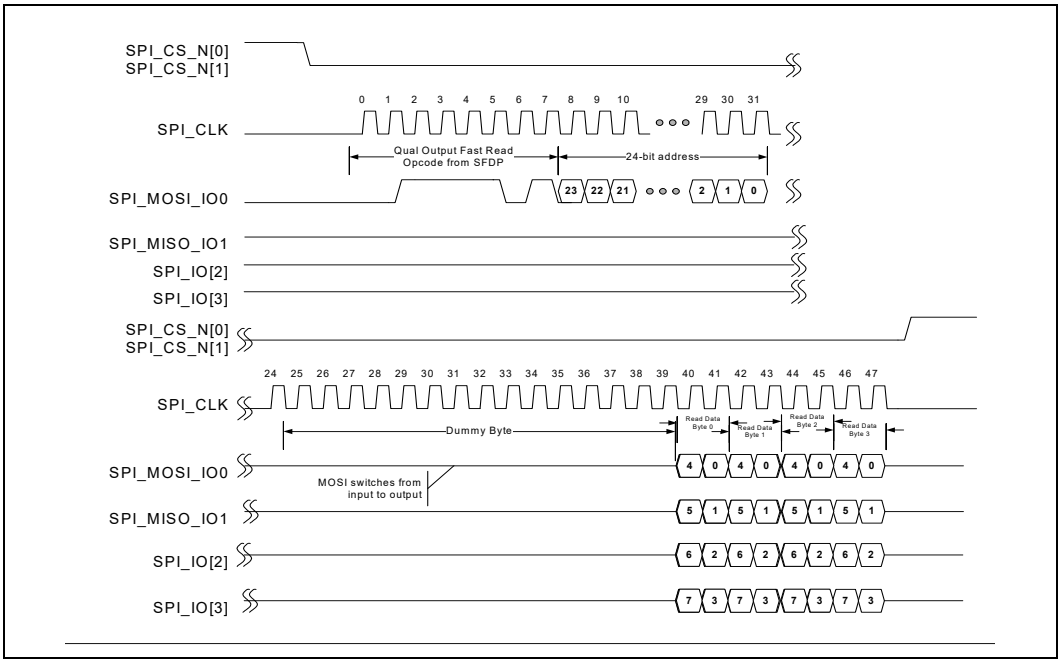


19.9.3 Quad-Output Fast Read

Quad-output fast read allows the read data from the Flash be presented on the MOSI, MISO, SPI_IO2, and SPI_IO3 pins, at the rate of 4 data bits per clock.

Note: When in the 32-bit addressing mode, the address bits in the waveform in Figure 19-8 will be extended to 32 bits (i.e. 4 bytes) instead of 24 bits.

Figure 19-8. Quad Output Fast Read Timing

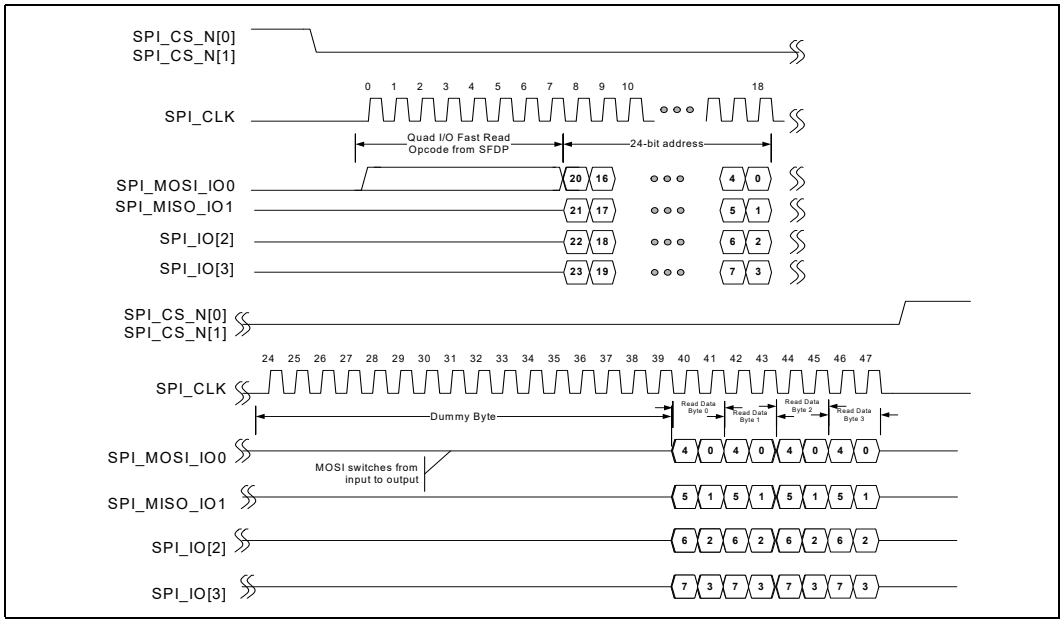


19.9.4 Quad-I/O Fast Read

Quad-I/O fast read allows the address, the dummy byte and the read data be presented on the MOSI, MISO, SPI_IO2 and SPI_IO3 pins, thus achieving 4 bits per clock during both the address and data phases.

When in the 32-bit addressing mode, the address bits in the waveform in Figure 19-9 will be extended to 32 bits (i.e. 4 bytes) instead of 24 bits.

Figure 19-9. Quad-I/O-Fast-Read Timing



19.9.5 JEDEC ID

Since each serial Flash device may have unique capabilities and commands, the JEDEC ID is the necessary mechanism for identifying the device so the uniqueness of the device is comprehended by the controller (master). The JEDEC ID uses the opcode 9Fh and a specified implementation and usage model. This JEDEC standard manufacturer and device ID read method is defined in Standard JESD21-C, PRN03-NV.

Note: Once software has locked down the BIOS or Host Protected Range registers, this mechanism remains in place until the next partition reset.

19.10 SPI Support for Trusted Platform Module (TPM)

The SoC supports one discrete TPM device with SPI_TPM_CS_N. The SPI controller decodes the TPM read/write directly. There is no register programming model for the TPM.

The requirements for the support are:

- The platform must have no more than 1 TPM. Therefore, the SoC must route all TPM transactions either to LPC or SPI depending on the configuration bits. Some platforms may be without TPM.
- A chip select for the SPI TPM (SPI_TPM_CS_N)
  - When the soft strap sets the TPM on SPI, the TPM chip select must only assert on the decode of TPM transactions.
  - TPM chip select cannot assert based on any programmed registers or other SW mechanism.
- The SPI controller supports accesses to the SPI TPM at whatever frequency the SPI bus has been configured.
- The TPM requires the support for the interrupt routing. However, the TPM interrupt pin is routed to the SoC. Thus, the TPM interrupt is completely independent from the SPI controller.
- The SPI controller is configurable to prevent TPM access when the descriptor is invalid (or no Flash is attached). This is a security requirement for the SoC. When configured to prevent TPM access when the descriptor is invalid, the Flash controller behaves as if the TPM on the SPI does not exist on the system.

19.10.1 TPM Protocol on SPI

Though the SPI controller supports 26-bit addressing on SPI, only 24-address bits are sent to the TPM. The FEh byte is dropped. For example, an incoming address of FED4_4024h would be sent on the SPI as D4_4024h.

Access to the SPI TPM is always with single-address input and single output at the single data rate. Dual-output, dual-I/O, quad-output and quad-I/O operations are not supported on SPI_TPM_CS_N with the TPM.

The following rules apply for the data transfer:

- Data is shifted Most Significant Bit (MSB) first, Least Significant Byte (LSB) first.
- The address and command are shifted MSB first for the entire field.
  - The 24-bit address shifts A23 first, then A22, A21..., A0.
- Master and slave both drive data on the falling edge of the clock.
- The TPM accesses always get a 24-bit address that is the offset from FE00_0000h.
  - Asserting the SPI_TPM_CS_N is an indication that the SoC did a full decode and the cycle is in the FED4_xxxxh range.
- Only SPI mode 0 is supported (CPHA = 0, CPOL = 0).

It is legal to transmit any number of bytes from 1 to 64. Zero length reads or writes are not allowed. If the transfer is less than 4B, then the corresponding bits would be left out. For instance, on a 2B write the last transfer on MOSI would be Data[8] (LSB of MSB).

There is no status byte for the transfer. If the write to the TPM failed, the TPM would not honor what was received, and SW/driver will understand the SW command did not succeed and perform the appropriate recovery mechanisms. If the read fails, then the SoC would return all FFs for the data, which would signal a failure to the driver.

Table 19-7. Address and Data Transfer for TPM

Bit Transfer Order on MISO/MOSI	BYTE on MISO/MOSI	Usage	Notes
	67 for 64B transaction 11 for 8B transaction	Reserved	
57-63 – last bits on wire	7	Data[30:24]	
56		Data[31]	MSB of fourth LSB
49-55	6	Data[22:16]	
48		Data[23]	MSB of third LSB
41-47	5	Data[14:8]	
40		Data[15]	MSB of second LSB
33-39	4	Data[6:0]	
32		Data[7]	MSB of LSB
Optional flow control can be done in this window. This is the only place in the bit transfer where flow control can be done.			
31	3	Addr[0]	LSB of address
9-30	1-3	Addr[22] down to Addr[1]	
8	1	Addr[23]	MSB of address
2-7	0	Bits [5:0] Size of transfer where bit [5] of this field is the third bit transferred on the wire, and bit [0] is the eighth bit on the wire. This field is a 0s-based count of the bytes. Any byte count from 1 to 64 is legal.	Bit [5:0] decode 11_1111 = 64 bytes (For 63 down to 6 bytes) 00_0100 = 5 bytes 00_0011 = 4 bytes 00_0010 = 3 bytes 00_0001 = 2 bytes 00_0000 = 1 byte
1		bit [6]. Reserved	
0-first bit on wire		Byte0, bit [7]. Read/Write	1 = read 0 = write

19.10.2 TPM Flow Control on SPI

Note: This description uses idealized, zero-delay timing for illustrative purposes.

For the TPM operation, it involves HW generating transactions directly to the TPM with minimum or no SW involvement. As such, there needs to be a simple flow control mechanism on SPI since HW can't poll busy bits or use other SW mechanisms. Therefore the following flow control is allowed by the TPM.

SPI protocol doesn't have a defined flow control mechanism. Thus a new flow control mechanism is being created for the TPM on SPI.

The flow control is on a transaction basis and not on a byte basis. For example, a read or write to the data register can be at most 4B in length today, moving to 8B or 64B in the future. The TPM will accept the write data when it has the full size of buffer available to be written (1-64B), or provide the read data when it has the full amount of data (1-64B) ready to deliver, again based on the size of the transaction. The overhead of allowing flow control between each byte is too high with almost no benefit.

Since the specification allows for larger sizes of transactions in the future, the SoC will have limited, if any, HW checking on accesses to the TPM address space. If the SoC receives transaction for any size from 1B to 64B that doesn't cross a 64B boundary, it must issue that transaction on SPI as received. The SoC must accept all transactions of any length on any address boundary to FED4_0000h to FED4_4FFFh, as long as they don't cross a 64B boundary.

The TPM transaction on SPI consists of 1B of command, 3B of address, followed by write data from the SoC or read data from the TPM. The TPM may insert wait states after the 4B of command and address have been received.

The mechanism to insert wait states is as follows. For a read to the TPM, the command and address are driven on MOSI and the TPM responds with data on MISO. With no wait states, the TPM would drive data on the next falling clock edge after the falling clock edge that the SoC drove the last address bit. The flow control mechanism added for the TPM is that the SoC will monitor the MISO pin in the same clock window that A[0] (the last address bit) is valid.

The TPM receives the address, where address bit[2] is captured a clock and a half before it has to drive the flow control bit. For reads, the registers are on a 4B (or 8B) boundary, so that bit[2] of the address should be sufficient to determine if the register is available or not to be read. Then bit[1] and [0] are only used to steer the correct bytes to the bus, but shouldn't be needed to determine flow control.

Note: Having byte-based flow control allows the transaction layer to handle the retransmit of the data. This allows for faster clock speeds. It also keeps all transfers on a byte basis and not having a few bits in between. It provides plenty of time for the TPM to decode the address and determine if it is ready to receive the data or not. This allows faster SPI clocking to speed up the transfers.

There is no further flow control allowed. Once the data starts coming from the TPM, it must provide the entire transactions worth of data, which can be from 1 to 64 bytes. In this example, if the SoC had latched a '1' on the 5th rising clock, then it would start latching in data starting on the 6th rising edge, which is the normal behavior without wait states. The TPM may insert any number of wait states that it needs.

If the TPM intends to drive wait states, it should drive MISO low when it detects CS# asserted. Once the TPM determines the address and whether it can accept or return the data, it drives MISO high for one clock in the wait state window.

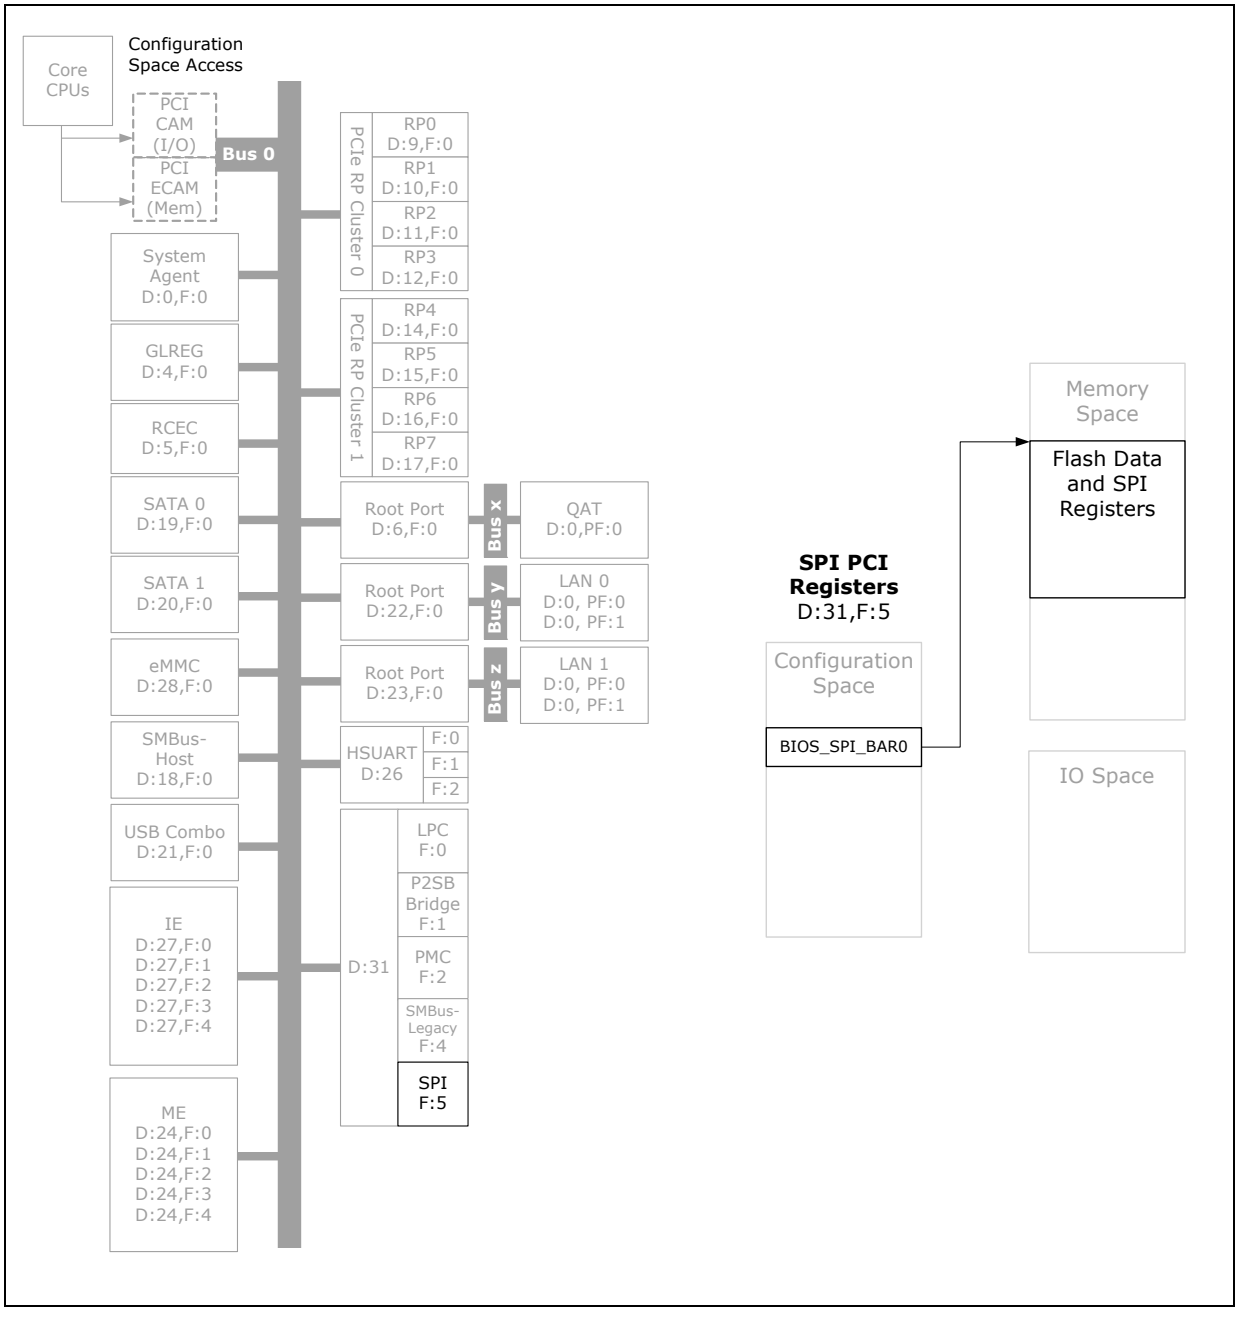
Note: The wait state is defined as '0' on MISO, so that if there is no TPM present at all, then the design has a weak pull-up on MISO. Having a pull-up means that the SPI controller sees a '1', which indicates no wait states, and will latch in FFh on the read. This follows standard master abort behavior of FFh for read data and matches the behavior when the TPM was on LPC.

For writes, the mechanism is similar. The SoC will latch the value of MISO on the 5th rising edge. This is the same edge that the last address bit is latched by the slave. In other words, the slave drives MISO to '0' in the same clock that the master drives the last bit of the address. The master samples MISO every 8 clocks after that and will only continue when it samples a '1' during this bit position. If MISO is '0' to request a wait state, then the data during that byte is not valid and the TPM must drop the data. If there is a wait state, the master will drive invalid data over and over until the slave stops requesting wait states. The SoC will sample MISO on the last data bit of the byte (multiples of 8 clocks after the first wait state window). Again, the TPM must hold MISO as '0' for 8 clocks each time it requests a wait state. If MISO is '1', this indicates the TPM is ready for the entire write, and the SoC will drive the 1st and subsequent data bytes on the following clocks. If MISO is still '0', the SoC will continue sending invalid data until it receives a '1' on MISO in the wait state window. Note that the flow control only applies to the first byte and not between each byte. Once the data starts transmitting, the entire write data will be sent with no further flow control. An example for a 2B write that has 2 wait states would be, drive command and address for 4 bytes, then invalid data byte, invalid data byte, valid data byte 0, valid data byte 1.

19.11 Register Map

The SPI controller is a standalone PCI device in the host root space at bus 0, device 31 (decimal), and function 5. The registers listed in Figure 19-10 are described in detail.

Figure 19-10.Register Map



19.11.1 PCI Configuration and Capabilities

The SPI controller also has fixed mappings, independent of the PCI configuration header, in the ranges:

- 4G - 16M to 4G -- direct reads to the BIOS regions. This depends on the boot interface. These could go to LPC.
- Legacy E -- Reads and Writes to E segment are to DRAM only not the BIOS regions
- Legacy F -- Reads and Writes to F segment are to DRAM only not the BIOS regions
- 0xFED4_xxxx -- TPM direct reads and writes if the TPM over the SPI is enabled.
- The registers marked no in the SPI supported column behave as Read Only (RO) and return zero.

Table 19-8. Configuration and Capabilities Register Map

Offset from Configuration Space of B0:D31:F5 (decimal)	Register Short Name	Description	SPI Supported
0x0	BIOS_SPI_DID_VID	Device ID and Vendor ID	Yes
0x4	BIOS_SPI_STS_CMD	Status and Command	Yes
0x8	BIOS_SPI_CC_RID	Revision ID	Yes
0xC	BIOS_SPI_BIST_HTYPE_LT_CLS	BIST, Header Type, Latency Timer, Cache Line Size	No
0x10	BIOS_SPI_BAR0	SPI BAR0 MMIO	Yes
0x28	BIOS_SPI_CCP	Cardbus CIS Pointer	No
0x2C	BIOS_SPI_SID_SVID	Subsystem and Vendor ID	No
0x30	BIOS_SPI_XRBAR	Expansion ROM Base Address	No
0x34	BIOS_SPI_CAPP	Capabilities List Pointer	No
0xD0	BIOS_SPI_UR_STS_CTL	SPI Unsupported Request Status	Yes
0xD8	BIOS_SPI_BDE	BIOS Decode Enable	Yes
0xDC	BIOS_SPI_BC	BIOS Control	Yes

19.11.2 Memory Mapped Registers

These registers are mapped in the host root space. The address offsets are relative to BIOS_SPI_BAR0. Reads to unimplemented addresses return 0s.

Table 19-9. BIOS Flash Program Register Address Map (Sheet 1 of 2)

Base Address	MEM Address	Instance Name	Name
BIOS_SPI_BAR0	0x0	BIOS_BFPREG	SPI BIOS MMIO PRI

§ §

20 Low Pin Count (LPC) Controller

The LPC serves as a PCI-to-Industry Standard Architecture (ISA) bridge to devices connected to the LPC interface pins. The bridge is discovered by the software at bus 0, device 31 (decimal), function 0 in the configuration address space. This bridge also accommodates a number of integrated legacy peripherals, most of which were originally designed for the ISA.

Note: 3.3V must be supplied to VCC_LPC_ESPI_3P3_1P8.

Figure 20-1. What is Covered in This Chapter

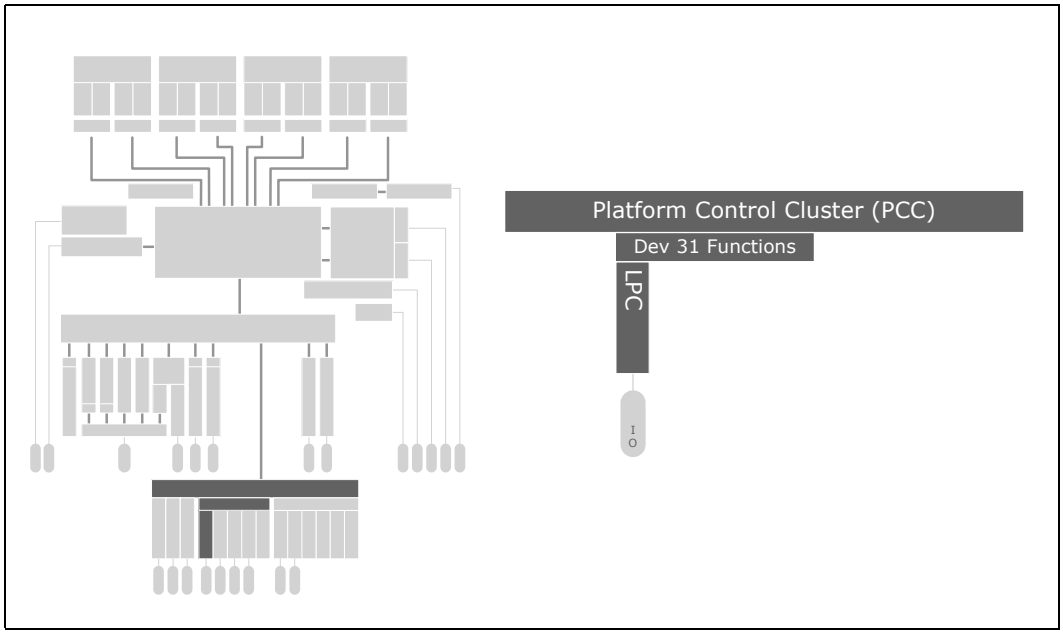

Table 20-1. References

Reference	Revision	Date	Document Title
LPC Specification	1.1	August 2002	*Intel® Low Pin Count (LPC) Interface Specification*
PCI Specification	3.0	February 2004	*PCI Local Bus Specification, Revision 3.0*

20.1 Signal Descriptions

The signal descriptions are shown in Table 20-2. For additional signal information, including whether a signal is assigned to shared-function pin or can be used as a Customer GPIO signals see Section 39.1, "Directory of Signal Names and Pin Names" on page 993. The Direction/Type column of Table 20-2 is interpreted as follows:

- I = Input signal. The SoC has receiver circuit.
- O = Output signal. The SoC has driver circuit.
- O-Tri = Tri-state Output. SoC output circuit uses a three-state driver.

Table 20-2. Signal Names and Descriptions

Signal Names	Direction	Shared	Description
LPC_AD[3:0]	I,O-Tri	Yes	Multiplexed command, address, and data
LPC_FRAME_N	O	Yes	**Frame:** Indicates start of a new cycle and termination of a broken cycle. The SoC provides an internal 20-kΩ Pull-Up (PU) resistor on this signal pin.
LPC_CLKOUT[1:0]	O	Yes	**Clock:** Same 24-MHz clock for LPC bus interface. The SoC provides an internal 20-kΩ Pull-Down (PD) resistor on each of these signal pins.
LPC_CLKRUN_N	I,O-Tri	Yes	**Clock Run:** As an input, this active-low signal is generated by LPC peripherals that need the LPC_CLKOUT for a period of time beyond the four clocks guaranteed at the end of a transfer cycle. The SoC, as the central resource that generates the LPC_CLKOUT, monitors the LPC_CLKRUN_N signal to regulate its frequency for low-power operation. As an output, the SoC provides a sustained tri-state signal. When the SoC drives the LPC_CLKRUN_N signal low (asserted), it indicates the LPC_CLKOUT is operating at its normal frequency. When driven high (de-asserted), the SoC indicates a stopped or very-slow clock frequency. The platform board must provide a Pull-Up (PU) resistor to sustain a logic-high voltage when the SoC and attached LPC peripherals float this tri-state bus.
LPC_SERIRQ	I,O-Tri	Yes	**Serialized IRQ:** SERIRQ is an active-low sustained tri-state bus, synchronized with the LPC_CLKOUT signal. As the Serialized Interrupt Host Controller, the SoC drives this pin low for a periods of time, high for a periods of time, and other times floats this pin. The external agents attached to this pin provide the interrupt IRQ and I/O Check indications through low and high signaling, and float this line when they do not own the bus cycle. Electrically, LPC_SERIRQ conforms with the sustained tri-state parameters defined in the PCI Local Bus Specification, Revision 3.0. The platform board must provide a Pull-Up (PU) resistor to sustain a logic-high voltage when the SoC and attached agents float this tri-state bus.
ESPI_IRCOMP	I,O	No	**ESPI_IRCOMP:** Special compensation resistor to support 3.3V. The platform board must provide a 100 Ω, 1% resistor connected from this pin to VSS.
Boot BIOS Strap	I	Yes	See Chapter 4, "Strapping and Configuration."
LPC Decode Select	I	Yes	See Chapter 4, "Strapping and Configuration."
VCC_LPC_ESPI_3P3_1P8	I (Voltage)	n/a	The platform must supply V3P30 to this voltage-supply pin. The SoC voltage-supply pins are listed in Section 39.3, "Directory of Voltage Supply and Sense Pin Names" on page 1029. Also see Chapter 4, "Strapping and Configuration".

20.2 Feature List

LPC controller implements a *Intel® Low Pin Count (LPC) Interface Specification*.

20.3 Architectural Overview

The LPC controller implements a *Intel® Low Pin Count (LPC) Interface Specification*. The LPC bus is operating at a clock frequency of 24 MHz. The LPC interface is used for connection of various legacy components.

20.3.1 LPC Cycle Types

The LPC controller implements all of the cycle types described in the *Intel® Low Pin Count (LPC) Interface Specification*.

There is no support for DMA or bus mastering from the LPC.

20.3.2 Memory Cycle

The LPC provides a generic memory range for decoding memory cycles and forwarding as standard LPC memory cycles on the LPC bus. The generic memory decode range is 64 KB in size, locatable anywhere within the 4 GB memory space. The range is configured by the BIOS during POST to provide the memory resources needed. The BIOS will advertise the range to the operating system (OS) as reserved memory to avoid any resource conflict.

For cycles targeting firmware, firmware memory cycles are used. Only 8-bit transfers are performed. If a larger transfer appears on the backbone, the LPC controller will break it into multiple 8-bit transfers until the request is satisfied.

If the cycle is not claimed by any peripheral (and subsequently aborted), the LPC controller will return a value of all 1s to the SoC core. This is to maintain compatibility with ISA memory cycles where pull-up resistors would keep the bus high if no device responds.

20.3.3 I/O Cycle

All I/O cycles will be performed as 8-bit transfers per the LPC specification. If a larger size is attempted, the LPC controller will perform multiple 8-bit transfers until the request is satisfied.

20.3.4 DMA Cycle

DMA is not supported.

20.3.5 Bus Master Cycle Notes

Bus mastering to the LPC is not supported.

20.3.6 LFRAME# Usage

The controller follows the usage of LFRAME# as defined in the *Intel® Low Pin Count (LPC) Interface Specification*.

20.3.7 LPC PD# Protocol

This signal is provided to the LPC peripherals using the SoC output signal SUS_STAT_N. After driving SUS_STAT_N low (active), the SoC drives LPC_FRAME_N (LFRAME#) low, and tri-states or drives low the LPC_AD[3:0] bus.

Note: *Intel® Low Pin Count (LPC) Interface Specification* defines LPCPD# protocol where at least 30µs is from LPCPD# assertion to LRESET# assertion. This specification explicitly states the protocol only applies to entry or exit of low-power states which does not include asynchronous reset events. The SoC asserts both SUS_STAT_N (LPCPD#) and PMU_PLTRST_N (LRESET#) at the same time during a global reset.

20.3.8 LPC Interface Decoders

In order to allow I/O and memory mapped cycles to go to the LPC interface, the LPC controller includes several decoders. The decoders are located at offset 80h - 9Fh in the device configuration space.

20.3.9 SERR# Generation

When the LPC receives an error SYNC on the LPC bus, an internal SERR# will be generated. This occurs only if SERR reporting is enabled for the LPC.

20.3.10 Dynamic LPC Clock Control

This LPC clock control is achieved through the LPC_CLKRUN_N signal. If an LPC device needs the 24 MHz LPC clock, then it can assert.

20.3.10.1 Verifying if Safe to Stop the LPC Clock

With a lack of LPC activity, the SoC is able to shut off the LPC clocks to conserve power. LPC activity is defined as any activity that would require the LPC clock to be running.

Any of the following conditions will indicate that it is *not* safe to stop the LPC clock:

- Cycles on the LPC (as a target)
- Cycles of any internal device that would need to go on the LPC bus (as a target)
- SERIRQ activity (as a target and master)

Behavioral description:

1. When there is a lack of activity (as defined above) for t90 clocks, the SoC will drive the LPC_CLKRUN_N signal high t91 later.
2. One clock later, the SoC will tri-state the LPC_CLKRUN_N signal.

20.3.10.2 Conditions for Maintaining the LPC Clock

LPC devices that wish to maintain the LPC clock running will observe the LPC_CLKRUN_N signal high, and then must drive it low within t92 clocks.

Behavioral description:

1. When the SoC has driven the LPC_CLKRUN_N signal high, it will then check to see if it is driven low (externally).
2. After observing the LPC_CLKRUN_N signal low for 1 clock, the SoC will then start driving the signal low.
3. If an internal device needs the LPC bus, then the SoC will drive LPC_CLKRUN_N the clock signal active.

20.3.10.3 Conditions for Stopping the LPC Clock

If no device drives LPC_CLKRUN_N low once it has been high for t93 clocks, the SoC will stop the LPC clocks.

20.3.10.4 Conditions for Restarting the LPC Clock

Behavioral description:

1. If a peripheral asserts the LPC_CLKRUN_N signal, the SoC will restart the clock.
2. The SoC will drive LPC_CLKRUN_N low 1 clock after the first rise edge of the LPC clock. The peripheral likewise must continue to drive LPC_CLKRUN_N low until the second rising edge of the LPC clock is detected.
3. If an internal source requests the clock to be restarted, the SoC will assert LPC_CLKRUN_N.

Figure 20-2. LPC_CLKRUN_N Timings

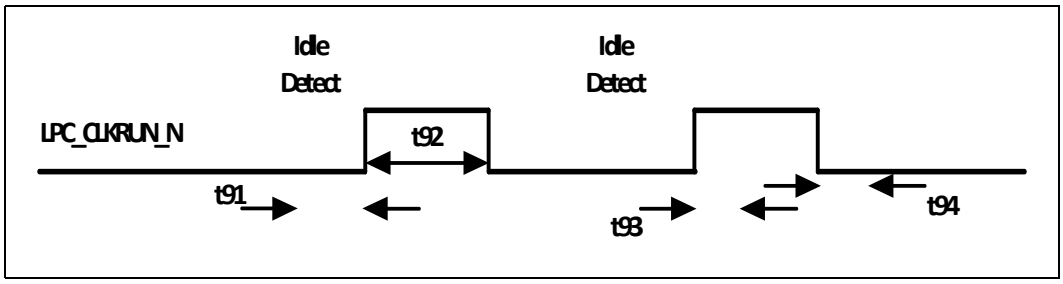

Table 20-3. LPC_CLKRUN_N Timings

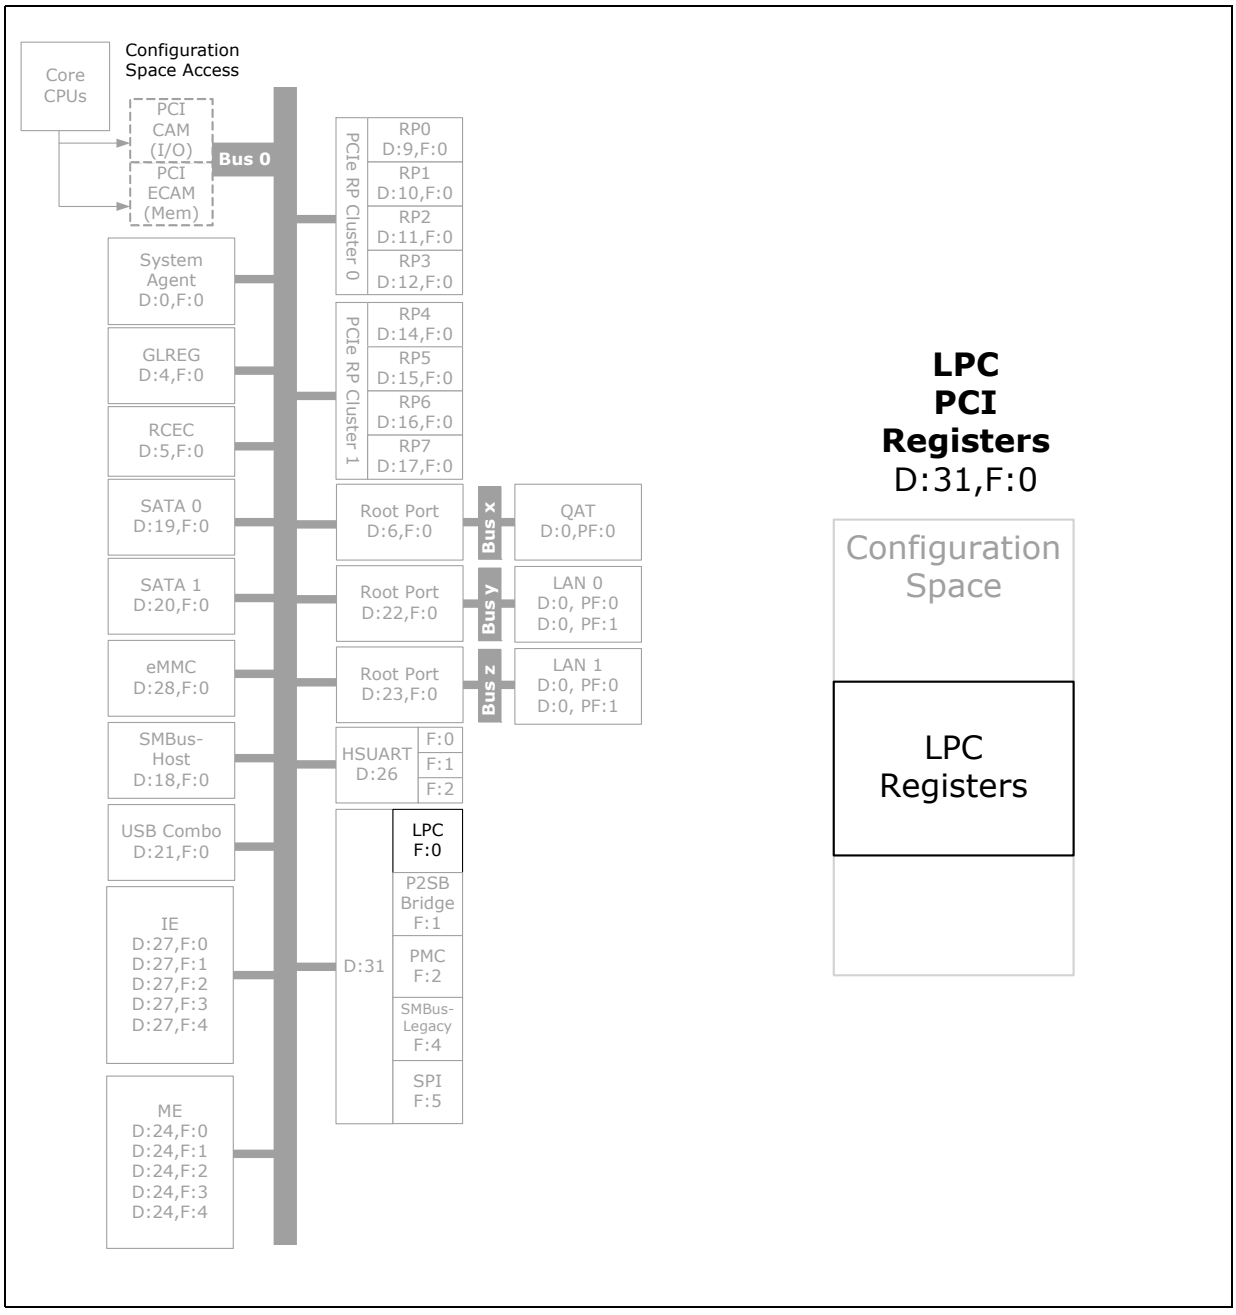
Symbol	Minimum	Maximum	Units	Description
t90	29	30	LPC CLK	No activity to idle detect
t91	1	1	LPC CLK	Idle detect to LPC_CLKRUN_N high
t92	2	3	LPC CLK	LPC_CLKRUN_N high to LPC_CLKRUN_N (no stop) [if low from external source] ***Note:*** The maximum can be 5 if LPC_CLKRUN_N low (no stop) due to an internal source
t93	6		LPC CLK	LPC_CLKRUN_N high (stop)
t94	1		LPC CLK	LPC_CLKRUN_N low (restart)

Note: Timing t94 only applies to external devices asserting LPC_CLKRUN_N. If an internal source is active and requests for LPC CLK to be restarted, the SoC will assert LPC_CLKRUN_N. This is because clock synchronization is not required.

20.4 Register Map

Figure 20-3 shows the associated registers from a system software viewpoint.

Figure 20-3. Register Map



20.4.1 PCI Configuration and Capabilities

25	FF10_0000h – FF1F_FFFFh	1 MB	0xD8h[1]	LPC or SPI primary. The source decode to determine the claiming agent using the boot BIOS and LPC SoC hard (pin) straps.	BIOS 50-5F Feature space
26	FF40_0000h – FF4F_FFFFh	1 MB	0xD8h[0]		BIOS 40-4F Data space
27	FF00_0000h – FF0F_FFFFh	1 MB	0xD8h[0]		BIOS 40-4F Feature space

1. Intel is not validating legacy support.

20.4.4.1 BIOS Write Protect and Top Swap Range

Table 20-8, "LPC Claimable Configurable I/O Range as Target on Primary Interface" lists the BIOS Decode Address range that are subjected to the Write Protect Disable, Enable InSMM.STS (EISS) and Top Swap configuration.

Table 20-8. LPC Claimable Configurable I/O Range as Target on Primary Interface

BIOS Decode Address Range	WPD	EISS	Writes	Top Swap
All ranges: Feature Space	X	X	Allowed	No
Other BIOS decode ranges (Data Space) & Legacy E/F Segments	0	X	Blocked	Only apply to EF8 (FFF80000h - FFFFFFFFh)
	1	0	Allowed	
Note: Intel is not validating legacy support.	1	1	Allowed if InSMM.STS = 1	

20.4.4.2 BIOS Boot Decode Claiming Agent

Table 20-9, "BIOS Boot Decode Claiming Agent" lists the claiming agents for the BIOS cycles to access the Boot codes and the respective BIOS Decode Range Register location. The Boot BIOS Pin Strap goes out to 2 locations, namely SPI and LPC. The BBS register for these registers are programmable to override the SoC hard (pin) strap value. BIOS needs to ensure that the BBS values on both locations (SPI and LPC) are set the same (match).

Table 20-9. BIOS Boot Decode Claiming Agent

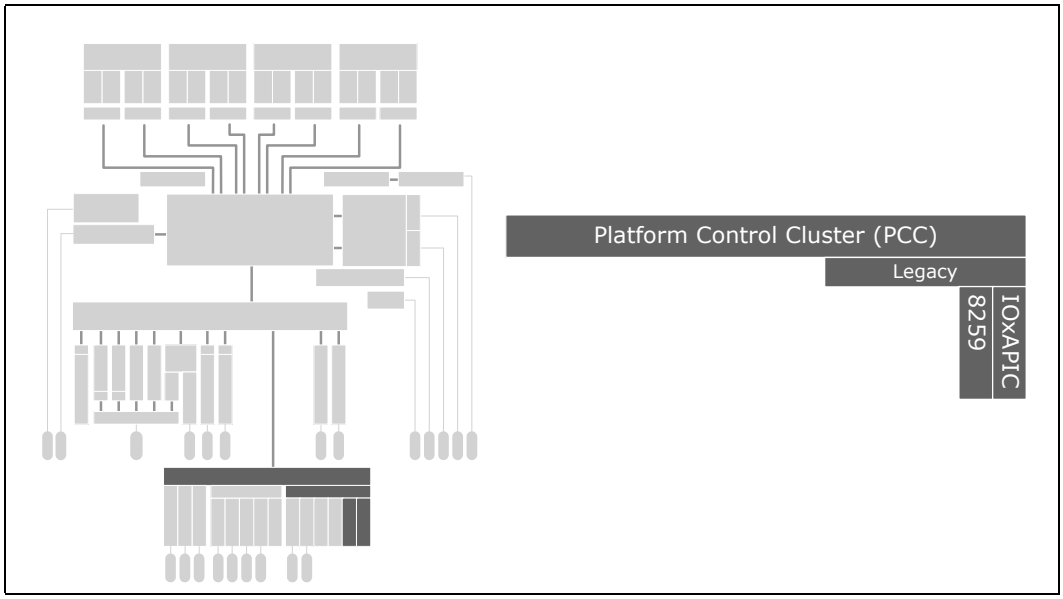
Pin BR58 Boot BIOS Strap (BBS)	Pin BL52 LPC Decode Select	BIOS Boot Location	BIOS Boot Decode Range Register Location
0	0	SPI	SPI PCI Configuration Register. Program SPI PCI-configuration (D31:F5) BIOS Decode Range Configuration Registers. SPI uses its own BIOS Decode Range to determine the BIOS Boot Location
0	1	SPI	
1	0	LPC	LPC PCI Configuration Register. Program LPC PCI-configuration (D31:F0) BIOS Decode Range Configuration Registers. LPC uses its own BIOS Decode Range to determine the BIOS Boot Location.

§ §

21 PIC and I/O APIC Controllers

This chapter describes the Programmable Interrupt Controller (PIC). The design is based on the legacy 8259 PIC device. This chapter also describes the I/O Advanced Programmable Interrupt Controller (IOxAPIC).

Figure 21-1. What is Covered in This Chapter



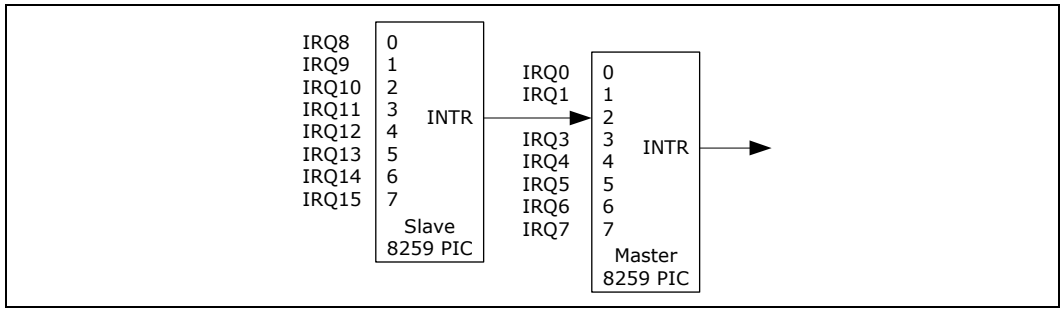
21.1 Signal Descriptions

There are no signal pins or signal names associated with this chapter.

21.2 Programmable Interrupt Controller (PIC)

The design is based on the legacy 8259 PIC device. The slave controller is cascaded onto the master controller through master controller interrupt input 2. This means there are 15 possible Interrupt Requests (IRQ) routed internally to the SoC PIC, see Figure 21-2. The interrupt routing is described in Chapter 8, "Interrupts and Events".

Figure 21-2. Master and Slave PIC



21.2.1 Special Internal Circuitry

Interrupts can be individually-programmed to be edge-triggered or level-sensitive, except for IRQ0, IRQ1, IRQ2 and IRQ8 which always default to edge-triggered.

Active-low interrupt sources, such as the PIRQ#, are internally inverted before being sent to the PIC. In the following descriptions of the 8259, the interrupt levels are in reference to the signals at the internal interface of the 8259, after the required inversions have occurred. Therefore, the term "high" indicates "active", which means "low" on an originating PIRQ#.

21.2.2 Generating Interrupts

The PIC interrupt sequence involves 3 bits, from the IRR, ISR, and IMR, for each interrupt level. These bits are used to determine the interrupt vector returned and the status of any other pending interrupts. Table 21-1 defines the IRR, ISR, and IMR.

Table 21-1. Interrupt Status Registers

Bit	Description
IRR	**Interrupt Request Register:** This bit is set on a low-to-high transition of the interrupt line in the edge mode and by an active high level in the level mode. This bit is set whether or not the interrupt is masked. However, a masked interrupt will not generate the internal INTR signal.
ISR	**Interrupt Service Register:** This bit is set, and the corresponding IRR bit cleared, when an interrupt acknowledge cycle is seen, and the vector returned is for that interrupt.
IMR	**Interrupt Mask Register:** This bit determines whether an interrupt is masked. Masked interrupts do not generate the internal INTR signal.

21.2.3 Acknowledging Interrupts

The processor generates an interrupt acknowledge cycle that is translated into a interrupt acknowledge cycle to the SoC. The PIC translates this command into two internal INTA# pulses expected by the 8259 controllers. The PIC uses the first internal INTA# pulse to freeze the state of the interrupts for priority resolution. On the second INTA# pulse, the master or slave sends the interrupt vector to the processor with the acknowledged interrupt code. This code is based on the five Interrupt Vector Base Address (IVBA) bits of the Master/Slave Initialization Command Word 2 (MICW2 or SICW2), combined with the three Interrupt Request Level (IRL) bits of the MICW2 or SICW2 which represent the interrupt within that controller.

Table 21-2 applies to the Master 8259 controller and to the Slave 8259 controller.

Table 21-2. Content of Interrupt Vector Byte

Master, Slave Interrupt to be serviced by the Interrupt Acknowledge cycle	Master/Slave ICW2 Bits [7:3] generated by the controller	Master/Slave ICW2 Bits [2:0] generated by the controller
IRQ7,15	Interrupt Vector Base Address (IVBA) in the Interrupt Vector Table for the interrupt routine	111
IRQ6,14		110
IRQ5,13		101
IRQ4,12		100
IRQ3,11		011
IRQ2,10		010
IRQ1,9		001
IRQ0,8		000

21.2.4 Hardware/Software Interrupt Sequence

1. One or more of the Interrupt Request lines (IRQ) are raised high in the edge mode or seen high in the level mode, setting the corresponding IRR bit.
2. The PIC sends the internal INTR signal to the processor if an asserted interrupt is not masked.
3. The processor acknowledges the INTR and responds with an internal interrupt acknowledge cycle.
4. When observing the special cycle, the SoC converts it into the two cycles that the internal 8259 pair need to responds. Each cycle appears as an interrupt acknowledge pulse on the internal INTA# signal of the cascaded interrupt controllers.
5. When receiving the first internally-generated INTA# pulse, the highest priority ISR bit is set and the corresponding IRR bit is reset. On the trailing edge of the first pulse, a slave identification code is broadcast by the master to the slave on a private, internal 3-bit wide bus. The slave controller uses these bits to determine if it must respond with an interrupt vector during the second, internal INTA# pulse.
6. When receiving the second internally generated INTA# pulse, the PIC returns the interrupt vector. If no interrupt request is present because the request was too short in duration, the PIC indicates a spurious interrupt by returning interrupt vector 7 from the master controller.
7. This completes the interrupt cycle. In Automatic End of Interrupt (AEOI) mode, the ISR bit is reset at the end of the second INTA# pulse. Otherwise, the ISR bit remains set until an appropriate EOI command is issued at the end of the interrupt subroutine.

21.2.5 Initialization Command Words (ICWx)

Before an operation begins, each 8259 must be initialized. In the SoC, this is a four-byte sequence. The four Initialization Command Words (ICW) are referred by their acronyms: ICW1, ICW2, ICW3, and ICW4.

The base address for each 8259 initialization command word is a fixed location in Host I/O Space address 20h for the master controller and address A0h for the slave controller.

21.2.5.1 ICW1

A write to the master or slave controller base address with data bit 4 equal to 1 is interpreted as a write to ICW1. Upon sensing this write, the PIC expects three more byte writes to 21h for the master controller or A1h for the slave controller to complete the ICW sequence.

A write to ICW1 starts the initialization sequence during which the following automatically occurs:

1. Following initialization, an Interrupt Request (IRQ) input must make a low-to-high transition to generate an interrupt.
2. The Interrupt Mask Register is cleared.
3. IRQ7 input is assigned priority 7.
4. The slave mode address is set to 7.
5. Special mask mode is cleared, and the status read is set to IRR.

21.2.5.2 ICW2

The second write in the sequence (ICW2) is programmed to provide bits [7:3] of the interrupt vector that are released during an interrupt acknowledge. A different base is selected for each interrupt controller. See Table 21-2, “Content of Interrupt Vector Byte” on page 640.

21.2.5.3 ICW3

The third write in the sequence (ICW3) has a different meaning for each controller.

- For the master controller, ICW3 indicates which of the master’s IRQ input lines cascades the IRQ[15:8] of the slave controller. Within the SoC, IRQ2 is used. Therefore, the Cascaded Controller Connection (CCC) indication, bit 2 of the MICW3 is set to a 1 and the other bits are set to 0s.
- For the slave controller, ICW3 is the slave identification code used during an interrupt acknowledge cycle. On interrupt acknowledge cycles, the master controller broadcasts a code to the slave controller if the cascaded interrupt won arbitration on the master controller. The slave controller compares this identification code to the value stored in its ICW3, and if it matches, the slave controller assumes responsibility for broadcasting the interrupt vector.

21.2.5.4 ICW4

The final write in the sequence (ICW4) must be programmed for the master controller and for the slave controller. At least the Microprocessor Mode (MM) indication, bit 0 of the ICW4, must be set to a 1 to indicate the controllers are operating in an Intel® architecture system.

21.2.6 Operation Command Words (OCW)

These command words reprogram the interrupt controller to operate in various interrupt modes:

- OCW1 masks and unmasks the interrupt lines.
- OCW2 controls the rotation of interrupt priorities when in rotating priority mode and controls the EOI function.
- OCW3 sets up the ISR/IRR reads, enables/disables the Special Mask Mode (SMM), and enables/disables the polled interrupt mode.

21.2.7 Fully-Nested Mode

In this mode, interrupt requests are ordered in priority from 0 through 7, with 0 being the highest. When an interrupt is acknowledged, the highest priority request is determined and its vector placed on the bus. Additionally, the ISR for the interrupt is set. This ISR bit remains set until: the processor issues an End of Interrupt (EOI) command immediately before returning from the service routine or if in Automatic End of Interrupt (AEOI) mode, on the trailing edge of the second, internal INTA# signal. While the ISR bit is set, all further interrupts of the same or lower priority are inhibited, while higher levels generate another interrupt. Interrupt priorities are changed in the rotating priority mode.

21.2.8 Special Fully-Nested Mode

This mode is used in the case of a system where cascading is used, and the priority has to be conserved within each slave. In this case, the special fully-nested mode is programmed to the master controller. This mode is similar to the fully-nested mode with the following exceptions:

- When an interrupt request from a certain slave is in service, this slave is not locked out from the master priority logic, and further interrupt requests from higher priority interrupts within the slave are recognized by the master and initiate the interrupts to the processor. In the normal-nested mode, a slave is masked out when its request is in service.
- When exiting the interrupt service routine, the software has to check whether the interrupt serviced was the only one from that slave. This is done by sending a Non-specific EOI command to the slave and then reading its ISR. If it is 0, a non-specific EOI is also sent to the master.

21.2.9 Automatic Rotation Mode (Equal Priority Devices)

In some applications, there are a number of interrupting devices of equal priority. The automatic rotation mode provides for a sequential eight-way rotation. In this mode, a device receives the lowest priority after being serviced. In the worst case, a device requesting an interrupt has to wait until each of the seven other devices are serviced at most once.

Two ways to accomplish automatic rotation using the three-bit Rotate and EOI Codes (REOI) bits [7:5] of the OCW2 are:

101 = Rotation on the Non-Specific EOI command
100 = Rotation in the Automatic EOI mode

21.2.10 Specific Rotation Mode (Specific Priority)

The software changes the interrupt priorities by programming the bottom priority. For example, if IRQ5 is programmed as the bottom-priority device, then IRQ6 is the highest-priority device. This is accomplished by using the three-bit Rotate and EOI Codes (REOI) field, bits [7:5] of the OCW2:

110 = Set Priority command

along with the three-bit Interrupt Level Select (L2, L1, L0) (ILSLT) field, bits [2:0] of the OCW2 to indicate the binary priority level code of the bottom priority device.

In this mode, the internal status is updated by the software control during OCW2. However, it is independent of the EOI command. Priority changes are executed during an EOI command by using REOI set to:

111 = Rotate on Specific EOI command

along with the three-bit ILSLT to indicate the binary priority level code of the bottom priority device.

21.2.11 Poll Mode

The poll mode conserves space in the interrupt vector table. Multiple interrupts that are serviced by one interrupt service routine do not need separate vectors if the service routine uses the Poll command. The poll mode is also used to expand the number of interrupts. The polling interrupt service routine calls the appropriate service routine instead of providing the interrupt vectors in the vector table. In this mode, the internal INTR output signal is not used and the processor internal interrupt enable flip-flop is reset, disabling its interrupt input. Service to the devices is achieved by the software using a Poll command.

The Poll command is issued by setting the Poll Mode Command (PMC), bit 2 of the OCW3. The PIC treats its next Host I/O Read as an interrupt acknowledge, sets the appropriate ISR bit if there is a request, and reads the priority level. Interrupts are frozen from the OCW3 write to the Host I/O Read. The byte returned during the Host I/O Read contains a 1 in bit 7 if there is an interrupt, and the binary code of the highest-priority level is indicated by bits [2:0].

21.2.12 Edge- and Level-Triggered Mode

In Industry Standard Architecture (ISA) systems, this mode is programmed using the Level-Triggered Interrupt Mode (LITM), bit 3 of the ICW1, which sets level or edge for the entire controller. In the SoC, this bit is disabled and a register for edge- and level-triggered mode selection is provided per interrupt input. These make up the Master Edge/Level Control (ELCR1) and Slave Edge/Level Control (ELCR2) registers.

If the ELCR bit is 0, an interrupt request is recognized by a low-to-high transition on the corresponding IRQ input. The IRQ input remains high without generating another interrupt. If the ELCR bit is 1, an interrupt request is recognized by a high level on the corresponding IRQ input, and an edge detection is not needed. The interrupt request must be removed before the EOI command is issued to prevent a second interrupt from occurring.

In both the edge- and level-triggered modes, the IRQ inputs must remain active until after the falling edge of the first internal INTA# signal. If the IRQ input goes inactive before this time, a default IRQ7 vector is returned indicating a spurious interrupt.

21.2.13 End of Interrupt (EOI) Operations

An EOI occurs in one of two fashions:

- Normal EOI - by a command word write issued to the PIC before returning from a service routine, the EOI command
- Automatic EOI - when the Automatic End of Interrupt (AEOI), bit 1 of ICW4, is set to 1.

21.2.13.1 Normal End of Interrupt (EOI) Mode

In normal EOI mode, the software writes an EOI command before leaving the interrupt service routine to mark the interrupt as completed. The two forms of EOI commands are: Specific and Non-Specific.

When a Non-Specific EOI command is issued, the PIC clears the highest ISR bit of those that are set to 1. A Non-Specific EOI is the normal mode of operation of the PIC within the SoC, as the interrupt being serviced currently is the interrupt entered with the interrupt acknowledge. When the PIC is operated in the modes that preserve the fully-nested structure, the software determines which ISR bit to clear by issuing a specific EOI.

An ISR bit that is masked is not cleared by a non-specific EOI if the PIC is in the special mask mode. An EOI command must be issued for both the master and slave controller.

21.2.13.2 Automatic End of Interrupt (AEOI) Mode

In this mode, the PIC automatically performs a Non-Specific EOI operation at the trailing edge of the last interrupt acknowledge pulse. From a system standpoint, this mode is used only when a nested multi-level interrupt structure is not required within a single PIC. The AEOI mode is only used in the master controller and not the slave controller.

Note: Both the master and slave PICs have an AEOI bit in MICW4 and SICW4 respectively. Only the AEOI bit of MICW4 is set by the software. The AEOI bit of SICW4 is not set by the software.

21.2.14 Masking Interrupts

21.2.14.1 Masking on an Individual Interrupt Request

Each interrupt request is masked individually by the Interrupt Mask Register (IMR). This register is programmed through OCW1. Each bit in the IMR masks one interrupt channel. Masking IRQ2 on the master controller masks all requests for service from the slave controller.

21.2.14.2 Special Mask Mode

Some applications may require an interrupt service routine to dynamically alter the system priority structure during its execution under software control. For example, the routine may wish to inhibit lower priority requests for a portion of its execution but enable some of them for another portion.

The Special Mask Mode enables all interrupts not masked by a bit set in the Mask Register. Normally, when an interrupt service routine acknowledges an interrupt without issuing an EOI to clear the ISR bit, the interrupt controller inhibits all lower priority requests. In the special mask mode, any interrupts are selectively enabled by loading the mask register with the appropriate pattern.

The Special Mask Mode is set when the Enable Special Mask Mode (ESMM), bit 5 of OCW3, and the Special Mask Mode (SMM), bit 6 of OCW3, are programmed to 1. Special Mask Mode is cleared when ESMM = 1 and SMM = 0. The SMM bit has no meaning when ESSM is 0.

21.3 I/O Advanced Programmable Interrupt Controller (IOxAPIC)

- Up to 120 interrupt requests (IRQ0 through IRQ119). Default-set to 24.
- Edge- or level-trigger mode per interrupt
- Active-low or -high polarity per interrupt
- Uses an MSI-like memory write cycle to send interrupts for local (processor) APICs
- Established APIC programming model

21.3.1 Interrupt Redirection Table

The interrupt Redirection Table of the SoC IOxAPIC provides 120 64-bit I/O Interrupt Redirection Table Entry (RTE) registers. Each RTE register is dedicated to one of the 120 internal, Interrupt Request (IRQ) input signals. For information about interrupts routed to the IOxAPIC see Chapter 8, "Interrupts and Events".

The information in each RTE is used to translate the interrupt manifestation on the corresponding IOxAPIC Interrupt Request input signal into a message to the local APICs.

The Maximum Redirection Entries (MRE) is default-set to indicate 24 (decimal) interrupts, IRQ[23:0]. BIOS can change this maximum number through the Read-Write-Once (RWO), eight-bit MRE field of the Version (VS) register. MRE contains the RTE number (0 being the lowest entry) of the highest entry in the Redirection Table.

BIOS must write to the MRE field after the SoC asserts the active-low PMU_PLTRST_N platform reset signal pin in order to lock-down the RWO value. This allows BIOS to utilize some of the entries for its own purpose and thus advertising fewer IOxAPIC Redirection Entries to OS. BIOS may program the eight-bit MRE field with a value up to 78h (maximum of 120 RTE registers).

Unlike IRQ pins of the 8259, the notion of interrupt priority is completely unrelated to the position of the physical interrupt input signal on the IOxAPIC. Instead, the software determines the vector (and therefore the priority) for each corresponding interrupt input signal. For each interrupt signal, the operating system also specifies the signal polarity (low active or high active), whether the interrupt is signaled as edges or levels, as well as the destination and delivery mode of the interrupt.

The information in the Redirection Table translates the corresponding interrupt pin information into an inter-APIC message.

21.3.2 Accessing the Redirection Table

A 32-bit Identification (ID) register, 32-bit Version (VS) register, and 120 64-bit RTE registers are accessible in Host Memory Space through an Index (IDX) - Window (WDW) mechanism. The mechanism itself can be relocated within Host Memory Space. See Table 21-6, "IOxAPIC Register Access Window in Host Memory Space" on page 652 and Table 21-7, "IOxAPIC Registers" on page 652.

When accessing the indexed registers, accesses must be done as 32-bit Double-Words or else unspecified behavior results. Software must not attempt to write to reserved registers. Some reserved registers may return non-zero values when read.

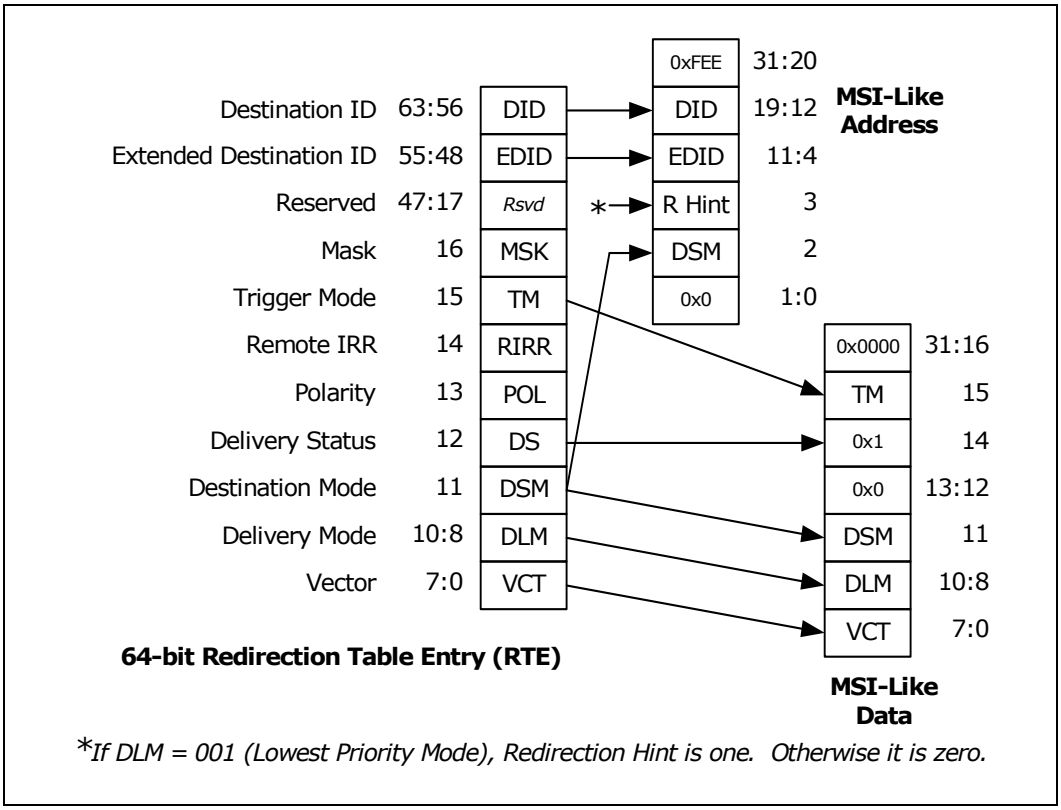
21.3.3 IOxAPIC Interrupts to the Local APICs

The VT-d architecture extension requires Interrupt Messages to go through the similar Address Remapping as any other memory requests. This is to allow domain isolation for interrupts such that a device assigned in one domain is not allowed to generate interrupts to another domain.

The Address Remapping for VT-d is based on the Bus:Device:Function field associated with the requests. Hence, it is required for the internal IOxAPIC to initiate the Interrupt Messages using a unique Bus:Device:Function.

The SoC Primary-to-Sideband (P2SB) Bridge PCI device (B:0, D:31, F:1) provides this VT-d capability and issues the MSI-like, IOxAPIC Interrupt Message to the processor local APICs on behalf of the IOxAPIC as an upstream 32-bit Memory Write-Cycle Transaction. The P2SB Bridge B/D/F is used in the Requester ID when the IOxAPIC initiates sending Interrupt Messages to the CPU. The Host Memory-Space address and data values are derived from the Relocation table Entry (RTE) for the interrupt and follow the format shown in Figure 21-3 on page 647.

Figure 21-3. MSI-Like IOxAPIC Interrupt Message for the Local APICs



The P2SB Bridge B/D/F is also used as the Completer ID in response to reads targeting the IOxAPICs Memory-Mapped I/O (MMIO) registers. See Section 21.3.2, "Accessing the Redirection Table" on page 646.

Note: While the P2SB Bridge is the designated PCI device to act on behalf of the IOxAPIC Interrupt Message Writes and Reads of its MMIO registers, there is a register that determines the B/D/F values for the IOxAPIC's surrogate PCI device. The register is the IOxAPIC Bus:Device:Function (IBDF) and is located in Host Configuration Space of the P2SB Bridge, offset 6Ch. The default for IBDF is B:0, D:31, F:0 (LPC) and must be changed to B:0, D:31, F:1 (P2SB Bridge).

The Host Memory Space address of the IOxAPIC Interrupt Message is formed as shown in Table 21-3. The data is shown in Table 21-4.

Table 21-3. IOxAPIC Interrupt Message Address

Address Bit	Short Description	Description
31:20	FEEh	Hardwired as FEEh
19:12	Destination ID	Destination ID of the local APIC - from DID field of the interrupt RTE
11:4	Extended Destination ID	Extended destination ID of the local APIC - from EDID field of the interrupt RTE
3	Redirection Hint	Redirection Hint - '1' If the DLM field = "Lowest Priority" (001) for the interrupt RTE. Otherwise '0'
2	Destination Mode	Used by the Local APIC to determine whether it is the destination of the Interrupt Message
1:0	00	Hardwired as 00 - Interrupt Message data is written as a Double Word (32 bits)

Table 21-4. IOxAPIC Interrupt Message Data

Data Bit	Short Description	Description
31:16	0000h	Hardwired as 0000h
15	Trigger Mode	From TM field of the RTE - '0' indicates the interrupt is edge sensitive. '1' indicates the interrupt is level sensitive.
14	Delivery Status	Is always '1' indicating an "Assert Message" cycle
13:12	00	Hardwired as 00
11	Destination Mode	From DSM field of the RTE - Used by the Local APIC to determine whether it is the destination of the message
10:8	Delivery Mode	From DLM field of the RTE - How the APICs listed in the destination field should act upon reception of this signal. Certain Delivery Modes will only operate as intended when used in conjunction with a specific trigger mode. The supported modes are described in Section 21.3.4, "Interrupt Delivery Modes" on page 649.
7:0	Vector	From VCT field of the RTE - Interrupt Vector for this interrupt. Values range between 10h and Feh

21.3.4 Interrupt Delivery Modes

The IOxAPIC supports these Interrupt Delivery Modes (DLM) to the local APICs:

- 000 = Fixed. Deliver the signal on the INTR (internal) signal of all processor cores listed in the Destination field of the RTE. The Trigger Mode field of the RTE can be edge or level.
- 001 = Lowest Priority. Deliver the signal on the INTR (internal) signal of the processor core that is executing at the lowest priority among all the processors listed in the specified Destination field of the RTE. Trigger Mode can be edge or level.
- 111 = ExtINT. Deliver the signal to the INTR signal of all processor cores listed in the Destination field as an interrupt that originated in the 8259 interrupt controller. The INTA cycle that corresponds to this ExtINT delivery is routed to the 8259 controller which is expected to supply the vector. Requires the interrupt to be programmed as edge triggered.

The IOxAPIC does not support the NMI, INIT, or SMI Delivery Modes. However, the SoC does send the Delivery Mode (DLM) value programmed in the Redirection Table as part of the Interrupt Message.

Note: Software is required to take precaution as the SoC does not internally route the NMI/INIT/SMI events to the IOxAPIC, nor attempting to resolve any dependency with the NMI/INIT/SMI delivery as described above even though the DLM field is programmed as such. If needed, this must be addressed outside of the SoC.

21.3.5 Determining Safe Message Delivery Time

When the IOxAPIC sends an Interrupt Message, it first ensures that all buffers that may contain main-memory-directed posted writes from legacy devices have been flushed to the point that when the interrupt is delivered to the CPU, any write data that needs to be processed by the Interrupt Service Software is available in the memory complex. When the legacy-device buffers are empty, the IOxAPIC delivers the interrupt that initiated the flush.

21.3.6 End Of Interrupt (EOI) Register

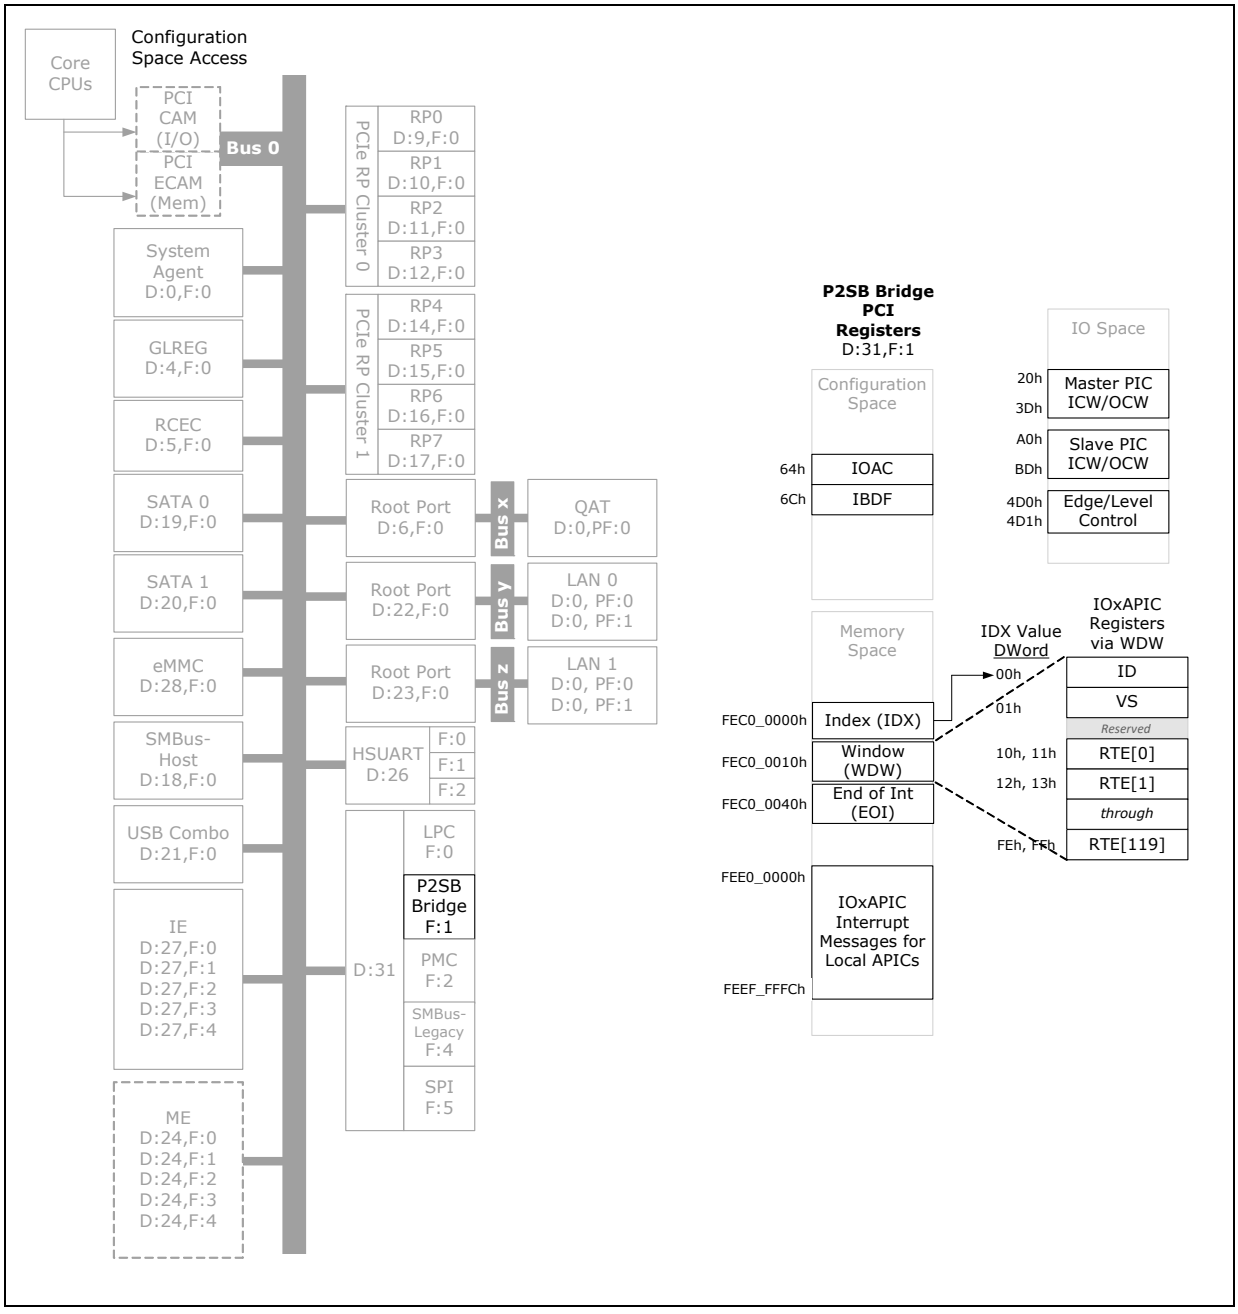
The 32-bit IOxAPIC EOI register is in Host Memory Space at address FEC0_0040h. The SoC P2SB Bridge PCI device (B:0, D:31, F:1) acts on the IOxAPIC's behalf. When a Host memory Write is issued to the 32-bit EOI register, the P2SB Bridge I/O checks the lower 8 bits written to this register and compares them with the Vector (VCT) field for each of the Redirection Table Entries (RTE 0 through RTE 119) in the Redirection Table.

When a match is found, the P2SB Bridge informs the IOxAPIC to clear the Remote IRR (RIRR) bit for that entry. If multiple entries have the same vector, each of those entries has its RIRR bit cleared.

21.4 Register Map

Figure 21-4 on page 650 shows the associated registers from a system software viewpoint.

Figure 21-4. Register Map



21.4.1 PCI Configuration and Capabilities

Table 21-5. Configuration and Capabilities Register Map

Offset from Configuration Space of B0:D31:F1 (hex)	Register Short Name	Description
64	IOAC	IOxAPIC Configuration
6C	IBDF	IOxAPIC Bus:Device:Function

21.4.2 Memory-Mapped Registers

The registers listed in Table 21-7 are described in detail in Chapter 64, "PIC and I/O APIC Controllers".

The IOxAPIC Configuration (IOAC) register is located in Host Configuration Space Bus 0, Device 31 (decimal), Function 1, offset 0x64. When Address Enable (AE) is set in IOAC bit 8, IOAC bits 7:0 define bits 19:12 of the Host Memory Space address used to access the IOxAPIC memory-mapped registers.

Table 21-6 shows the resulting memory addresses when bit 8 of the IOAC register is zero, the default register setting. The default setting of IOAC enables compatibility with the default setting of prior Intel products.

Table 21-6. IOxAPIC Register Access Window in Host Memory Space

Memory Address (hex)	Register Short Name	Register Long Name
FEC0_0000	IDX	Index Register
FEC0_0010	WDW	Window Register
FEC0_0040	EOI	EOI Register

Table 21-7 shows the IOxAPIC register accessed through the Window (WDW) Register for a given Index (IDX) register value. The register is indexed as 32-bit data entries as explained in Section 21.3.2, "Accessing the Redirection Table" on page 646.

Table 21-7. IOxAPIC Registers

Index Register Value (hex)	Information Accessed in the Window Register Short Name	Information Accessed in the Window Register Long Name
00	ID	Identification Register
01	VS	Version
02 through 0E	Reserved	Reserved
10 through FE	RTE0 through RTE119 (decimal)	Redirection Table Entry 0 through 119

Table 21-8 shows the IOxAPIC Interrupt Message locations in Host Memory Space.

Table 21-8. IOxAPIC Interrupt Messages for Local APICs in Host Memory Space

Memory Address (hex)	Register Short Name	Register Long Name
FEE0_0000 FEE0_0004 FEE0_0008 through FEEF_FFFC	-	IOxAPIC Interrupt Messages for processor Local APICs

21.4.3 I/O-Mapped Registers

Table 21-9. 8259 (PIC) Registers in Host I/O Space

I/O Port (hex)	Alias I/O Ports (hex)	Register Short Name	Register Name and Function
20	24h, 28h, 2Ch, 30h, 34h, 38h, 3Ch	MICW1	Master Initialization Command Word 1
		MOCW2	Master Operational Control Word 2
		MOCW3	Master Operational Control Word 3
21	25h, 29h, 2Dh, 31h, 35h, 39h, 3Dh	MICW2	Master Initialization Command Word 2
		MICW3	Master Initialization Command Word 3
		MICW4	Master Initialization Command Word 4

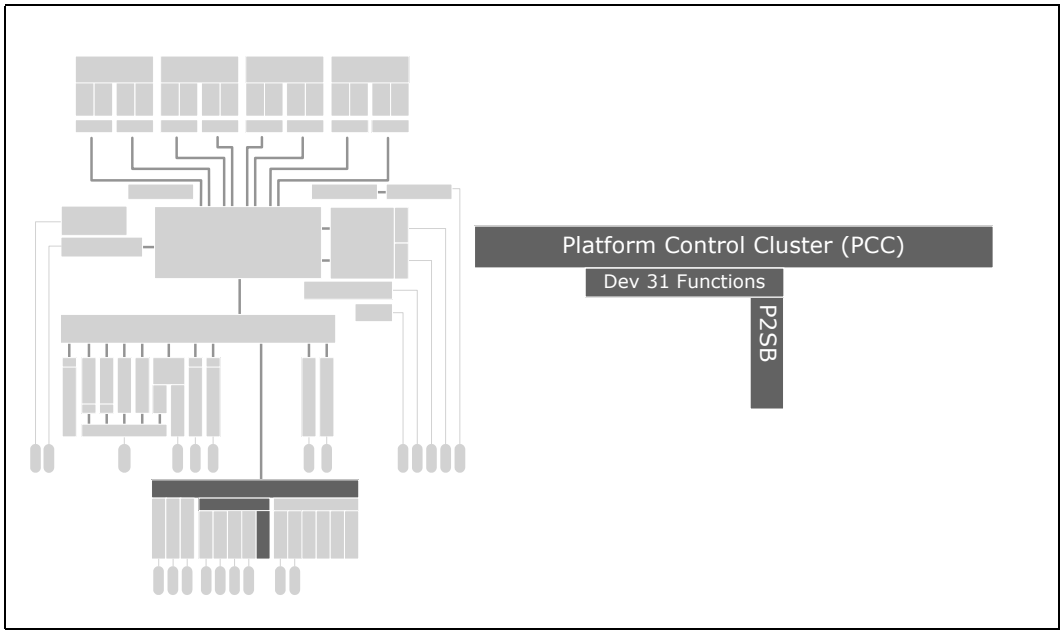
§ §

22 Primary to Side Band (P2SB) Bridge

This chapter describes software access to the SoC Sideband registers.

Figure 22-1. What is Covered in This Chapter



22.1 Signal Descriptions

There are no signal pins or signal names associated with this chapter.

22.2 Feature List

- SoC Sideband Registers are accessed through Memory Space
- SBREG_BAR points to the 16-MB area in 64-bit-addressable memory

22.3 Architectural Overview

The Sideband Register access mechanism is configured at Bus 0, Device 31 (decimal), Function 1 of Configuration Space. Its PCI class designation is that of an unspecified other memory controller. SBREG_BAR and SBREG_BARH form the 64-bit memory Base Address Register (BAR) which points to a non-prefetchable, 16-MB region of memory-mapped space.

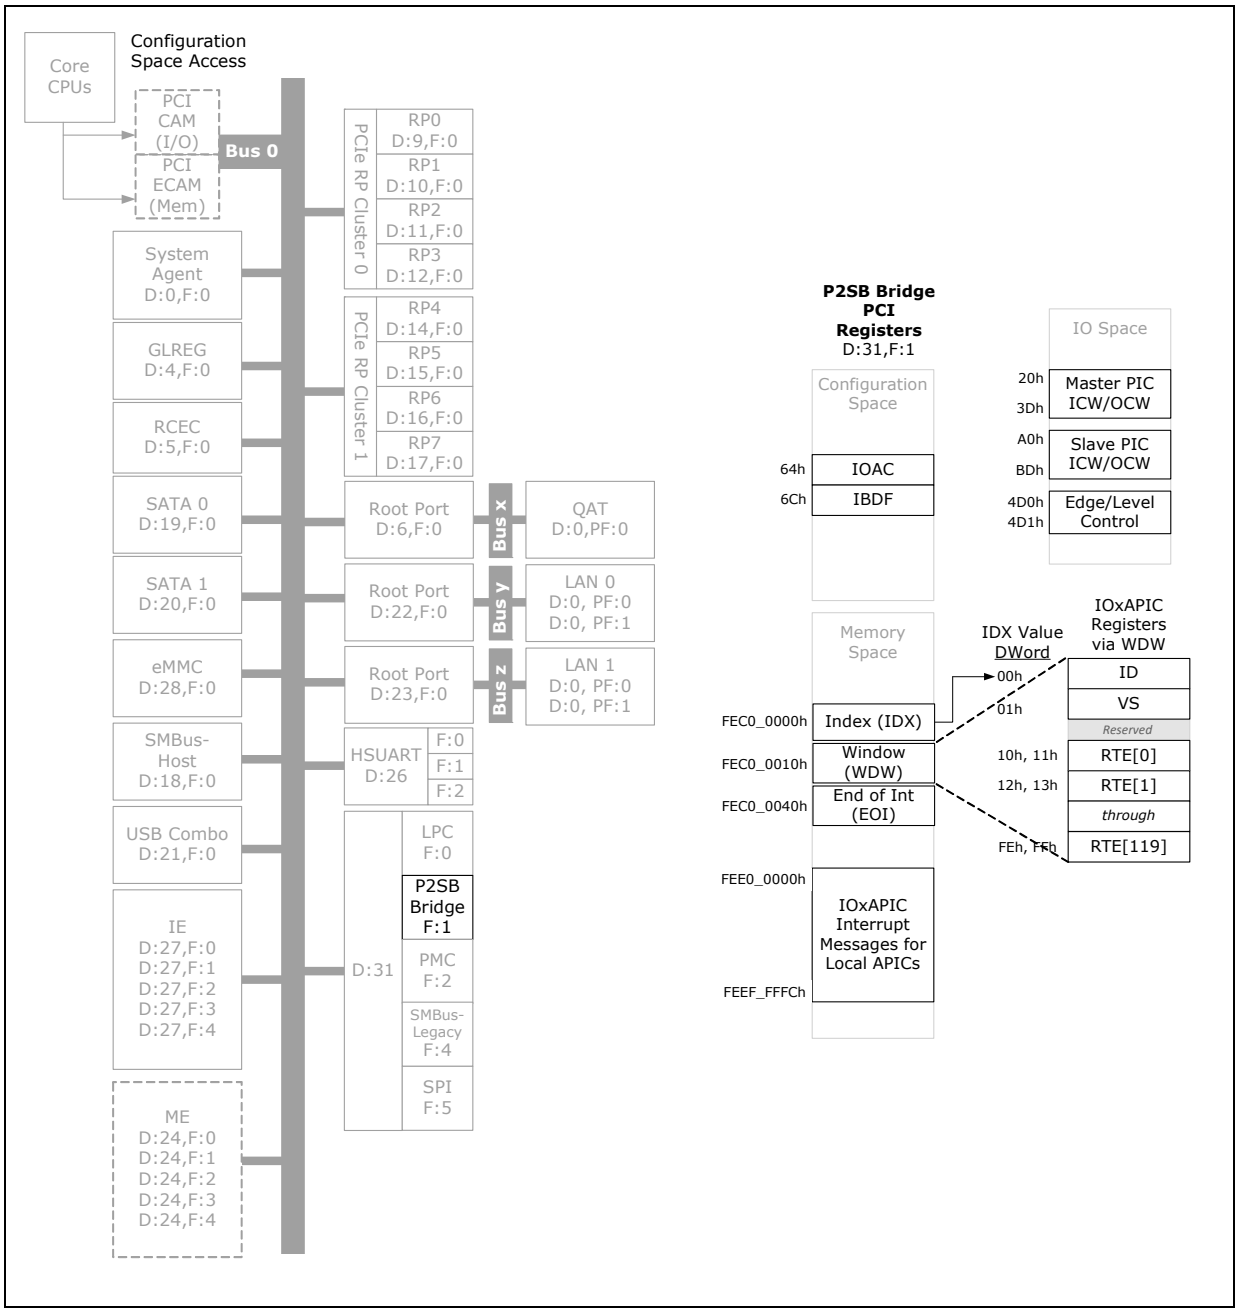
Warning: All accesses to the SBREG_BAR region are DWORD aligned DWORDS. Writes larger than one DWORD are completed normally, but the write data beyond the first DWORD is discarded. Reads larger than one DWORD result in a Unsupported Request (UR) response. Byte enables within the DWORD are honored normally, enabling accesses of less than one DWORD.

The Sideband Register map is not provided in this chapter. Other chapters that refer to Sideband Registers provide the appropriate memory-mapped locations to access.

22.4 Register Map

Figure 22-2 shows the associated registers from a system software viewpoint.

Figure 22-2. Register Map



22.4.1 PCI Configuration and Capabilities

Table 22-1. Configuration and Capabilities Register Map

Offset from Configuration Space of B0:D31:F1 (hex)	Register Short Name	Description
Standard Type 0 PCI Configuration Registers		
0	PCIID	PCI Identifier
4	PCICMD	PCI Command
6	PCISTS	PCI Status
8	PCIRID	Revision ID
9	PCICC	Class Code
D	PCIMLT	PCI Master Latency Timer
E	PCIHTYPE	PCI Header Type
10	SBREG_BAR	Sideband Register Access BAR
14	SBREG_BARH	Sideband Register BAR High DWORD
2C	PCIHSS	PCI Subsystem Identifiers
Device-Specific PCI Configuration Registers

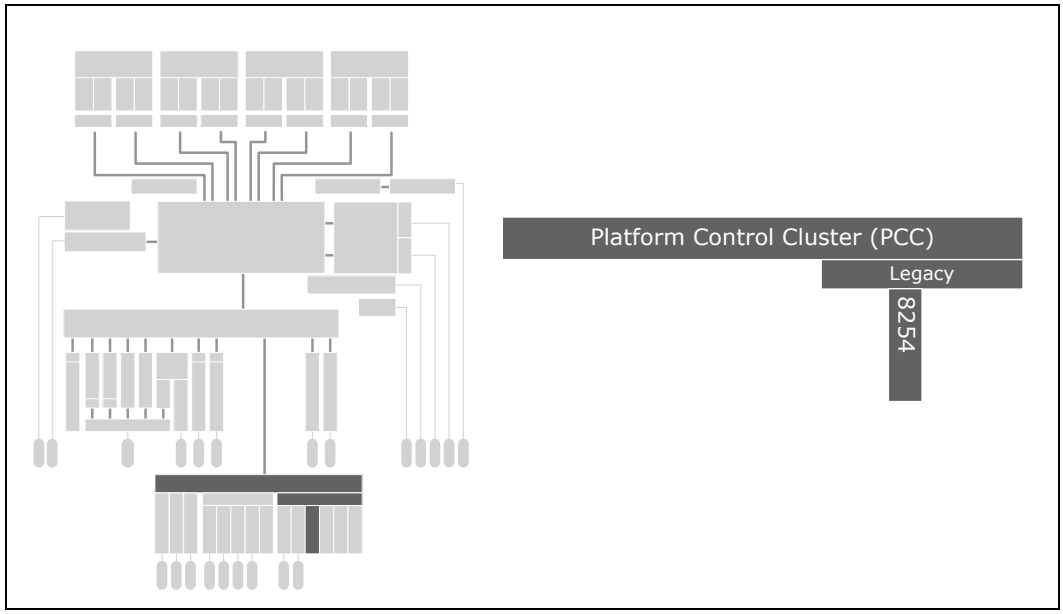
23 Programmable Interval Timer (PIT)

This chapter describes the Programmable Interval Timer (PIT). The design is based on the legacy 8254 PIT device.

Figure 23-1. What is Covered in This Chapter



23.1 Signal Descriptions

There are no signal pins or signal names associated with this chapter.

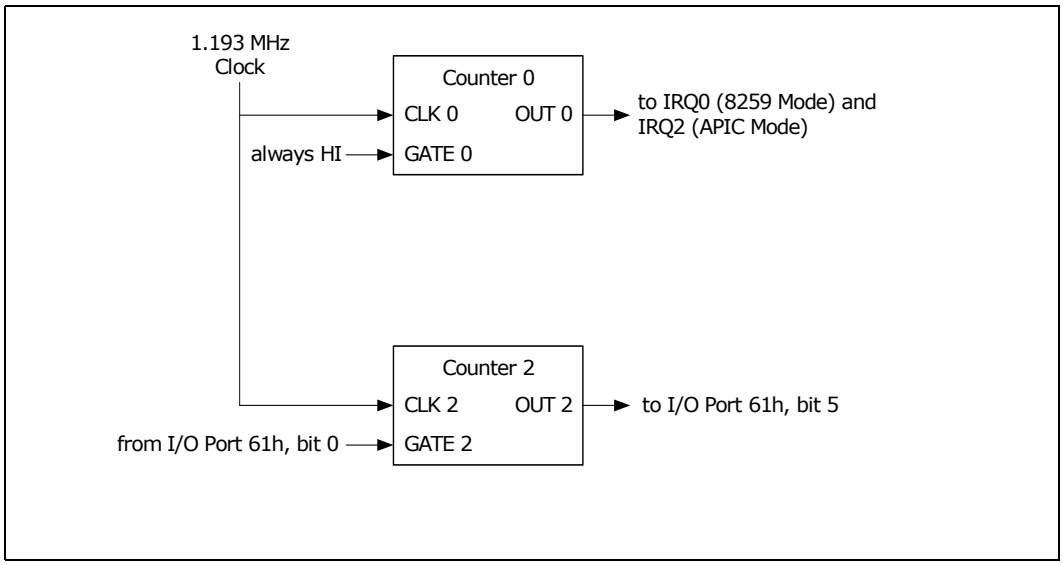
23.2 Feature List

- Legacy 8254 PIT functions.

23.3 Architectural Overview

The SoC contains two counters that have fixed uses. All registers and functions associated with the 8254 timers are in the Core power well. The 8254 unit is clocked by a 1.193-MHz clock derived from 25-MHz internal ISCLK clock. Figure 23-2 shows how the 8254 PIT is implemented in the SoC.

Figure 23-2. Programmable Interval Timer (PIT) Implementation



23.3.1 Counter 0, System Timer

Counter 0 functions as the system timer by controlling the state of IRQ0 and is typically programmed for Mode 3 operation. See Table 23-1, “Counter Operating Modes” on page 662. The counter produces a square wave with a period equal to the product of the counter period (838 ns) and the initial count value. The counter loads the initial count value 1 counter period after software writes the count value to the counter I/O address. The counter initially asserts IRQ0 and decrements the count value by two each counter period. The counter negates IRQ0 when the count value reaches 0. It then reloads the initial count value and again decrements the initial count value by two each counter period. The counter then asserts IRQ0 when the count value reaches 0, reloads the initial count value, and repeats the cycle, alternately asserting and negating IRQ0.

23.3.2 Counter 2

Counter 2 was used in the original IBM PC to drive a speaker pin. The SoC does not have a dedicated speaker pin. The counter must be enabled by a write to TIM_CNT2_EN, bit 0 of the NMI_STS_CNT register at I/O Port 061h.

23.4 Counter Mode Definitions

Table 23-1 lists the six operating modes for the interval counters.

Table 23-1. Counter Operating Modes

Mode	Function	Description
0	Out signal on end of count (=0)	Output is 0. When count goes to 0, output goes to 1 and stays at 1 until counter is reprogrammed.
1	Hardware retriggerable one-shot	Output is 0. When count goes to 0, output goes to 1 for one clock time.
2	Rate generator (divide by n counter)	Output is 1. Goes to 0 for 1 clock time, then back to 1 and counter is reloaded.
3	Square wave output	Output is 1. Output goes to 0 when counter rolls over, and counter is reloaded. Output goes to 1 when counter rolls over, and counter is reloaded, and so on
4	Software triggered strobe	Output is 1. Output goes to 0 when count expires for one clock time.
5	Hardware triggered strobe	Output is 1. Output goes to 0 when count expires for one clock time.

23.5 Timer Programming

23.5.1 Writing to the Interval Timer

The counter/timers are programmed in the following fashion:

1. Write a control word to select a counter.
2. Write an initial count for that counter.
3. Load least and/or most significant bytes (as required by Control Word Bits 5, 4) of the 16-bit counter.
4. Repeat with other counters.

Only two conventions need to be observed when programming the counters.

1. For each counter, control word must be written before the initial count is written.
2. Initial count must follow the count format specified in the control word (least significant byte only, most significant byte only, or least significant byte, and then most significant byte).

A new initial count may be written to a counter at any time without affecting the counter's programmed mode. Counting is affected as described in the mode definitions. The new count must follow the programmed count format.

If a counter is programmed to read/write two-byte counts, the following precaution applies – a program must not transfer control between writing the first and second byte to another routine which also writes into that same counter. Otherwise, the counter will be loaded with an incorrect count.

The Timer Control Word (TCW) Register at I/O Port 43h controls the operation of all three counters. Several commands are available:

- Control Word Command. Specifies which counter to read or write, the operating mode, and the count format (binary or BCD). See Section 23.5.2.1, “Simple Read” on page 663.
- Counter Latch Command. Latches the current count so that it can be read by the system. The countdown process continues. See Section 23.5.2.2, “Counter Latch Command” on page 663.
- Read Back Command. Reads the count value, programmed mode, the current state of the OUT pins, and the state of the Null Count Flag of the selected counter. See Section 23.5.2.3, “Read Back Command” on page 664.

23.5.2 Reading from the Interval Timer

It is often desirable to read the value of a counter without disturbing the count in progress. There are three methods for reading the counters—a simple read operation, counter Latch command, and the Read-Back command. Each is explained below.

With the simple read and counter latch command methods, the count must be read according to the programmed format; specifically, if the counter is programmed for two byte counts, two bytes must be read. The two bytes do not have to be read one right after the other. Read, write, or programming operations for other counters may be inserted between them.

23.5.2.1 Simple Read

The first method is to perform a simple read operation. The counter is selected through C0_CAPR at I/O Port 40h (Counter 0) or C2_CAPR at I/O Port 42h (Counter 2).

Note: Performing a direct read from the counter does not return a determinate value, because the counting process is asynchronous to read operations. However, in the case of Counter 2, the count can be stopped by writing to the TIM_CNT2_EN bit, bit 0 of the NMI_STS_CNT register at I/O Port 061h.

23.5.2.2 Counter Latch Command

The Counter Latch command (CLC), written to I/O Port 43h, latches the count of a specific counter at the time the command is received. This command is used to ensure that the count read from the counter is accurate, particularly when reading a two-byte count. The count value is then read from each counter's Count register as was programmed by the Control register.

The count is held in the latch until it is read or the counter is reprogrammed. The count is then unlatched. This allows reading the contents of the counters on the fly without affecting counting in progress. Multiple Counter Latch Commands may be used to latch more than one counter. Counter Latch commands do not affect the programmed mode of the counter in any way.

If a Counter is latched and then, some time later, latched again before the count is read, the second Counter Latch command is ignored. The count read is the count at the time the first Counter Latch command was issued.

23.5.2.3 Read Back Command

The Read Back command (RBC), written to I/O Port 43h, latches the count value, programmed mode, and current states of the OUT pin and Null Count flag of the selected counter or counters. The value of the counter and its status may then be read by I/O access to the counter address.

The Read Back command may be used to latch multiple counter outputs at one time. This single command is functionally equivalent to several counter latch commands, one for each counter latched. Each counter's latched count is held until it is read or reprogrammed. Once read, a counter is unlatched. The other counters remain latched until they are read. If multiple count Read Back commands are issued to the same counter without reading the count, all but the first are ignored.

The Read Back command may additionally be used to latch status information of selected counters. The status of a counter is accessed by a read from that counter's I/O Port address. If multiple counter status latch operations are performed without reading the status, all but the first are ignored.

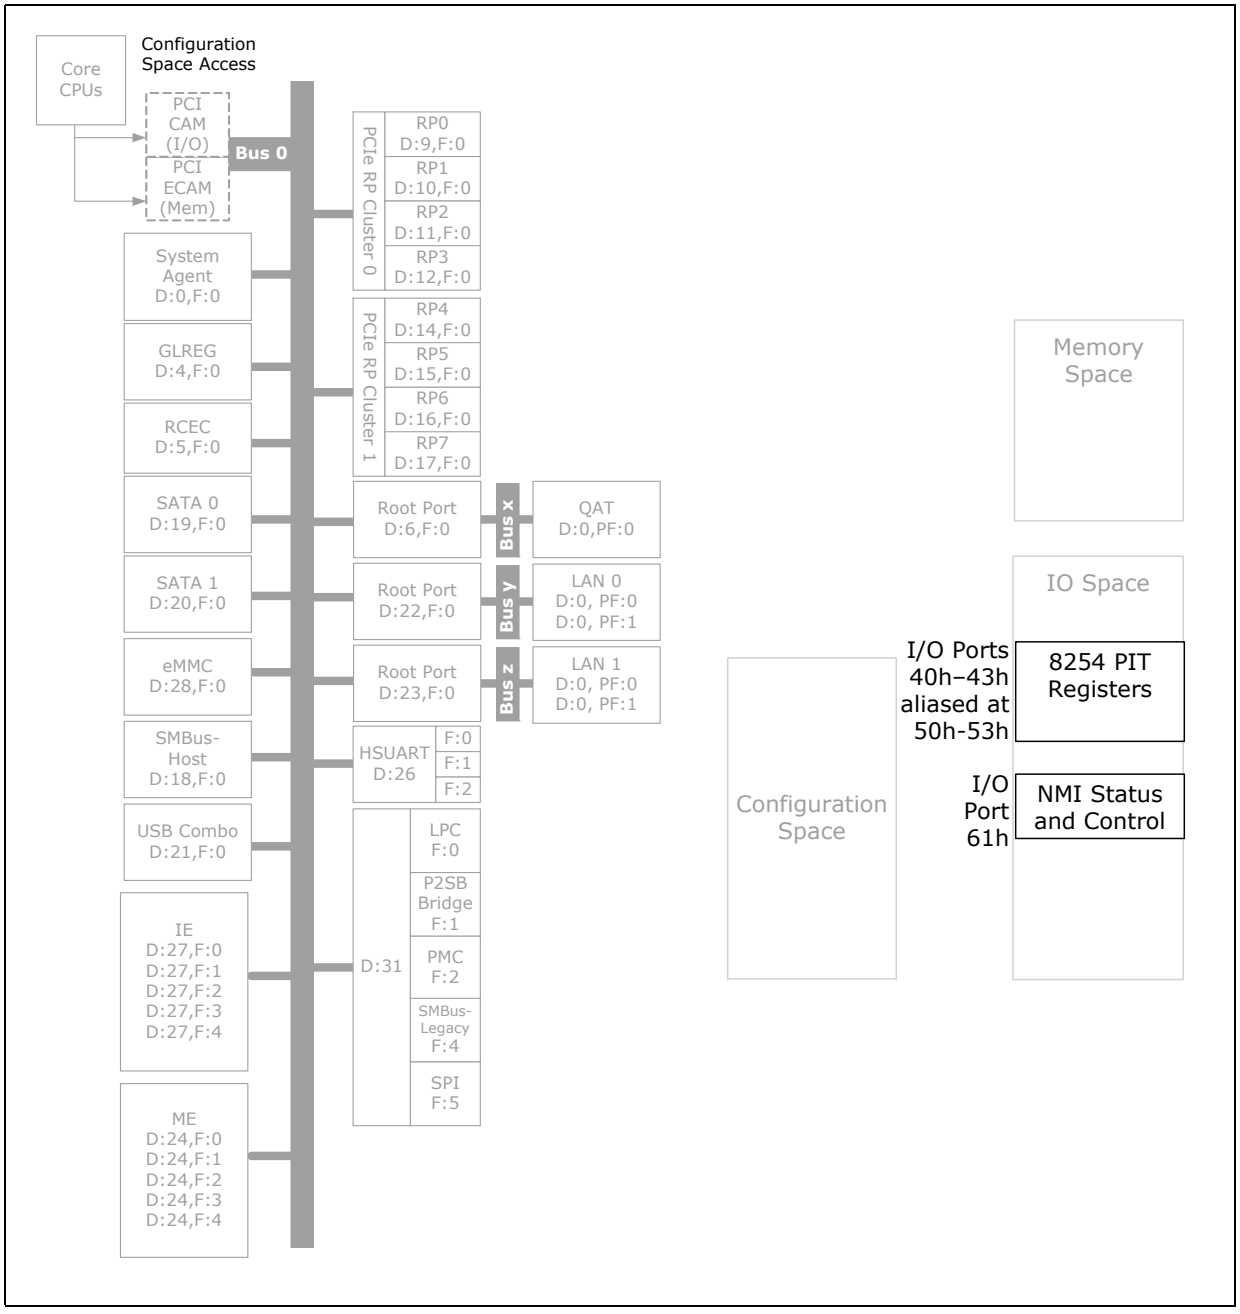
Both count and status of the selected counters may be latched simultaneously. This is functionally the same as issuing two consecutive, separate Read Back commands. If multiple count and/or status Read Back commands are issued to the same counters without any intervening reads, all but the first are ignored.

If both count and status of a counter are latched, the first read operation from that counter returns the latched status, regardless of which was latched first. The next one or two reads, depending on whether the counter is programmed for one or two type counts, returns the latched count. Subsequent reads return unlatched count.

23.6 Register Map

Figure 23-3 on page 665 shows the associated registers from a system software viewpoint.

Figure 23-3. Register Map



23.6.1 I/O-Mapped Registers

Table 23-2. Fixed-Address I/O-Mapped Registers

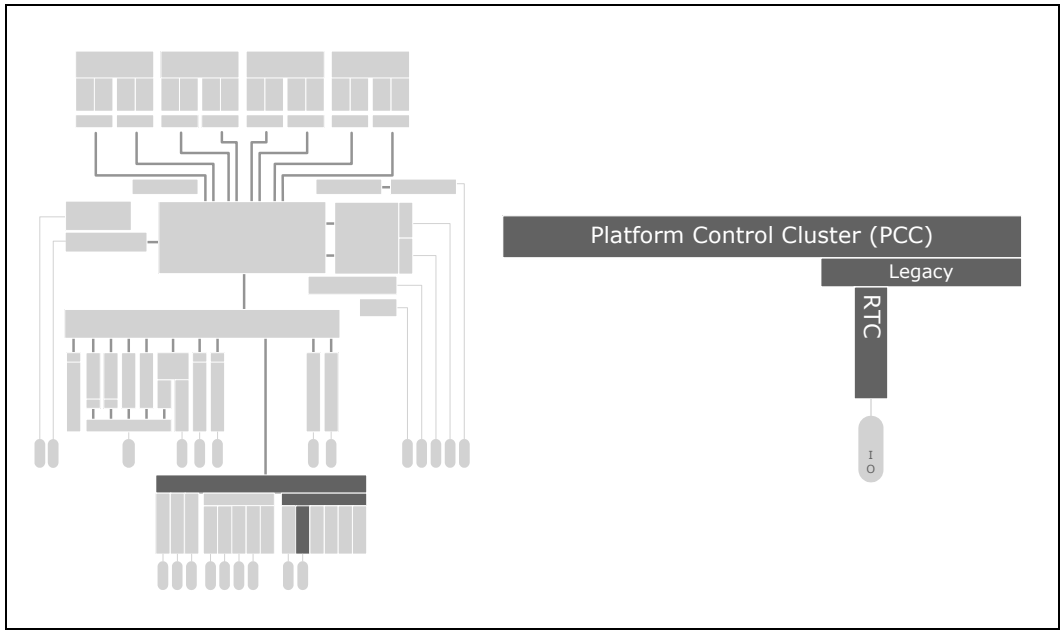
2. When data bits 7:6 are 11.
3. When data bits 7:6 are 00 or 10. The setting 01 is reserved. Also, data bits 5:4 must be 00.

§ §

24 Real Time Clock (RTC)

This chapter describes the SoC Real Time Clock (RTC).

Figure 24-1. What is Covered in This Chapter



24.1 Signal Descriptions

The signal descriptions are shown in Table 24-1. The signals associated with the RTC circuitry are shown as well as signal that reside in the SoC RTC power well. For additional signal information, including whether a signal is assigned to shared-function pin or can be used as a Customer GPIO signals see Chapter 39, "Signal Pin Names and Signal MUXing". The Direction/Type column of Table 24-1 is interpreted as follows:

- I = Input signal. The SoC has receiver circuit.
- O = Output signal. The SoC has driver circuit.

Table 24-1. Signal Names and Descriptions

Signal Names	Direction	Shared	Description
RTC_X1_PAD	I,O	No	**Crystal Input 1:** This signal is connected to the 32.768 KHz crystal (Max 50K ESR). If using an external oscillator, the RTCX1 Vih must be within the range of 0.8V to 1.5V (1.5V max).
RTC_X2_PAD	I,O	No	**Crystal Input 2:** This signal is connected to the 32.768 KHz crystal (Max 50K ESR). If using an external oscillator, RTCX2 should be left floating.
BVCCRTC_EXTPAD	I,O	No	**Internal VRM Filter:** Connect filter capacitor between this signal and ground.
COREPWROK	I	No	**Core Power OK:** When asserted, this active-high input signal indicates that all of the platform board Voltage Regulators (VRs) supplying the SoC core power rails have been stable for at least 10 ms. COREPWROK can be driven asynchronously. When COREPWROK is de-asserted, the SoC asynchronously asserts the active-low PMU_PLTRST_N signal.
INTRUDER_N	I	No	**Intruder Detect:** This signal can be used to disable the system if the box is detected open.
RSMRST_N	I	No	**Resume (SUS Power Well) Reset**: When asserted by the platform board, this active-low input signal resets the SoC SUS Power Well. An external RC circuit is required to guarantee that the SUS well power (VNN, 1.05V, 1.8V, and 3.3V) is valid for a minimum time prior to RSMRST_N signal going high (See Figure 33-1).
RTEST_N	I	No	**RTC Battery Test:** An external RC circuit creates a time delay for the signal such that it will go high (de-assert) sometime after the battery voltage is valid. If the battery is missing/weak, this signal appears low (asserted) at boot just after the suspend power rail (V3P3) is up since it will not have time to meet Vih when V3P3A is high. Upon booting, BIOS should recognize that RTCRCT# was asserted and clear CMOS RAM. ***Note:*** Unless CMOS is being cleared (only to be done in the G3 power state) or the battery is low, the signal input must always be high when all other RTC power planes are on.
SRTCRST_N	I	No	**RTC Reset:** An external RC circuit creates a time delay for the signal such that it will go high (de-assert) sometime after the battery voltage is valid. When asserted, this signal resets all register bits in the RTC well. ***Notes:*** 1. Unless registers are being cleared (only to be done in the G3 power state), the signal input must always be high when all other RTC power planes are on. 2. In the case where the RTC battery is dead or missing on the platform, the signal should go high (de-asserted) before the RSMRST_N signal goes high (de-asserted).

24.2 Feature List

- Maintaining power on VCCRTC_3P3_G3 (pin AU48) to the RTC when in the G3 state (e.g., coin-cell battery implementation) is optional.
- Legacy RTC features.

24.3 Architectural Overview

The Real Time Clock (RTC) module provides a battery backed-up date and time keeping device with two banks of static RAM with 128 bytes each, although the first bank has 114 bytes for general-purpose usage.

Three interrupt features are available:

- Time-of-day alarm with once-a-second to once-a-month range
- Periodic rates of 122 µs to 500 ms
- End-of-update cycle notification

Seconds, minutes, hours, days, day of week, month, and year are counted. Daylight savings compensation is optional. The hour is represented in twelve or twenty-four hour format and data can be represented in binary-coded decimal BCD or binary format.

The design is meant to be functionally compatible with the Motorola MS146818B. The time keeping comes from a 32.768 kHz oscillating source, which is divided to achieve an update every second. The RTC clock is not subject to any internal clock gating.

The lower 14 bytes of the lower static RAM block have very specific functions. The first ten are for time and date information. The next four (0Ah to 0Dh) are registers, which configure and report RTC functions.

The time and calendar data should match the data mode (BCD or binary) and hour mode (12 or 24 hour) as selected in register B. The programmer MUST make sure that data stored in these registers within the reasonable values ranges and represents a possible date and time. The exception to these ranges is to store a value of C0 - FF in the Alarm bytes to indicate a “don’t care” situation.

All Alarm conditions must match in order to trigger an Alarm Flag, which also triggers an Alarm Interrupt if enabled. The SET bit in register B should be 1 while programming these locations to avoid clashes with update cycles.

Access to time and date information is done through the static RAM locations. If a static-RAM read from the ten time and date bytes is attempted during an update cycle, the value read will not necessarily represent the true contents of those locations. Any static-RAM writes under the same conditions will be ignored.

Note: The leap year determination that adds a 29th day to the month of February does not take into account the end-of-the-century exceptions. The logic simply assumes that all years divisible by four are leap years. According to the Royal Observatory Greenwich, years that are divisible by 100 are typically not leap years. In every fourth century (years divisible by 400, like 2000), the 100-year-exception is over-ridden and a leap-year occurs. Note that the year 2100 will be the first time in which the current RTC implementation would incorrectly calculate the leap-year.

Note: The term RSMRST_N used within this chapter includes both the CF9h (in I/O Space) software-generated hardware reset and the RSMRST_N signal pin.

24.4 I/O Registers

The RTC internal registers and its static RAM are organized as two banks of 128 bytes each, called the Standard Bank and the Extended Bank:

- The first 14 bytes of the Standard Bank contain the RTC time and date information along with four registers: A; B; C; D. These four registers are used for configuration of the RTC but not physically exist in the static RAM.
- The Extended Bank, also called the "upper 128-byte bank," contains a full 128 bytes of battery-backed static RAM, and is accessible even when the RTC module is disabled via the RTC configuration register.

Table 24-2. RTC Standard and Extended Static RAM Banks

Index (hex)	Register Short Name	Register Long Name
Standard Bank		
00	Sec	Seconds
01	Sec_Alarm	Seconds Alarm
02	Minutes	Minutes
03	Minutes_Alarm	Minutes Alarm
04	Hours	Hours
05	Hours_Alarm	Hours Alarm
06	Day_of_Week	Day of Week
07	Day_of_Month	Day of Month
08	Month	Month
09	Year	Year
0A	Register_A	Register A
0B	Register_B	Register B - General Configuration
0C	Register_C	Register C - Flag Register
0D	Register_D	Register D - Flag Register
0E - 7F	114 Bytes of User RAM	
Extended Bank		
00 - 7F	128 Bytes of User RAM	

The two banks are accessible using an index mechanism. All data movement between the host CPU and the Real-Time Clock is done through registers mapped to Host Root I/O Space. The I/O register map appears below in Table 24-4, "Fixed-Address I/O-Mapped Registers".

The simplest way of reading the RTC registers is to:

- Use register pair located at I/O locations 74h and 75h to access the Standard Bank.
- Use register pair located at I/O locations 72h and 73h to access the Extended Bank.

24.4.1 Alternate-Access Mode

The NMI Enable bit located at I/O Port location 70h, bit 7, is best accessed ONLY when the chipset is put into Alternate-Access Mode. This guarantees successful read and write cycles regardless of the settings of the other registers. Alternate-Access Mode is enabled by setting Alternate Access Mode Enable (AME), bit 17 of the 32-bit General Interrupt Control (GIC) register in relocatable Memory Space at offset D0_31FCh from SBREG_BAR. When AME is set, read-only registers can be written, and write-only registers can be read.

24.5 Update Cycles

An Update Cycle occurs once a second if the SET bit of register B is not asserted and the divide chain is properly configured. During this procedure:

- the stored time and date will be incremented
- overflow will be checked
- a matching alarm condition will be checked
- the time and date will be rewritten to the static RAM locations.

The Update Cycle starts at least 488 µs after the UIP bit of register A is asserted. The entire cycle takes no more than 1984 µs to complete. The time and date static RAM locations (0-9) are disconnected from the external access bus during this time.

To avoid update and data corruption conditions, external static RAM access to these locations can safely occur upon the detection of either of two conditions:

- When an updated-ended interrupt is detected, almost 999 ms is available to read and write the valid time and date data.
- If the UIP bit of Register A is detected to be low, there is at least 488 µs before the update cycle begins.

Warning: The overflow conditions for leap years and daylight savings adjustments are based on more than one date or time item. To ensure proper operation when adjusting the time, the new time and data values should be set at least two seconds before one of these conditions (leap year, daylight savings time adjustments) occurs.

24.6 Interrupts

The real-time clock interrupt is internally routed to the I/O APIC or the 8259. It is mapped to interrupt vector 8. This interrupt is not shared with any other interrupt. IRQ8# from the Serialized Interrupt (SERIRQ) stream is ignored. However, the High Performance Event Timers (HPET) can also be mapped to IRQ8#. In this latter case, the RTC interrupt is blocked.

24.7 Lockable RAM Ranges

The RTCs battery-backed static RAM supports an 8-byte range (index 38h through 3Fh) for the Standard Bank and also one for the Extended Bank which can be locked via the RTC Configuration (RC) register. If the locking bit is set, the corresponding range in the static RAM bank will not be readable or writable. A write cycle to those locations has no effect. A read cycle to those locations will not return the location's actual value (the value is undefined).

Once a range is locked, the range can be unlocked only by a hard reset, which will invoke the UEFI IA Firmware and allow it to re-lock the static RAM range.

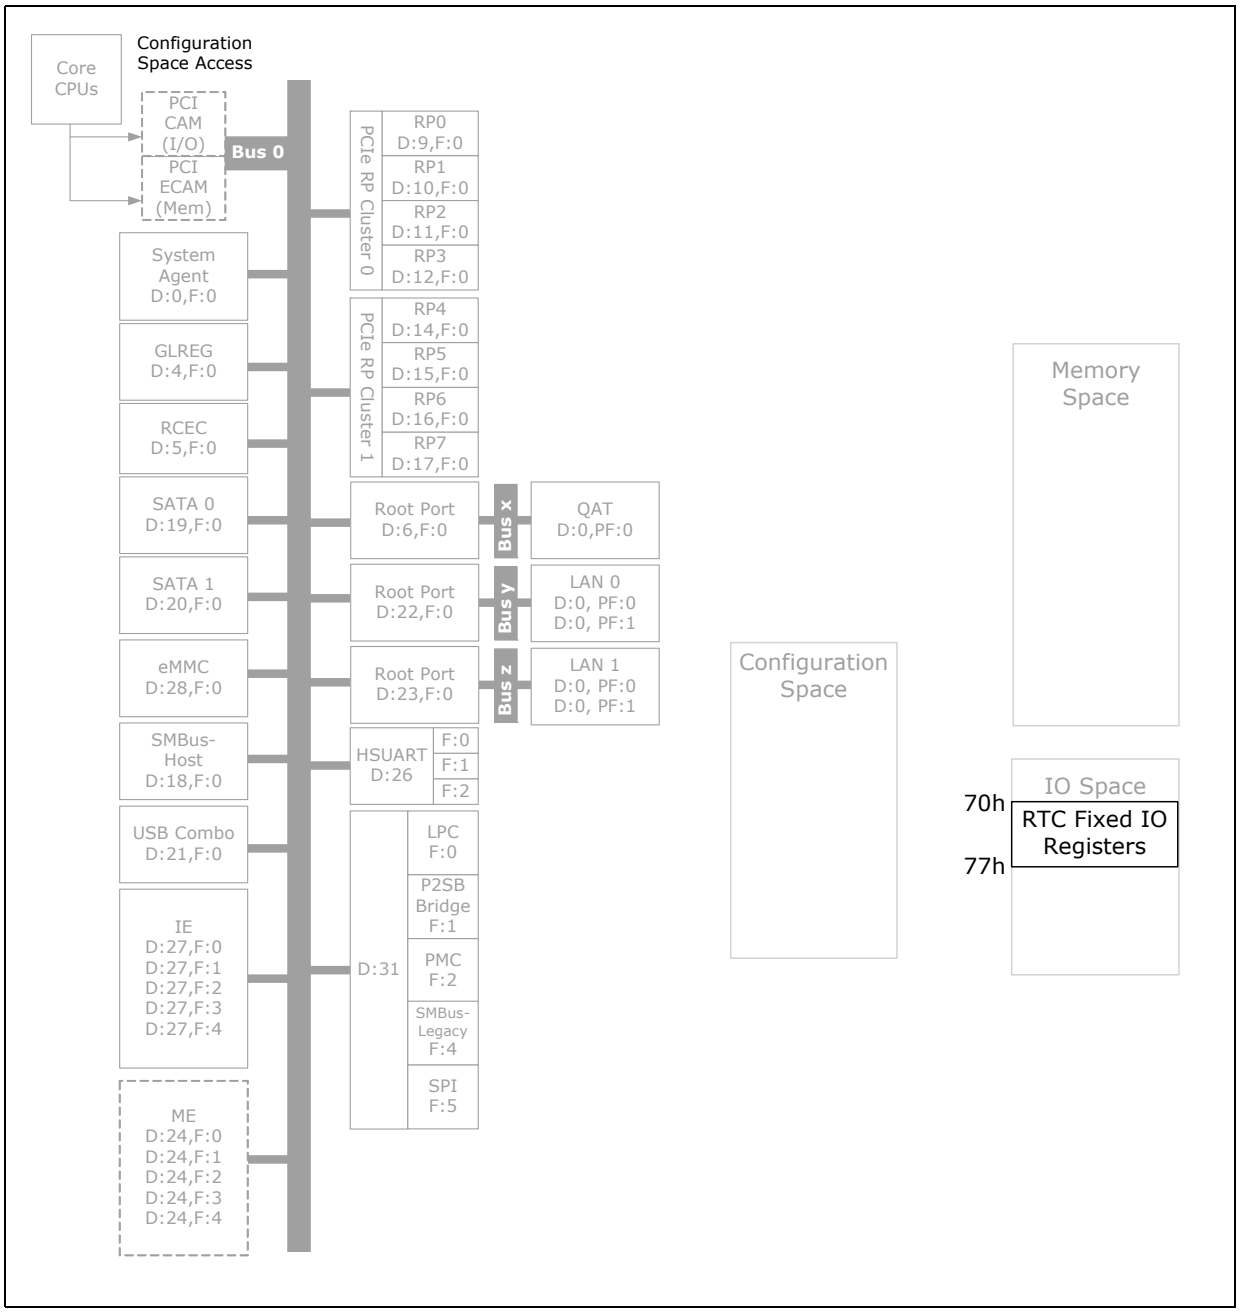
24.8 Month and Year Alarms

These functions are not implemented in the SoC.

24.9 Register Map

Table 24-2 shows how the RTC registers map to Host Root Space.

Figure 24-2. Register Map



24.9.1 PCI Configuration and Capabilities

There are no RTC registers in Host Root Configuration Space.

24.9.2 Memory-Mapped Registers

Table 24-3. Relocatable Memory-Mapped Registers

Base Address Register (BAR) Short Name	Offset from BAR (hex)	Register Short Name	Register Long Name
SBREG_BAR	D0_31FC	GIC	General Interrupt Control
SBREG_BAR	D1_3400	RC	RTC Configuration
SBREG_BAR	D1_3414	BUC	Backed Up Control
SBREG_BAR	D1_3F04	UIPSMI	RTC Update In Progress SMI Control
SBREG_BAR	D1_3418	RTCDCG	RTC Dynamic Clock Gating Control

24.9.3 I/O-Mapped Registers

Table 24-4. Fixed-Address I/O-Mapped Registers

I/O Locations (hex)	When Upper 128 Byte Enable (UE)[1] = 0	Function
70h and 74h	Also alias to 72h and 76h	Real-Time Clock (Standard RAM) Index Register ***Note:*** Writes to 72h, 74h, and 76h do not affect the NMI Enable bit (bit 7 of 70h)
71h and 75h	Also alias to 73h and 77h	Real-Time Clock (Standard RAM) Target Register
72h and 76h		Extended RAM Index Register (if enabled)
73h and 77h		Extended RAM Target Register (if enabled)

1. The Upper 128 Byte Enable (UE) register is bit 2 of the RTC Configuration (RC) register located in Host Root Memory Space at SBREG_BAR, offset D1_3400h.

§ §

25 High Precision Event Timer (HPET)

This chapter describes the High Precision Event Timer (HPET). One HPET Timer Block is provided which consists of a single counter that feeds eight comparators called Timer 0 through Timer 7. It is based on the *IA-PC HPET (High Precision Event Timers) Specification Revision 1.0a*.

Figure 25-1. What is Covered in This Chapter

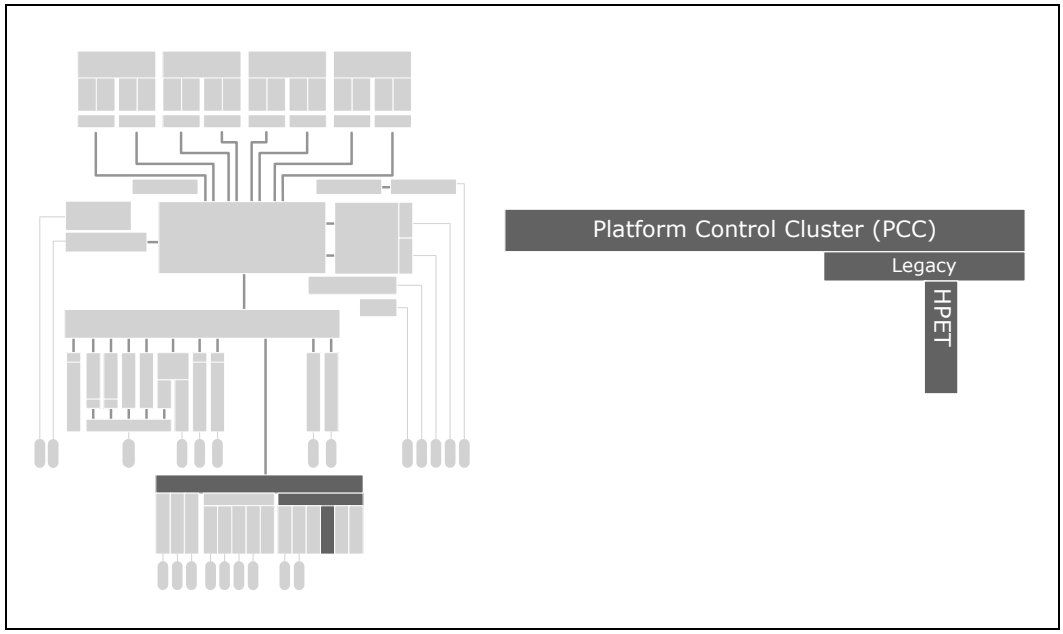


Table 25-1. References

Reference	Revision	Date	Document Title
Intel HPET Specification	1.0a	October 2004	*IA-PC HPET (High Precision Event Timers) Specification Revision 1.0a*

25.1 Signal Descriptions

There are no signal pins or signal names associated with this chapter.

25.2 Feature List

- The Time to Next Timer Event (TNTE) is conveyed internally from the HPET to the SoC Power Management Controller (PMC).
- HPET uses all 64-bit data as it allows two DW (QW) Register Write Access and Read Access.
- The HPET circuitry uses an internally-generated 24-MHz clock.

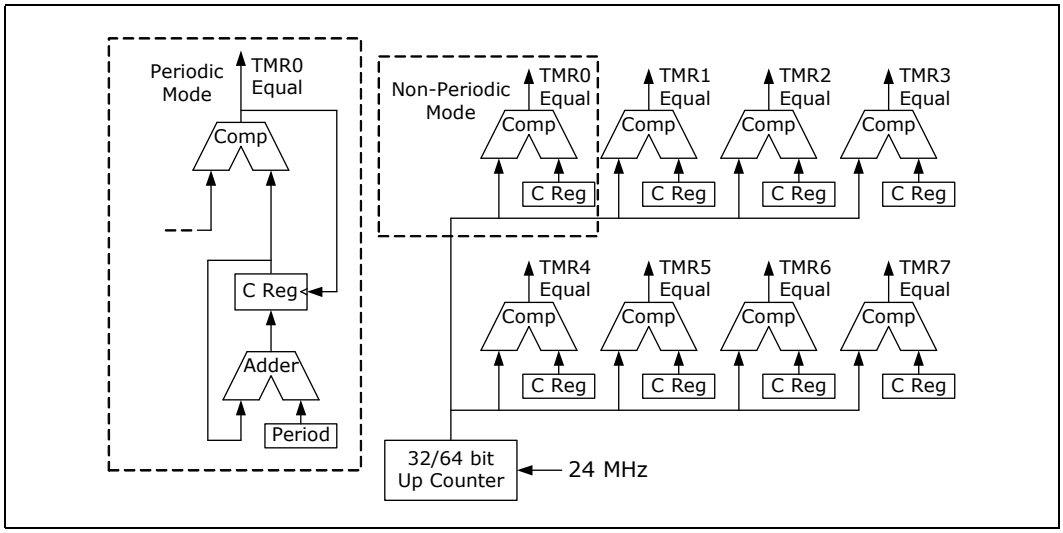
25.3 Architectural Overview

This function provides a set of timers that can be used by the operating system. The timers are defined such that the operating system may assign specific timers to be used directly by specific applications. Each timer can be configured to cause a separate interrupt.

The SoC provides eight timers. The timers are implemented as a single counter, and each timer has its own comparator and value register. The counter increases monotonically. Each individual timer can generate an interrupt when the value in its value register matches the value in the main counter. See Figure 25-2.

Timer 0 supports Periodic Interrupts.

Figure 25-2. HPET Counter and Timers



The registers associated with these timers are mapped to a range of fixed addresses in Host Root memory space. The UEFI IA Firmware (also known as BIOS) reports to the operating system the location of the register space via ACPI. The hardware can support an assignable decode space; however, UEFI IA Firmware sets this space to start at memory address 0xFED0_0000 prior to handing it over to the operating system. It is not expected that the operating system will move the location of these timers once it is set by UEFI IA Firmware.

25.3.1 Timer Accuracy

The timers are accurate over any 1-ms period to within 0.05% of the time specified in the timer resolution fields.

Within any 100-microsecond period, the timer reports a time that is up to two ticks too early or too late. Each tick is less than or equal to 100 ns; this represents an error of less than 0.2%.

The timer is monotonic. It does not return the same value on two consecutive reads unless the counter has rolled over and reached the same value.

The HPET main counter uses an internally-generated 24-MHz clock that is generated from the SoC 25-MHz crystal (ISCLK). The accuracy of the main counter is as accurate as the 25-MHz crystal that is used in the system. The HPET main counter increments in femtoseconds (10^{-15} seconds). The internal 24-MHz clock has a period of 41,666,667 femtoseconds.

Note: Since the SoC does not support the processor C11 power state, the 32-kHz RTC clock is not used by the HPET circuitry.

25.3.2 Timer Off-Load

The HPET Timer Off-Load feature is not available with the SoC.

25.3.3 Interrupt Mapping

The interrupts associated with the various timers have several interrupt-mapping options.

Software should mask interrupts prior to clearing the LEG_RT_CNF bit. When reprogramming the HPET interrupt routing scheme, the LEG_RT_CNF bit of the General Configuration (GEN_CFG) Register, a spurious interrupt may occur. This is because the other source of the interrupt (the SoC 8254 Timer) may be asserted.

25.3.3.1 Mapping Option #1 (Legacy Replacement Option)

In this case, the Legacy Replacement Rout (LEG_RT_CNF) bit of the General Configuration (GEN_CFG) Register is set. This forces the mapping found in Table 25-2.

Table 25-2. Legacy Replacement Routing

Timer	8259 Mapping	APIC Mapping	Comment
0	IRQ0	IRQ2	In this case, the 8254 Timer will not cause any interrupts
1	IRQ8	IRQ8	In this case, the RTC will not cause any interrupts.
2 and 3	Per IRQ Routing Field.	Per IRQ Routing Field	
4, 5, 6, 7	not available	not available	

Note: The Legacy Option does not preclude delivery of IRQ0/IRQ8 using processor interrupts messages.

25.3.3.2 Mapping Option #2 (Standard Option)

In this case, the Legacy Replacement Rout (LEG_RT_CNF) bit of the of the General Configuration (GEN_CFG) Register is 0. Each timer has its own routing control. The interrupts can be routed to various interrupts of the 8259 PIC or IOxAPIC. A capabilities field indicates which interrupts are valid options for routing. If a timer is set for edge-triggered mode, the timers should not be shared with any legacy interrupts.

For the SoC, the only supported interrupt values are as follows:

- Timer 0 and 1: IRQ20, 21, 22, and 23 (I/O APIC only).
- Timer 2: IRQ11 (8259 or I/O APIC) and IRQ20, 21, 22, and 23 (I/O APIC only).
- Timer 3: IRQ12 (8259 or I/O APIC) and IRQ 20, 21, 22, and 23 (I/O APIC only).

Note: Interrupts from Timers 4, 5, 6, and 7 can only be delivered using processor message interrupts.

25.3.3.3 Mapping Option #3 (Processor Message Option)

Here the interrupts are mapped directly to processor messages, also called FSB Interrupt Messages, without going to the 8259 PIC or IOxAPIC. To use this mode, the interrupt must be configured to edge-triggered mode. The TIMERn_FSB_EN_CNF bit of the Timer n Configuration and Capabilities (TMR0_CNF_CAP for example) Register must be set to enable this mode.

Software configures where the 32-bit message is written within memory-mapped space. Each of the eight timers has a 64-bit "Timer n FSB Interrupt Rout Register" (TMR0_FSB_INT_ROUT for example) for the 32-bit message address and the 32-bit message data.

Note: The processor message interrupt delivery option has HIGHER priority and is mutually exclusive to the standard interrupt delivery option. Thus, if the TIMERn_FSB_EN_CNF bit is set, the interrupts will be delivered directly to the processor, rather than by means of the APIC or 8259 PIC.

The processor message interrupt delivery can be used even when the legacy mapping is used.

25.3.4 Periodic Versus Non-Periodic Modes

25.3.4.1 Non-Periodic (One-Shot) Mode

This mode change can be thought of as creating a one-shot timer.

Timer 0 is configurable to 32- (default) or 64-bit mode, whereas Timers 1 through timer 7 only support 32-bit mode. All of the timers support Non-Periodic Mode. For details of this mode, see Section 2.3.9.2.1 of the *IA-PC HPET (High Precision Event Timers) Specification Revision 1.0a*.

Warning: Software must be careful when programming the comparator registers. If the value written to the register is not sufficiently far in the future, then the counter may pass the value before it reaches the register and the interrupt will be missed. The UEFI IA Firmware should pass a data structure to the operating system to indicate that the operating system should not attempt to program the periodic timer to a rate faster than 5 microseconds.

25.3.4.2 Periodic Mode

Timer 0 is the only timer that supports Periodic Mode. For details of this mode, see Section 2.3.9.2.2 of the *IA-PC HPET (High Precision Event Timers) Specification Revision 1.0a*.

If the software resets the main counter, the value in the comparator's value register needs to reset as well. This can be done by setting TIMER0_VAL_SET_CNF, bit 6 of the Timer 0 Configuration and Capabilities (TMR0_CNF_CAP) Register. Again, to avoid race conditions, this should be done with the main counter halted. The following usage model is expected:

1. Software clears the ENABLE_CNF, bit 0 of the General Configuration (GEN_CFG) Register, to prevent any interrupts.
2. Software Clears the main counter by writing a value of 00h to it.
3. Software sets the TIMER0_VAL_SET_CNF bit.
4. Software writes the new value in the TIMER0_COMPARATOR_VAL register.
5. Software sets the ENABLE_CNF bit to enable interrupts.

The Timer 0 Comparator Value register cannot be programmed reliably by a single 64-bit write in a 32-bit environment, except if only the periodic rate is being changed during run-time. If the actual Timer 0 Comparator Value needs to be reinitialized, then the following software solution will always work, regardless of the environment:

1. Set TIMER0_VAL_SET_CNF bit.
2. Set the lower 32 bits of the Timer0 Comparator Value register.
3. Set TIMER0_VAL_SET_CNF bit.
4. Set the upper 32 bits of the Timer0 Comparator Value register.

25.3.5 Enabling the Timers

The UEFI IA Firmware or operating system Plug and Play (PnP) code should route the interrupts. This includes the Legacy Replacement Rout bit, Interrupt Rout bit (for each timer), and interrupt type (to select the edge or level type for each timer).

The Device Driver code should do the following for an available timer:

1. Set the Overall Enable bit (ENABLE_CNF), bit 0 of the General Configuration (GEN_CFG) Register.

If Timer 0 is being set up, program the Timer 0 Type field, bit 3 of the Timer 0 Configuration and Capabilities (TMR0_CNF_CAP) Register, to either Periodic Mode or Non-Periodic Mode.

2. Set the interrupt enable.
3. Set the comparator value.

25.3.6 Interrupt Levels

Interrupts directed to the internal 8259 PIC are active high. See Chapter 21, "PIC and I/O APIC Controllers" for information regarding the programming the polarity of 8259 PIC for detecting internal interrupts.

If the interrupts are mapped to the 8259 or I/O APIC and set for level-triggered mode, they can be shared with legacy interrupts. They may be shared although it is unlikely for the operating system to attempt to do this.

If more than one timer is configured to share the same IRQ using the TIMERn_INT_ROUT_CNF fields of the Timer n Configuration and Capabilities (TMR0_CNF_CAP for example) Register, then the software must configure the timers to level- triggered mode. Edge-triggered interrupts cannot be shared.

25.3.7 Handling Interrupts

Section 2.4.6 of the *IA-PC HPET (High Precision Event Timers) Specification Revision 1.0a* describes handling interrupts.

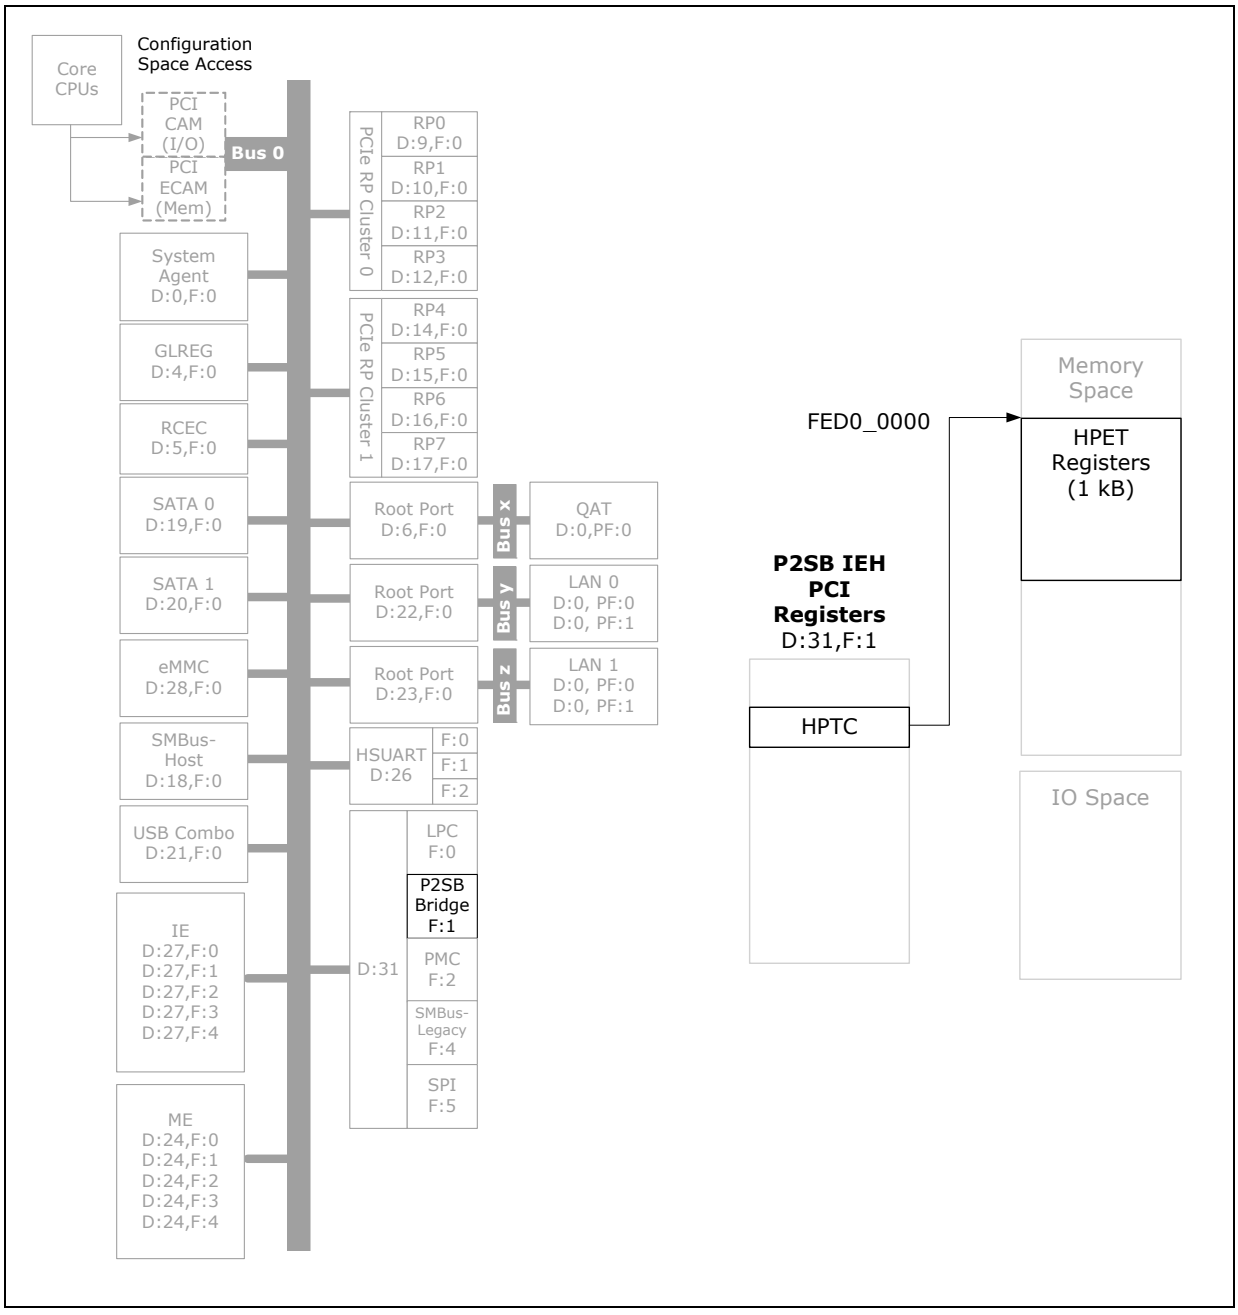
25.3.8 Issues Related to 64-Bit Timers with 32-Bit Processors

Section 2.4.7 of the *IA-PC HPET (High Precision Event Timers) Specification Revision 1.0a* describes issues related to 64-Bit timers with 32-Bit processors.

25.4 Register Map

Figure 25-3 shows the associated registers from a system software viewpoint.

Figure 25-3. Register Map



25.4.1 Memory-Mapped Registers

Note: The base memory address for the HPET registers is determined by the High Performance Event Timer Configuration (HPTC) register in configuration space at offset 60h of the P2SB Bridge (Bus 0, Device 31, Function 1). See Figure 25-3. Even though UEFI IA Firmware can configure the HPET timers to be located at one of four locations in memory space, only the location starting with 0xFED0_0000 is validated by Intel. The other three memory locations are not documented in this document.

Table 25-3. Fixed-Address Memory-Mapped Registers (Sheet 1 of 2)

Fixed Address in Memory Space	64-bit Register Short Name	64-bit Register Long Name
0xFED00000	GEN_CAP_ID	General Capabilities and ID Register
0xFED00008	*Reserved*	*Reserved*
0xFED00010	GEN_CFG	General Configuration Register

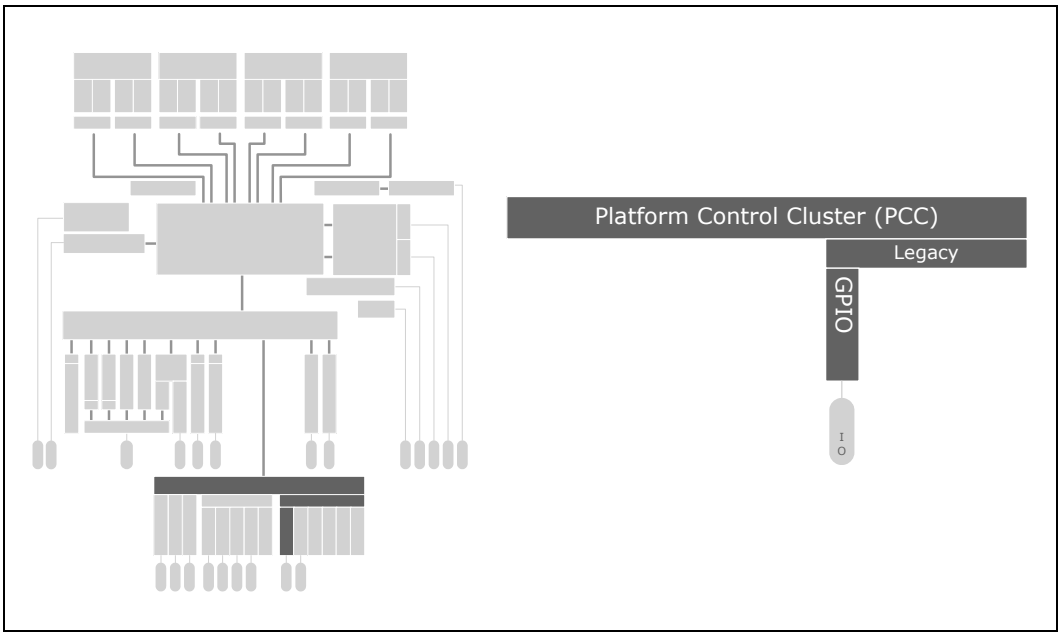
§ §

26 Customer General-Purpose I/O (GPIO)

A number of SoC signal pins have shared, native functions. These signals are called Configurable Flexible I/O (CFIO) signals. If the default setting is not needed for the customer board design, one of the other shared, native signals can be configured for the pin. The silicon pad connected to each CFIO signal pin contains a signal selector (also called MUX) that can be programmed. Of the SoC CFIO signal pins, the SoC provides 147 General-Purpose I/O (GPIO) signals that can be used by the SoC customer. These special CFIO signals are called Customer GPIOs. For example, the GPIO125 default function mode is eMMC clock. See details in Table 39-1, "Signal Pin Name Directory - Sorted by Name" on page 995.

- GPIO registers are accessible by the Host or IE through their MMIO space, using the P2SB (Primary to Sideband Bridge) (B:0 D:31 F:1) SBREG contents as the base address.
- NMI and SMI are capable only on selected GPIOs.
- SCI (GPE) and IOxAPIC interrupt are capable on all GPIOs.
- The Intel® ME assigns ownership of individual GPIO pads. The Intel® ME assigns ownership of individual GPIO pads to the HOST or IE or Intel® ME.
- Legacy I/O space control of GPIOs is not supported

Figure 26-1. What is Covered in This Chapter



26.1 GPIO Ball and Signal Names

The term "pad" is used in the register descriptions of the SoC. The pad is located on the SoC silicon. The signal is wired to a pin (a.k.a., ball) on the product package. The SoC pad control registers refer to the silicon pads, but in essence they apply to the signal at the pin. This chapter uses "pad" and "pin" interchangeably.

Table 26-1, "GPIO Ball and Pad Name" shows GPIO ball mapping to the signal names. The table is an extension to Table 39-1, "Signal Pin Name Directory - Sorted by Name" on page 995.

152	CA37	GPIO[152]	

Note: There are four types of 1.05V pads:
- DFX Set1 pads
- DFX Set2 pads
- SVID pads
- Thermal Management (TM) pads

The 1.05V pads have different buffer impedance ranges.

26.2 Pad Description

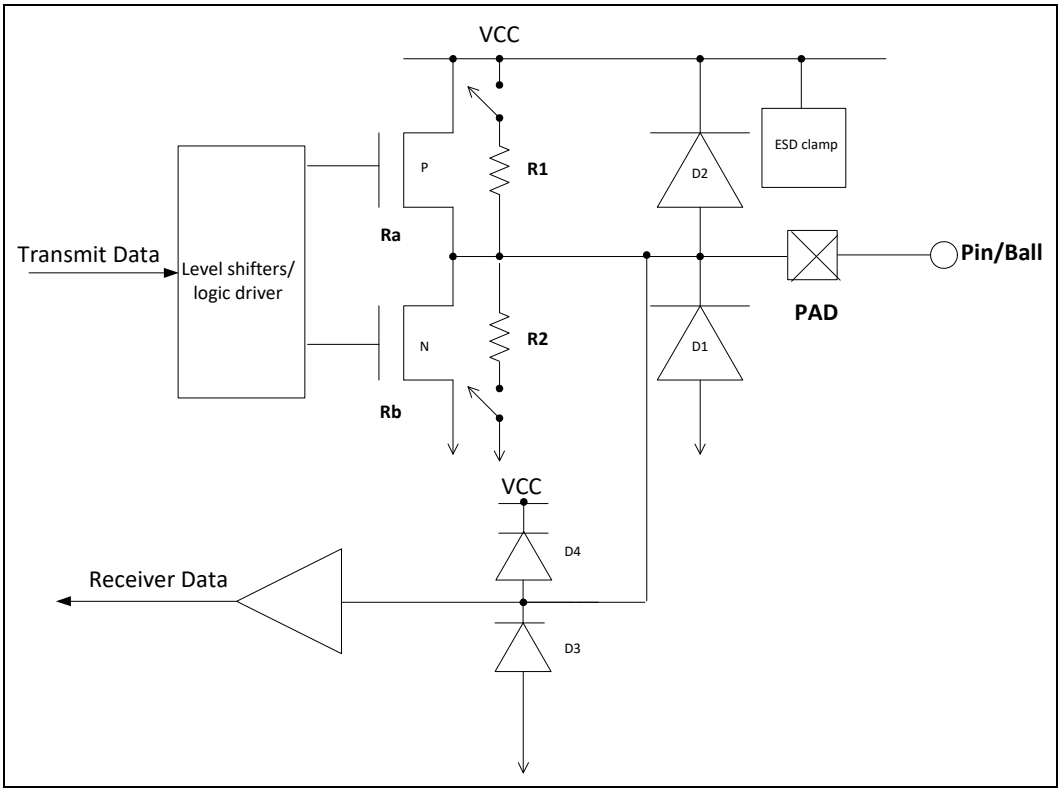
When the signal function is a native function signal (not a GPIO function) the signal is set by the SoC at reset time to be default values. Later on, once BIOS starts, the BIOS can keep all the defaults or alter settings, and then lock all of the configuration registers to be RO (Read Only).

When the signal function is a GPIO mode, the shared-signal pad circuitry contains specific, internal controls including individual pin signal multiplexing, pull-up/pull-down values, pin states and output buffer type (e.g., open drain). See Figure 26-2 for internal pad circuitry. Not all GPIO modes support the pull-up, pull-down options (R1 and R2) shown in Figure 26-2.

See the PAD_CFG_DW1 register configuration options for each GPIO for details of what is supported.

Some of the shared pads are also hard pin straps and have additional pull-up/pull-down circuitry. See Section 4.1, "SoC Hard (Pin) Straps" on page 193.

Figure 26-2. Custom GPIO Circuit Definition



Note: The internal pull-up resistor option is not supported for 1.8V GPIOs. The internal pull-down resistor option is not supported for 3.3V GPIOs.

The interface power source (VCC) for each pad is fixed and can be one of the three voltage levels (1.05V, 1.8V, or 3.3V).

26.3 Signal Configuration Overview

Other than the signal pins mentioned in Chapter 10, "Flexible I/O Adapter (FIA) Overview", the SoC contains signal pins that are shared by more than one native function. They can also be programmed to be Customer GPIO signals.

All 152 of these pins power-up in the high-impedance state and remain in that state until the internal reset for the pin circuitry deasserts. The pins are reset to the default state during a Warm Reset or a Cold Reset (See Chapter 33, "Resets and Voltage Sequencing"). The shared-signal pins that default as output signals are designed to be glitch-free during power-up and reset. For shared-signal pins that by default are Customer GPIO input pins, an external pull-up or pull-down resistor must be used to keep the SoC receiver from triggering an interrupt or event during the internal reset and when the reset is de-asserted.

In many cases, the customer platform design requires an SoC native signal that shares a pin with other SoC native signals. If the desired signal has a Function number that is not the one designated as "Default" in the "Pin States" column of Table 39-1, "Signal Pin Name Directory - Sorted by Name" on page 995, the Pad Mode [2:0] bit field of the pin Pad Configuration DW0 control register (PAD_CFG_DW0) can be programmed to alter the Function number to the desired signal.

If none of the shared SoC native signals are needed by the platform, the customer can set the PAD_CFG_DW0 to Function = 0 (Pad Mode [2:0] = 000), which is always a "Customer GPIO" function.

For pins, the PAD_CFG_DW0 control register and the Pad Configuration DW1 control register (PAD_CFG_DW1), contain bit fields that are customer programmable; used to create the desired signal driver, receiver, and internal pull-up or pull-down termination. Some Customer GPIOs generate interrupts and trigger events.

26.3.1 Pad Ownership

The Pad Ownership registers designate whether the Host, Intel® ME, or IE has control of the pad. The Pad Ownership Register (PAD_OWN) uses a two bit code to indicate the ownership of pad.

00 = Host GPIO Mode
01 = Intel® ME GPIO Mode
10 = Reserved
11 = IE GPIO Mode

When a Customer GPIO is programmed to generate an interrupt to the PIC or IOxAPIC, the GPIO Host Mode is also set to either Host GPIO ACPI Mode or GPIO Driver Mode. This is indicated by the Host Software Pad Ownership (HOSTSW_OWN) Register 1-bit code.

0 = GPIO ACPI Mode
1 = GPIO Driver Mode

Note:

1. All detail description about the Pad in this chapter is focused on Host GPIO Mode.
2. When the Pad is set as ME GPIO Mode, Intel® ME owns the Pad and controls the Pad. No customization is doable from the customer point of view.
3. When the Pad is set as IE GPIO Mode, the IE owns the Pad.

The BIOS default code does not allow all GPIOs to be reassigned to an IE. Most pins have a native function that prevents assignment to IE as a true GPIO. Please see Table 26-2 for details.

Table 26-2. Pin Name Descriptions

Pin Name	Usage Description
GPIO[3]	No native functions assigned; pure GPIO only
GPIO[5], GPIO[6], GPIO[7]	Native functions all belong to IE; IE can tradeoff internal features vs pure GPIO
SMB4_CSME0_DATA, SMB4_CSME0_CLK	Native functions shared by IE and ME; can tradeoff their relative features vs pure GPIO
PCIE_CLKREQ0_N, PCIE_CLKREQ1_N, PCIE_CLKREQ2_N, PCIE_CLKREQ3_N	Native functions shared with PCIe CLKREQ—can allocate some for IE GPIO if platform doesn't require so many CLKREQ
GPIO[10], GPIO[11]	Available
GPIO[12]	Available if not using TPM
GPIO[0], GPIO[1], GPIO[2], GPIO[4], GPIO[8], GPIO[9]	Can be GPIO by IE by turning off the features

Note: For ME recovery mode, SPS FW is able to use any SoC GPIO pin to configure Recover_Jumper mode by using Intel SPS Flash Image Tool (spsFITc.exe). For guidance of configuration, please refer to Tools for Intel Server Platform Service Firmware 4.0 User Guide in SPS release package.

26.3.2 Pad Multiplex Function

The Pad is set as GPIO mode (GPIO ACPI Mode / GPIO Driver Mode) or native function mode, through the Pad Configuration DW0 (PAD_CFG_DW0) register bit [12:10] (Pad Mode).

- 000 = GPIO Controller controls the Pad
- 001 = Native Function 1
- 010 = Native Function 2
- 011 = Native Function 3
- 100 = Native Function 4
- ...through
- 111 = Native Function 7

When the PAD is dedicated GPIO only, the PAD_CFG-DW0 bit [12:10] is all 000.

When the Pad Mode (PMode) is 0, the GPIO controller has the ability to control the RX/TX Disable and RX/TX State through the PAD_CFG_DW0 register bit [9:8] (GPIO RX/TX Disable) and bit[1:0] (GPIO RX/TX State). The pad is either an input or an output signal with different configurations.

When the PMode is not equal to 0, the corresponding GPIO works as the native function mode. The default value of the Pad Mode (PMode) field, also called the signal function value, is assigned when the SoC is reset.

26.3.3 Pad Internal Pull-up / Pull-down Configure

The pad has internal weak pull up/down termination which is controlled by register PAD_CFG_DW1 bit [13:10] (TERM). It is expected software/FW/BIOS shall program the termination settings appropriately. Some common sequences are:

1. Termination settings must be programmed before changing a pad from output to input to avoid the pad state “floating” momentarily.
2. If a given pad is configured as an output, termination must be enabled until the TXDATA is driven properly, to avoid pad state “floating”. This means the TX enable configuration has to be enabled in order to enable the TX buffer before termination is released.

26.3.4 Pad Configuration Logical Control Summary

The pad is configured as an input signal or an output signal, including an open drain output signal. When the signal is set as a Customer GPIO function Table 26-3 through Table 26-5 show how to configure the signal to be input or output.

Figure 26-3. GPIO Logic Overview Diagram

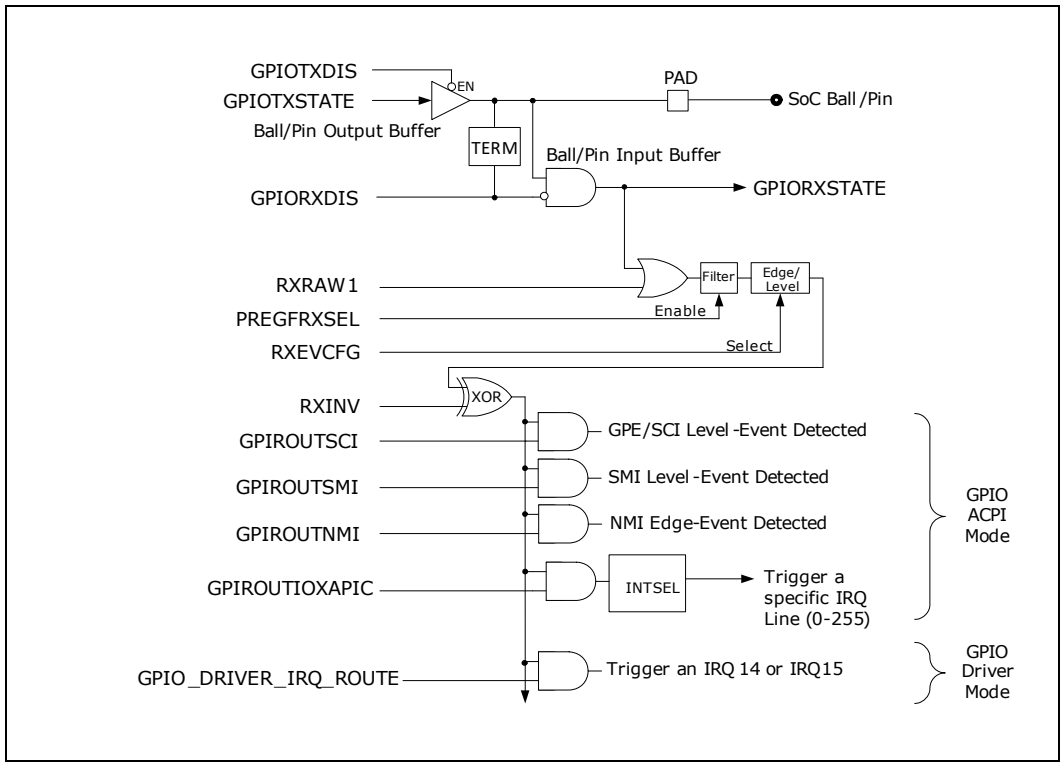


Table 26-3. Input Signal Configuration

Pad	GPIORXDIS	GPIOTXDIS	TERM	GPIORXSTATE	GPIOTXSTATE
0	0	1	0000	0	X
1	0	1	0000	1	X

Table 26-4. Output Signal Configuration

Pad	GPIORXDIS	GPIOTXDIS	TERM	GPIORXSTATE	GPIOTXSTATE
0*	1	0	0000	0	0
1*	1	0	0000	0	1
Hi-Z*	1	1	0000	0	0
Hi-Z	1	0	0000	0	0
0	1	1	0010/0100	0	0
1	1	1	1010/1100	0	0
* Open Drain Output Signal Configuration.					

26.3.5 Non-Maskable Interrupt (NMI)

When a Customer GPIO is customer-configured to be an input, an NMI can be generated by following programming steps:

1. Set Host Ownership - PAD_OWN[1:0] = '00'.
2. Set GPIO ACPI Mode - HOSTSW_OWN = '0'.
3. Set GPIO Input Mode – PAD_CFG_DW0 [12:10] = '000'.
4. NMI Routing enabling - PAD_CFG_DW0 bit [17] (GPIRoutNMI) = '1'.
5. GPI NMI Enable - GPI_NMI_EN = '1'.
6. GPI NMI Status - GPI_NMI_STS= '1'.

Note: Some GPIO signals do not support NMI. Please see detail in Table 26-5, "GPIO Pad Configuration Description".

26.3.6 System Management Interrupt (SMI)

When a Customer GPIO is customer-configured to be an input, an SMI can be generated by following programming steps:

1. Set Host Ownership - PAD_OWN[1:0]= '00'.
2. Set GPIO ACPI Mode - HOSTSW_OWN = '0'.
3. Set GPIO Input Mode – PAD_CFG_DW0 [12:10] = '000'.
4. SMI Routing enabling - PAD_CFG_DW0 bit [18] (GPIRoutSMI) = '1'.
5. GPI SMI Enable - GPI_SMI_EN = '1'.
6. GPI SMI Status - GPI_SMI_STS= '1'.

Note: Some GPIO signals do not support SMI. Please see detail in Table 26-5, "GPIO Pad Configuration Description".

26.3.7 System Control Interrupt (SCI)/General Purpose Event (GPE)

When a Customer GPIO is customer-configured to be an input, an SCI can be generated by following programming steps:

1. Set Host Ownership - PAD_OWN[1:0]= '00'.
2. Set GPIO ACPI Mode - HOSTSW_OWN = '0'.
3. Set GPIO Input Mode – PAD_CFG_DW0 [12:10] = '000'.
4. SCI/GPE Routing enabling - PAD_CFG_ DW0 bit [19] (GPIRoutSCI) = '1'.
5. GPI General Purpose Events Enable - GPI_GPE_EN = '1'.
6. GPI General Purpose Events Status - GPI_GPE_STS = '1'.

26.3.8 GPIO to IOxAPIC

When a Customer GPIO is customer-configured to be an input, a GPIO can directly send an interrupt to the IOxAPIC by following programming steps:

1. Set Host Ownership - PAD_OWN[1:0]= '00'.
2. Set GPIO ACPI Mode - HOSTSW_OWN = '0'.
3. Set GPIO Input Mode – PAD_CFG_DW0 [12:10] = '000'.
4. IOxAPIC Routing enabling - PAD_CFG_DW0 bit [20] (GPIRoutIOxAPIC) = '1'.
5. Specific IRQ Line Enable - PAD_CFG_DW1 bits [6:0] Interrupt Select (IntSel) = '0-119'.

Note: Each GPIO signal has a fixed Interrupt line. Please see detail in Table 27-8.

26.3.9 Legacy Interrupt Request (IRQ)

When a Customer GPIO is customer-configured to be an input, a Legacy IRQ can be generated by following programming steps:

1. Set Host Ownership - PAD_OWN[1:0]= '00'.
2. Set GPIO Driver Mode - HOSTSW_OWN = '1'.
3. Set GPIO Input Mode – PAD_CFG_DW0 [12:10] = '000'.
4. Miscellaneous Configuration Register - MISCCFG bit [3] (GPIO_DRIVER_IRQ_ROUTE) = '0' (IRQ14) or '1' (IRQ15).
5. GPI Interrupt Enable - GPI_INT_EN = '1'.
6. GPI Interrupt Status - GPI_INT_STS= '1'.

26.3.10 Pad Level/Edge Sensitive Detect Enable

The interrupt or wake triggering event for the input Customer GPIO are delivered to the GPIO controller as either Edge detected or Level detected by following program steps:

1. Set Host Ownership - PAD_OWN[1:0]= '00'.
2. Set GPIO Mode based on interrupt type.
3. Set GPIO Input Mode – PAD_CFG_DW0 [12:10] = '000'.
4. Select the polarity inversion stage - PAD_CFG_DW0 bit [23] (RXINV)
5. Enable RX Level/Edge configuration - PAD_CFG_DW0 two bits [26:25] (RXEVCFG).

The default uses Edge detection logic with no inversion.

26.4 Registers Lock Down

The intended use for the pad Configuration Lock (PADCFGLOCK), is for BIOS to lock down the registers related to the pad configuration. This is one-bit-per-pad to unlock/lock certain pad specific fields. After locking, the specific fields become Read-Only. BIOS can unlock PADCFGLOCK by sending opcode 0x13 to the individual GPIO community.

When PADCFGLOCK is written from "1" to "0" (unlock), a synchronous SMI# is generated when enabled. When the unlock is enabled, it cannot be disabled until PMU_PLRTST_N happens. This ensures that only the SMM code changes the register field settings after they are locked.

This configuration is meaningful and affects only the pad owned by the host - PAD_OWN[1:0]= '00'.

26.5 MMIO Address Access

All GPIO registers must be accessed through the Memory Mapped I/O (MMIO) space with the address offsets to SBREG_BAR (B:0 D:31 F:1).

The pad Control Register and Group Register field names identify the specific GPIO by its Pin Name as shown in Table 39-1, "Signal Pin Name Directory - Sorted by Name" on page 995. The Pin Name is used as the suffix of the register name. For example, the register PAD_CFG_DW0_GPIO_0 and the bit PAD_OWN_GPIO_0 for the pin named "*_GPIO_0" has part of the register name.

Note: The register name with the suffix shown in Table 26-5 is used by BIOS/FW for code development/register programming. Some register names have a different suffix name than the name of the pin. These are noted in Table 26-5.

Table 26-5. GPIO Pad Configuration Description (Sheet 1 of 5)

GPIO	Suffix of Pad Register Name	Pad Configuration DW0 Offset (hex)	Pad Configuration DW1 Offset (hex)	SMI/NMI Capability	IOxAPIC Interrupt INTSEL (hex)	Comment
14	*_GBE0_SDP0	C2_0400	C2_0404		18	1

1. The Ball/Pin Name is not same as the suffix of the pad's register name.
2. Until RSMRST_N de-asserts these signals are indeterminate.

For GPIO registers access, there are two ways. One way is using P2SB to access GPIO registers. Another way is to reach GPIO by PMC through Sideband.

The GPIO controllers have 7 Dwords of GPE status and enable registers (NORTH_ALL_1/0 and SOURTH_DFX/GROUP0/1). But PMC exposes only 3 Dwords to SW. So BIOS must choose which 3 of the 7 to make visible.

Programming steps:

1. BIOS programs GPIO_CFG.GPE0_DW0, GPE0_DW1, GPE0_DW2 with the 3 GPIO groups to make visible. There are now 96 GPE available:
   - GPE[31:0] → GPIO selected by GPE0_DW0
   - GPE[63:32] → GPIO selected by GPE0_DW1
   - GPE[95:64] → GPIO selected by GPE0_DW2

2. BIOS enables GPE within the 96 available by writing to PMC. PMC forwards the writes to the GPIO based on mapping in 1)
   - Program GPE0_EN_31_0 → GPIO selected by GPE0_DW0
   - Program GPE0_EN_63_32 → GPIO selected by GPE0_DW1
   - Program GPE0_EN_95_64 → GPIO selected by GPE0_DW2

3. BIOS checks GPE status within the 96 available by reading from PMC. PMC forwards the reads to the GPIO based on mapping in 1)
   - Read I/O 0x80 → GPIO selected by GPE0_DW0
   - Read I/O 0x84 → GPIO selected by GPE0_DW1
   - Read I/O 0x88 → GPIO selected by GPE0_DW2

§ §

27 System Management Bus (SMBus) Controller - Overview

The SoC provides multiple System Management Bus (SMBus) 2.0 controllers. The interfaces comply to *System Management Bus (SMBus) Specification, Version 3.0*. The controllers provide a mechanism for various system components [SoC, Baseboard Management Controller (BMC), etc.] to communicate with each other and with the entire system. The SoC is also capable of operating in a mode that communicates with I^2C*-compatible devices.

Note: There are only seven sets of SMBus pins so a maximum of seven SMBus controllers maybe active.

The SoC includes the following SMBus controllers:

- Legacy SMBus (wire ORed with CLTT SMBus):
  - IA cores use the master/slave legacy interface to communicate with managed devices in the system.
  - The BIOS uses this interface to detect and configure memory devices.
- Host SMBus:
  - IA cores use this master/slave interface to enable the SoC to send/receive out-of-band messages over the SMBus to peripherals. The controller operation is DMA-based and utilizes descriptors to initiate transactions on the bus.
- Platform Environment Control Interface (PECI) SMBus:
  - A slave only interface which enables external management devices (BMC) to obtain system information like thermal data through PECI commands encapsulated within SMBus packets to the SoC.
- Three Intel® Management Engine (Intel® ME) SMBuses:
  - The Intel® ME SMBus Message Transport (SMT) controllers are configured as a master or slave for internal agents inside the SoC to communicate to the external management devices [BMC/External Circuitry (EC)] over SMBus.
  - The silicon-enabling firmware and Intel® Node Manager (Intel® NM) of the Intel® Server Platform Services (SPS) firmware defines the SMT interface configuration and connection.
- LAN SMBus:
  - This master/slave sideband interface provides a mechanism for the network management traffic to be routed to and from a management controller (BMC). The SMBus in each LAN controller is wire-ANDed in silicon.
- Three Innovation Engine (IE) SMBuses:
  - IE uses master/slave interfaces to communicate with devices in the system.

System Management Bus (SMBus) Specification, Version 3.0	http://smbus.org/specs/SMBus_3_0_20141220.pdf

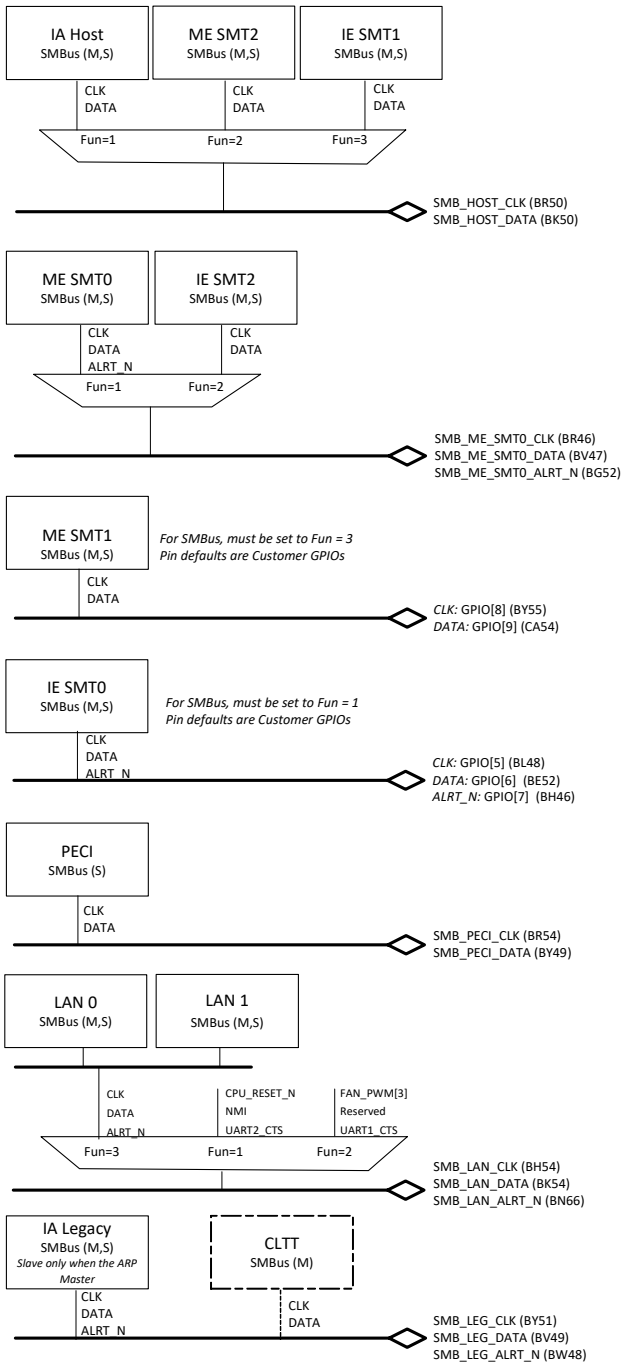
27.1 General Architecture

At its network layer, the *System Management Bus (SMBus) Specification, Version 3.0* refers to three types of devices:

- **Slave Device** - A device that is receiving or responding to a command.
- **Master** - A device that issues commands, generates the clocks, and terminates the transfer.
- **Host** - A specialized master that provides the main interface to the system CPU. A host must be a master-slave and must support the SMBus host notify protocol. At most, one host exists in a system.

Figure 27-1 shows the overall SMBus arrangement in the SoC, M = Master, S = Slave.

Figure 27-1. Arrangement of SMBus in SoC



Note: If software running on the IA uses the legacy SMBus (SMBus master), then there are multiple masters active. When multiple master are active on the same bus, software using the legacy SMBus controller must check for Bus Error (BERR) in the Status register (HSTS) to determine if a bus collision has occurred, and retry the transaction if needed.

27.2 Feature List

The following are key features of the various controllers:

- Legacy SMBus:
  - Serial interface providing a mechanism for the processor to initiate communications with the SMBus peripherals
  - Access initiated through registers in Host Root Memory Space and Host Root I/O Space.
  - The Memory Reference Code (MRC) uses this bus to detect and configure the DIMMs
  - Closed loop thermal throttling (CLTT) which requires the controller to act as a bus master to monitor DIMM temperature (Refer Chapter 35, "Thermal Management")
  - Chapter 28, "SMBus Controller - Legacy"
- Host SMBus:
  - Operates as an SMBus master or slave
  - Supports Address Resolution Protocol (ARP) in master or slave mode
  - Access initiated through the descriptors
  - OS controlled to communicate with any platform device
  - Packet Error Checking (PEC) is enabled for SMBus transactions
  - Chapter 29, "SMBus Controller - Host"
- PECI SMBus:
  - Supports external BMC
  - Operates in slave mode only
  - Supports one command at a time
  - Chapter 30, "SMBus Controller - Platform Environment Control Interface"
- Intel® ME SMBuses:
  - Sends Out-Of-Band (OOB) manageability messages to managed devices or management controllers
  - SMT controllers operate with full master and slave interfaces
  - Supports Management Component Transport Protocol (MCTP) and Alert Standard Format (ASF) usage models
  - Interrupt generation capability for SMBAlert# signaling received from External SMBus device
  - Chapter 36, "System Management"

- LAN SMBus:
  - Pass-through and/or configuration traffic between an external Manageability Controller (MC) and Integrated Ethernet LAN ports
  - Operates as master or slave
  - Supports MCTP over SMBus
  - Supports ARP
  - Interface pins MUXed with the Network Controller Sideband Interface (NC-SI).
  - Chapter 13, “LAN Controllers”
- IE SMBuses:
  - BMC offload engine to access PECI services
  - Operates as master or slave
  - Chapter 37, “Innovation Engine”

§ §

28 SMBus Controller - Legacy

The SMBus controller described in this chapter is located in the Platform Control Cluster (PCC) of the SoC. In SoC diagrams, it is labeled Legacy SMBus.

The controller provides a mechanism for the processor to initiate communications with SMBus peripherals (slaves). The SoC is also capable of operating in a mode that communicates with I^2C-compatible devices.

The SoC performs SMBus messages with Packet Error Checking (PEC) enabled or disabled. The actual PEC calculation and checking are performed in either the hardware or the software.

The SMBus Address Resolution Protocol (ARP) is supported by using the existing SMBus controller commands through the software. The controller can be the designated SMBus ARP Master.

This SMBus interface is shared with the Closed Loop Temperature Throttling (CLTT) circuitry to allow the CLTT to access the thermal information, if available, through the system memory DIMMs' Temperature Sensor On DIMM (TSOD) circuitry. See Section 35.5.1.5, "Legacy SMBus Used for Accessing Information for CLTT."

Document Title	Document ID / Location
System Management Bus (SMBus) Specification, Version 3.0	http://smbus.org/specs/SMBus_3_0_20141220.pdf

28.1 Signal Descriptions

The signal descriptions are shown in Table 28-2, "Signal Names." For additional signal information, including whether a signal is assigned to shared-function pin or can be used as a Customer GPIO signals, see Section 39.1, "Directory of Signal Names and Pin Names." The Direction/Type column of Table 28-2, "Signal Names" is interpreted as follows:

- I = Input signal. The SoC has receiver circuit.
- O-OD = Open-Drain Output. SoC output circuit uses an open-drain driver.

Table 28-2. Signal Names

Signal Name	Direction	Shared	Description
SMB_LEG_CLK	I, O-OD	Yes	**SMBus Clock (SMBCLK)**
SMB_LEG_DATA	I, O-OD	Yes	**SMBus Data (SMBDAT)**
SMB_LEG_ALRT_N	I, O-OD	Yes	**SMBus Alert (SMBALERT#):** This signal wakes the system or generates a System Management Interrupt (SMI).

The optional SMBus 2.0 signal, SMBSUS#, is not supported.

28.2 General Architecture

From a software driver perspective, the Legacy SMBus controller described in this chapter exists as a PCI device on Bus 0, Device 31 (decimal), Function 4 of configuration space. Its logic is controlled by the SoC RTC Clock. The controller's I/O registers are relocatable. The I/O base address registers are:

- SBA - SoC Host I/O Space
- SMBMBAR - SoC Host Memory Space

The registers and offsets are the same for SBA access and SMBAR access.

Key capabilities supported and not supported by the SoC Legacy SMBus controller:

- It is not supported as an SMBus Slave except when it is acting as the SMBus ARP Master. It functions as an SMBus Master as defined in the *System Management Bus (SMBus) Specification, Version 3.0*.
- Acting as the SMBus Host is not supported.

  As defined by the *System Management Bus (SMBus) Specification, Version 3.0*, an SMBus Host is a specialized SMBus Master that provides the main interface to the system's CPU. An SMBus Host must be an SMBus Master-Slave and must support the SMBus Host Notify protocol. There may be at most one SMBus Host in a system.
- Can be designated as the SMBus Address Resolution Protocol (ARP) Master.

  A system design usually defines the SMBus Host (defined above) to be the SMBus ARP Master but under some circumstances another SMBus Master, like the SoC Legacy SMBus controller, may be given the role by system software. There can only be one active SMBus ARP Master at any time.
- Functions as an SMBus version 2.0 Master or ARP Master device when the I2C_EN (I2CEN) bit of the Host Configuration (HCFG) register is 0.
- Functions as an I^2C Master when the I2CEN bit is 1. Not all protocols are supported when I2CEN is 1. The protocol descriptions in this chapter describe what is supported. When the I2CEN bit is set, the SoC never uses its 32-byte buffer for any block commands.
  - The SoC supports an I^2C Read command which is independent of the setting of the I2CEN bit.

28.3 Legacy SMBus Controller Operation

In order to initiate an SMBus operation as an SMBus Master, software sets up the registers of the SoC Legacy SMBus controller with a Slave Address (to which the operation is directed), a command to issue to the addressed Slave, and for write protocols, data to be sent to the Slave and an optional Packet Error Checking (PEC) bits. For read protocols, there is a designated SoC register for the data received from the Slave. The following registers are involved:

- Transmit Slave Address Register (TSA) - TSA bit field 7:1 is the seven-bit Slave address to be used of the targeted SMBus Slave. TSA bit 0 is 0 for write (to Slave) and 1 for read (from Slave). Transactions with TSA[7:0] values of 1010_xxx0 are blocked if the SPD Write Disable (SPDWD) bit = 1 in the Host Configuration (HCFG) register in Configuration Space. SPDWD prevents writing into the DIMM's SPD EEPROM.
- Host Command Register (HCMD) - Contains the eight-bit information to use as the transaction's SMBus command field. "Host" has nothing to do with the term "SMBus Host" mentioned earlier.
- Data 0 Register (HD0), Data 1 Register (HD1), and Host Block Data (HBD) - Used for the data transfer cycles of the particular protocol transaction.

Software then initiates the hardware operation by writing to the Start bit of the Host Control (HCTL) register. While the hardware executes the HCMD command, it sets the Host Busy (HBSY) bit of the Host Status Register Address (HSTS).

When completed, the hardware generates an interrupt or SMI to notify the software to access the HSTS register to view the status and error bits. If the command completed successfully, the Interrupt (INTR) bit of the HSTS register is set. Software must not alter the TSA, HCMD, HD0, HD1 and HBDregisters, until the INTR bit is set.

If the Slave device does not respond with an SMBus Acknowledge (ACK), or holds the SMBus Clock (SMB_LEG_CLK SoC signal pin) lower than the allowed timeout (25 ms which is 800 RTC clock cycles) the transaction times out. Here the hardware discards the cycle and the Device Error (DEVERR) bit is set. If the software sets the Kill (KILL) bit of the Host Control (HCTL) register is set by software while the command is running, the transaction stops and the Failed (FAIL) bit of the HSTS register is set.

The SoC Legacy SMBus controller uses PIRQB# as its interrupt pin. However, the system can alternatively be setup to generate an internal SMI# instead of an IRQ interrupt, by setting the SMB_SMI_EN (SSEN) bit of the HCFG register. More is said about this in Section 28.8, "Interrupts and SMI." Also see Section 8.1.1, "Interrupt Pin Route Overview" for PIRQB# routing. The SoC SMI is described in Section 8.3, "System Management Interrupt (SMI)."

28.3.1 Supported SMBus Protocols

The Legacy SMBus controller supports the SMBus protocols and I^2C transactions shown in Table 28-3, "Supported SMBus ARP, SMBus, and I^2C Protocols." For details of the bus cycles for each protocol, see the *System Management Bus (SMBus) Specification, Version 3.0*.

Table 28-3. Supported SMBus ARP, SMBus, and I²C Protocols

Protocol	Supported	
SMBus ARP Commands	**Sent as ARP Master**	**Received as ARP Slave**
Prepare to ARP	Yes, by Software Driver	Cannot be an SMBus slave
Reset Device *General and directed*		
Get UDID *General and directed*		
Assign Address		
SMBus ARP Commands	**Sent as ARP Slave**	**Received as ARP Master**
Notify ARP Master	Cannot be an SMBus slave	Yes
SMBus Commands	**Sent as Master**	**Received as Slave**
Quick Command	Yes	Cannot be an SMBus slave
Send Byte	Yes	
Receive Byte	Yes	
Write Byte/Word	Yes	
Read Byte/Word	Yes	
Process Call	Yes	
Block Write	Yes	
Block Read	Yes	
Block Write-Block Read Process Call	Yes	
SMBus Host Notify	Yes	
I²C Commands	**Sent as Master**	**Received as Slave**
Master-TX writes to Slave-RX (MTx-to-SRx) *No direction change*	Yes	Cannot be an I²C slave
Master-RX reads Slave-TX (STx-to-MRx)	Yes	
Combined format, write-then-read *direction change after initial write*	No	
Combined format, read-then-write *direction change after initial read*	No	

28.3.2 SMBus CRC Generation and Checking

If the Automatically Append CRC (AAC) bit of the Auxiliary Control (AUXC) register is set, the SoC automatically calculates and drives the Cyclic Redundancy Check (CRC) at the end of the transmitted packet for write cycles and checks the CRC for read cycles. It does not transmit the contents of the Packet Error Check Data (PEC) PEC register for a CRC. The PEC Enable (PEC_EN) bit of the Host Control Register (HCTL) must not be set if the AAC bit is set, or else unspecified behavior results.

If the read cycle results in a CRC error, the Device Error (DERR) bit of the Host Status Register Address (HSTS) and the CRC Error (CRCE) bit of the Auxiliary Status (AUXS) register are set.

28.4 Protocols as an SMBus Master

Software sets up registers and instructs the SoC Legacy SMBus Controller to issue various protocols and commands. Programming details are presented here.

When the I2C_EN (I2CEN) bit of the Host Configuration (HCFG) register is 1, the SoC Legacy SMBus Controller is enabled to communicate with I^2C devices. This is also called I^2C mode and changes the formatting of some commands. When I2CEN is 0, behavior is for SMBus as defined in the *System Management Bus (SMBus) Specification, Version 3.0*. The command descriptions below mention the I2CEN bit and how it affects the transaction.

28.4.1 Quick Command

When the Legacy SMBus Controller is programmed to issue a Quick Command, the Transmit Slave Address (TSA) register is sent. The PEC byte is never appended to the quick protocol. The software forces the PEC Enable (PEC_EN) bit of the Host Control Register (HCTL) to 0 when performing the Quick Command. Software must force the I2C_EN (I2CEN) bit of the Host Configuration (HCFG) register to 0 when running this command. See Section 5.5.1 of the *System Management Bus (SMBus) Specification, Version 3.0* for the format of the protocol.

28.4.2 Send Byte and Receive Byte Commands

For the Send Byte command, the Transmit Slave Address (TSA) and Host Command (HCMD) registers are sent. For the Receive Byte command, the Transmit Slave Address (TSA) register is sent. The data received is stored in the Data 0 (HD0) register. Software must force the I2C_EN (I2CEN) bit of the Host Configuration (HCFG) register to bit to 0 when running this command.

The Receive Byte is similar to a Send Byte, the only difference is the direction of data transfer. See Sections 5.5.2 and 5.5.3 of the *System Management Bus (SMBus) Specification, Version 3.0* for the format of the protocol.

28.4.3 Write Byte and Write Word Commands

The first byte of a Write Byte/Word access is the command code. The next 1 or 2 bytes are the data to be written. When programmed for a Write Byte/Word command, the Transmit Slave Address (TSA), Host Command (HCMD), and Data 0 (HD0) registers are sent. In addition, the Data 1 (HD1) register is sent on a Write Word command. Software must force the I2C_EN (I2CEN) bit of the Host Configuration (HCFG) register to 0 when running this command. See Section 5.5.4 of the *System Management Bus (SMBus) Specification, Version 3.0* for the format of the protocol.

28.4.4 Read Byte and Read Word Commands

Reading data is slightly more complicated than writing data. First the SoC must write a command to the slave device. Then it must follow that command with a repeated start condition to denote a read from that device address. The slave then returns 1 or 2 bytes of data. Software must force the I2C_EN (I2CEN) bit of the Host Configuration (HCFG) register to 0 when running this command.

When programmed for the Read Byte/Word command, the Transmit Slave Address (TSA) and Host Command (HCMD) registers are sent. Data is received into the Data 0 (HD0) on the read byte, and the Data 0 (HD0) and Data 1 (HD1) registers on the read word. See Section 5.5.5 of the *System Management Bus (SMBus) Specification, Version 3.0* for the format of the protocol.

28.4.5 Process Call Command

The Process Call is so named because a command sends data and waits for the slave to return a value dependent on that data. The protocol is a Write Word followed by a Read Word, but without a second command or stop condition.

When programmed for the Process Call command, the SoC transmits the Transmit Slave Address (TSA), Host Command (HCMD), Data 0 (HD0) and Data 1 (HD1) registers. Data received from the device is stored in the Data 0 (HD0) and Data 1 (HD1) registers.

The Process Call command produces undefined results when both the I2C_EN (I2CEN) bit of the Host Configuration (HCFG) register and the PEC Enable (PEC_EN) bit of the Host Control (HCTL) register are set. Software must force either the IC2EN bit to 0 or both the PCE_EN and the Automatically Append CRC (AAC) bits of the Auxiliary Control (AUXC) register to 0 when running this command. See Section 5.5.6 of the *System Management Bus (SMBus) Specification, Version 3.0* for the format of the protocol.

Note: For the Process Call command, the RW bit of the TSA register must to be programmed to 0 (indicating Write).

Note: If the I2CEN bit is set, the protocol sequence changes slightly. The command code (bits [18:11] in the bit sequence) is not sent, and as a result, the targeted Slave device does not Acknowledge (bit 19 in the sequence).

28.4.6 Block Read and Block Write Commands

The SoC contains a 32-byte buffer for read and write data which is enabled by setting the Enable 32-byte Buffer (E32B) bit of the Auxiliary Control (AUXC) register. If E32B is 0, single-byte buffering is used. This 32-byte buffer is filled with write data before transmission and filled with read data on reception. In the SoC, the interrupt is generated only after a transmission or reception of 32 bytes, or when the entire byte count has been transmitted/received.

Note: If the I2C_EN (I2CEN) bit of the Host Configuration (HCFG) register is set, the SoC never uses the 32-byte buffer for any Block commands.

The byte count field is transmitted but ignored by the SoC as the software ends the transfer after all bytes it cares about have been sent or received.

For a Block Write, software must force either the IC2EN bit to 0 or both the PCE_EN and the Automatically Append CRC (AAC) bits of the Auxiliary Control (AUXC) register to 0 when running this command.

The Block Write begins with issuing a Slave Address and a Write indication. After the command code, the SoC issues a byte count describing how many more bytes follow in the message. If the Slave device has 20 bytes to send, the first byte is the number 20 (14h), followed by 20 bytes of data. The byte count is not 0. A Block Read or Write is allowed to transfer a maximum of 32-data bytes.

When programmed for a Block Write command, the Transmit Slave Address (TSA), Host Command (HCMD) and Data 0 (HD0) registers are sent. Data is then sent from the Host Block Data (HBD) register; the total data sent being the value stored in the Data 0 (HD0) register. On Block Read commands, the first byte received is stored in the Data 0 (HD0) register, and the remaining bytes are stored in the Host Block Data (HBD) register. See Section 5.5.7 of the *System Management Bus (SMBus) Specification, Version 3.0* for the format of the protocol.

Note: For a Block Write, if the I2CEN bit is set, the format of the command changes slightly. The SoC still sends the number of bytes (on writes) or receives the number of bytes (on reads) indicated in the Data 0 (HD0) register. However, it does not send the contents of the Data 0 (HD0) register as part of the message. Also, the Block Write protocol sequence changes slightly. The byte count (bits [27:20] in the bit sequence) is not sent, and as a result, the Slave device does not Acknowledge (bit 28 in the sequence).

28.4.7 Block Write-Block Read Process Call Command

The Block Write-Block Read Process Call command is a two-part message.

The call begins with a Slave Address and a Write indication. After the command code, the host issues a write byte count (M) that describes how many more bytes are written in the first part of the message. If a master has six bytes to send, the byte count field has the value six (0000_0110), followed by the six bytes of data. The write byte count (M) cannot be 0.

The second part of the message is a block of read data beginning with a repeated start condition followed by the slave address and a read bit. The next byte is the read byte count (N), which differs from the write byte count (M). The read byte count (N) cannot be 0.

The combined data payload must not exceed 32 bytes. The byte-length restrictions of this process call are summarized as follows:

- M ≥ 1 byte
- N ≥ 1 byte
- M + N ≤ 32 bytes

The read byte count does not include the Packet Error Checking (PEC) byte. The PEC is computed on the total message beginning with the first slave address and using the normal PEC computational rules. Intel recommends that a PEC byte be used with the Block Write-Block Read Process Call command. The software must read the Host Command (HCMD) register to reset the 32-byte buffer pointer before reading the Host Block Data (HBD) register.

Note: No STOP condition is before the repeated START condition, and that a NACK signifies the end of the read transfer.

Note: The Enable 32-byte Buffer (E32B) bit of the Auxiliary Control (AUXC) register must be set when using this protocol.

See Section 5.5.8 of the *System Management Bus (SMBus) Specification, Version 3.0* for the format of the protocol.

28.4.8 SMBus Host Notify Command

See Section 5.5.9 SMBus Host Notify Protocol of the *System Management Bus (SMBus) Specification, Version 3.0*.

The SoC Legacy SMBus Controller uses this protocol to communicate with the SMBus Host which has its Slave address defined as 0001_000.

28.5 Protocols and Commands as the ARP Master

The SoC Legacy SMBus controller and associated software driver can act as the SMBus ARP Master. Details of the role of the Address Resolution Protocol (ARP) Master are in Section 5.6.3 ARP Commands of the *System Management Bus (SMBus) Specification, Version 3.0*.

The ARP Master operation is supported via software that uses the existing Legacy SMBus controller commands in the Host Controller Command (HCMD) register in I/O Space and also in Memory Space. When acting as the ARP Master, bits [6:0] of the Receive Slave Address (RSA) register must be programmed to 0001_000.

The supported ARP commands are shown in Table 28-3, "Supported SMBus ARP, SMBus, and I^2C Protocols." The recommended software-driver flow is shown in Figure 29-3, "ARP Master Behavior Flow Diagram." This diagram is taken from the *System Management Bus (SMBus) Specification, Version 3.0*.

28.5.1 ARP Enumeration and the Notify ARP Master Command

Any SMBus Master, including the Legacy SMBus Controller, can be delegated to perform ARP enumeration. Enumeration is the process that assigns Slave Addresses to the ARP-Capable Slave devices on the SMBus. Enumeration begins with a Master issuing the Prepare to ARP command as described in Section 5.6.3.2 Prepare to ARP of the *System Management Bus (SMBus) Specification, Version 3.0*. The controller performs a write to Slave Address 1100_001 which is the SMBus Device Default Address.

If it is the SMBus ARP Master (there can only be one on an SMBus interface), the SoC Legacy SMBus Controller is also responsible for responding to the Notify ARP Master directed to the Slave Address 0001_000 which is the Slave Address that can also be assigned to the SMBus Host.

If the Legacy SMBus Controller is not the ARP Master, because the SoC controller cannot act as an SMBus Slave, it has no Slave Address that can be assigned by the ARP Master and requires no ARP enumeration.

28.6 I²C Read Command

This command allows the SoC to perform Block Reads from certain I²C devices, such as serial EEPROMs. The SMBus Block Read supports the 7-bit addressing mode only. However, this does not allow access to devices using the I²C combined format that has data bytes after the address. Typically these data bytes correspond to an offset (address) within the serial memory chips.

Note: This command is supported independent of the setting of the I2C_EN (I2CEN) bit of the Host Configuration (HCFG) register. The I²C Read command with the PEC Enable (PEC_EN) bit set of the Host Control (HCTL) register produces undefined results. Undefined results also occurs when the The I²C Read command is started and the Append CRC (AAC) bits of the Auxiliary Control (AUXC) register is set.

For an I²C Read command, the RW bit of the TSA register RW must to be programmed to 1 (indicating Read). The format that is used for the command is shown in Table 28-4, "I²C Block Read."

Table 28-4. I²C Block Read

Bit	Description
1	START indication driven by the SoC Legacy SMBus Controller
8:2	Slave Address – 7 bits
9	Write
10	Acknowledge (ACK) from the Slave device
18:11	Send Data 1 (HD1) register
19	ACK from the Slave device
20	Repeated START indication
27:21	Slave Address – 7 bits
28	Read
29	ACK from the Slave device
37:30	Data byte 1 from slave – 8 bits
38	ACK from the Slave device
46:39	Data byte 2 from the Slave device– 8 bits
47	ACK from the Slave device
–	Data bytes from the Slave device and associated ACKs[1]
–	Data byte N from the Slave device – 8 bits
–	NOT Acknowledge (NACK)
–	STOP indication driven by the SoC.

1. The SoC continues reading data from the I²C Slave device until the NACK is received.

28.7 Bus Arbitration as an SMBus Master

See Section 4.3.2 Arbitration of the *System Management Bus (SMBus) Specification, Version 3.0*.

As an SMBus Master, if the SoC Legacy SMBus Controller starts to initiate a transaction on the bus and loses arbitration, the SoC sets the Bus Error (BERR) of the Host Status Register Address (HSTS) and, if enabled, generates an interrupt or SMI. The processor restarts the transaction.

When the controller wins arbitration, it drives the SMBCLK (the SoC SMB_LEG_CLK signal pin) during the transaction. The minimum frequency of the clock is 10 kHz and the maximum is 100 kHz. The SMBDAT (the SoC SMB_LEG_DATA signal pin) is driven or sensed by the SoC during the transaction defined by the protocol. The SoC also ensures minimum time between SMBus transactions it initiates.

28.7.1 SMBCLK Signal Stretching by an SMBus Slave

See Section 4.3.3 Clock low Extending of the *System Management Bus (SMBus) Specification, Version 3.0*.

The Slave device of the transaction may be slower than the Legacy SMBus Controller and may need additional time to respond to the controller. Slower Slave devices are allowed to stretch the low portion of the SMBCLK signal by driving it low (along with the Master) during the transfer of one message up to the maximum limits described in the AC specifications of the *System Management Bus (SMBus) Specification, Version 3.0*. The Slave device must not extend the SMBCLK too long and must maintain an SMBCLK period of no more than 100 µs (minimum SMBCLK frequency of 10 kHz). There are some exceptions to this and are mentioned in the SMBus specification.

28.7.2 SMBus Timeout

See Section 3.1.1.2 Timeouts of the *System Management Bus (SMBus) Specification, Version 3.0*.

If an error is in the transaction, such that an SMBus Slave device does not signal an Acknowledge (ACK) to the Legacy SMBus Controller, or holds the SMBCLK low (stretching) longer than the allowed timeout duration, the transaction times out. The SoC discards the cycle and sets the Device Error (DERR) bit of the Host Status Register Address (HSTS). The minimum timeout duration is 25 ms (800 RTC clock periods). The time-out counter inside the SoC starts after the first bit of data is transferred. The 25-ms time-out counter does not count when the Byte Done Status bit (BYTE_DONE_STS) of the Host Status Register Address (HSTS) is set.

28.8 Interrupts and SMI

The SMBus controller uses PIRQB# as its interrupt pin. However, the system is alternatively set up to generate a System Management Interrupt (SMI) instead of an interrupt, by setting the SMB_SMI_EN (SSEN) bit of the Host Configuration (HCFG) Register.

The following tables specify how the various enable bits in the SMBus function control the generation of the interrupt, host SMI, and wake internal signals:

- Table 28-5, “Enable for SMBALERT# (SMB_LEG_ALRT_N)”
- Table 28-6, “Enables for Legacy SMBus Controller Events”
- Table 28-7, “Enables for a Received Notify ARP Master Command”

The rows in the tables are additive, which means that if more than one row is true for a particular scenario then the results for all of the activated rows occur.

Table 28-5. Enable for SMBALERT# (SMB_LEG_ALRT_N)

Event	INTREN (INTREN) bit of the Host Control (HCTL) Register	SMB_SMI_EN (SSEN) bit of the Host Configuration (HCFG) Register	SMBALERT_DIS (SMB_D) bit of the Slave Command (SCMD) Register	Result
SMBALERT# (SMB_LEG_ALRT_N) asserted low *Always reported in SMBALERT bit of the Host Status Register Address (HSTS)*	X	X	X	Wake Event generated to PMC via the SMB_WAK_STS bit of the General Purpose Event 0 Status [127:96] (GPE0_STS_127_96) register of the SoC PMC. *Depends on Intel® Management Engine settings*
	X	1	0	Besides the Wake Event, an SMI is generated by the Legacy SMBus Controller via the SMBALERT_STS of the Host Status Register Address (HSTS) register. Also, when in the S0 state, this also sets SMBUS_SMI_STS bit of the SMI Status (SMI_STS) register of the SoC PMC.
	1	0	0	IRQ Interrupt generated

Table 28-6. Enables for Legacy SMBus Controller Events

Event	INTREN (INTREN) bit of the Host Control (HCTL) Register	SMB_SMI_EN (SSEN) bit of the Host Configuration (HCFG) Register	Result
Any combination of FAIL, BERR, DERR, and INTR bits of the Host Status Register Address (HSTS) provided they are individually enabled to generate and interrupt.	0	X	None
	1	0	IRQ interrupt generated
	1	1	SMI generated to the PMC when in S0 state via the LEGACY_USB2_STS bit of the SMI Status (SMI_STS) register of the SoC PMC.

Table 28-7. Enables for a Received Notify ARP Master Command

HOST_NOTIFY_INTREN (HNI) bit of the Slave Command (SCMD) Register	SMB_SMI_EN (SSEN) bit of the Host Configuration (HCFG) Register	HOST_NOTIFY_WKEN (HNW) bit of the Slave Command (SCMD) Register	Result
0	X	0	None
X	X	1	Wake Event generated to PMC via the SMB_WAK_STS bit of the General Purpose Event 0 Status [127:96] (GPE0_STS_127_96) register. *Depends on Intel® Management Engine settings*
1	0	X	IRQ interrupt generated
1	1	X	SMI generated to the PMC when in S0 state via the SMBUS_SMI_STS bit of the SMI Status (SMI_STS) register of the SoC PMC.

28.9 Optional SMBALERT# Signal

The optional SMBALERT# signal is multiplexed with Customer GPIO[112]. If not blocked by the SMBALERT_DIS (SMB_D) bit of the Slave Command (SCMD) register, the SoC generates an interrupt or an SMI when SMBALERT# is asserted by an SMBus Slave device. This signal is a wake event from the system S4 or S5 (soft off) power state. See Table 28-5, "Enable for SMBALERT# (SMB_LEG_ALRT_N)." The SMBUSALERT# signal is described in the Appendix A – Optional SMBus Signals section of the *System Management Bus (SMBus) Specification, Version 3.0*.

The interrupt is meant to alert software to setup the Legacy SMBus controller to issue a message over the SMBus with the slave address set to the Alert Response Address (0001_000). This message accesses all SMBUSALERT# devices on the bus. There could be more than one Slave device asserting the SMB_LEG_ALRT_N signal. The controller observes the returned Slave-device address(es) and performs device-address arbitration as defined in the *System Management Bus (SMBus) Specification, Version 3.0* to determine which SMBus Slave device shall be attributed to the alert.

28.10 Register Map

Figure 28-2, "Register Map" shows the associated registers from a system software viewpoint. The TCO Registers are used by the SoC Power Management Controller. See Chapter 16, "Power Management Controller (PMC)."

§ §

29 SMBus Controller - Host

The SMBus Message Transport (SMT) controller provides a mechanism whereby the SoC sends and receives out-of-band manageability messages over the SMBus to managed devices or to management controllers. This allows it to participate in manageability services with Intel and third-party devices like embedded controllers, sensors, and other devices through the SMBus interface.

Figure 29-1. What is Covered in This Chapter

Alert Standard Format (ASF) Specification, Version 2.0	https://www.dmtf.org/sites/default/files/standards/documents/DSP0136.pdf
Management Component Transport Protocol (MCTP) Base Specification, Version 1.1.0	https://www.dmtf.org/sites/default/files/standards/documents/DSP0236_1.1.0.pdf

29.1 Signal Descriptions

The signal descriptions are shown in Table 29-2. For additional signal information, including whether a signal is assigned to shared-function pin or can be used as a customer GPIO signals, see Section 39.1, "Directory of Signal Names and Pin Names" on page 993. The Direction/Type column of Table 29-2 is interpreted as follows:

- I = Input signal. The SoC has receiver circuit.
- O-OD = Open-Drain Output. SoC output circuit uses an open-drain driver.

Table 29-2. Signal Names

Signal Name	Direction Type	Shared	Description
SMB_HOST_CLK	I, O-OD	Yes	SMBus Clock (SMBCLK)
SMB_HOST_DATA	I, O-OD	Yes	SMBus Data (SMBDAT)

The optional SMBus 2.0 signals, SMBALERT# and SMBSUS#, are not supported on this controller interface.

29.2 Features

- Operates as an SMBus master or slave.
- Supports ARP in the master or slave mode.
- Packet Error Code (PEC) is enabled for SMBus transactions.
- Compatible with certain I^2C master (all commands except read-then-write) and slave (only MTx-to-SRx) modes.
- Status and errors are communicated by polling or interrupts.
- Supports INTx or Message Signaled Interrupt (MSI).

29.3 Architectural Overview

The SMBus Message Transport (SMT) controller has three regions in the configuration space. These are discovered by software in the configuration space as bus 0, device 18 (decimal), function (0). The address offsets and capability IDs of the contents of these regions are:

1. PCI Standard Header
   - Type 0
2. PCI Capabilities List
   - 40h: PCI Express* - Capability ID = 10h
   - 80h: PCI Power Management - Capability ID = 01h
   - 8Ch: Message Signaled Interrupts (MSI) - Capability ID = 05h
   - Various implementation-specific and Intel-reserved registers
3. PCI Express Extended Capabilities List
   - 100h: Advanced Error Reporting (AER) - Extended Capability ID = 0001h

The SMT controller operation is DMA-based in which descriptors and data are exchanged between the SoC hardware and the firmware through system memory. This DMA mode is available for the SMT acting both as the master and target.

As transport layer functionality, SMT transfers messages between the devices on the SMBus segment (to which it is physically connected) and the SoC firmware. The SMT hardware is physically located within the SoC and resides within its PCIe* space. In the PCIe hierarchy, SMT is bus 0, device 18 (decimal), function 0.

Table 29-3 summarizes which SMBus ARP, SMBus, and I2C protocols are supported by the SMT controller.

Table 29-3. List of Supported SMBus ARP, SMBus, and I2C Protocols

Protocol	Supported	
SMBus ARP Commands	**Sent as ARP Master**	**Received as ARP Slave**
Prepare to ARP	Yes	
Reset Device *General and directed*		
Get UDID *General and directed*		
Assign Address		
SMBus ARP Commands	**Sent as ARP Slave**	**Received as ARP Master**
Notify ARP Master	Yes	
SMBus Commands	**Sent as Master**	**Received as Slave**
Quick Command	Yes	Yes
Send Byte	Yes	Yes
Receive Byte	Yes	No
Write Byte/Word	Yes	Yes
Read Byte/Word	Yes	No
Process Call	Yes	No
Block Write	Yes	Yes
Block Read	Yes	Yes
Block Write-Block Read Process Call	Yes	No
SMBus Host Notify	Yes	Yes
I2C Commands	**Sent as Master**	**Received as Slave**
Master-TX writes slave-RX (MTx-to-SRx) *No direction change*	Yes	Yes
Master-RX reads slave-TX (STx-to-MRx)	Yes	No
Combined format, write-then-read *direction change after initial write*	Yes	No
Combined format, read-then-write *direction change after initial read*	No	No

29.4 Controller Characteristics and Operation

29.4.1 SMBus Behavior on PCIe Reset

When power is applied to an SMBus device, it performs default initialization of the internal state as specified in the *System Management Bus (SMBus) Specification, Version 3.0*. The SMBus device interface logic is not affected by PERST#. This normally allows the SMBus to support communications when the PCIe interface cannot.

29.4.2 Addressing and Configuration

An Address Resolution Protocol (ARP) is defined in the *System Management Bus (SMBus) Specification, Version 3.0* as assigning slave addresses to the SMBus devices. It is required that systems that connect the SMBus to PCIe slots implement the ARP for assignment of SMBus slave addresses to the SMBus interface devices on the PCIe add-in cards. The system must execute the ARP on a logical SMBus whenever any PCIe device in an individual slot associated with the logical SMBus exits the $D3_{COLD}$ state. Before executing the ARP, the system must ensure that all ARP-capable SMBus interface devices are returned to their default address state.

29.4.2.1 ARP Nomenclature

The following are some definitions pertaining to SMBus ARP.

Table 29-4. ARP Nomenclature

Term	Definition
Address Resolution Protocol (ARP)	A protocol by which SMBus devices with assignable addresses on the bus are enumerated and assigned non-conflicting slave addresses.
Address Resolved (AR) Flag	A flag bit or state internal to the SoC that indicates whether or not the device slave address has been resolved by the ARP master.
Address Valid (AV) Flag	A flag bit or state internal to the SoC that indicates whether or not the device slave address is valid. This bit must be non-volatile for devices that support the persistent slave address.
ARP Master	The SMBus master executes the ARP and assigns addresses to the ARP-capable slave devices. The SMBus host usually is the ARP master, but under some circumstances another SMBus master assumes the role. Only one active ARP master exists at any time.
Persistent Slave Address (PSA)	An assigned slave address that is retained through the loss of device power.
SMBus Device Default Address	The address of all the ARP-capable slave devices must respond to. After a slave address has been assigned, a device must still respond to commands at the SMBus device default address for ARP management. This address is fixed at 1100 001.
SMBus Host	A specialized SMBus master that provides the main interface to the system CPU. It must be a master-slave and must support the SMBus host notify protocol. At most, one host is in a system.
Unique Device Identifier (UDID)	A 128-bit value that a device uses during the ARP process to uniquely identify itself.

Table 29-5. Device Decodes of AV and AR Flags

Address Valid (AV)	Address Resolved (AR)	Meaning
Cleared	Cleared	The device does not have a valid slave address and participates in the ARP process. This is the POR state for a device that does not support the Persistent Slave Address (PSA) or if it does it has not previously been assigned a slave address.
Cleared	Set	ILLEGAL STATE
Set	Cleared	The device has a valid slave address but still must participate in the ARP process.
Set	Set	The device has a valid slave address that has been resolved by the ARP master. The device does not respond to the Get UDID (general) command. However, it subsequently receives an Assign Address command and changed its slave address accordingly.

29.4.2.2 Unique Device Identifier (UDID) Format

The UDID is a 128-bit value that a device uses during the ARP process to uniquely identify itself.

Table 29-6. UDID Format

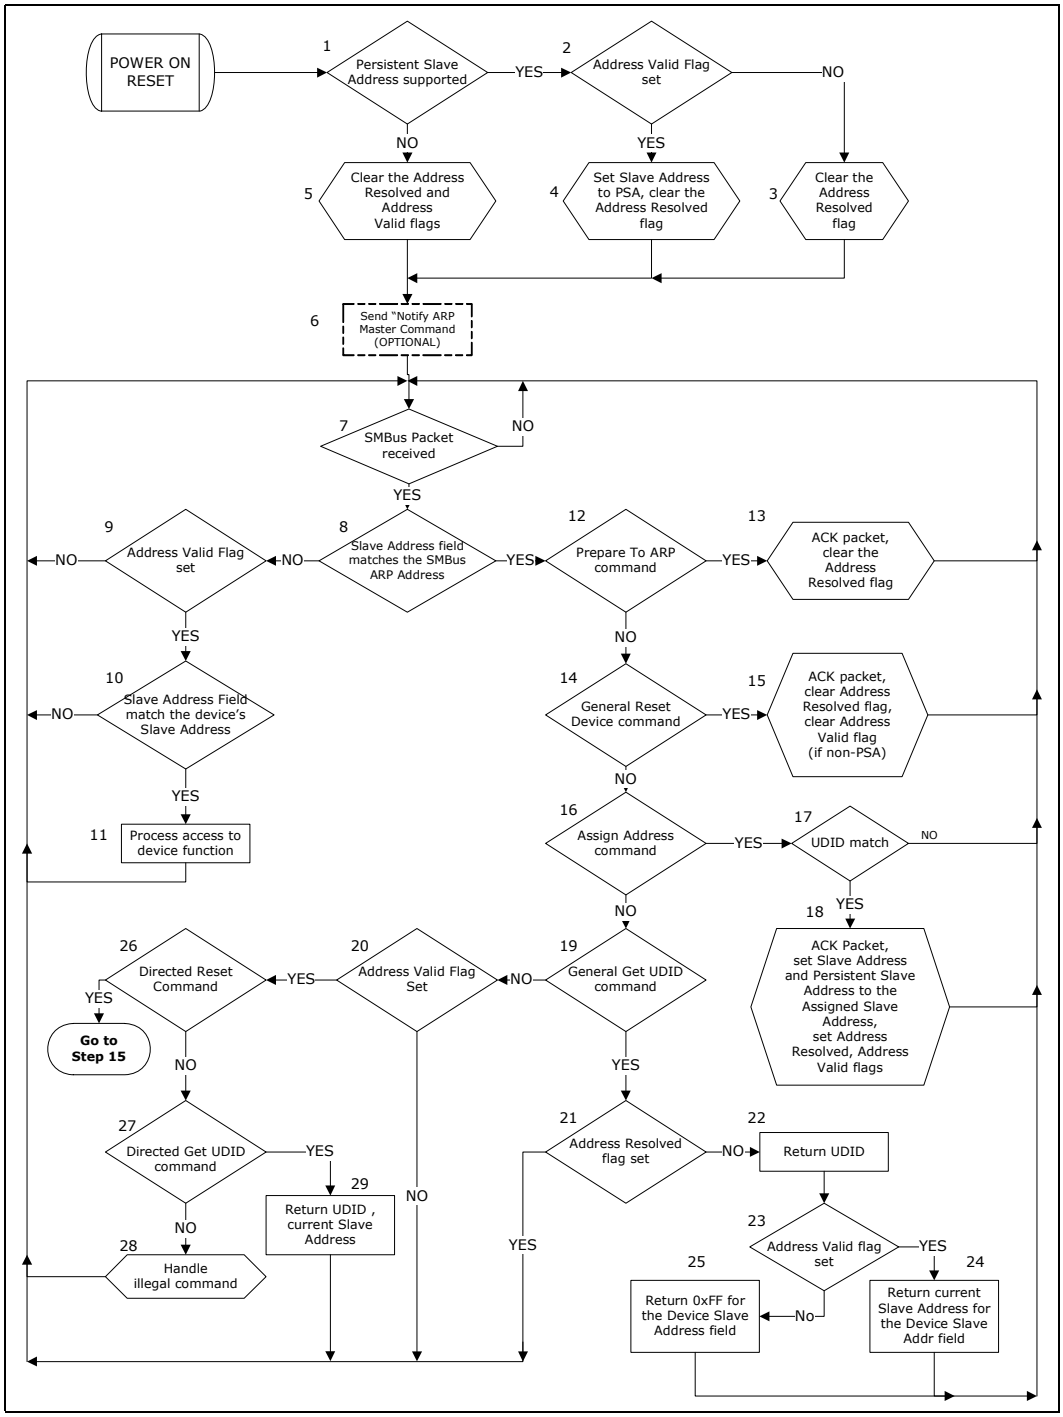
Size	Field	Comments
8 bits Most Significant Bit (MSB)	Device Capabilities	Includes the selection of a fixed or dynamic ARP address
8 bits	Version/Revision	
16 bits	Vendor ID	
16 bits	Device ID	
16 bits	Interface	
16 bits	Subsystem Vendor ID	
16 bits	Subsystem Device ID	
32 bits Least Significant Bit (LSB)	Vendor Specific ID	Includes bits to uniquely identify each device UDIDs

The vendor-specific field provides a unique ID for functionally equivalent devices. This field is for devices that otherwise return identical UDIDs for the purpose of the address assignment. A unique ID in this field is required since this device supports an assigned slave address. For a pre-assigned unique ID, at least 24 bits must be unique; however, the full 32 bits is recommended. Uniqueness is important to guarantee that two like devices are identified discretely.

The Vendor Specific ID (VSID) fields of the UDID0 Data Register (UDID0) and the UDID1 Data Register (UDID1) are located in the SMT controller MMIO.

29.4.2.3 ARP Slave Behavior

Figure 29-2. ARP-Capable (Slave) Device Behavior Flow Diagram



With reference to Table 29-7 the ARP slave operates as follows (steps which are shaded are the responsibility of the firmware alone or of the firmware to trigger the hardware).

Table 29-7. ARP Slave Operations (Sheet 1 of 3)

Step		Description
0.	Perform ARP slave initialization.	• [FW[1]] See Section 29.4.2.5, "ARP Initialization Flow" on page 746
1.	After exiting the power-on-reset state, a device that supports PSA goes to step 2 to verify if its slave address is valid. If the device does not support PSA, proceed to step 5.	• [FW] SoC does not support PSA; jump past PSA-related steps to step 5.
2.	A device supporting PSA must check its address valid flag which is non-volatile. If that flag is set then it has previously received an assigned slave address; proceed to step 4. If the address valid flag is cleared then proceed to step 3.	• N/A
3.	Although the device supports PSA the value is currently invalid. The device must clear the address resolved flag to indicate that it has not had its slave address assigned. Proceed to step 6.	• N/A
4.	The device has a valid PSA so it assumes that slave address for now. However, this address has not been resolved by the ARP master so the device must clear its address resolved flag. Proceed to step 6.	• N/A
5.	The device does not support PSA so it must clear its address valid and address resolved flags. Proceed to step 6.	• [FW] De-assert SMTARPCTRL.AV*n*. • [FW] De-assert SMTARPCTRL.AR*n*.
6.	If supported, the device masters the SMBus and sends the Notify ARP Master command. This informs the ARP master that a new device is present. Proceed to step 7.	• [FW] Determine if supported; check SMTARPCTRL.NOTIFYENB. • [FW and HW[2]] Initiate master transaction (see Section 29.4.6.4, "Master Transactions Flow" on page 758).
7.	The device waits for an SMBus packet.	• [FW and HW] Wait
8.	Upon receipt of an SMBus packet the device must first check the received slave address against the SMBus device default address. If a match is present, then proceed to step 12, otherwise proceed to step 9.	• [HW] Match the default address. • [HW] ACK the transaction if received slave address matches device default address.
9.	The received address is not the SMBus device default address so the packet is potentially addressed to one of the device core functions. The device must check its Address Valid bits to determine whether or not to respond. If any of the Address Valid bits are set then proceed to step 10, otherwise return to step 7 and wait for another SMBus packet.	• [HW] Check if any SMTARPCTRL.AV*n* are asserted.
10.	Since the device has a valid slave address it must compare the received slave address to its internal slave address. If a match is present, then proceed to step 11, otherwise return to step 7 and wait for another SMBus packet.	• [HW] Match any of the internal slave addresses. • [HW] ACK the transaction if received slave address matches **any** target address **and** that target Address Valid bit (SMTARPCTRL.AV*n*) is asserted.
11.	The device has received a packet addressed to a core function so it acknowledges the packet and processes it accordingly. Proceed to step 7 and wait for another SMBus packet.	• [FW and HW] Initiate target transaction (see Section 29.4.7.4, "Target Memory Buffer Hardware-Firmware Flow" on page 772).
12.	The device detected a packet addressed to the SMBus Device default address. Check the command field to determine if this is the Prepare To ARP command. If so, then proceed to step 13, otherwise proceed to step 14.	• [FW] Inspects command field and determines how to proceed.
13.	Upon receipt of the Prepare To ARP command the device must acknowledge the packet and make sure its address resolved flag is clear to participate in the ARP process. Proceed to step 7 and wait for another SMBus packet.	• [FW] De-assert SMTARPCTRL.AR*n*.
14.	The device checks the command field to verify if the Reset Device command was issued. If so, then proceed to step 15, otherwise proceed to step 16.	• [FW] Inspects command field and determines how to proceed.

Table 29-7. ARP Slave Operations (Sheet 2 of 3)

Step		Description
15.	Upon receipt of the Reset Device command the device must acknowledge the packet and make sure its address valid (if non-PSA) and address resolved flags are cleared. This allows the ARP master to re-assign all device addresses without cycling power. Proceed to step 7 and wait for another SMBus packet.	• [FW] De-assert SMTARPCTRL.AV*n*. • [FW] De-assert SMTARPCTRL.AR*n*.
16.	The device checks the command field to verify if the Assign Address command was issued. If so, then proceed to step 17, otherwise proceed to step 19.	• [FW] Inspects the command field and determines how to proceed.
17.	Upon receipt of the Assign Address command the device must compare its UDID to the one it is receiving. If any byte does not match then it must not acknowledge that byte or subsequent ones. If all bytes in the UDID compare then proceed to step 18, otherwise return to step 7 and wait for another SMBus packet.	• [HW] Check the command field **only if** received slave address matches device default address. • [HW] If the Assign Address command, then verify each byte of received UDID against all SMT UDIDs. • [HW] NACK the transaction if received UDID fails to match any SMT UDID. ***Note:*** All ARP protocols are directed only to the device default address. ***Note:*** SMT must respond to this command even if its SMTARPCTRL.AR flag is set (i.e., ARP master overwrites a valid and resolved target address). ***Note:*** This also implies the hardware cannot detect an ARP-pending flag to selectively monitor the command field for Assign Address command. ***Note:*** If UDID is NACKed, the hardware is not required to notify the firmware.
18.	Since the UDID matched, the device must assume the received slave address and update its PSA, if supported. The device must set its address valid and address resolved flags; this indicates it no longer responds to the Get UDID command unless it receives the Prepare To ARP or Reset Device commands or is power cycled. Proceed to step 7 and wait for another SMBus packet.	• [FW] Assign the received slave address to the matched UDID. • [FW] Assert SMTARPCTRL.AV*n*. • [FW] Assert SMTARPCTRL.AR*n*.
19.	The device checks the command field to verify if the Get UDID command was issued. If so, then proceed to step 21, otherwise proceed to step 20.	• [HW] Inspects the command field and determines how to proceed.
20.	The device is receiving a directed command. Directed commands must be acknowledged only by slaves with a valid address. If the address is not valid then ignore the packet and return to step 7 and wait for another SMBus packet. If the address is valid then proceed to step 26.	• [HW] Inspects the address valid flag.
21.	Upon receipt of the Get UDID command, the device must check its address resolved flag to determine whether or not it participates in the ARP process. If set then its address has already been resolved by the ARP master so the device proceeds to step 7 to wait for another SMBus packet. If the AR flag is cleared then the device proceeds to step 22.	• [HW] Inspects the address resolved flag and determines how to proceed.
22.	The device returns its UDID and monitors the SMBus data line for collisions. If a collision is detected at any time the device must stop transmitting and proceed to step 7 and wait for another SMBus packet. If no collisions were detected then proceed to step 23.	• [HW] UDID is returned as read data to master.
23.	The device must now check its address valid flag to determine what value to return for the device slave address field. If the AV flag is set then proceed to step 24, otherwise proceed to step 25.	• [HW] Inspects the address valid flag and determines how to proceed.
24.	The current slave address is valid so the device returns this for the device slave address field (with bit 0 set) and monitors the SMBus data line for collisions (i.e., another device driving a 0 when this device is driving a 1). Proceed to step 7 and wait for another SMBus packet.	• [HW] UDID and current slave address are returned as read data to master (as per generic block-read payload).
25.	The current slave address is invalid so the device returns a value of 0xFF and monitors the SMBus data line for collisions. If the ARP master receives the 0xFF value it knows that the device requires address assignment. Proceed to step 7 and wait for another SMBus packet.	• [HW] UDID and 0xFF address are returned as read data to master (as per generic block-read payload).

Table 29-7. ARP Slave Operations (Sheet 3 of 3)

Step		Description
26.	Is this a directed Reset Device command? If so then proceed to step 15. Otherwise proceed to step 27.	• [FW] Inspects the command field and determines how to proceed.
27.	Is this the Get UDID (directed) command? If so then proceed to step 29. Return the UDID information. If not, then proceed to step 28.	• [HW] Inspects the command field and determines how to proceed.
28.	The device has not received a valid command so it must handle the illegal command in accordance with SMBus rules for error handling. Proceed to step 7 and wait for another SMBus packet.	• [FW] Perform error handling.
29.	Return the UDID information and current slave address, then proceed to step 7 and wait for another SMBus packet.	• [HW] UDID and current slave address are returned as read data to master (as per generic block-read payload).

1. FW means Firmware.
2. HW means Hardware.

Table 29-8 identifies the hardware pattern-matching which is required to decode ARP and ordinary SMBus protocols. The UDID matching applies only to the assign address protocol.

Since ARP protocols are typically writes to the ARP slave by the ARP host, the R/W# bit (LSB) of the first byte is usually 0; however, the general and directed forms of Get UDID require the ARP slave to return its UDID to the ARP host, such that the LSB of the first byte after the repeated start is 1. During either Get UDID protocol, the hardware matching must detect the repeated start and subsequently match a slave address of C3h.

Likewise, most ordinary SMBus protocols begin with a write to the slave/target by the master. However, since certain protocols begin with a read to the slave, the hardware matching treats the LSB of the first byte as a (don't care). For those protocols which require the slave to return data to the master, the LSB of the first byte after the repeated start is 1. Therefore, the hardware matching must detect the repeated start and subsequently match a slave address with an appended 1 LSB.

Table 29-8. Hardware Decoding of ARP, SMBus, and I²C Target Transactions

Byte 1 Slave Address[1]	Byte 2 ARP Command	Bytes 4-19 UDID	Hardware-Decoded Protocol
ARP protocols applicable to all SMT UDIDs			
C2h	01h	N/A	Prepare to ARP
C2h	02h	N/A	Reset Device (general)
C2h	03h	N/A	Get UDID (general)
C3h[2]	N/A	N/A	Get UDID (general) —after repeated start
ARP protocols specific to only matched UDID (128 bits)			
C2h	04h	Matches an SMT UDID	Assign Address
ARP protocols specific to only matched slave address (7 bits)			
C2h	{target address, 1}	N/A	Get UDID (directed)
C3h[2]	N/A	N/A	Get UDID (directed) —after repeated start
C2h	{target address, 0}	N/A	Reset Device (directed)
10h	C2h	N/A	Notify ARP master
10h	!= C2h[3]	N/A	SMBus Host Notify
Ordinary SMBus (and I²C) protocol specific to only matched slave address (7 bits)			
{slave address, x}	N/A	N/A	Ordinary SMBus transaction. LSB = x to be protocol agnostic • Quick Command • Send Byte • Write Byte/Word • Block Write • Block Read
{slave address, **1**}[2]	N/A	N/A	Ordinary SMBus transaction. LSB = 1 —after repeated start • Block Read

1. Hardware checking of LSB during start address cycle is controlled by SUSCHKB.IRWST. (Applies to SMBus target addresses, C2h, and 10h.) See also Section 29.4.7.5, "Target Flow" on page 775 and Table 29-20, "Target Transaction Behavior Due to SUSCHKB.IRWST" on page 776 for more implications to the firmware and the hardware regarding IRWST.
2. Hardware checking of LSB during repeated-start address cycle is controlled by SUSCHKB.IRWRST. (Applies to SMBus target addresses and C2h.)
3. For a transaction directed to 10h if the command byte is not C2h then the transaction is SMBus host notify and the command code format is {initiator slave address, 0}.

Certain SMBus protocols are disallowed in the target mode since they violate the hardware-firmware descriptor mechanism. First, the descriptor is passed to the firmware only after the transaction stop; this architecture does not permit the firmware to return a payload within the same transaction. Second, waiting for a descriptor from the firmware requires the hardware to perform excessive SMBus clock-stretching.

Table 29-9 captures the responses of the hardware/firmware under the various combinations of ARP protocol, address and UDID fields, and ARP status flags. The states mentioned refer to Table 29-9.

Table 29-9. Hardware/Firmware Response to SMBus and ARP Protocols

Received ARP Protocol	AV Flag	AR Flag	ARP States (1-8,...)	SoC Hardware and Firmware Response
Ordinary SMBus protocol				
Ordinary SMBus protocol	T	N/A	9, 10, 11	Normal hardware-firmware flow
SMBus block-read	T	N/A	9, 10, 11	The hardware returns the specified number of bytes from the hardware buffers.
ARP protocol				
Prepare to ARP	N/A	N/A	12, 13	Normal hardware-firmware flow
Reset Device (general)	N/A	N/A	12, 14, 15	Normal hardware-firmware flow
Assign Address	N/A	N/A	12, 14, 16, 17, 18	Normal hardware-firmware flow
Get UDID (general)	N/A	T	12, 14, 16, 19, 21	The hardware does NACK the ARP command byte to indicate it has a valid assigned slave address (ARP is complete).
Get UDID (general)	T	F	12, 14, 16, 19, 21, 22, 23, 24	The hardware returns its UDID and corresponding slave address.
Get UDID (general)	F	F	12, 14, 16, 19, 21, 22, 23, 25	The hardware returns its UDID and 0xFF for its address.
Reset Device (directed)	T	N/A	12, 14, 15, 19, 20, 26, 15	Normal hardware-firmware flow
Get UDID (directed)	T	N/A	12, 14, 16, 19, 20, 26, 27, 29	The hardware returns its UDID and corresponding slave address.
None of the above ARP protocols	N/A	N/A	12, 14, 16, 19, 20, 26, 27, 28	Normal hardware-firmware flow (error handling situation)

The hardware will ACK all valid transactions above. An exception is when processing the assign address protocol, if the received UDID does not match any internal UDID the hardware begins NACKing after the first unmatched byte. Another exception is that if the address resolved flag is asserted and a Get UDID (general) command is received, the command byte is NACKed. Finally, a PEC failure causes a transaction to be NACKed.

In both directed protocols, Get UDID (directed) and reset device (directed), the second byte, or ARP command byte, consists of the target slave address with an appended 0 or 1 to denote a reset device or Get UDID protocol, respectively. Therefore, the hardware uses address bits [7:1] for address comparison and LSB bit 0 to determine the protocol.

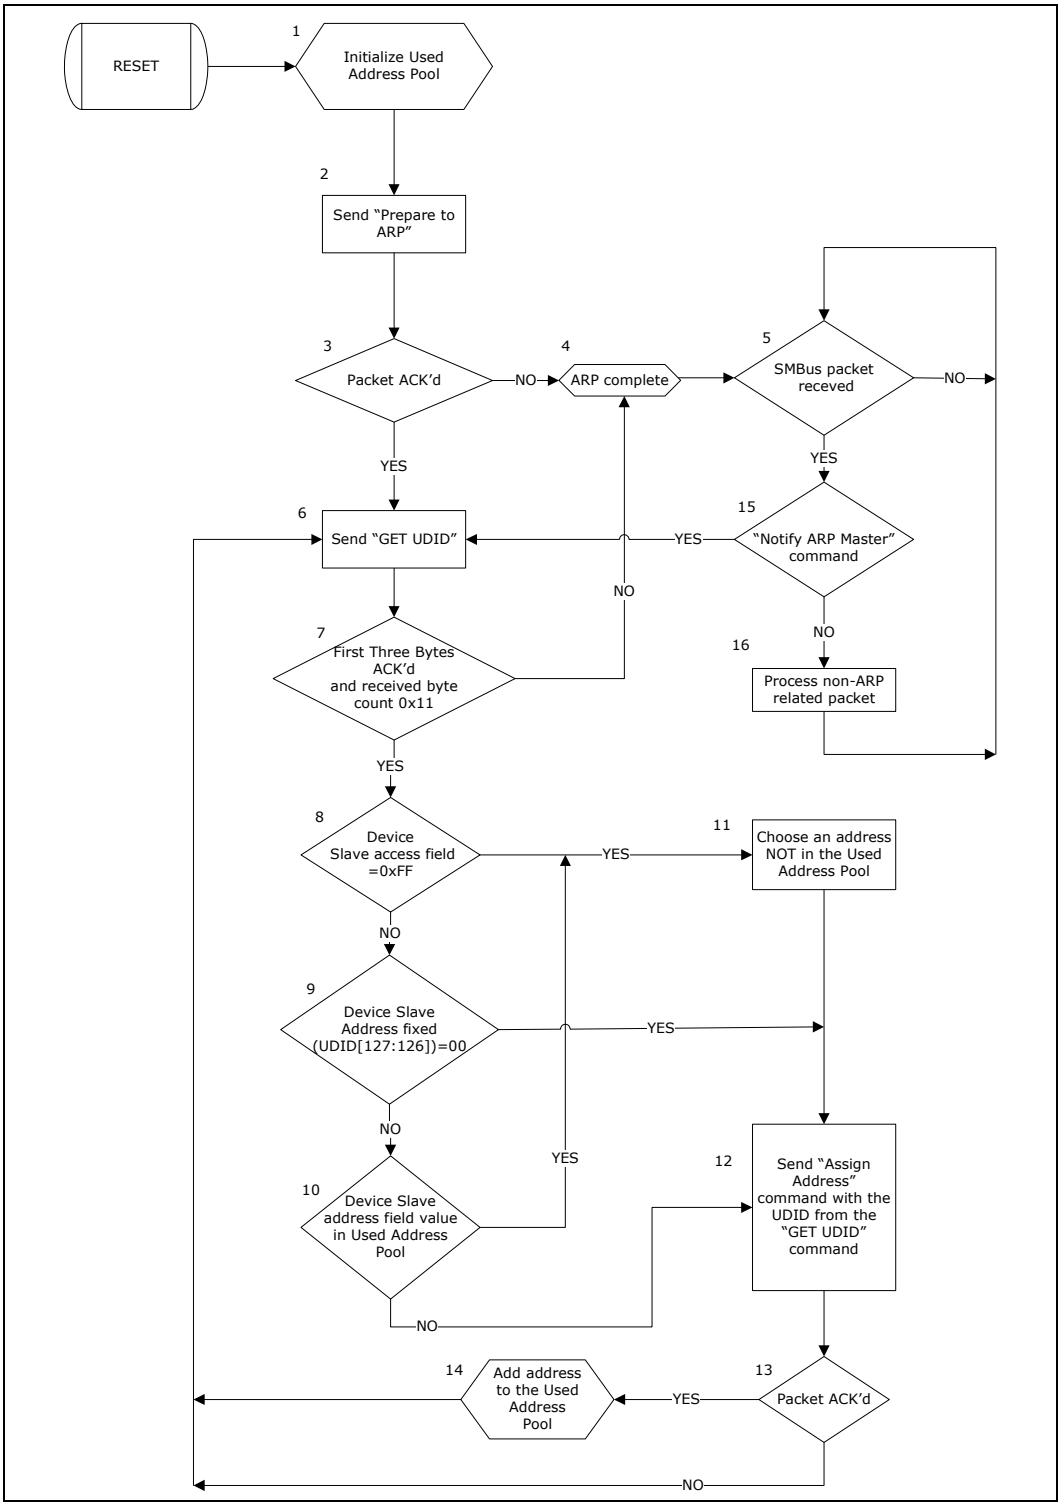
Since the SMT supports multiple UDIDs, during the ARP process it participates in the Get UDID (general) and assign address protocols once for each UDID such that each UDID has a slave address which is resolved by the ARP master.

For GPBR and all both Get UDID flavors, the transaction is descriptor-only with no target data written to memory, and the descriptor is managed by the hardware.

Note: The firmware implements a time-out mechanism such that if the SoC issues the Notify ARP Master command and the ARP master does not respond within a particular time period, then the SoC re-issues the Notify ARP Master command. It is implemented to comply with the *System Management Bus (SMBus) Specification, Version 3.0* for bus timing.

29.4.2.4 ARP Master Behavior

Figure 29-3. ARP Master Behavior Flow Diagram



The ARP master must always execute the ARP when it enters the working state and anytime it receives an SMBus status change indication (due to device addition or removal). The process begins with the ARP master issuing the Prepare To ARP command. In all cases the ARP master must be able to resolve addresses when it receives the Notify ARP Master command.

Since SMBus devices join the system without a corresponding system reset (i.e., a hot-plug event), the ARP master optionally chooses to issue the Get UDID (general) command at least once every 10 seconds to discover newly added devices that require address resolution but which do not support the Notify ARP Master command. No device whose AR flag is set responds to this command. However, a newly added device enters the system with a power-up reset, which resets its AR flag; it responds to a Get UDID (general) command with its UDID. The host chooses to assign such a newly added device a non-conflicting address or chooses to re-ARP the entire bus.

Until the ARP process is complete, the ARP master must not wait more than 2 seconds before issuing a Get UDID (general) command after issuing the previous Get UDID (general) command. This restriction is important to allow another SMBus master to determine when it is safe to do an enumeration of the bus.

Table 29-10. ARP Master Operation (Sheet 1 of 2)

Step		Description
0.	Perform ARP master initialization.	• [FW] See Section 29.4.2.5, "ARP Initialization Flow" on page 746.
1.	Upon starting, the ARP master initializes its used address pool. Initially this consists of the slave addresses of fixed-address SMBus devices known to the ARP master and reserved addresses (as defined in *SMBus 2.0 Specification*).	• [FW]
2.	Send the Prepare To ARP command.	• [FW]
3.	Check for an acknowledgment for all bytes in the previous packet. If any bytes were not acknowledged then the ARP master assumes that no ARP-capable devices are present and therefore consider the ARP process complete; proceed to step 4. If all bytes were acknowledged then go to step 6.	• [FW]
4.	The ARP master found no response to the Prepare To ARP command so it assumes that no ARP-capable devices are present in the system at this time. The ARP master periodically re-issues the Prepare To ARP command to discover any ARP-capable devices added. Proceed to step 5.	• [FW]
5.	Wait for an SMBus packet. If a packet is received proceed to step 15.	• [FW]
6.	Send the Get UDID command.	• [FW]
7.	Check for an acknowledgment for the first three bytes and verify that the byte count value received is 0x11. If not, then the ARP master assumes that an ARP-capable device(s) is no longer present and therefore consider the ARP process complete; proceed to step 4. Otherwise proceed to step 8.	• [HW and FW] HW verifies the byte count before sending descriptor to FW.
8.	Check the value of the device slave address received. If 0xFF then proceed to step 11 since this device does not possess a valid slave address. Otherwise proceed to step 9.	• [FW]
9.	Determine if this device has a fixed slave address. If bits 127 and 126 of the UDID are 00b then it has a fixed address, so proceed to step 12. Otherwise proceed to step 10.	• [FW]
10.	The device possesses a valid slave address. However, the ARP master must check this address against the used address pool to ensure that no other device has already been assigned the same address. If the received device slave address is found in the used address pool then proceed to step 11. If not, then the device keeps its current slave address but needs acknowledgment from the ARP master; proceed to step 12.	• [FW]

Table 29-10. ARP Master Operation (Sheet 2 of 2)

Step		Description
11.	Select a slave address that is not in the used address pool and proceed to step 12.	• [FW]
12.	Send the Assign Address command with the UDID returned by the device in the Get UDID command packet.	• [FW]
13.	Check for acknowledgment of all bytes in the Assign Address command packet. If any byte was not acknowledged then the ARP master assumes the device is no longer present; proceed to step 6 to determine if more devices require address resolution. If all bytes were acknowledged then the ARP master assumes that the device has accepted the address assignment; proceed to step 14.	• [HW and FW] HW monitors slave ACK before sending descriptor to FW.
14.	The device now has a valid slave address. The ARP master must add this address to the used address pool. Proceed to step 6 to determine if more devices require address resolution.	• [FW]
15.	The ARP master checks if the received packet was the Notify ARP Master command. If so, then it must execute the ARP to resolve the address for the newly added device(s); proceed to step 6. If not, then proceed to step 16.	• [FW]
16.	The ARP master received a non-ARP related packet. Process it accordingly and proceed to step 5.	• [FW]

These steps cover the case when the ARP master has exited a reset state. Since ARP supports hot-plug, the master must be prepared to execute the ARP at any time; step 15 covers the case when a device issues the Notify ARP Master command. If during the ARP process, a previously detected device is now not discovered, then the slave address associated with that device is removed from the used address pool.

The diagram does not consider bus time-out mechanisms or retries. These are implemented to comply with SMBus timing requirements.

29.4.2.5 ARP Initialization Flow

The firmware initializes the SoC for ARP protocols before any SMBus traffic. Because the SMT master behavior applies to both master-transmitter (e.g., ARP host issuing a prepare to ARP) and slave-transmitter (e.g., ARP slave issuing a host notify), and SMT target behavior applies to both master-receiver (e.g., ARP host receiving a host notify) and slave-receiver (e.g., ARP slave receiving a prepare to ARP), many ARP initialization steps are common to host and slave devices.

The exception is UDID assignment. This pertains only to ARP slaves.

Table 29-11. ARP Initialization Flow (Sheet 1 of 2)

Initialization Flow for an ARP Slave	Initialization Flow for the ARP Host
Configure the SoC bootstrap configuration information programmed fields. • Preset UDID fields are loaded from the SoC bootstrap configuration information. • Also, the SoC bootstrap configuration information is loaded to configure the unique UDID field (VSID)—the hardware permutes the SoC bootstrap configuration information to program multiple UDIDs as necessary. ***Example:*** To support two functions each with two UDIDs, combine three hard-coded LSBs with a sufficient number of SoC bootstrap configuration information bits (n) to distinguish all SoC devices. **Bit Fields:** VSID = [31:32-*n*] [32-*n*-1:3] [2:1] [0] VSID = SoC bootstrap configuration information bits static-bits function UDID Fn0/UDID0 = {SoC bootstrap configuration information bits}{static bits}{00}{0} Fn0/UDID1 = {SoC bootstrap configuration information bits}{static bits}{00}{1} ... Fn1/UDID1 = {SoC bootstrap configuration information bits}{static bits}{01}{1} The SoC bootstrap configuration information bits are shared by all functions and UDIDs. • Preset other fields based on the SoC bootstrap configuration information: GPBRCTRL.GPTRADR, SPGT.SPD, TPOLICY.ADDR0_EN, TPOLICY.ADDR1_EN, and TPOLICY.Host_SMBADDR_EN.	Configure the SoC bootstrap configuration information programmed fields. • N/A • N/A • Preset other fields based on the SoC bootstrap configuration information: GPBRCTRL.GPTRADR, SPGT.SPD, TPOLICY.ADDR0_EN, TPOLICY.ADDR1_EN, and TPOLICY.Host_SMBADDR_EN.
Program SMBus address to any fixed-address target. • Program TACTRL.ADDR0 if required based on UDID0.DEVCAP field. • Program TACTRL.ADDR1 if required based on UDID1.DEVCAP field.	
Verify transaction status flags (no invalid state flags). • Verify all 0s in fields TSTS.IP and MSTS.IP. • Likewise, verify numerous error-status registers.	
Program descriptor base address and buffer entries. • Program MDBA and MDS. • Program TBBA and TBS. • Program SMTICL.	
Program head and/or tail pointers. • Program MCTRL.FMHP and MSTS.HMTP. • Program HTHP.HTBHP and FTTP.FTBTP.	

Table 29-11. ARP Initialization Flow (Sheet 2 of 2)

Initialization Flow for an ARP Slave	Initialization Flow for the ARP Host
Enable (unmask) interrupts from the hardware due to certain conditions. • Assert/de-assert ERRINTMSK, ERRAERMSK, TCTRL.TIE, MCTRL.MEIE.	
Configure policies. • Program RPOLICY.TBRCLKCNT, RPOLICY.COLRTRY, RPOLICY.TBRBCLK, RPOLICY.RETRY.	
Configure GPBR • Set GPBRCTRL.EN. • Assert/de-assert GPBRCTRL.PECEN. • Assert/de-assert GPBRCTRL.HWCLRDIS. • Program GPBRCTRL.BC. • Program GPBRCTRL.CMD. • Program GPBRCTRL.GPTRADR.	

29.4.3 SMT System Usage Models

The SMT architecture takes into account various usage models as envisioned on the SoC-based platforms. The focus of the architecture is to keep the hardware overhead low for supporting the various usage models and protocols:

- SMBus ARP mastering or ARP target
- Embedded Controller (EC) on the SMBus communicating with the SoC

29.4.4 SMT Security Requirements

The SMT has no security requirements.

29.4.5 SMT Timing Modes

The SMT currently supports three different timing modes: standard (up to 100 kHz), fast-mode (up to 400 kHz), and fast-mode plus (up to 1 MHz). The timing requirements for fast-mode and fast-mode plus are found in the I^2C industry specification.

The following section covers design targets for the various timing modes in various operating conditions. The SMT controller does not contain dynamic timing adjustment to account for varying bus loads or pull-up resistor selections, thus SMT is designed and have default settings to meet the specification in the worst-case scenarios. This comes at the cost of not having optimal frequency for any given timing mode in nominal conditions.

Note: Devices also stretch the clock low thus reducing the frequency. These timing estimates are assuming the device is not further impacting the timings.

Table 29-12. SMT Timing Mode Maximum Clock Frequency Ranges

Mode	Maximum Clock Frequency Range
Standard	90-100 kHz*
Fast Mode	350-400 kHz*
Fast Mode Plus	750-1000 kHz*

*Timing assumes the platform design is within the specification for maximum rise time allowed requiring appropriate Rpullup value selection for the given capacitive load on the bus.

29.4.6 SMT as Master

The SMT as the initiator provides the hardware for the internal agents inside the SoC to send/receive data across the SMBus. Due to the various usage models that SMT supports, the hardware support exists for initiating reads/writes from/to external devices on the SMBus. The SMT has the hardware capability to transport them over the physical SMBus and report the status back to the firmware.

Note: The firmware must ensure the data in the transmit data buffers is arranged in the order that it wants to send on the bus, i.e., data pointed to by the Tx data pointer are sent first on the SMBus, then the next byte, etc.

With respect to the receive buffer, data are written to memory as-is received from the physical SMBus, i.e., the first byte received is placed in the lowest address, then the next byte, etc.

29.4.6.1 Hardware Buffering for Master Support

The hardware implements a 240-byte buffer which it uses to queue transactions (both master-transmitter and master-receiver) as a descriptor-based master. Though the hardware supports a maximum read/write of 240 bytes, the firmware driver restricts the payloads to <=32B to compliance SMBUS spec. Please see Section 29.4.6.3.2, “PEC-Enabled SMBus Transactions” for details.

The storage queues are not shared between the master and the target. Both logical sides function independently without dependency on each other.

Note: Although SMT theoretically supports master-initiated write and read cycles of arbitrary length, the practical expectation is that the transaction size does not exceed 32B with Intel firmware driver.

Note: When SMT as master sends I2C write or read, the hardware can support a maximum payload 240 bytes with custom external driver.

29.4.6.2 Master Descriptor

The master descriptor is a ring buffer of individual descriptors set up by the firmware as shown in Figure 29-4. The descriptor ring buffer is pointed to by the base (MDBA) and the size is indicated by the MD Size register (MDS). See register definitions for details. Individual descriptors have a 64-bit pointer into the data buffer with an expected transmit and/or receive length programmed in the control field of the descriptors.

The hardware updates the status WB field in Figure 29-4 and Figure 29-5. See Table 29-13, "Master Descriptor Field Descriptions" for detailed descriptions. The remaining three Dwords are updated by the firmware.

The firmware always leads and points by the FWmHeadPtr (MCTRL.FMHP). The hardware always points by the HWmTailPtr (MSTS.HMTP).

Figure 29-4. Master Descriptor Ring Buffer

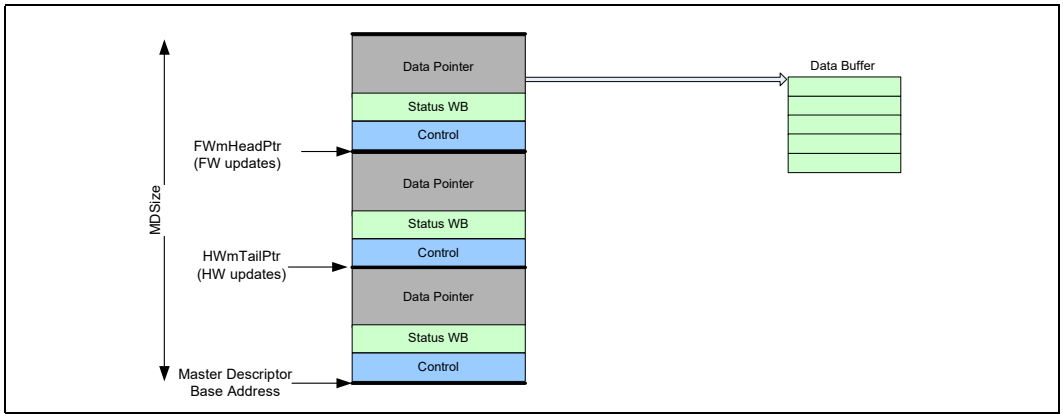


Figure 29-5. Master Descriptor Format

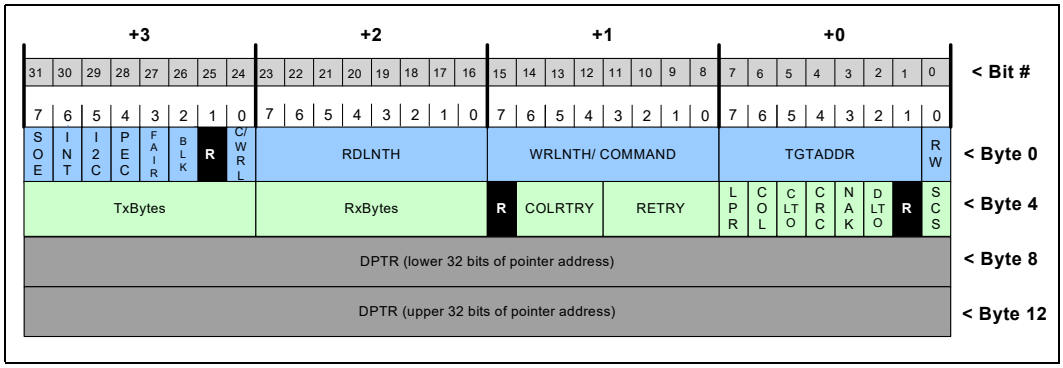

Table 29-13. Master Descriptor Field Descriptions (Sheet 1 of 3)

Dword #	Bit #	Field	Description
0	31	SOE	**Stop On Error**: This bit is set to 1 to direct the hardware that if a descriptor-based master cycle results in an unsuccessful transaction on SMBus, the hardware must clear the Start/Stop bit (MCTRL.SS) and stop the engine. If this bit is clear if the hardware encounters an error while sending a transaction on SMBus, it sets the Master Error Status bit (MSTS.MEIS) and continues to process the next descriptor in the queue.
0	30	INT	**Interrupt**: This bit is set to 1 to direct the hardware that it must generate an MSI to the firmware when it has completed the requested transaction successfully. This interrupt is generated only after the status Dword of the descriptor is written back to memory. Interrupts due to unsuccessful transactions on the SMBus are not affected by this bit. If this bit is clear and the transaction is successful on the SMBus, no interrupt is generated; however, the firmware polls the MSTS.MIS bit. ***Note:*** When using legacy interrupts, this bit has no effect; a legacy interrupt is always generated even if not requested by the master descriptor (firmware).
0	29	I^2C	I^2C **Enable:** This bit is set to 1 to indicate the hardware must perform the transaction using I^2C protocol.
0	28	PEC	**Packet Error Code**: This bit is set to 1 to indicate the hardware must append CRC (or PEC) as the master of the requested transaction if it is a write or check received CRC (PEC) of the requested transaction if it is a read. PEC is calculated over the entire message (including address and read/write bits) and supplied by the device which puts out the last-data byte of the message.
0	27	FAIR	**Fair**: This bit is set to 1 to indicate if the hardware is able to successfully win arbitration on the bus and master the transaction, it must set its internal fairness flag. This allows a mechanism for fairness on the SMBus per *MCTP Specification*.
0	26	BLK	**Block**: Set to 1 by the firmware to indicate the hardware must perform a block transaction on the bus. The hardware determines one of three block transactions based on the following fields {BLK, C/WRL and R/W}. 100: Perform an SMBus block write. 111: Perform an SMBus block read. 101: Perform an SMBus block process call. Others: Reserved
0	25	Reserved	Reserved
0	24	C/WRL	**Command/Write Length**: Set to 1 by the firmware when it has overloaded the write length field with the command code of the SMBus transaction.
0	23:16	RDLNTH	**Read Length**: Indicates the number of bytes the hardware receives from the target, and writes to the receive data buffer one-based counting, i.e., the value 0h means 0 bytes of receive data and the value Ah means 10 bytes of receive data. The maximum read length currently supported by the hardware is 240 bytes due to its internal buffer size.
0	15:8	WRLNTH	**Write Length**: Indicates the number of bytes the hardware transmits as a master (except the first address byte, byte count, and any subsequent address bytes for reads) one-based counting, i.e., the value 0h means 0 bytes of transmit data and the value Ah means 10 bytes of transmit data. The maximum write length supported by the hardware is 240 bytes including address due to the size of its internal buffer. The byte count for the SMBus transactions is calculated by the hardware based on the write length field. Example: If WRLNTH = 8, the hardware calculates byte count = 7 and sends on the SMBus. The WRLNTH field itself contains command code and 7 bytes of data. When the C/WRL flag is set, this field contains the command code of the SMBus transaction.

Table 29-13. Master Descriptor Field Descriptions (Sheet 2 of 3)

Dword #	Bit #	Field	Description
0	7:1	TGTADDR	**Target Address**: 7-bit address field indicating the target SMBus/I^2C address. ***Note:*** See Section 29.4.6.7, "Write Disabling to DIMM SPD EEPROM Addresses" on page 764 for restrictions on writes to certain addresses.
0	0	RW	**Read/Write**: Set to 1 to indicate a read request. Cleared to 0 to indicate a write request. Combinations of this bit and the WRLNTH, RDLNTH, and C/WRL fields are decoded by the hardware to distinguish between various types of SMBus cycles and I^2C cycles. ***Note:*** For SMBus Process Call commands, this bit must always be cleared to 0. ***Note:*** See Section 29.4.6.7, "Write Disabling to DIMM SPD EEPROM Addresses" on page 764 for restrictions on writes to certain addresses.
1	31:24	TxBytes	**Transmitted Bytes**: The hardware updates this field to indicate how many bytes transmitted by it were ACKed by the target. This field provides the firmware the ability to reconstruct which particular byte was NACKed by the target. This count is one-based and includes all the bytes sent by the hardware which are ACKed by the target including the address. Value of 0 means address phase NACKed or collision on the address phase.
1	23:16	RXBytes	**Received Bytes**: The hardware indicates how many bytes of received data it is writing to memory (into the data buffer). The count is one-based, i.e., the value 0h means 0 bytes of data. The hardware limitation is for a 240-bytes data buffer implying that for a maximum SMBus legal block read of 32 bytes with the PEC, it forwards to memory the 240 bytes of data; the byte count received. ***Note:*** PEC is not forwarded to the firmware, since the firmware explicitly enables/disables PEC per master transaction. The hardware returns the PEC check in the CRC field, which the firmware inspects.
1	15	Reserved	Reserved
1	14:12	COLRTRY	**Collision Retry**: The hardware indicates the number of collisions on the last attempt before retiring the descriptor.
1	11:8	RETRY	**Retry Count**: The hardware indicates the count with the number of retries attempted before retiring the descriptor.
1	7	LPR	**Large Packet Received**: The hardware sets this bit to indicate that more data was sent by the target than expected by the firmware and exceeds the allocated receive data space (TRxCTRL.MRxB). The hardware must DMA the data to the buffer in memory in the space allocated, dropping the extra bytes.
1	6	COL	**Collisions**: Set to 1 by the hardware to indicate that failure was due to number of collisions exceeding the collision retry count (RPOLICY.COLRTRY).
1	5	CLTO	**Clock Low Time Out**: Set to 1 by the hardware to indicate unexpected time-out seen on the bus during the course of the request. This bit being set indicates that SMB clock signal was held low by the external device for the count as programmed in CNT.
1	4	CRC	**CRC Error:** Set to 1 by the hardware to indicate CRC error[1] on the request. For read requests with PEC, the hardware sets this bit if the PEC received from the target does not match the PEC calculated by the hardware. For write requests with PEC, the hardware sets this bit if the target NACKs the PEC byte.
1	3	NAK	**NACK Received:** Set to 1 by the hardware to indicate unexpected NACK asserted by the target.
1	2:0	Reserved	Reserved
1	0	SCS	**Success**: Set to 1 by the hardware to indicate that the cycle was transferred successfully. Zero indicates that some error was encountered and other bits in the status indicate the error.

Table 29-13. Master Descriptor Field Descriptions (Sheet 3 of 3)

Dword #	Bit #	Field	Description
2	31:0	DPTR	**Data Pointer:** Byte-aligned pointer to the starting location of the data buffer. The hardware reads from memory and transmits exactly as many bytes as is indicated by the WRLNTH field. This does not include the address fields of the message (i.e., start address/repeated start address) and byte count if any. The hardware is expected to write to memory exactly as many bytes as is indicated by the RDLNTH field (unless an error condition exists and the target fails to provide the expected number of bytes, in which case the appropriate error bits are set).
3	63:32	DPTR	

1. The *System Management Bus (SMBus) Specification, Version 3.0* is vague about the condition of the CRC error when the master is initiating a READ and the target provides the CRC. Irrespective of the fact that the CRC is correct or incorrect, the master must NACK the cycle and assert STOP. The SMT hardware informs the firmware of the incorrectness of the received CRC and leaves it up to the firmware for further action. See the *System Management Bus (SMBus) Specification, Version 3.0*.

29.4.6.3 Master Descriptor Usage

Descriptors are used for SMT transactions the are initiated by the firmware. The hardware decodes the I^2C, PEC, WRLNTH, and RDLNTH fields to differentiate between the types of SMBus transactions (see Section 29.4.6.3.1, "SMBus Protocol Transfers" on page 754) and I^2C transactions (see Section 29.4.6.3.3, "I^2C Protocol Transfers" on page 757).

The master transaction flow is defined in Section 29.4.6.4, "Master Transactions Flow" on page 758.

The master retry flow is defined in Section 29.4.6.6, "Master Retry Flow" on page 762.

29.4.6.3.1 SMBus Protocol Transfers

Table 29-14 illustrates how the hardware uses the control information in the descriptor.

Note:

1. The firmware must ensure that the I^2C bit is 0 when initiating SMBus transactions.
2. Target address and R/W# indication is taken from the descriptor.
3. PEC-enabled write transactions proceed in the same manner except that the hardware appends PEC after the last data phase.
4. PEC-enabled read transactions instruct the hardware to check CRC and report the status to the firmware.

Note: See Section 29.4.6.7, "Write Disabling to DIMM SPD EEPROM Addresses" on page 764 for restrictions on writes to certain addresses.

Table 29-14. SMBus Transaction Encodings (Sheet 1 of 2)

SMBus Command	BLK	C/WRL	WRLNTH	RDLNTH	RW (0=W; 1=R)	DPTR (Points to TX Data)	DPTR (Points to RX Data)
Quick Command	0	0	0	0	Read/ Write	X	X
Send Byte	0	1	Command	0	0	X	X
Receive Byte	0	0	0	1	1	X	Valid and points to a buffer where the received byte is placed.
Write Byte	0	0	2	0	0	Valid and points to 2 bytes (command and 1-data byte).	X
Write Word	0	0	3	0	0	Valid and points to 3 bytes (command and 2-data bytes).	X
Read Byte	0	1	Command	1	1	X	Valid and points to a buffer where the received byte is placed.
Read Word	0	1	Command	2	1	X	Valid and points to a buffer where the received 2 bytes are placed.
Process Call	0	0	3	2	0	Valid and points to 3 bytes (command and 2-data bytes).	Valid and points to a buffer where the received 2 bytes are placed.

Table 29-14. SMBus Transaction Encodings (Sheet 2 of 2)

SMBus Command	BLK	C/WRL	WRLNTH	RDLNTH	RW (0=W; 1=R)	DPTR (Points to TX Data)	DPTR (Points to RX Data)
Block Write (1 byte)	1	0	2	0	0	Valid and points to 2 bytes (command and 1-data byte); the byte count is calculated by the hardware.	X
Block Write (2 bytes)	1	0	3	0	0	Valid and points to 3 bytes (command and 2-data bytes); the byte count is calculated by the hardware.	X
Block Write (3 bytes or more)	1	0	4 or more[1]	0	0	Valid and points to at least 4 bytes (command and 3-data bytes); the byte count is calculated by the hardware.	X
Block Read (1 byte)	1	1	Command	2	1	X	Valid and points to a buffer where the received 2 bytes are placed (byte count, data byte 1).
Block Read (2 bytes or more)		1	Command	3 or more[2]	1	X	Valid and points to a buffer where at least the received 3 bytes are placed (byte count, data byte 1, etc.).
Block Write-Block Read Process Call[3] (write 1 byte, read N)	1	0	2	N[4]+1	1	Valid and points to 2 bytes (command and 1-data byte); the byte count is calculated by the hardware.	Valid and points to a buffer where at least the received (N+1) bytes are placed (byte count, N data bytes).
Block Write-Block Read Process Call (write 2 bytes, read N)	1	0	3	N+1	1	Valid and points to 3 bytes (command and 2-data bytes); the byte count is calculated by the hardware.	Valid and points to a buffer where at least the received (N+1) bytes are placed (byte count, N data bytes).
Block Write-Block Read Process Call (write >2 bytes, read N)	1	0	4 or more	N+1	1	Valid and points to at least 4 bytes (command and 3-data bytes); the byte count is calculated by the hardware.	Valid and points to a buffer where at least the received (N+1) bytes are placed (byte count, N data bytes).

1. Per the *System Management Bus (SMBus) Specification, Version 3.0*, having a block write of exactly 3 bytes can occur. However, a block write of 3 bytes and a write word have identical signaling on the bus.
2. Per the *System Management Bus (SMBus) Specification, Version 3.0*, having a block read of exactly 2 bytes can occur. However, a block read of 1 data byte (address, command, byte count = 1, followed by 1 data byte) and a read word from the target (address, command, DataByte1, DataByte2) have identical signaling on the bus.
3. The sum of the data bytes in the write and read phases must not exceed 32 bytes per the *System Management Bus (SMBus) Specification, Version 3.0*.
4. N must be greater than 1.

29.4.6.3.2 PEC-Enabled SMBus Transactions

For writes going out from the SMT to the SMBus, the PEC is calculated by the hardware and appended. For reads, the PEC byte is received from the target and verified by the hardware (incorrectness notification is provided to the firmware by the status bits). The PEC byte is not sent to the buffer.

Note: Firmware-specific:

1. If the firmware wants to send a large amount of data (more than 32 data bytes without counting command byte and byte count) to a target using the SMBus 2.0 protocol and indicates to the hardware to send data using block write protocol, the firmware is responsible to break the data into multiple packets and set up individual descriptors for each packet.
2. The firmware honors all SMBus 2.0 rules for transactions of write, read, transcribe of the total data transfer on the SMBus being not more than 32 bytes (including BlockWr-BlockRd process call).
3. The firmware sets the PEC bit when initiating a PEC-accompanied read from a target so that the hardware verifies and reports PEC accuracy, or when initiating a PEC-accompanied write transaction so that the hardware automatically appends the PEC byte.
4. The firmware must clear the I^2C bit when initiating the SMBus transactions.
5. Because a single pointer is used, for SMBus transactions which both transmit and receive data (i.e., process call and block write-block read process call), the received data overwrites the transmitted data. Before beginning the transaction, the firmware must copy the transmit data if the transmit data are preserved after the transaction.

29.4.6.3.3 I²C Protocol Transfers

For I²C transactions, Table 29-15 illustrates how the hardware uses the control information in the descriptor. The following are the I²C support limitations:

1. Support is limited to 7-bit addressing mode only.
2. Write-read combined format is supported with SMT as a master.
3. As a target, the hardware supports only writes initiated by an external master.
4. When the SMT sends/receives I2C write/read, Hardware supports payloads any size up to 240B.

Table 29-15. I²C Commands

I²C Command	C/WRL	WRLNTH	RDLNTH	RW (0=W; 1=R)	DPTR (points to TX data)	DPTR (points to RX data)
I²C Writes (MTx-to-SRx)	1	Command (1 byte of write data)	0	0	X	X
I²C Writes (MTx-to-SRx)	0	2 or more	0	0	Points to the transmit buffer containing at least 2 bytes of write data.	X
I²C Reads (STx-to-MRx)	0	0	1 or more	1	X	Points to the receive buffer where the receive data are placed.
I²C Combined Format (write followed by read)	1	Command (1 byte of write data)	1 or more	0	X	Points to the receive buffer where the receive data are placed.
I²C Combined Format (write followed by read)	0	2 or more	1 or more	0	Points to the transmit buffer containing at least 2 bytes of write data	Points to the receive buffer where the receive data are placed.

Notes:
1. This table assumes the target address is programmed in the descriptor and is not part of the WRLNTH field.
2. The I²C bit must be set for all I²C transactions.
3. PEC is not supported for any I²C transaction.
4. The BLK bit must be 0 for all I²C transactions.

29.4.6.4 Master Transactions Flow

All master transactions on the physical SMBus pins use descriptors. The high-level flow typically is:

1. The firmware sets the data structures in memory.
2. The firmware programs the descriptors and the associated hardware.
3. The firmware sets the Start bit to initiate the transactions.
4. The hardware processes the descriptor, first setting the InProgress bit, and completes the transaction.
5. The hardware writes data back to memory (if any).
6. The hardware writes back the status to memory for the processed descriptor.
7. If no more descriptors are processed, the hardware clears the InProgress bit.

29.4.6.4.1 Firmware Assumptions

The assumption is an SMT firmware driver exists that understands the SMT hardware register interface and the usage for sending and receiving SMBus messages.

29.4.6.4.2 Initialization

1. The firmware allocates a 64B aligned buffer in memory to be used as the master descriptor ring buffer. Each descriptor is 16B long.
2. The firmware then programs up the MD Base Address (MDBA) register with the lower memory address of the descriptor ring buffer, and MD Size (MDS) register containing the number of descriptors in the ring.
3. The firmware initializes the FWmHeadPtr (MCTRL.FMHP) and HWmTailPtr (MSTS.HMTP) by writing all 0 into it.
4. The firmware also programs interrupts as needed.

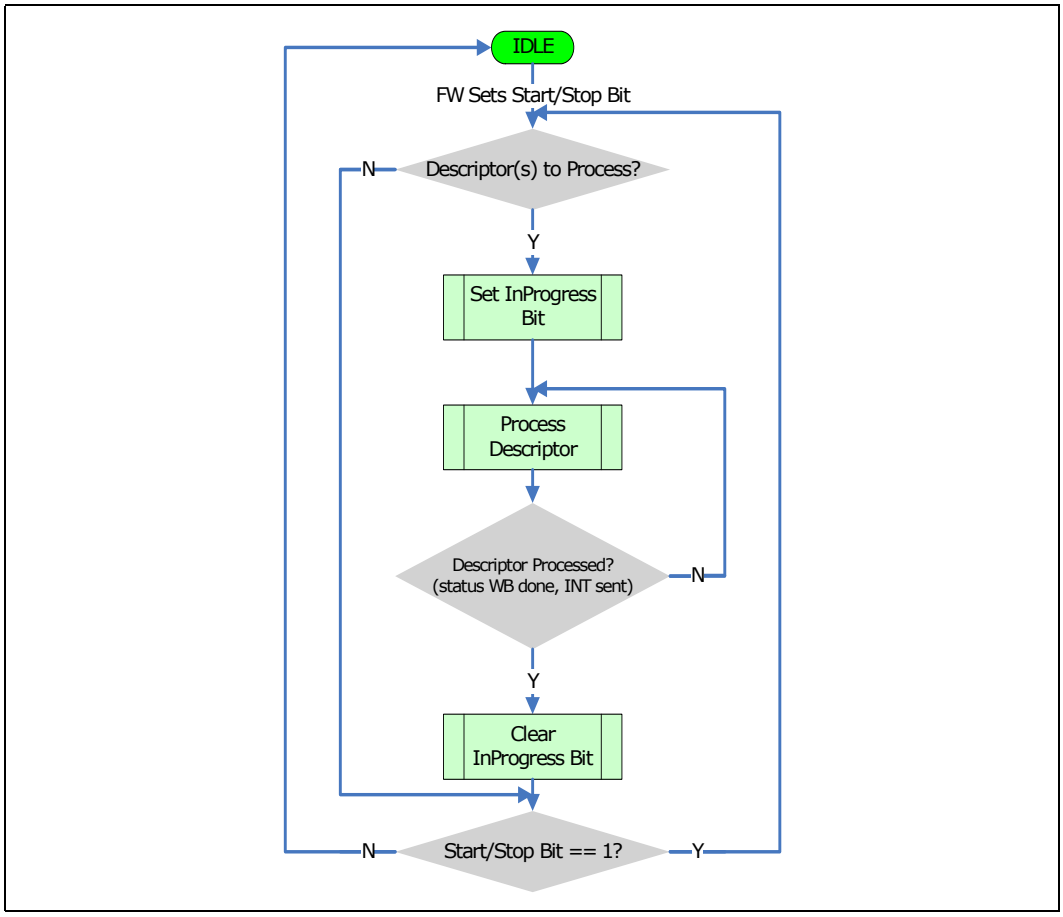
Note: The firmware schedules a master transaction in the descriptor ring buffer if the buffer is not full. The descriptor ring buffer is full if (FWmHeadPtr == HWmTailPtr - 1). The –1 subtraction here needs to account for buffer utilization of N-1 for an N-deep buffer.

29.4.6.4.3 Hardware-Firmware Flow

When the firmware driver has to initiate a transaction on the SMBus, and the descriptor ring buffer is not full, the following steps are performed:

1. The firmware programs a 16B descriptor with the attributes of the transaction in memory.
2. The firmware increments the FWmHeadPtr register.
3. The firmware then sets the Start bit (MCTRL.SS) in the hardware.
4. The hardware continuously checks if a descriptor needs to be processed by checking (FWmHeadPtr != HWmTailPtr):
   a. Buffer empty condition: MSTS.HMTP = MCTRL.FMHP
   b. Buffer full: MCTRL.FMHP = MSTS.HMTP-1 or MCTRL.FMHP-MSTS.HMTP = MDS
   c. Buffer wrap condition: When MSTS.HMTP = MDS, and MCTRL.FMHP has already wrapped around, i.e., >= 00h, the hardware reads the 16B descriptor, processes it and if the criteria to increment the pointer are met, it wraps to 00h.
5. If a descriptor (see Section 29-6, "Hardware-Firmware Flow Diagram—DMA Mode" on page 760) is available, the hardware first sets the InProgress bit (MSTS.IP), and then reads the 16B descriptor from memory by combining (MD Base + HWmTailPtr) from which it:
   a. Decodes the control Dword for transaction type and other attributes.
   b. Loads the write data and read data pointers as required.
   c. For writes, the hardware fetches data from the memory pointed to by the DPTR and transmits on the wire. For reads, the hardware stores the DPTR pointer so it can Direct Memory Access (DMA) the data to that address when data is provided by the target.
6. Once the transaction is completed, the hardware does a status write back to the status WB Dword.
7. The hardware then increments HWmTailPtr and sends the interrupt to the firmware if enabled to do so.
   a. Before issuing the MSI, the hardware denotes the master completion in SMTICL and any error status.
8. The hardware then clears the InProgress bit to indicate it has completed processing of the descriptor.
9. The hardware then checks if the Start bit is set. If so, flow follows from #4, or else from #1.

Figure 29-6. Hardware-Firmware Flow Diagram—DMA Mode



29.4.6.5 Clearing of the Start Bit

Under certain conditions, the hardware clears the Start bit (MCTRL.SS).

The hardware clears this register for the following fatal error scenarios:

- The transaction is unsuccessful on the final retry (if enabled), including collisions.
- The hardware receives unsuccessful completion on the internal SoC I/O fabric.

The hardware clears this register for the following non-fatal scenario:

- Master descriptor Stop-on-Error (SOE) bit was set and the transaction was unsuccessful.

The firmware clears the Start bit when it kills a master transaction:

1. The firmware clears MCTRL.SS.
2. The firmware sets GCTRL.KILL.
3. The firmware polls MSTS.IP; the transaction is killed when the bit is detected as cleared.

29.4.6.6 Master Retry Flow

The hardware contains separate timers and counters to auto-retry unsuccessful SMBus cycles that it masters on the SMBus.

Two counters for time between retries and retries due to collision are on the bus. Any failed cycle due to a collision first exhausts the collision counter before decrementing the retry counter. The time between retries is maintained only between two successive transaction retries and not between two successive retries due to a collision.

The high-level flow in the pseudo code is:

```
//Master Transaction begin

MASTER_FLOW

// All registers are defined in RPOLICY register

RELOAD RETRY

// Collision retries

COLRTRY

// Time between retries

TBR

While (RETRY >= 0) {

    RELOAD TBR

    RELOAD COLRTRY

    Send Cycle on SMBus

    While (SMBus COLLISION & (COLRTRY > 0)) {

        COLRTRY = COLRTRY - 1

        WAIT for SMBus IDLE

        Send Cycle on SMBus

    }

    If (SMBus ACK) {

    // Successful cycle

    Update Status in descriptor and WB to memory

    Send Interrupt if enabled

    GOTO MASTERFLOW and wait for new cycle

        BREAK

    } else if

    // Unsuccessful cycle

    (((RETRY == 0) & SMBus NACK) || SMBus Timeout) {

    Update Status in descriptor and WB to memory
```

```
    Set Master Error and send MSI (if enabled) after updating SMTICL

    Clear DMA Start/Stop Bit

GOTO MASTERFLOW and wait for FW to set Start bit

    BREAK

    } else if (SMBus NACK & (RETRY > 0)){

        RETRY = RETRY - 1

        CNTDOWN TBR

        WAIT for TBR to expire

    }

}
```

29.4.6.7 Write Disabling to DIMM SPD EEPROM Addresses

Although this controller is not intended to participate in the DIMM Serial Presence Detect (SPD), an attacker connects its data and clock lines to the segment which includes the SPD EEPROM and mounts an attack. To prevent this, a write disable (MCTRL.SPDDIS) is introduced. If SPDDIS is deasserted, writes are not restricted; however, if SPDDIS is set then writes to the address range A0h-AEh are blocked and an error is flagged. Writes to addresses outside the range A0h-AEh are not affected by SPDDIS, and reads are never affected.

Table 29-16. DIMM SPD EEPROM Write-Disable Mechanism

Target Address [7:4]	Target Address [0] (Read/Write Operation)	SPD Disable Bit (MCTRL.SPDDIS)	SMBus Behavior
Ah	0 (write)	0 (enabled)	Allow writes to addresses A0-AEh.
Ah	0 (write)	1 (disabled)	Deny writes to addresses A0-AEh and log error (ERRSTS.SPDWE).
Ah	1 (read)	Any	Allow reads to addresses A0-AEh.
!= Ah	Any	Any	Allow writes and reads.

The SPDDIS is read-write-once, and the BIOS Memory Reference Code (MRC) is expected to set this bit when SPD is complete. Since the SMBus (host) controller is not intended for SPD, the BIOS must set its SPDDIS at any time in the boot flow.

29.4.7 SMT as Target

The SMT has a fully-functional target interface for other masters on the SMBus intending to communicate with the SMT. The usage models for this are:

- SMBus ARP mastering or ARP target
- Embedded Controller (EC) on the SMBus communicating with the SoC

The hardware aspect of the target interface is highly generalized. Most transactions are treated as raw data which are pushed to the firmware, where the firmware transacts level activity like protocol detection. Acceleration in hardware is limited to interception of ARP Get UDID and SMBus block-read protocols, which require an immediate return of data to an external master and PEC CRC calculation. The other hardware responsibility is inspection of enough transaction bytes (e.g., target address, command code, UDID) to ascertain the protocol type and to engage the appropriate hardware flow.

29.4.7.1 Hardware Buffering for Target Support

The hardware implements a separate 240-bytes buffer to store the bytes it receives as a target, but when SMT is target to receive SMBus block write/read, the support maximum payload is <=32B.

The hardware also implements a separate 32-byte buffer which provides generic read data to external masters for any reads that they perform. This is a generic usage model in which firmware repeatedly programs the generic read-data buffer register (GPBRDBUF) with data, programs a MMIO offset (GPBRCTRL) with address, command, and byte count of how much data is present in the generic read data buffer, and communicates to the external master the hardware is ready for taking the read (in-band through the SMBus). The external master then launches a block read to the address programmed with the command, and the hardware provides the byte count and data bytes associated with it.

Note: When SMT as slave receives I2C write, the maximum buffer size supported can be 240 bytes with custom I2C driver.

29.4.7.2 Target Descriptor

Unlike the master descriptor, the target descriptor is a ring buffer of data and status, all existing concurrently. This simplified model results in the hardware writing a status of a received cycle immediately followed by the data received in the cycle (if applicable).

See also TRxSTS, which is used for debug.

Figure 29-7. Target Ring Buffer

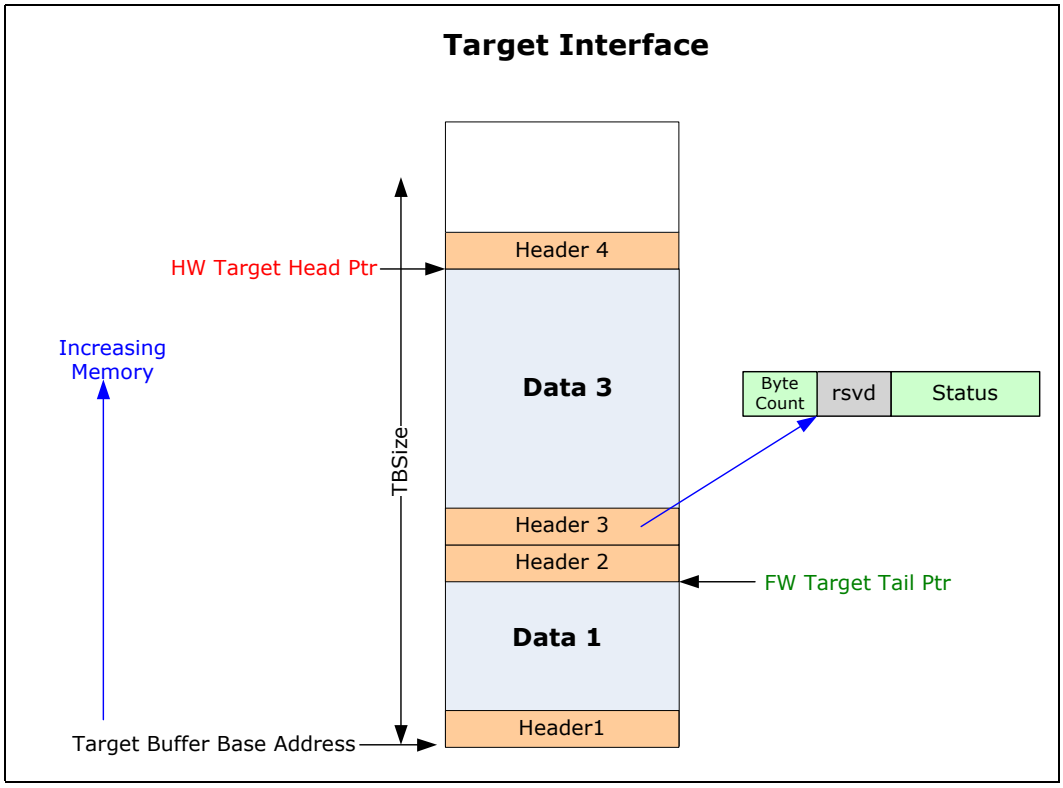


Figure 29-8. Target Header Format

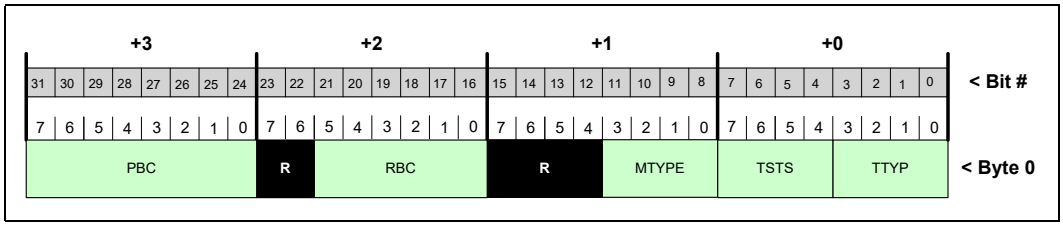

Table 29-17. Target Header Descriptor (Sheet 1 of 2)

Bit #	Field	Description
31:24	PBC	**Payload Byte Count:** The hardware updates this field to indicate how many bytes of payload data follows after the header in the target buffer. For writes coming in, this data includes the sum total of all bytes ACKed from start to stop. The hardware does then DMA all those bytes to memory. • For error scenarios where the master drives more data than expected or command code does not match, the hardware does DMA all bytes ACKed on the SMBus from start until the first byte NACKed by the hardware (this byte is not sent to memory), and the total number of bytes DMAed to memory is reflected in this field. A value of all zeros in this field means no payload is following the header.
23:22	Reserved	Reserved
21:16	RBC	**Read Byte Count**: For external master-generated reads, this data includes the sum total of bytes provided by the hardware which were successfully transferred over SMBus. For example: for an externally generated block read, the hardware provides byte count, X number of bytes, and PEC (if PEC-enabled transaction). In this case, the RBC field is 1+X+1 (for PEC). ***Note:*** For SMBus block reads, the last byte transferred is NACKed by the external master per definition. This is a data byte or PEC byte supplied by the hardware. The data bytes are not written to memory, only the byte count indicates how many bytes provided by the hardware were successfully transferred over SMBus. This field is all zeros if the transaction was an externally-generated write. The header is written to memory (if enabled to do so) containing the status of the transaction. For error scenarios in reads, the status register in the header provides details of the error, and this field contains incorrect values due to the pipelined nature of the hardware.
15:12	Reserved	Reserved
11:8	MTYPE	**Message Type**: These bits indicate which expected transaction happened on the bus since they are expected in the usage model and some have pre-programmed data provided by the firmware. • 0000: SMBus/I^2C transaction • 0111: Block read to general purpose read data buffer • 1000: SMBus ARP prepare to ARP • 1001: SMBus ARP reset device (general) • 1010: SMBus ARP Get UDID (general) • 1011: SMBus ARP assign address • 1100: SMBus ARP Get UDID (directed) • 1101: SMBus ARP reset device (directed) • 1111: SMBus ARP notify ARP master or SMBus host notify • Others: Reserved ***Note:*** Firmware: The cycle does not progress far enough for the hardware to encode the correct encodings. In this case, the hardware inserts some reserved value.

Table 29-17. Target Header Descriptor (Sheet 2 of 2)

Bit #	Field	Description
7:4	TSTS	**Transaction Status**: This field indicates the overall completion status of the transaction, i.e., success, fail, error condition, etc. Multiple error conditions occur in the same transaction (e.g., the hardware NACKs a byte and instead of an external master signaling stop, it continues to toggle the clock and eventually holds the clock low and causes time-out). The hardware captures the first error condition, i.e., the register reads 0011 for the example listed above. Refer to Table 29-19, "Target Header Encodings (TSTS) Per Transaction Type (TTYPE)" on page 770. • 0000: Success with no errors. • 0001: Speculative PEC error detected (the hardware always presumes PEC-enabled writes received). • 0010: Protocol error, i.e., the external master violated the SMBus protocol. For example, this is asserting STOP in the middle of the byte, or a stopped toggling clock, or doing an illegal repeated start, collision, etc. • 0011: Hardware NACK, i.e., the hardware NACKed one or more bytes as the byte did not match the expected byte of the sequence or exceeded hardware limitations. ***Note:*** This is the hardware overflow and does not comprehend overflow of an individual protocol (e.g., block write, received bytes > indicated byte count). • 0100: External NACK (external master NACKed at least 1 byte supplied by the hardware on an externally generated read). • 0101: Clock-low time-out • 0110: Data-low time-out • Others: Reserved
3:0	TTYPE	**Transaction Type**: This field indicates the type of transaction received by the hardware in terms of the various usage models supported: • 0000: Default SMBus transaction to C2h • 0001: Transaction targeting address (TACTRL.ADDR0) of UDID0 • 0010: Transaction targeting address (TACTRL.ADDR1) of UDID1 • 0100: Host notify transaction targeting 10h • 0101: Generic programmable block read to the programmed address in GPBRCTRL.GPTRADR • Others: Reserved ***Note:*** This definition is consistent with TSTS.TCIP.

Only certain combinations of target descriptor MTYPE and TTYPE are valid. These are summarized in Table 29-18 (shaded cells and all unlisted combinations are invalid). For each valid (MTYPE, TTYPE) pair a reference is included to the detailed hardware flowchart.

Table 29-18. Valid Target Descriptor MTYPE and TTYPE Combinations

		MTYPE			
		ARP-Related **1000** **1001** **1010** **1011** **1100** **1101**	**SMBus/I²C** **0000**	**Notify Host** **1111**	**GPBR** **0111**
TTYPE	0000	Section 29.4.7.5.2	Invalid	Invalid	Invalid
	0001 0010	Invalid	Section 29.4.7.5.6	Invalid	Invalid
	0100	Invalid	Invalid	Section 29.4.7.5.1	Invalid
	0101	Invalid	Invalid	Invalid	Section 29.4.7.5.3

29.4.7.3 Target Transaction Status

Table 29-19 provides a reference of the encodings of the transaction status (TSTS) nibble in the header WB for all valid target cycles (TTYPE).

Table 29-19. Target Header Encodings (TSTS) Per Transaction Type (TTYPE) (Sheet 1 of 2)

TTYPE Cycle Type	TSTS 0000 Success	TSTS 0001 PEC Error	TSTS 0010 Protocol Error	TSTS 0011 Hardware NACK	TSTS 0100 External NACK	TSTS 0101 Clock Low Time Out	TSTS 0110 Data Low Time Out
0101 GP Block Read	No errors	N/A (The hardware transmits the PEC.)	• A collision is detected by the hardware. This happens when the hardware intended to drive NACK and saw an ACK on the bus. • The external master signals stop/restart, and so on in the middle of a byte. • The external master signals a stop on a byte boundary before the byte count expired. • The external master continues driving more clocks even after the hardware has provided all the bytes. • The external master drives ACK instead of NACK on the PEC byte sent by the hardware. • Bits [7:1] of the repeated start address do not match the GPBR address. • Bit 0 of the repeated start address is 0, and the policy is to check for 1.	The command code byte received from the external master does not match the expected value.	The external master NACKs at least one of the bytes provided by the hardware, i.e., Byte Count, Data1, Data2, Data3,..., DataN.	The hardware detects the SMBus clock low time-out anywhere in the middle of the transaction that it is actively servicing.	The hardware detects the SMBus data low time-out anywhere in the middle of the transaction that it is actively servicing.

Table 29-19. Target Header Encodings (TSTS) Per Transaction Type (TTYPE) (Sheet 2 of 2)

TTYPE Cycle Type	TSTS 0000 Success	TSTS 0001 PEC Error	TSTS 0010 Protocol Error	TSTS 0011 Hardware NACK	TSTS 0100 External NACK	TSTS 0101 Clock Low Time Out	TSTS 0110 Data Low Time Out
0001 Cycles to ADDR0/UDID0 or 0010 Cycles to ADDR1/UDID1 or 0000 Cycles to Default Address	No errors	PEC received from the external master did not match the hardware-calculated PEC. ***Note:*** This is a speculative error only since the firmware confirms it was a PEC-enabled SMBus transaction (see Section 29.4.7.5.6).	• A collision is detected by the hardware. This happens when the hardware intended to drive NACK and saw an ACK on the bus. • The external master signals stop/restart, and so on in the middle of a byte. • The external master signals stop on a byte boundary before the byte count expired. • The external master drives more bytes than indicated by the byte count. • The external master generates a start instead of a stop on a byte boundary as a response to the hardware NACK in the previous data phase.	• The hardware NACKs when the external master drives more data than the limit programmed in TRxCTRL.MRxB • The hardware detects the protocol/address violation (see Table 29-8 and Table 29-9).	N/A (The hardware does not provide any bytes.)	The hardware detects the SMBus clock low time-out anywhere in the middle of the transaction that it is actively servicing.	The hardware detects the SMBus data low time-out anywhere in the middle of the transaction that it is actively servicing.
0100 Host Notify *or* Notify ARP Master	No errors	N/A (no PEC)	• A collision detected by the hardware. This happens when the hardware intended to drive NACK and saw an ACK on the bus. • The external master signals stop/restart, and so on in the middle of a byte. • The external master signals a stop on a byte boundary before it sends three data bytes. • The external master drives more than three data bytes after the address phase.	N/A (The hardware does not check any bytes.)	N/A (The hardware does not provide any bytes.)	The hardware detects the SMBus clock low time-out anywhere in the middle of the transaction that it is actively servicing.	The hardware detects the SMBus data low time-out anywhere in the middle of the transaction that it is actively servicing.

Note: All references to the TRxCTRL.MRxb registers must take into account the description of MRxB, i.e., the value is not directly matched since it takes into account some arithmetic based on I^2C/MCTP protocol.

Note: For time-out detection as a target, the hardware must be actively servicing the transaction when the time-out occurs. This means the hardware must have at least ACKed the address phase on the SMBus and must be committed to the transaction based on the settings of the policies in SUSCHKB register.

29.4.7.4 Target Memory Buffer Hardware-Firmware Flow

As described in the target descriptor section, a ring buffer is maintained by the firmware where the hardware sends the notifications to the firmware. The various notifications are:

1. External master initiates a read: notification of a success/failure is sent to the firmware in header. Read data is returned by the hardware (data is pre-programmed by the firmware).
2. External master initiates a write: notification of a success/failure is sent to the firmware in the header. Write data received by the hardware is sent as a payload to the memory.

Note:

1. The target buffer is empty when HWtHeadPtr = FWtTailPtr (HTHP = FTTP).
2. The target buffer is full when (HTHP = FTTP - 4B) or (HTHP - FTTP = TBS).
3. A buffer wrap for HTHP is when HTHP = TBS. When this exists, the hardware writes Dword to memory and then rolls over to 0x0000 unless a buffer full condition exists, i.e., FTTP = 0x0000.
4. The firmware must never increment the FWtTailPtr to a value greater than HWtHeadPtr.
5. If the target ring buffer is N-bytes deep, only N-1 bytes are utilized since the hardware/firmware does not implement a wrap bit.

29.4.7.4.1 Initialization

1. The firmware allocates a buffer in the firmware memory to be used as the target ring buffer as one contiguous space.
2. The firmware then programs up the Target Buffer Base Address (TBBA) register with a 64B-aligned memory address of the ring buffer.
3. The firmware assigns the Target Buffer Size (TBS) register with the actual size of the ring buffer with the maximum limit of 64 KB.
4. The hardware reset initializes HWtHeadPtr and FWtTailPtr to 0.
5. The firmware enables all target addresses as needed, and programs the register-based read data as needed.
6. The firmware also programs interrupts as needed.
7. Finally, the firmware sets the TPOLICY.TGTEN bit to enable the target logic.

29.4.7.4.2 Hardware-Firmware Flow

Once the firmware has completed initialization, the hardware target logic continues to idle until an external SMBus master sends a transaction.

External Master Initiating Writes:

1. Once the hardware receives a write transaction targeting one of its slave addresses, the hardware responds to the address and command phases.
2. Each byte ACKed is eventually DMAed to the memory starting at location Base + HWtHeadPtr + 4B as Dword writes.
3. Once the transaction is completed, the hardware writes the final bytes to memory (PBC field in the header indicates to the firmware how many true bytes are in the payload).
4. Upon completion of the transaction, the hardware writes the header Dword of that transaction into the location pointed to by HWtHeadPtr. This contains all the status information for the transaction. (See Figure 29-9, “High-Level Target Flow” on page 775.)
5. The hardware then updates the HWtHeadPtr to the next free Dword location in the target memory.
6. The hardware then writes interrupt information to the Dwords as pointed to by SMTICL. (See Table 29-20, “Target Transaction Behavior Due to SUSCHKB.IRWST” on page 776.)
   a. The hardware writes the current value of the HWtHeadPtr to TRGT.HTHP and sets TRGT.VALID.
   b. Also, if the transaction terminated abnormally the error condition is written (e.g., to ERR.TRBAF, ERR.TRBF, ERR.CKLTO) and ERR.VALID is set to indicate an error was present.
   c. Finally, if enabled, the hardware then sends MSI to the firmware.

External Master Initiating Reads:

1. Once the hardware receives a read transaction targeting one of its slave addresses, the hardware checks the address, command, and any other bytes sent by the external master and ACK/NACK appropriately.
2. If all the bytes sent by the external initiator are ACKed by the hardware, the hardware provides read data to the initiator. (See Figure 29-9, "High-Level Target Flow" on page 775.)
   a. If the initiator takes all the bytes as expected and terminates the transaction normally, depending on the state of TCTRL.SCHWBP bit, the hardware creates (or does not create) a header Dword and writes to memory at a location pointed by HWtHeadPtr with the BC field updated.
   b. If error conditions are read, the hardware updates the error status registers in the status Dword, creates the header with the appropriate BC field, and writes to memory at a location pointed by HWtHeadPtr.
3. The hardware then updates the HWtHeadPtr to the next free Dword location in the target memory.
4. The hardware then writes interrupt information to the Dwords as pointed to by SMTICL. (See Table 29-20, "Target Transaction Behavior Due to SUSCHKB.IRWST" on page 776.)
   a. The hardware writes the current value of HWtHeadPtr to TRGT.HTHP and sets TRGT.VALID.
   b. Also, if the transaction terminated abnormally, the error condition is written (e.g., to ERR.TRBAF, ERR.TRBF, ERR.CKLTO), and ERR.VALID is set to indicate an error was present.
   c. Finally, if enabled, the hardware then sends an MSI to the firmware.

29.4.7.5 Target Flow

Target flow for the hardware depends on the target address seen on the SMBus. The hardware has deterministic behavior based on the address. A high-level flowchart is shown in Figure 29-9. It does not capture all possibilities of errors, but aims to highlight the sequence of events. Depending on the received address, detailed flowcharts follow in later sections for four protocol categories.

The hardware address matching after an SMBus start condition is subject to SUSCHKB.IRWST; if asserted it causes the hardware to ignore the R/W# bit during matching. This behavior is not shown in the flowchart. It does have implications for how the Quick command, receive byte, and I^2C read are handled.

Figure 29-9. High-Level Target Flow

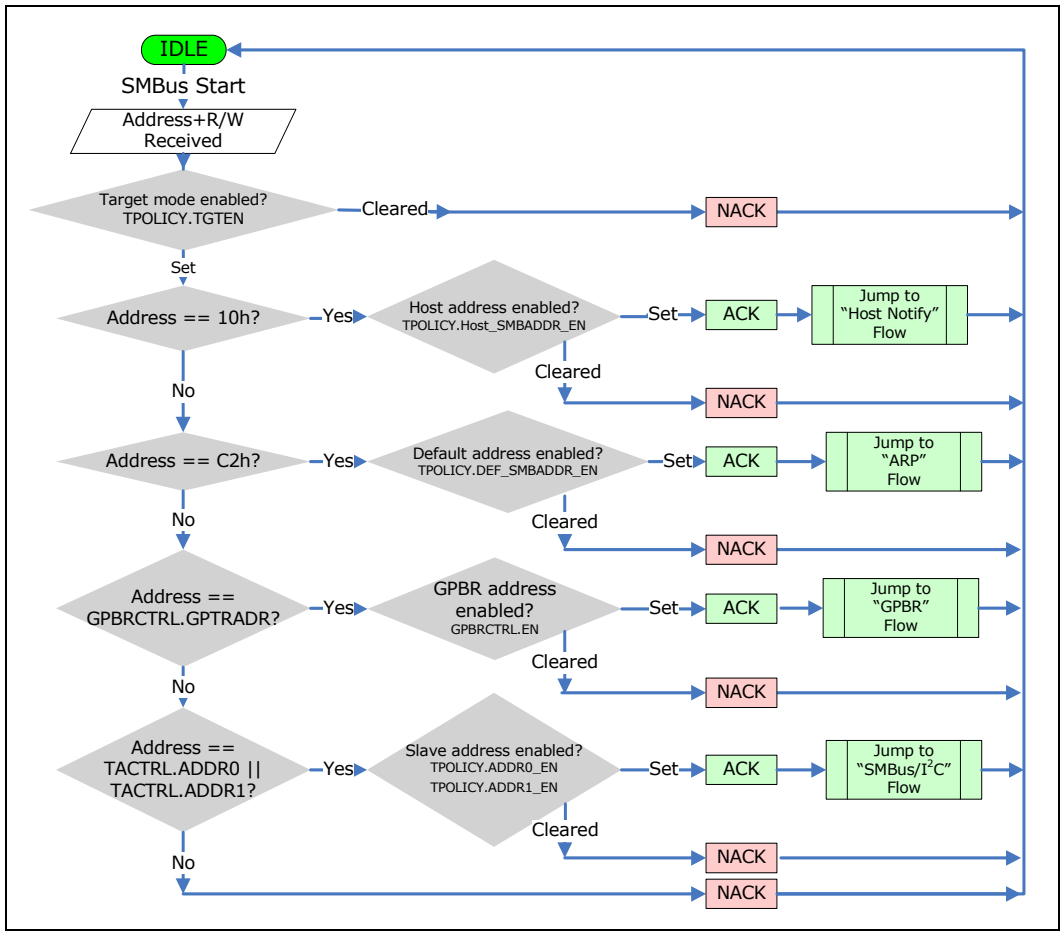

Table 29-20. Target Transaction Behavior Due to SUSCHKB.IRWST

	Quick Command		Receive Byte	I^2C Read
IRWST	**R/W# Bit = Read**	**R/W# Bit = Write#**	**R/W# Bit = Read**	**R/W# Bit = Read**
0	Transaction is ACKed and then dropped. No descriptor is sent. The hardware incorrectly invalidates a supported command option.	Transaction is ACKed and a descriptor is sent to the ring buffer for the firmware.	Transaction is ACKed and then dropped. No descriptor is sent. The hardware invalidates this unsupported command.	Transaction is ACKed and then dropped. No descriptor is sent. The hardware invalidates this unsupported command.
1	Transaction is ACKed and a descriptor is sent to the ring buffer for the firmware.	Transaction is ACKed and a descriptor is sent to the ring buffer for the firmware.	Transaction is ACKed and a descriptor is sent to the ring buffer for the firmware. The command is aliased and treated by the hardware as a send byte. The firmware must invalidate (drop) this unsupported command by detecting the R/W# bit is set in the descriptor.	Transaction is ACKed and a descriptor is sent to the ring buffer for the firmware. The command is aliased and treated by the hardware as an I^2C write. The firmware must invalidate (drop) this unsupported command by detecting the R/W# bit is set in the descriptor.

Note: Based on the interaction between SUSCHKB.IRWST and certain supported and unsupported commands, the following recommendations are made:

- If a Quick command is unused (or if its usage is restricted to R/W# bit cleared), then IRWST is cleared. The hardware invalidates the unsupported commands receive byte and I^2C read.
- Otherwise, IRWST is set, and the firmware invalidates (drops) both of these unsupported commands.

29.4.7.5.1 Host Notify Target Flow

TTYPE = 0100 and **MTYPE = 1111**

The host notify flow comprehends both the ARP host notification and the ordinary SMBus host notify protocols since they differ only in the content of the second received byte. If the firmware has declared this address to be busy (TPOLICY.HOSTBSY), then the hardware will ACK the address byte but NACK all subsequent bytes.

29.4.7.5.2 SMBus ARP Target Flow

TTYPE = 0000 and **MTYPE = 1000, 1001, 1010, 1011, 1100, 1101**

The ARP target flow comprehends all ARP protocols, including general and directed flavors. The priority shown in the flowchart for decoding the command byte is illustrative only. All ARP-related transactions require PEC processing: for Get UDID, the hardware must calculate and transmit the PEC. In all other protocols the hardware must calculate the PEC and compare that against the received PEC byte.

If the firmware has declared this address to be busy (TPOLICY.C2_BSY), then the hardware will ACK the address byte but NACK all subsequent bytes.

The hardware address matching after an SMBus repeated-start condition is subject to SUSCHKB.IRWRST; if asserted it causes the hardware to ignore the R/W# bit during matching. This behavior is not shown in the flowchart.

Figure 29-10.Host Notify Target Flow

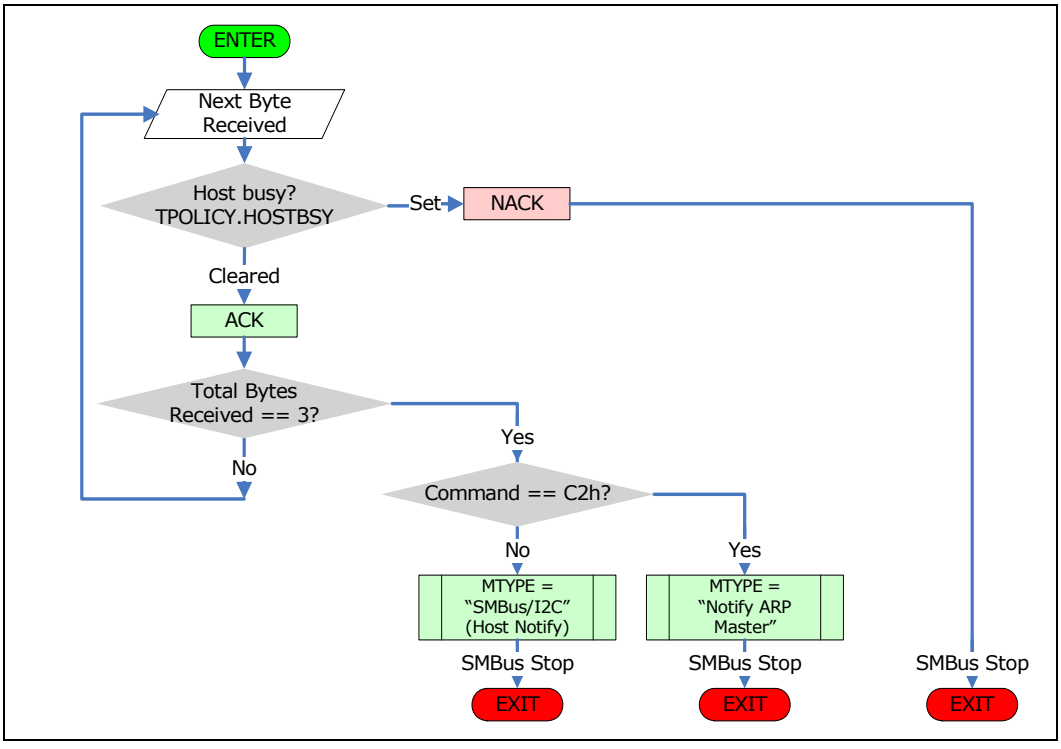

Figure 29-11.SMBus ARP Target Flow

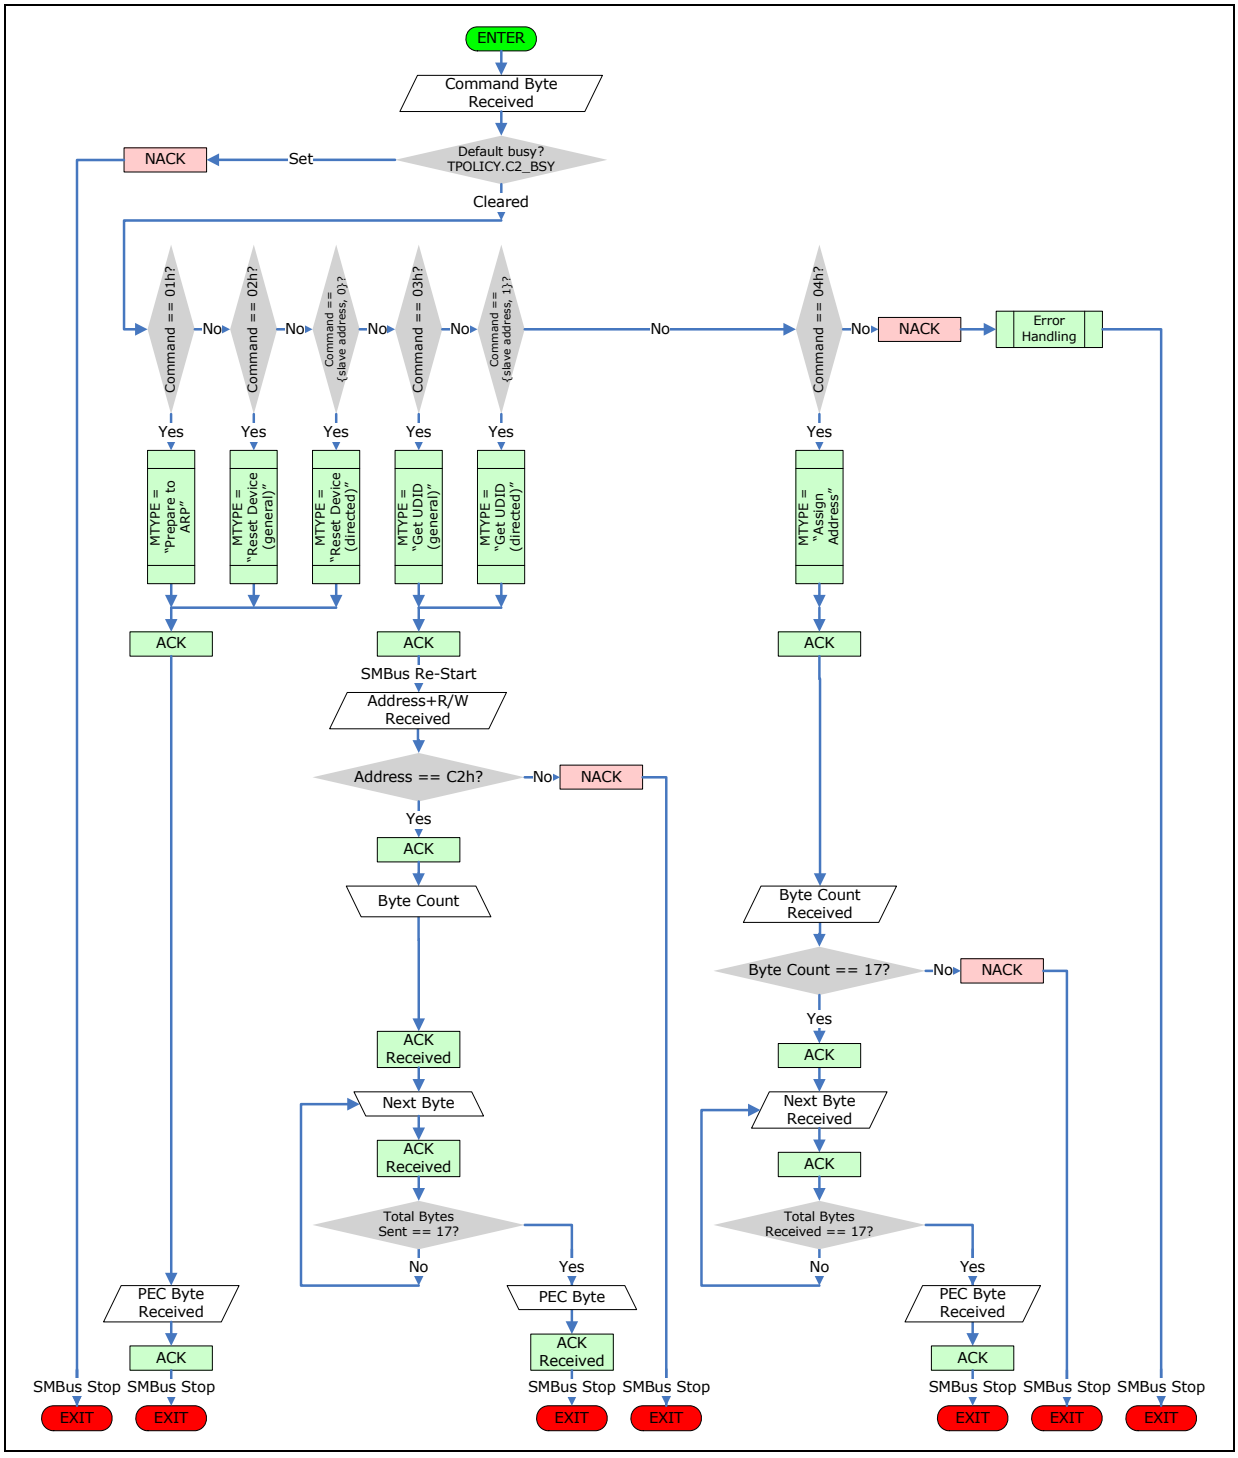


29.4.7.5.3 General-Purpose Block Read Flow

TTYPE = 0101 and **MTYPE = 0111**

SMT provides a mechanism for an external master to read up to 32B of data from the SMT.

The rules are:

- The external master cannot asynchronously launch a read request.
- The address to read from is programmed by the firmware (GPBRCTRL.GPTRADR), and this address must be unique from all other target addresses that SMT supports.
- The external master must read data only as defined by an SMBus 2.0 Block Read command.
- The firmware programs the data into the Data Buffer register (GPBRDBUF) and enables the hardware to support a Read command from the external master (GPBRCTRL.EN).
- The firmware sends a message to the external master requesting it to read the data.

The sequence of events is indicated by the flowchart shown in Figure 29-12.

The hardware matches the received command code against a Firmware-programmed Expected command (GPBRCTRL.CMD). A mismatch causes the transaction to be terminated with a NACK. This matching is required since GPBR is handled entirely in the hardware; the firmware does not participate in validating the address and command.

An appended PEC is optional and is enabled by the firmware (GPBRCTRL.PECEN). Its usage is determined by high-level policy negotiation between the SoC and the external master.

Nominally, the hardware clears its enable bit immediately after ACKing the command byte. This enables a handshake between the hardware and the firmware such that the hardware transmits read data only after being programmed and its trigger set by the firmware. Alternately, the hardware is enabled (GPBRCTRL.HWCLRDIS) to continually respond to read requests from an external master; however, in this mode, determinism is not guaranteed between the firmware programming to and the master reads of the data registers.

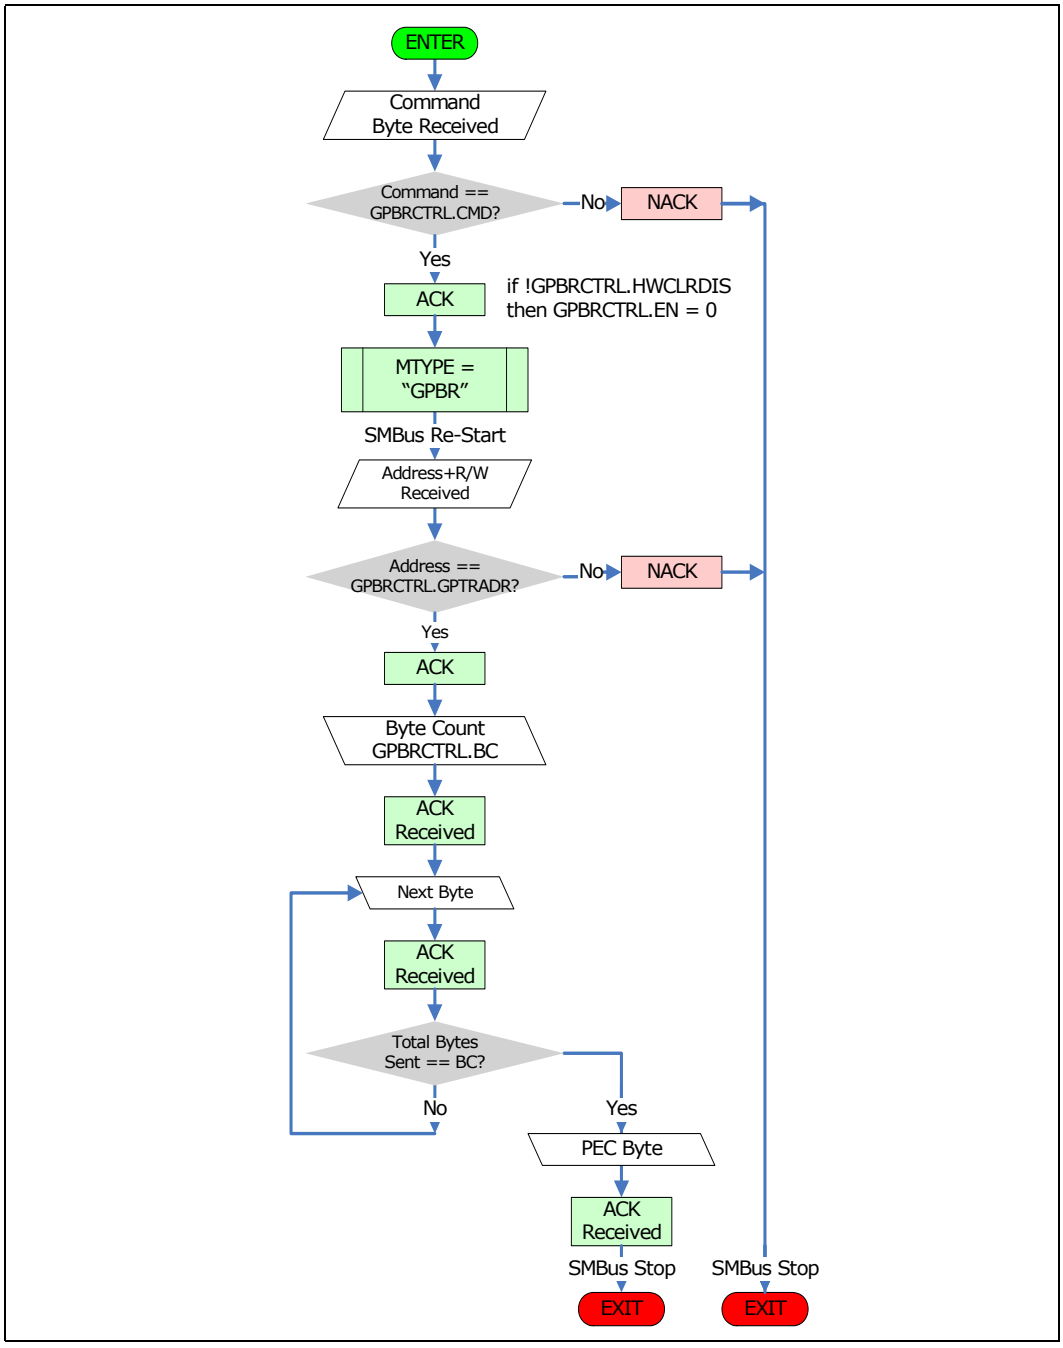
The hardware address matching after an SMBus repeated-start condition is subject to SUSCHKB.IRWRST; if asserted it causes the hardware to ignore the R/W# bit during matching. This behavior is not shown in the flowchart.

The generic programmable read data buffer register (GPBRDBUF) loads data into the generic programmable read data buffer. The buffer provides a mechanism of supporting Generic Programmable Reads (GPBR) by an external SMBus master under the firmware initiated flow.

The data buffer is filled by the firmware initiating DW writes to this register. A hidden pointer always points to the next available buffer location—reading and writing to GPBRDBUF cause the pointer to increment automatically.

Note: Because the pointer auto-increments after each read and write, a read of GPBRDBUF does NOT return the most recently written data. Normal usage requires the buffer contents to be cleared before filling it with a new data payload. Therefore, a read (of the next empty location) returns 0s. (See also GPBRCTRL.BUFRST and GPBRCTRL.PTRRST.)

Figure 29-12.General Purpose Block Read with PEC Target Flow



29.4.7.5.4 Normal Usage

Before programming new data into the GPBR buffer, the firmware sets both GPBRCTRL.BUFRST (which resets the buffer contents to 0) and GPBRCTRL.PTRRST (which resets the buffer pointer position). After the hardware has completed the reset, it clears both bits.

29.4.7.5.5 Debug Usage

To enable the firmware to read back (verify) the contents of the GPBR buffer, the firmware sets only GPBRCTRL.PTRRST, which resets the buffer pointer position but leaves the buffer contents intact. Consecutive reads then return the previously written buffer data.

The hardware provides read data payload starting from bits [7:0] of Dword0 of the buffer, then bits [15:8] of Dword0, and so on. All bytes must be programmed in the sequence to be sent out without gaps. The hardware counts the number of bytes indicated in the GPBRCTRL.BC register and starts sending them out sequentially starting at byte 0 of Dword 0 until the byte count is decremented to 0.

29.4.7.5.6 SMBus/I^{2}C Target Flow

TTYPE = 0001, 0010 and **MTYPE = 0000**

SMT supports being a target of certain SMBus and I^{2}C transactions (see Figure 29-13, "SMBus/I^{2}C Target Flow" on page 782), and it acknowledges transactions directed to either of its two target addresses (TACTRL.ADDR0 or TACTRL.ADDR1). The basic flow is depicted in Figure 29-13. In general the target hardware interface is agnostic of command and PEC bytes. The firmware handles these bytes.

Note: It is assumed that block reads to SMT as a target are directed only to the dedicated GPBR address (GPBRCTRL.GPTRADR) and are not considered in this flow.

Write cycles received by the SMT target interface nominally terminate when the external master produces a stop condition. A premature hardware NACK occurs if the interface is busy or overflows. The SMBus Quick command is comprised only of the address byte, with the data encoded entirely within the R/W# bit. All other SMBus and I^{2}C transactions have additional data bytes.

The optional PEC byte is not shown explicitly because the firmware determines the actual presence of PEC. This provides for PEC to be enabled on a per-function, per-address, per-protocol, or even per-transaction basis. The hardware always performs a **speculative** internal PEC calculation, which it then compares to the final received byte. If the received and calculated bytes match, this is a strong indication that the transaction was PEC-enabled, but the firmware has the final authority. Conversely, a mismatch is not proof of a transmission error—it may have been a PEC-less transaction. In this case, the firmware ignores the PEC status flag in the target descriptor TSTS field, which resulted from the hardware invalid speculative of the PEC comparison.

Since some protocols have identical transmission templates it is also the responsibility of the firmware to prevent or resolve apparent aliasing (e.g., aliasing of a send byte with the PEC and a write byte; aliasing of a write byte with the PEC and a write word; aliasing of the SMBus write byte and I^{2}C MTx-to-SRx). It is assumed this is accomplished through negotiation between the firmware and the external master. For instance, the command byte differentiates protocols or certain protocol combinations are excluded.

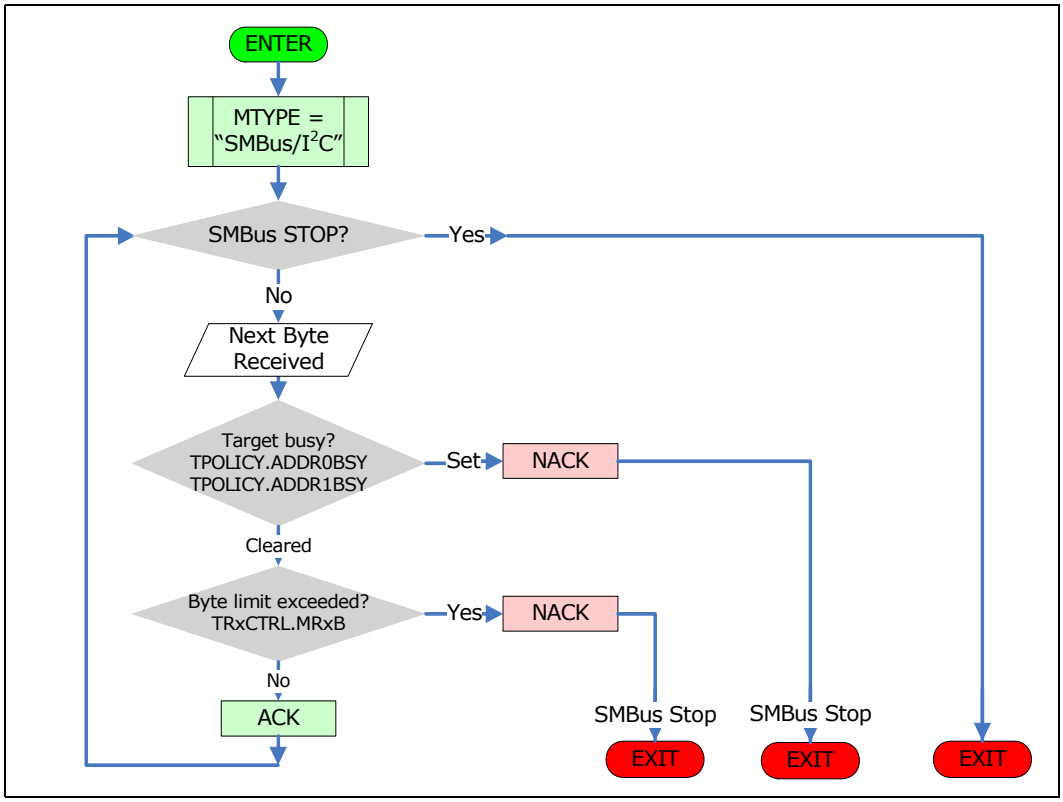
A special case of aliasing occurs for the SMBus block write. Since the hardware ignores the command byte, it cannot distinguish the block write byte count from an ordinary data byte. Therefore, the hardware captures and pushes all bytes to the firmware for processing, and the hardware is not required to verify the received byte count. In the target mode, the firmware programs a ceiling (TRxCTRL.MRxB) on the write length such that if a transaction overflows the ceiling, then the hardware must NACK any unexpected data bytes. This ceiling must not exceed the buffer size. The hardware NACK flag in the target descriptor TSTS field is set upon a hardware (buffer) overflow, but this flag does not comprehend overflow of an individual protocol (e.g., a block write where received bytes > the indicated byte count).

Note: If a target address receives both I^2C and SMBus protocols, the maximum permitted write length (TRxCTRL.MRxB) must accommodate both. For example, if a target receives an SMBus block write with PEC, the write length must be greater than or equal to 36 bytes (= address + command + byte count + N data bytes + PEC, where N<=32).

If the firmware has declared a matched address to be busy (TPOLICY.ADDR0BSY or TPOLICY.ADDR1BSY), then the hardware will ACK the address byte but NACK all subsequent bytes.

The hardware address matching after any SMBus repeated-start condition is subject to SUSCHKB.IRWRST; if asserted it causes the hardware to ignore the R/W# bit during matching. This behavior is not shown in the flowchart.

Figure 29-13.SMBus/I^2C Target Flow



29.4.8 Dynamic SMT Policy Update

The hardware provides a mechanism for the firmware to change the policies of the hardware and other registers by the firmware without requiring a reset to the system.

29.4.8.1 Master Policy

For updates to the master side of the registers, the firmware already has the control by stopping the hardware DMA engine and halting new master transactions. This ensures that the hardware master side is completely disabled and the firmware chooses to update the policy and registers.

29.4.8.2 Target Policy

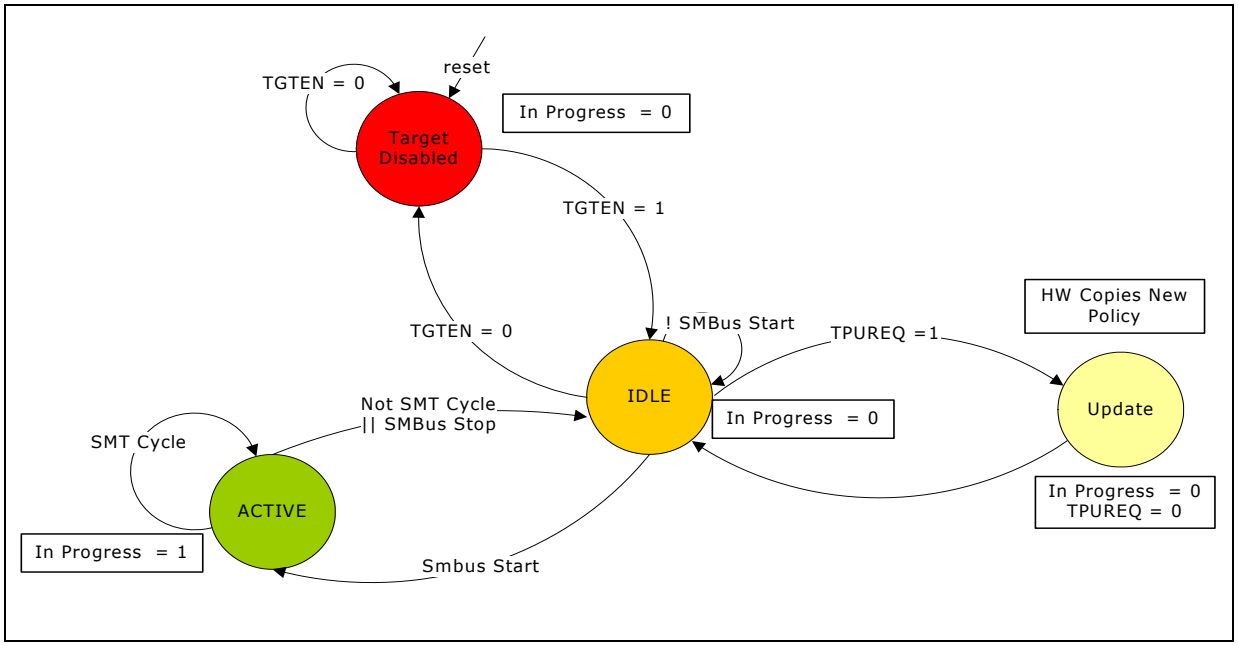
Updates to the target policy require a flow, since the hardware asynchronously receives a target cycle.

The hardware maintains a current target policy internally without direct visibility to the firmware. The firmware sees the current policy by reading the TPOLICY register. When TPOLICY.PTUREQ=0, it means the current policy settings are effective in the hardware (assuming the firmware follows flow and did not write to any other register without first setting the PTUREQ bit). To change the policy, the firmware first disables the target completely or selectively disables addresses so while the firmware is extensively updating registers, the hardware NACKs appropriately in the address or command phase as desired. After that is done, the firmware must again update the policy following the same flow to have the final desired policy in effect.

1. The firmware sets the intermediate policy desired by programming the TPOLICY register with TPOLICY.PTUREQ also set.
2. When the hardware reaches the SMBus idle state, it checks if PTUREQ is:
   a. If set, the hardware captures the current setting of the policy in PTUREQ and loads into its internal registers. It also clears the PTUREQ bit once the policy is captured.
   b. If clear, the hardware continues to be in idle until another SMBus start is seen.
3. The hardware continues to act on an intermediate policy resulting in NACK on the address phase or on the command phase of incoming cycles (programmed by the firmware).
4. The firmware polls or reads the PTUREQ register to make sure it is clear before reprogramming the registers, etc.
5. Once the firmware is ready to ungate the hardware, the firmware again follows step #1 in which it sets the new policy.
6. The flow again follows steps 2-4 before the final firmware policy is set and active in the hardware.

A conceptual flow is shown in Figure 29-14.

Figure 29-14.Target Dynamic Policy Update



29.5 Interrupts

The SMT hardware has the following causes of interrupts (if enabled).

1. Master Interrupt - The hardware generates master interrupts for transactions ending successfully or in a failure.
2. Target Interrupt - Generated whenever the hardware writes data and/or the header to memory.
3. Error Interrupt - Generated whenever the hardware detects a bus error or a resources error.

Table 29-21. Summary of SMT Interrupt Enables and Sources

Interrupt Enable/Mask	Interrupt Source	Governed By	Asserted Upon
Master Interrupts			
Master Descriptor INT field	MSTS.MIS		Successful completion of master cycles
MCTRL.MEIE	MSTS.MEIS		Unsuccessful completion of master cycles
Target Interrupts			
TCTRL.TIE	TSTS.TIS	TCTRL.SCHWBP TCTRL.UCHWBP TCTRL.URxTWP	Successful completion of target cycles Unsuccessful completion of target cycles Unsuccessful completion of write to target
Error Interrupts			
ERRINTMSK.CKLTO	ERRSTS.CKLTO		SMBus clock-low time-out
ERRINTMSK.TRBF	ERRSTS.TRBF		Target ring buffer is full.
ERRINTMSK.TRBAF	ERRSTS.TRBAF		Target ring buffer is almost full.
ERRINTMSK.IHIE	ERRSTS.IHIE		Read completion with non-successful status
ERRINTMSK.IMAE	ERRSTS.IMAE		Request is made when PCICMD.BME is clear.
ERRINTMSK.ITE	ERRSTS.ITE		Error in IPI transmit transaction
ERRINTMSK.IRDPE	ERRSTS.IRDPE		Data parity error in IPI receive transaction
ERRINTMSK.IRE	ERRSTS.IRE		Error in IPI receive transaction
ERRINTMSK.SPDWE	ERRSTS.SPDWE	MCTRL.SPDDIS	Write is attempted to SPD address range
ERRINTMSK.CPE	ERRSTS.CPE		CSR parity error

Note: First-error cause information is logged in ERRINFO. Also, error interrupts also support masking of escalation to Advanced Error Reporting (AER); see ERRAERMSK.

Note: ERRINTMSK.IMAE: this bit is assumed to be 1 when MSICTL.MSIE is set. IMAE occurs only if PCICMD.BME is clear, and MSI requires BME to be set.

29.5.1 Master Interrupts

Two causes for a master interrupt are:

1. **Successful** - The Interrupt bit in the descriptor is set to indicate the hardware must generate an interrupt on successful completion of the descriptor. An Interrupt Status Register bit is defined in the MMIO space (MSTS.MIS), which is set every time the hardware retires a descriptor. The enable for this interrupt is defined within each individual descriptor.
2. **Failure** - The descriptor is not successfully completed due to an SMBus error. This interrupt has a Cause Enable (MCTRL.MEIE) and a Cause Status bit (MSTS.MEIS) in the device MMIO space.

Upon completion of descriptor processing, either MSTS.MIS (successful completion) or MSTS.MEIS (unsuccessful completion) must be set by the hardware. This distinction is required so that if the firmware disables MSI (i.e., chooses to operate in the polling mode) by polling both flags, it determines when the descriptor has completed and its completion status.

The master interrupts are sent for the descriptor-based transactions. Therefore, they are serialized and ordered with respect to the descriptor writeback and specifically tied to the descriptor just processed due to the operand requirement.

1. Run the descriptor-based master transaction on the SMBus.
2. Perform the descriptor status WB to memory. (See the status WB field in Figure 29-4, “Master Descriptor Ring Buffer” on page 750, Figure 29-5, “Master Descriptor Format” on page 750, and Table 29-13, “Master Descriptor Field Descriptions” on page 751.)
3. Write 1 to the appropriate Cause Status bit (MCTRL.MEIS or MSTS.MIS).
4. If that appropriate interrupt is enabled (locally and globally), an MSI is sent and the cause status is auto-cleared, else an MSI is not sent and the cause remains set and the firmware is expected to poll the response.

Note: MSTS.MEIS itself merely indicates an unsuccessful completion. The descriptor status WB field contains full details of transaction and error conditions.

Note: Firmware implementation:

1. If the cause is set for a previous descriptor-based transaction and the firmware enables the global (and local) interrupt enable, the hardware does not send an interrupt for a previously set cause.
2. The firmware is responsible to ensure that if the cause is set, the previous transactions are accounted for before enabling the MSI (globally and locally).

29.5.2 Target Interrupts

Since the target ring buffer is a single buffer in the memory, the interrupts sent on behalf of the target are simplified to be sent every time the hardware writes data and/or the header to the memory (depending on if target interrupts are enabled and if global MSIen is set).

The conditions which result in a status header being written are further governed by these policies:

- TCTRL.SCHWBP: upon successful completion of target cycles
- TCTRL.UCHWBP: upon unsuccessful completion of target cycles
- TCTRL.URxTWP: upon unsuccessful completion of writes to the target

This simplified model is used since the hardware supports multiple logical devices and transactions of each type are pushed to memory by the hardware in a sequential manner. The firmware then has to parse each header to determine what each transaction is before the firmware takes the appropriate action.

A single Target Interrupt Enable bit is maintained in the MMIO space (TCTRL.TIE) which gates the sending of this interrupt. An Associated Status bit (TSTS.TIS) is also maintained in the hardware.

Similar to master interrupts, target interrupts are also serialized and ordered. The decision to send an MSI is made after the hardware has written back the header for the received transaction to the memory ring buffer.

1. Receive the target cycle from the SMBus.
2. Perform data and header WB to memory.
3. Write 1 to the appropriate Cause Status bit (TSTS.TIS).

If TCTRL.TIE is enabled (locally and globally), an MSI is sent and the cause status is auto cleared else an MSI is not sent and the cause remains set.

Note: Firmware implementation:

1. If the cause is set for a previous target transaction written to memory and the firmware enables the global (and local) interrupt enable, the hardware does not send an interrupt for a previously set cause.
2. The firmware is responsible to ensure that if the cause is set, the previous transactions are accounted for before enabling an MSI (globally and locally).

29.5.3 Error Interrupts

The hardware tracks the following conditions for errors:

1. SMBus clock-low time-out: status is set when the hardware observes the SMBus clock is asserted low for more than the value programmed by the firmware.
2. SMBus data-low time-out: status is set when the hardware observes the SMBus data is asserted low for more than the value programmed by the firmware.
3. Target ring buffer almost full: status is set when the hardware detects the target ring buffer has less than 85B free space remaining in the target ring buffer. This check is done after the hardware performs a memory write for data/header.
4. Target ring buffer full: status is set when the hardware in unable to evict its internal buffer/header WB to memory due to lack of space in the target ring buffer. This check is done every time the hardware needs to write to memory.

Table 29-22. Error MSI Scheduling

Event	Global MSIen	Cause Interrupt Enable[1]	Cause Interrupt Status[2]	MSI Action
Cause occurs, but interrupts are not enabled.	0	0	0 -> 1	No MSI sent.
MSI enable is set, cause enable and cause status are previously set.	0 -> 1	1	1	Send MSI.
MSI enable and cause status previously set, cause interrupt enable is set.	1	0 -> 1	1	Send MSI.
Cause Status register gets set, interrupts are enabled.	1	1	0 -> 1	Send MSI.
Cause Status register previously set, interrupts are enabled, new cause occurs.	1	1	1 -> 1	Does not occur if interrupts are enabled. Cause Status is cleared. If the clearing happens on the same clock as the new cause is set, it is the rule in the next row before.
New cause occurs in the same clock as the previous MSI scheduled was sent.	1	1	1 -> 1	Send MSI.
Scheduled MSI was sent.	1	1	1 -> 0	The hardware auto-clears the cause register.
MSI is scheduled to be sent when MSI enable is cleared.	1 -> 0	1	0 -> 1 or 1 -> 1	The hardware schedules the MSI or drops it. Any pending MSIs must be reflected in the MSI Pending register.

1. Cause interrupt mask: see ERRINTMSK and ERRAERMSK.
2. Cause interrupt status: see ERRSTS.

29.5.4 Interrupt Cause Logging

Before sending any MSI, the hardware writes information pertinent to the interrupt cause to a memory location identified by Table 29-23.

As indicated in Table 29-23, the Dwords of SMTICL are divided into three categories. The hardware updates only the relevant Dword depending on the nature of the interrupt: interrupts generated during a master transaction involves updates only to Dword #0, likewise target transactions involve only Dword #1. However, if an error condition is present, the hardware requires also writing to Dword #2 to capture the nature of the error.

The firmware always reads all three Dwords, and upon reading them clears any Dword which has non-zero data. (At a minimum two Dwords must be read—master + error or target + error.)

Table 29-23. Interrupt Cause Information

Dword	Bit	Field	Description
Information from MASTER			
0	31	MSTR.VALID	Master interrupt cause is valid. 1: Denotes master status (MSTS), including the master hardware tail pointer, has been written.
0	30:0	Reserved	
Information from TARGET			
1	31	TRGT.VALID	Target interrupt cause is valid. 1: Denotes the Target Hardware Head Pointer (HTHP) has been written.
1	30:0	Reserved	
Error Information			
2	31	ERR.VALID	Error interrupt cause is valid. 1: Denotes errors status (ERRSTS) has been written.
2	30:0	Reserved	

29.6 SMT RAS Architecture

29.6.1 Soft Reset (DEVCTL.IFLR and GCTRL.SRST)

The SMT supports several types of soft reset including:

- Function-level reset as defined by the *PCI Local Bus Specification*, Revision 3.0 (see DEVCTL.IFLR).
- Soft reset directed to the SMT controller (see GCTRL.SRST).

In each case, the soft reset applies only to the specific SMT function addressed. Asserting a soft reset has these effects:

- An immediate and abrupt reset of the SMT master and target logic (which causes a protocol violation of any pending master or target cycles),
- Clear all the MMIO registers except those register bits denoted as sticky or read-write-once (RW-O) or primary-reset-only (PRST) as listed in Table 29-24, and
- Release the SMBus clock and data lines.

Table 29-24. SMT Soft Reset Exceptions

Register Fields	Comments
Sticky (S)	
AERCAPCTL.FEP	
AERHDRLOG.TLPHDRLOG	
ERRCORMSK.x, x = CIEM, ANFEM	
ERRCORSTS.x, x = CIE, ANFE	
ERRUNCMSK.x, x = UIEM, UREM, MTLPEM, UCEM, CAEM, CTEM, PTLPEM	
ERRUNCSEV.x, x = UIES, URES, MTLPES, UCES, CAES, CTES, PTLPES	
ERRUNCSTS.x, x = UIE, URE, MTLPE, UCE, CAE, CTE, PTLPE

Register Fields	Comments
DEVCTL.x, x = IFLR and MPS	In addition to any RWS, ROS, and RW1CS fields.
IOSFDEVCLKGCTL.x, x = ICGE and ICT	
SBDEVCLKGCTL.x, x = ICGE and ICT	

29.6.2 Target Reset (GCTRL.TRST)

The scope of this reset is limited to the target FSM. Upon assertion, the hardware gracefully terminates any pending transaction at the next byte boundary and builds a descriptor which the firmware rejects.

29.7 MCTP Over SMBus Packet Header Format

This section is informational. The hardware does not inspect or decode any portion of an Management Component Transport Protocol (MCTP) packet.

MCTP messages with SMBus packet headers can encapsulate data from various protocols like ASF, Network, etc. The command code in the packet (byte 1) identifies this packet as MCTP and the firmware takes appropriate action. Refer to the *Management Component Transport Protocol (MCTP) Base Specification, Version 1.1.0* for further details on the protocol.

The following information is contained in the *Management Component Transport Protocol (MCTP) Base Specification, Version 1.1.0* but is reproduced here for completeness.

https://www.dmtf.org/sites/default/files/standards/documents/DSP0236_1.1.0.pdf

Figure 29-15.MCTP Over SMBus Packet Format

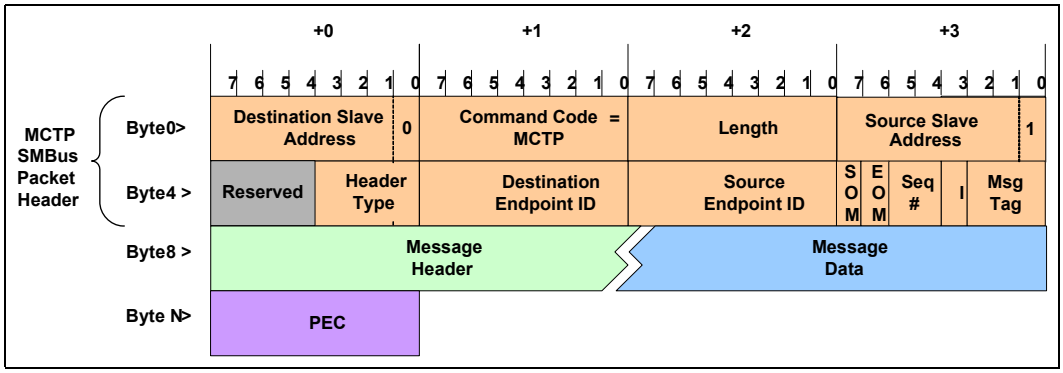

Table 29-26. MCTP Over SMBus Packet Format

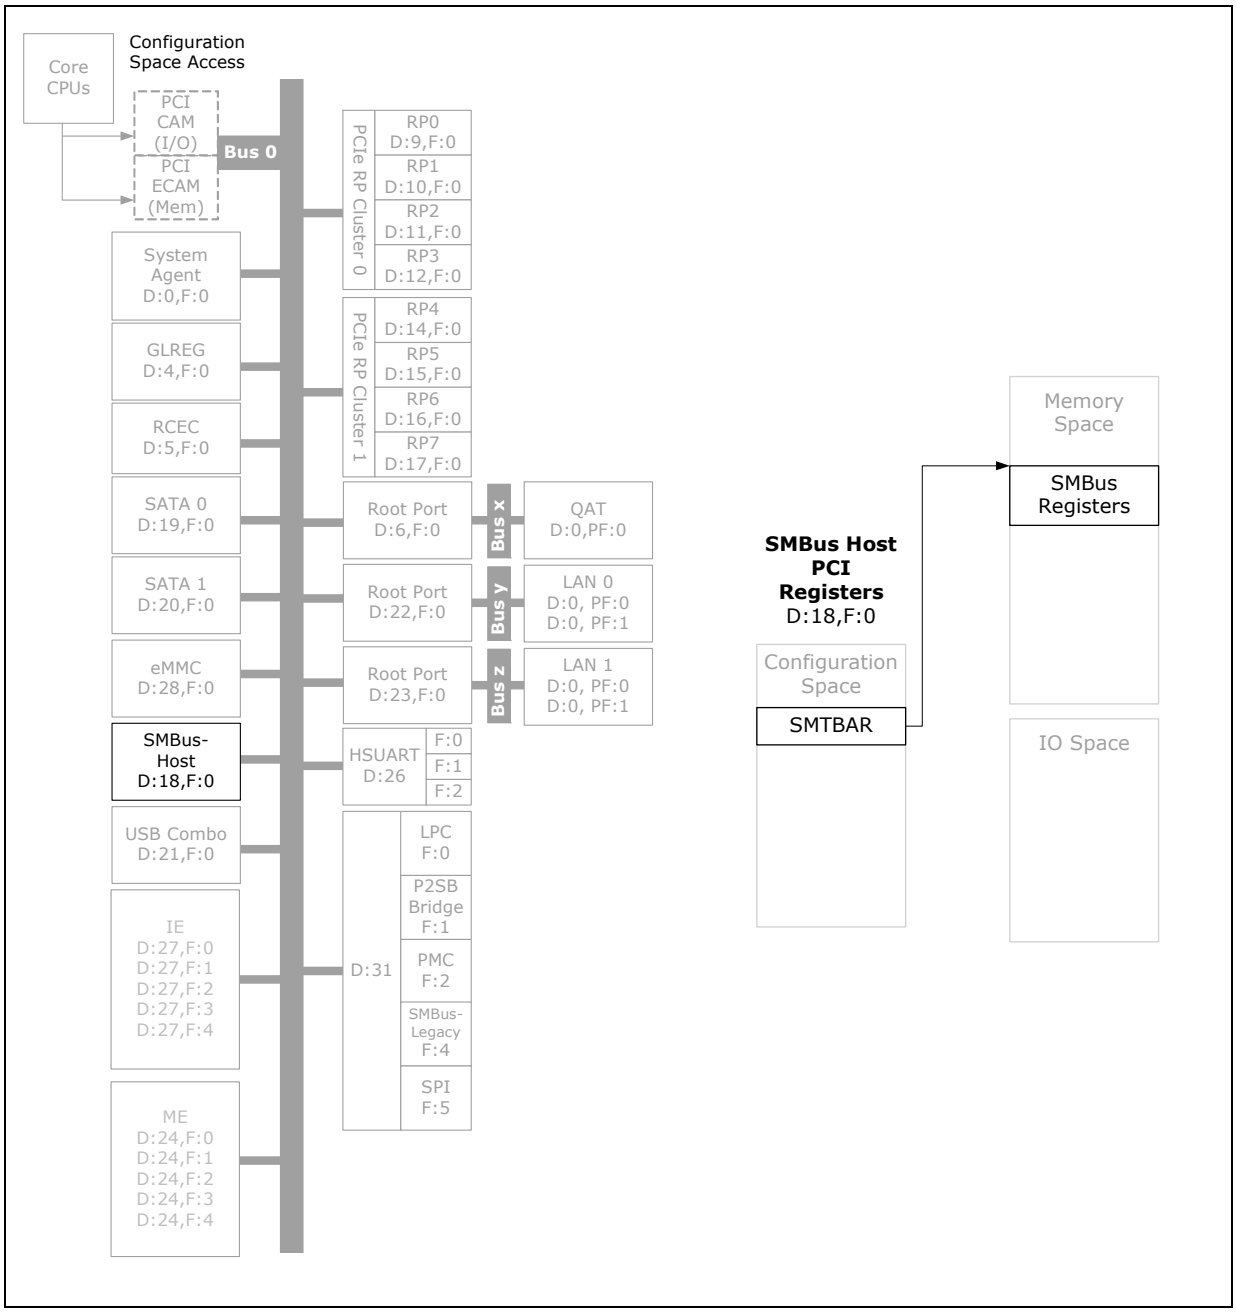
Byte #	Field	Description
0	Destination Slave Address	For the local SMBus, slave address for the target device. Bit 0 is always 0 since all MCTP messages are writes.
1	Command Code	Command code indicating the MCTP packet. This value is fixed at 0Fh.
2	Length	Length of the block write. Analogous to the byte count field of the SMBus Block write except length is not limited to 32 bytes. This count indicates the number of bytes to follow in the current message without counting the PEC byte.
3	Slave Address	Bits [7:1]: For the local SMBus, the slave address of the message initiator. This initiator is a repeater and cannot be assumed to be the original initiator. Bit 0: Reserved, always 1b.
4	Header Type	Bits [7:4]: Reserved Bits [3:0]: MCTP Version: 1h for all MCTP device compliant to the *Management Component Transport Protocol (MCTP) Base Specification,* Version 1.0.0.
5	Destination Endpoint ID	Unique ID on the system for the destination of the message. This ID reflects the final destination of the message. Reserved Values: 0 = Local bus only. Terminate at the receiver. 1 = Route to the root management controller. 2-7 = Reserved for future definition.
6	Source Endpoint ID	Unique ID on the system for the originator of the message. This ID reflects the true initiator of the message.
7	Message Control	Bit 7: **Start of Message** (SOM): Set to 1 if the packet is the start of message. Bit 6: **End of Message** (EOM): Set to 1 if the packet is the end of message. Combinations of SOM and EOM are used to identify the start, middle, and end of a message that is split across one or more packets. Bits [5:4]: **Sequence Number**: For messages that span multiple packets, this field helps identify lost intermediate packets. Increments on each successive packet. The value of the sequence number for Packet N, is the Packet N-1 Sequence Number + 1 mod 4. Bit 3: **Initiator** (I): Set to 1 if the value of the message tag field was assigned by the source (for requests) or set to 0 if the message tag was assigned by the destination (for responses). Bits [2:0]: **Message Tag** (MT): This field, along with the source endpoint ID, identifies a unique message ID. The message ID must be unique for all outstanding request transactions that require a response and have not yet received the response. For response messages, the message tag sent with the request is returned in the response.
8	Message Header	Begin MCTP message header.
M	Message Data	MCTP defined
N	PEC	Single byte packet error check accompanies all MCTP messages

29.8 Register Map

Figure 29-16 shows the associated registers from a system software viewpoint.

Figure 29-16.Register Map



§ §

30 SMBus Controller - Platform Environment Control Interface

The Platform Environment Control Interface (PECI) was developed to replace I^2C as the methodology of reading CPU temperatures. The PECI specification has evolved overtime to provide a broader management interface to manage the platform. In non-SoC environments, the PECI slave interface is implemented in the CPU complex, while the master interface is in the Platform Control Hub (PCH) and/or Baseboard Management Controller (BMC). The PECI implementation only allows a single master on the bus.

On the SoC platform, the BMC/IE acts as a PECI over SMBus master and the SoC SMBus-for-PECI controller described in this chapter acts as a slave PECI proxy controller. The PECI commands are encapsulated within SMBus packets sent to the SoC. Additional, new PECI commands have been defined for the SoC, specific to its architecture.

Figure 30-1. What is Covered in This Chapter

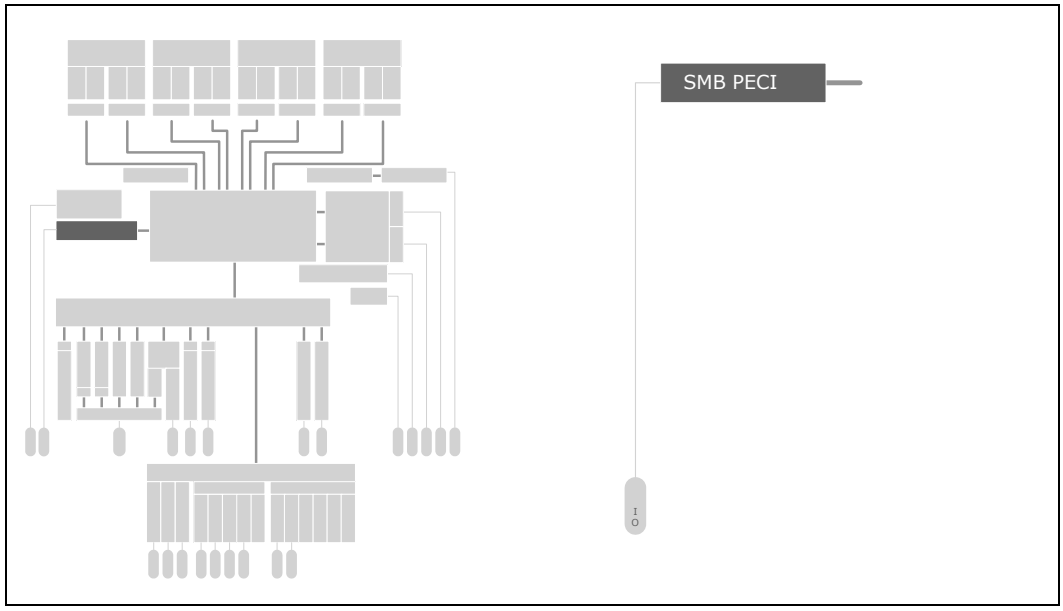


Table 30-1. References

Document Title	Document ID / Location
System Management Bus (SMBus) Specification, Version 3.0	http://smbus.org/specs/SMBus_3_0_20141220.pdf

30.1 Signal Descriptions

The signal descriptions are shown in Table 30-2, "Signal Names." For additional signal information, including whether a signal is assigned to shared-function pin or can be used as a customer GPIO signals, see Section 39.1, "Directory of Signal Names and Pin Names." The Direction/Type column of Table 30-2, "Signal Names" is interpreted as follows:

- I = Input signal. The SoC has receiver circuit.
- O = Output signal. The SoC has driver circuit.

Table 30-2. Signal Names

Signal Name	Direction Type	Shared	Description
SMB_PECI_CLK	I, O-OD	Yes	SMBus Clock (SMBCLK)
SMB_PECI_DATA	I, O-OD	Yes	SMBus Data (SMBDAT)

The optional SMBus 2.0 signals, SMBALERT# and SMBSUS#, are not supported on this controller interface.

30.2 PECI over SMBus Features

The SMBus supports the external BMC or IE, operates in slave mode only and comprehends the PECI command structure.

The PECI processes one command at time and support for multiple outstanding commands is not supported.

The PECI commands supported by the SoC are in Table 30-7, "Supported PECI Commands."

30.3 SMBus Supported Transactions

In the SoC, the communication between the SMBus controller and the internal PECI bridge utilizes the SMBus block write and block read transactions as defined in the SMBus 2.0 specifications.

The SMBus PECI device is assigned two SMBus Slave Addresses. The two Slave Addresses are assigned default values but can be altered by the customer Soft Straps. See the PECI category in Section 4.2, "SoC Soft Straps."

- 4Bh = Default SMBus Slave Address for all SMBus Read transactions
- 4Ch = Default SMBus Slave Address for all SMBus Write transactions

The SMBus Slave Addresses are located in sideband registers.

- for SMBus Read transactions: GPTRADR[7:0] field of the GPBRCTRL register located at sideband Port CEh, offset 240h
- for SMBus Write transactions: ADDR0[7:1] field of the TACTRL register located at sideband Port CEh, offset 228h

See Figure 30-2, "SMBus Protocol" to interpret the SMBus protocol drawing.

Figure 30-2. SMBus Protocol

S	Start Condition
Sr	Repeated Start Condition
Rd	Read (bit value of 1)
Wr	Write (bit value 0)
X	Shown under a field indicates that field is required To have the value of 'x'
A	Acknowledge (this bit position is 0 for an ACK or 1 for a NACK)
P	Stop Condition
PEC	Packet Error Code
…	Continuation of Protocol
	Master to Slave
	Slave to Master

30.4 SMBus Block Read/Write Transaction Formats

PECI Mode	Reset PECI	0x4C	0x64	0		

1. See Section 30.6.2.1, "PECI Proxy Command Format."

Table 30-4. SMBus Read Command

Operating Mode	Transaction	Slave Address (CMD Phase)	Read Command Code	Slave Address (Data Phase)	Byte Count (N)	Bytes [N:1]
PECI Mode	PECI Proxy Read Command	0x4B	0x40	0x4B	0x01...N[1]	

1. See Section 30.6.2.2, "PECI Proxy Read Command."

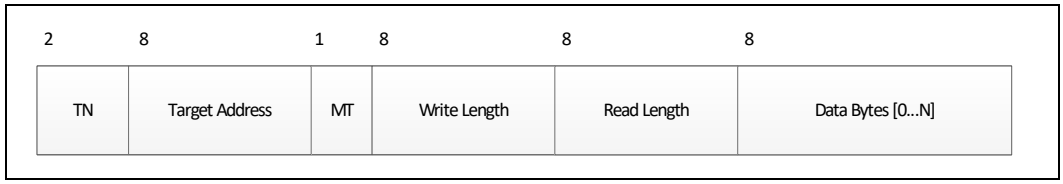
30.6 PECI Over SMBus

PECI uses a simple structure of message header and a write-read protocol. All PECI devices have a command field. The following section describes PECI protocol.

30.6.1 PECI Message Header in SMBus

The header conveys to the target device how many bytes the master intends to send and how many it expects to receive back. The first byte of the write data is interpreted as a command to the device and must be present in all messages. The Ping() command is the only exception to this rule. Additional bytes are written to convey sub commands or to send data to the device. A zero value in the read length field means no data is read from the target device. See Figure 30-5, "PECI Message Header in the SMBus Packet" for the PECI message header. In the figure, N bytes are to be written to the target and M bytes are to be read back from the target.

Figure 30-5. PECI Message Header in the SMBus Packet



In the PECI message header, the Address Timing Negotiation (NT) and Message Timing Negotiation (MT) bits are not present. The BMC is responsible to not include these timing bits in the header.

30.6.1.1 Target Address Field

The PECI device address is defined as 0x30 + a socket identifier of 0…7. In the SoC, only a single socket model is supported, thus the PECI target address is always 0x30. Other PECI device addresses are rejected as errors.

30.6.1.2 Write Length Field

The Write Length byte conveys the number of bytes the originator sends the target device. Since all PECI message headers are identical in size, with the exception of Ping(), the Write Length byte only describes the number of command bytes sent. The target address, write length and read length fields are not included in the write length count. The following rules apply for the write length field:

- The maximum value is 0xFF.
- The command byte is included in the length.
- A write length of 0x0 is only for the Ping() command.

30.6.1.3 Read Length Field

The Read Length byte conveys the number of bytes the target device must supply the originator before returning the Frame Check Sequence (FCS) byte calculated over that data. The read length is in the range of 0x00 and 0xFF.

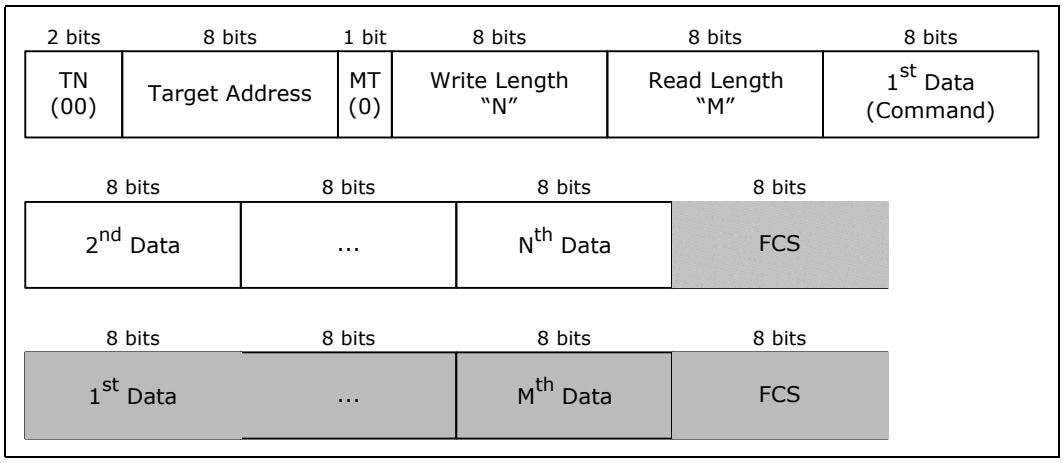
30.6.1.4 Command Byte

All SoC PECI commands except Ping() require a command byte. The command code is positioned as the first data byte, that is, data_byte[0].

30.6.2 PECI Write-Read Protocol

The write-read protocol shown in Figure 30-6, "PECI Write-Read Protocol" is the only protocol defined for messaging between devices on the PECI. The write-read protocol allows an atomic operation that first writes and then reads data between an originator and a target. Format of a write-read message is given in Figure 30-6, "PECI Write-Read Protocol". The read and write Frame Check Sequence (FCS) bytes are not calculated but may be required to have a byte allocated as part of the specific command where described in Section 30.6.2.1, "PECI Proxy Command Format."

Figure 30-6. PECI Write-Read Protocol



Legend:

Master to Slave

Slave to Master

Similar to Figure 30-5, "PECI Message Header in the SMBus Packet," the PECI message header, the Address Timing Negotiation (NT) and Message Timing Negotiation (MT) bits are not present. The BMC is responsible to not include these timing bits in the header.

30.6.2.1 PECI Proxy Command Format

Unlike some Intel Platform Control Hub (PCH) products, the SoC PECI-over-SMBus controller only operates in PECI mode. The SMBus Interface PECI Proxy Command protocol is an encapsulation of PECI specification commands onto the SMBus by the SMBus master. Two new SoC-specific PECI commands are also supported.

The PECI proxy command bytes, encapsulated in bytes [N:2] of the protocol, conform to Figure 30-6, "PECI Write-Read Protocol". The SoC PECI-over-SMBus controller provides a transparent pass-through of the PECI command to the integrated PECI client and does not verify the validity of the command. It is the burden of the BMC or platform board External Circuitry (EC) to provide valid data in the PECI proxy command fields of the incoming packet.

Because the SMBus is used and not the serial PECI electrical interface, it is unnecessary to calculate the Frame Check Sequence (FCS). The SoC design does keep the PECI commands consist with non-SoC Intel products and carry additional bytes that are set to 0x0. These are called out where appropriate. The PECI proxy command format is shown in Table 30-5, "PECI Proxy Command Protocol Format."

Table 30-5. PECI Proxy Command Protocol Format

PECI Proxy Command							
SMBus Default Data			SMBus to PECI Handshake Control Data	PECI Command Data as Described for Each Supported PECI Command in the PECI Specification			
Slave Address	PECI Mode Command Code	Byte Count	Byte 1	Byte 2	Byte 3	Byte 4	Byte [N:5]
0x4C (default)	0x62	0x04...N	Control Byte (Reserved)	PECI Target Address[1] 0x30 = CPU	PECI Write Length[2]	PECI Read Length[3]	Remaining Part of PECI Command[4]

1. Required PECI header byte.
2. Required PECI header byte. Must be set to the proper value as defined by the particular PECI command. If an Assured Write FCS (AW FCS) is needed, the PECI write length value must also include the AW FCS byte.
3. Required PECI Header byte. Must be set to the proper value as defined by the particular PECI command.
4. This field does not exist for the PECI Ping() command. This field is used for write data bytes including a placeholder for an AW FCS byte. Note that the Retry bit shall be set to zero and the command code byte must be one of the codes supported by the SoC.

30.6.2.2 PECI Proxy Read Command

The SMBus Read command uses one SMBus command code (0x40). The SMBus Read command returns PECI command status or PECI response payload data from the executed PECI Proxy command.

Table 30-6, "PECI Proxy Read" shows the structure of PECI response data from a PECI mode read.

Table 30-6. PECI Proxy Read (Sheet 1 of 2)

SMBus Field	Value	Data Source	Description
Slave Address	0x4B	BMC	Slave address for the command phase
Command Code – SMBus Read	0x40	BMC	Command code for SMBus read
Slave Address	0x4B	BMC	Slave address for data phase

Table 30-6. PECI Proxy Read (Sheet 2 of 2)

SMBus Field	Value	Data Source	Description
Byte Count (N)	0x01...N	SoC	N = 0x01 for busy state: • Byte 1 = 0x01 (CMD_BUSY bit set) N = 0x02 for transaction errors • Byte 1 = 0x02 (CMD_ERR bit set) • Byte 2 = Error code N > 2 indicates the request PECI command executed successfully: • Byte 1 = 0x0 • Byte 2 = 0x0 • Byte [N:3] = PECI response data
Byte 1	Control Data		**Status Byte (CMD_STAT):** Bits [7:2] = Reserved Bit 1 = CMD_ERR • This bit is set by the SoC if the PECI proxy interface detects a transaction error. The error code is defined in Byte 2. Bit 0 = CMD_BUSY • This bit is set by the SoC while a PECI command is executing. It is reset by the SoC when the PECI command operation is completed.
Byte 2	Control Data		**Error Code (ERR_CODE):** 0x00 = PECI_ST_OK • PECI command completed successfully 0x01 = PECI_ST_BAD_FORMAT • SMBus PECI message incorrectly formatted 0x09 = PECI_ST_DISABLED • PECI driver disabled 0x3E = PECI_INVALID_SOCKET • Invalid PECI socket number 0xE1 = PECI_ST_TRANS_TIMEOUT_ERROR • PECI transaction time-out (e.g., PECI controller not responding to commands or hangs) 0xFE = PECI_ST_FAILURE • General PECI failure 0xFF = PECI_ST_UNKNOWN • Unknown status **Unsupported Error Codes:** 0x02 = PECI_ST_FCS_REQ_ERROR • Error in PECI request FCS 0x04 = PECI_ST_FCS_RSP_ERROR • Error in PECI response FCS 0x08 = PECI_ST_LINK_ERROR • PECI link error
Byte [N:3]	PECI Response Data		**PECI Response Data:** PECI response data as described for each PECI command in the PECI specification. It contains all data returned by the PECI client that resides between the Write FCS byte and Read FCS byte. These bytes are valid only when the PECI command completes successfully and the CMD_ERR bit in the Status byte (Byte 1; Bit [1]) is cleared.

30.6.3 PECI Proxy Command Handling Procedure

A BMC requests read and write PECI proxy commands over the SMBus that are formatted to conform to the PECI command protocol. The PECI command handler performs the following on receipt of the SMBus packet:

- Validates that the PECI command is valid.
- Either processes the command locally or forwards the command to other SoC internal units for processing.
- Repackages the command into the appropriate format upon command completion.

The BMC retrieves the PECI response data by performing the SMBus block read transactions. The number of data bytes returned from the Block Read command on the SMBus indicates the completion status of the PECI command.

1. If N=1, then only the Status byte is sent with CMB_BUSY bit set (CMD_BUSY=1b).
   Indicates that the PECI command transaction is still in progress.
2. If N=2, then both Status and Error Code bytes are sent with CMD_BUSY bit reset (CMD_BUSY = 0b) and CMD_ERR bit set (CMD_ERR = 1b).
   Indicates that the PECI command resulted in an error. Byte 2 contains the error code.
3. If N>2, then both CMD_BUSY and CMD_ERR will be reset (CMD_BUSY = 0b, CMD_ERR = 0b).
   Indicates that the PECI command completed successfully and the read-back data is valid.

Note: The BMC should only trigger a new PECI command when the previous command is completed. The SoC does not support posted or multiple commands.

Note: If the Reset PECI SMBus command is received, any pending state will be reset. The initiator would be expected to reissue the last command.

30.6.4 PECI Proxy Command Trigger

This process provides the functions performed by the SMBus master (the BMC) and the SoC to trigger and complete a PECI Proxy command.

1. The BMC performs an SMBus block write transaction, formatted with the data associated with the requested PECI proxy command as shown in Table 30-6, "PECI Proxy Read."
2. The SoC sets the CMD_BUSY bit in the Status byte and handles the requested PECI command.
3. After completing the PECI operation, the SoC performs the following functions:
   — Resets the CMD_BUSY bit in the Status byte.
   — Sets the CMD_ERR bit if a PECI transaction error occurred; otherwise, it resets CMD_ERR bit.
   — Sets the ERR_CODE byte with the end of transaction condition.
   — If the PECI transaction completed successfully, stores the PECI response data and transfers it to the BMC on the next Read command.
4. The BMC polls the Status byte until the CMD_BUSY bit is cleared to indicate the completion of the command. If the PECI transaction completed successfully (CMD_ERR = 0), the PECI response data is valid.

30.6.4.1 Unsupported PECI Command

In the case of an unsupported PECI command, the SoC responds with the appropriate error code.

30.6.4.2 Illegally Formatted Command

In the case of an unsupported PECI command, the SoC responds with the appropriate error code.

30.7 PECI Proxy Commands

Table 30-7, "Supported PECI Commands" is a summary of the PECI Proxy commands supported by the SoC. Each is described in this section following the table.

Table 30-7. Supported PECI Commands

Command	In PECI Specification, Rev. 3.1	Supported by SoC	Command Code	Definition
Ping()	Yes	Yes	none	This command detects that PECI functionality exists.
GetDIB()	Yes	Yes	0xF7	This command returns the PECI device-specific information.
GetTemp()	Yes	Yes	0x01	This command returns the processor die information.
RdPkgConfig()	Yes	Yes	0xA1	This command reads the SoC package configuration space.
WrPkgConfig()	Yes	Yes	0xA5	This command writes the SoC package configuration space.
RdIAMSR()	Yes	Yes	0xB1	
WrIAMSR()	Yes	No	-	
RdPCIConfig()	Yes	No	-	
WrPCIConfig()	Yes	No	-	
RdPCIConfigLocal()	Yes	Yes	0xE1	This command reads the SoC PCI space.
WrPCIConfigLocal()	Yes	Yes	0xE5	This command writes the SoC PCI space.
RdEndPointConfig()	No	Yes	0xC1	This command reads the register space over the sideband.
WrEndPointConfig()	No	Yes	0xC5	This command writes the register space over the sideband.

30.7.1 Ping()

Ping() is a required message for all PECI devices. This message is used to enumerate devices or determine if a device has been removed, been powered-off, etc. A Ping() sent to a device address always returns a non-zero write FCS if the device at the targeted address is able to respond.

Table 30-8, "Ping - PECI Proxy Block Write" shows the ping PECI proxy block write format and Table 30-9, "Ping - PECI Proxy Block Read" shows the ping PECI proxy block read format.

Table 30-8. Ping - PECI Proxy Block Write

SMBus	Function		Value	Data Source	Comment
Slave Address (Write)	Write Address	SMBus Command	0x4C	BMC	
Command Code	PECI Mode command code		0x62		
Byte Count	N	Control Data	0x04		
Byte 1	SMBUS-PECI Handshake Control		0x00		
Byte 2	PECI Client Address	PECI Command	0x30		
Byte 3	PECI Write Length		0x00		Ping() command has no command code. • Write Length = 0x00 • Read Length = 0x00
Byte 4	PECI Read Length		0x00		

Table 30-9. Ping - PECI Proxy Block Read

SMBus	Function		Value	Data Source	Comment
Slave Address (Command Phase)	Write Address	SMBus Command	0x4B	BMC	
SMBUS Read Command Code	SMBUS Read Code		0x40		
Slave Address (Data Phase)	Read Address		0x4B		
Byte Count	N	Control Data	{0x01, 0x02}	SoC	N = 0x01 for busy state • Byte 1 = 0x01 N = 0x02 for PECI client status • Byte 1 = 0x00 If Byte 2 = 0x00 • PECI client active If Byte 2 = 0x02 • PECI client not active
Byte 1	Status Byte		CMD_STAT		See Byte[1] of Table 30-6, "PECI Proxy Read.".
Byte 2	Error Byte		ERR_CODE		If Byte 2 = 0x00 • PECI client active If Byte 2 = 0x02 • PECI client not active. See Byte[2] of Table 30-6, "PECI Proxy Read" for error code definitions.

30.7.2 GetDIB()

The SoC PECI client implementation of GetDIB() includes an 8-byte response and provides information regarding client revision number and the number of supported domains.

Table 30-10, "GetDIB() PECI Proxy Block Write" shows the GetDIB PECI proxy block write format and Table 30-11, "GetDIB() PECI Proxy Block Read" shows the GetDIB PECI proxy block read format.

Table 30-10. GetDIB() PECI Proxy Block Write

SMBus	Function		Value	Data Source	Comment
Slave Address (Write)	Write Address	SMBus Command	0x4C	BMC	
Command Code	PECI Mode command code		0x62		
Byte Count	N	Control Data	0x05		
Byte 1	SMBus-PECI Handshake Control		0x00		Value = 0x00 No AW FCS Required
Byte 2	PECI Client Address	PECI Command	0x30		Socket ID. Always 0x30 for the SoC.
Byte 3	PECI Write Length		0x01		
Byte 4	PECI Read Length		0x08		
Byte 5	GetDIB() Command Code		0xF7		

Table 30-11. GetDIB() PECI Proxy Block Read

SMBus	Function		Value	Data Source	Comment
Slave Address (Command Phase)	Write Address	SMBus Command	0x4B	BMC	
SMBus Read Command Code	SMBus Read Code		0x40		
Slave Address (Data Phase)	Read Address		0x4B		
Byte Count	N	Control Data	{0x01, 0x02, 0x0A}	SoC	N = 0x01 for busy state • Byte 1 = 0x01 N = 0x02 for Transaction errors • Byte 1 = 0x02 • Byte 2 = Error Code defined in Table 30-6, "PECI Proxy Read." N = 0xA indicates a successful PECI transaction • Byte 1 = 0x00 • Byte 2= 0x00 • Byte[10:3] = PECI response data
Byte 1	Status Byte		CMD_STAT		See Byte[1] of Table 30-6, "PECI Proxy Read."
Byte 2	Error Byte		ERR_CODE		See Byte[2] of Table 30-6, "PECI Proxy Read."
Byte 3	PECI Response Byte 1	PECI Response Data	PECI Device Info		See Section 30.7.2.1, "PECI Device Info Field." Returns the number of domains in addition to Domain#0 as shown below.
Byte 4	PECI Response Byte 2		PECI Device Revision		See Section 30.7.2.2, "PECI Revision Number."

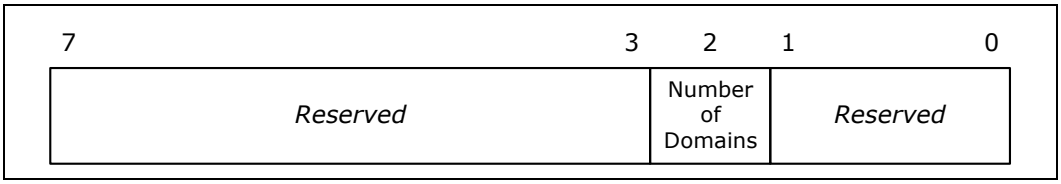
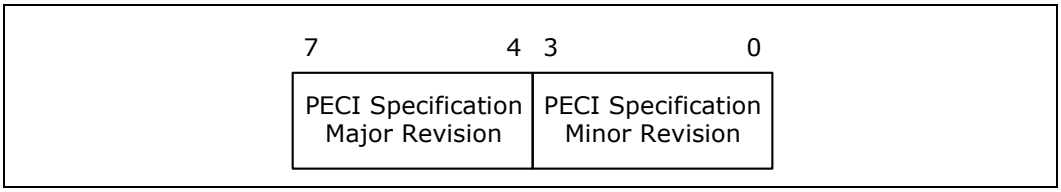
Figure 30-7. PECI Device Info Field Definition



30.7.2.2 PECI Revision Number

The revision number returned is 0011_0001b.

Table 30-12. PECI Revision Number Definition



30.7.3 GetTemp()

The GetTemp() command is used to retrieve the temperature from a target PECI address. The temperature is used by the BMC to regulate the temperature on the die. The data is returned as a negative value representing the number of degrees Celsius below the maximum processor Junction Temperature ($T_{J\text{-}MAX}$).

Note: The maximum PECI temperature value of zero corresponds to the processor $T_{J\text{-}MAX}$. This also represents the default temperature at which the processor Thermal Control Circuit (TCC) activates. The actual value that the thermal management system uses as a control set point ($T_{CONTROL}$) is also defined as a negative number below $T_{J\text{-}MAX}$.

See Section 30.11, "DTS Temperature Data" for the data format and error codes. Table 30-13 shows the GetTemp PECI proxy block write format and Table 30-14, "GetTemp() PECI Proxy Block Read" shows the GetTemp PECI proxy block read format.

Table 30-13. GetTemp() PECI Proxy Block Write

SMBus	Function		Value	Data Source	Comment
Slave Address (Write)	Write Address	SMBus Command	0x4C	BMC	
Command Code	PECI Mode command code		0x62		
Byte Count	N	Control Data	0x05

Byte 4	PECI Response Byte 2		PECI Device Temp [15:8]		

30.7.4 RdPkgConfig()

The RdPkgConfig() command provides read access to the Package Configuration Space (PCS) within the processor including various power and thermal management functions. Typical PCS read services supported by the processor may include access to temperature data, energy status, run time information, DIMM temperatures and so on.

This command does provide multi-domain support. Table 30-15, "RdPkgConfig() PECI Proxy Block Write" shows the RdPkgConfig PECI proxy block write format and Table 30-16, "RdPkgConfig() PECI Proxy Block Read" shows the RdPkgConfig PECI proxy block read format.

Table 30-15. RdPkgConfig() PECI Proxy Block Write

SMBus	Function		Value	Data Source	Comment
Slave Address (Write)	Write Address	SMBus Command	0x4C	BMC	
Command Code	PECI Mode command code		0x62		
Byte Count	N	Control Data	0x09		
Byte 1	SMBus-PECI Handshake Control		0x00		Value = 0x00 No AW FCS Required
Byte 2	PECI Client Address	PECI Command	0x30		
Byte 3	PECI Write Length		0x05		
Byte 4	PECI Read Length		{0x02, 0x3, 0x5}		
Byte 5	RdPkgConfig() Command Code		0xA1		
Byte 6	Host ID and Retry		0x00		
Byte 7	Index				See Section 30.7.11, "MCA Access via RdEndPointConfig()" and Section 30.9, "CPU Thermal and Power Optimization Capabilities" for the supported capabilities and their index and parameter information.
Byte 8	Parameter LSB				
Byte 9	Parameter MSB

SMBus	Function		Value	Data Source	Comment
Slave Address (Command Phase)	Write Address	SMBus Command	0x4B	BMC	
SMBus Read Command Code	SMBus Read Code		0x40		
Slave Address (Data Phase)	Read Address		0x4B		
Byte Count	N	Control Data	{0x01, 0x02, 0x04, 0x05, 0x07}	SoC	N = 0x01 for busy state • Byte 1 = 0x01 N = 0x02 for transaction errors • Byte 1 = 0x02 • Byte 2 = Error Code defined in Table 30-6, "PECI Proxy Read." N = {0x4,0x5,0x7} indicates a successful PECI transaction • Byte 1 = 0x00 • Byte 2 = 0x00 • Byte [7:3] = PECI response data N = {0x04, 0x05, 0x07} value is determined by the number of PECI Response Data bytes returned in Byte [7:4] on the SMBus. N Value: • 0x04 = 1 data byte • 0x05 = 2 data bytes • 0x07 = 4 data bytes
Byte 1	Status Byte		CMD_STAT		See Byte [1] of defined in Table 30-6, "PECI Proxy Read."
Byte 2	Error Byte		ERR_CODE		See Byte [2] of defined in Table 30-6, "PECI Proxy Read."
Byte 3	PECI Transaction Status	PECI Response Data	PECI Completion Code		Completion Code decode: • 0x40 = Command successful • 0x80 = Response time-out • 0x90 = Illegal command
Byte 4	Data 1 (LSB)		Data = 1, 2, or 4 bytes		See Section 30.7.11, "MCA Access via RdEndPointConfig()" and Section 30.9, "CPU Thermal and Power Optimization Capabilities" for the supported capabilities and their returned data structures.
Byte 5	Data 2				
Byte 6	Data 3				
Byte 7	Data 4 (MSB)				

30.7.5 WrPkgConfig()

The WrPkgConfig() command provides write access to the Package Configuration Space (PCS) within the processor including various power and thermal management functions. Typical PCS write services supported by the processor may include power limiting, thermal averaging constant programming, and other write services.

Table 30-17, "WrPkgConfig() PECI Proxy Block Write" shows the WrPkgConfig PECI proxy block write format and Table 30-18, "WrPkgConfig() PECI Proxy Block Read" shows the WrPkgConfig PECI proxy block read format.

Table 30-17. WrPkgConfig() PECI Proxy Block Write

SMBus	Function		Value	Data Source	Comment
Slave Address (Write)	Write Address	SMBus Command	0x4C	BMC	
Command Code	PECI Mode command code		0x62		
Byte Count	N	Control Data	{0x0B, 0x0C, 0x0E}		N = {0x0b, 0x0c, 0x0e} value is determined by the number of PECI Write Data bytes transmitted in Byte [13:10] on the SMBus. N Value: • 0x0b = 1 data byte • 0x0c = 2 data bytes • 0x0e = 4 data bytes
Byte 1	SMBus-PECI Handshake Control		0x01		Value = 0x01 • Assured Write (AW) Frame-Check Sequence (FCS) is not required. However, to maintain compatibility included is the AW space for the byte per the PECI specification.
Byte 2	PECI Client Address	PECI Command	0x30		
Byte 3	PECI Write Length		{0x07, 0x08, 0x0A}

N = {0x03} indicates successful PECI transaction • Byte 1 = 0x00 • Byte 2 = 0x00 • Byte3 = PECI Completion code
Byte 1	Status Byte		CMD_STAT		See Byte [1] of defined in Table 30-6, "PECI Proxy Read."
Byte 2	Error Byte		ERR_CODE		See Byte [2] of defined in Table 30-6, "PECI Proxy Read."
Byte 3	PECI Transaction Status	PECI Response Data	PECI Completion Code		Completion code decode: • 0x40 = Command successful • 0x80 = Response time-out • 0x90 = Illegal command

30.7.6 RdIAMSR()

The RdIAMSR() PECI command provides read access to Model Specific Registers (MSRs) defined in the processor's Intel® Architecture (IA). MSR definitions can be found in the *Intel® 64 and IA-32 Architectures Software Developer's Manual*.

The processor PECI client allows PECI RdIAMSR() access to the registers pertaining to the SoC error banks (machine check banks 0 through 19). The exact number of accessible banks for the SoC may be obtained by reading the IA32_MCG_CAP[7:0]MSR (0x0179). Attempts to read MSRs that are not accessible over PECI or not implemented result in a completion code of 0x90.

PECI access to these registers is expected only when in-band access mechanisms are not available. Valid processor ID values may be obtained by using the enumeration methods described in Section 30.7.6.1, "Processor ID Enumeration." The PECI host must determine the total number of machine check banks and the validity of the MCi_ADDR and MCi_MISC register contents prior to issuing a read to the machine check bank similar to standard machine check architecture enumeration and accesses. The processor machine check banks 4 through 21 reside outside the processor and hence will return the same value independent of the processor ID used to access these banks. PECI accesses to the machine check banks may not be possible in the event of a core hang. A warm reset of the processor may be required to read any sticky machine check banks.

30.7.6.1 Processor ID Enumeration

The 'Processor ID' field that is used to address the IA MSR space refers to a specific logical processor within the CPU. The 'Processor ID' always refers to the same physical location in the processor silicon regardless of configuration. For example, if certain logical processors are disabled by BIOS, the Processor ID mapping will not change. The total number of Processor IDs on a CPU is product-specific. Processor ID does not always refer to the same physical location across processor types and SKUs.

'Processor ID' enumeration involves discovering the logical processors enabled within the CPU package. This can be accomplished by reading the 'Max Thread ID' value through the RdPkgConfig() command (Index 0, Parameter 3) and subsequently querying each of the supported processor threads. Unavailable processor threads will return a completion code of 0x90.

Table 30-19, "RdIAMSR() PECI Proxy Block Write" shows the RdIAMSR PECI proxy block write format.

Table 30-20, "RdIAMSR() PECI Proxy Block Read" shows the RdIAMSR PECI proxy block read format.

Table 30-19. RdIAMSR() PECI Proxy Block Write

SMBUS	Function		Value	Data Source	Comment
Slave Address (Write)	Write Address	SMBUS Command	0x4C	BMC	
Command Code	PECI Mode command code		0x62		
Byte Count	N	Control Data	0x09		
Byte 1	SMBUSPECI Handshake Control		0x00		Value = 0x00 No AW FCS Required
Byte 2	PECI Client Address	PECI Command	0x30		
Byte 3	PECI Write Length		0x05		
Byte 4	PECI Read Length		{0x02, 0x3, 0x5, 0x9}		
Byte 5	RdIAMSR () Command Code		0xB1		
Byte 6	Host ID & Retry		0x00		
Byte 7	Processor ID				See supported Structure sections for details.
Byte 8	MSR Address (LSB)				
Byte 9	MSR Address (MSB)				

Note: The "Processor ID" field used to address the IA MSR space refers to a specific logical processor in the CPU. The Processor ID always refers to the same physical location in the processor silicon regardless of configuration. For example, if certain logical processors are disabled by BIOS, the Processor ID mapping will not change. The total number of Processor IDs on an SoC is product-specific.

30.7.7 RdPCIConfigLocal()

The RdPCIConfigLocal() command provides sideband read access to the entire PCI configuration space of the SoC. This includes all SoC registers within the PCI configuration space as described in register document.

PECI originators may conduct a device/function enumeration sweep of this space by issuing reads in the same manner that the BIOS would. A response of all 1's may indicate that the device/function/register is unimplemented even with a 'passing' completion code. Alternatively, reads to unimplemented or hidden registers may return a completion code of 0x90 indicating an invalid request. It is also possible that reads to function 0 of non-existent IIO devices issued prior to BIOS POST may return all '0's with a passing completion code. PECI originators can access this space even prior to BIOS enumeration of the system buses. There is no read restriction on accesses to locked registers.

PCI configuration addresses are constructed as shown in Figure 30-8, "PCI Configuration Address Format." Under normal inband procedures, the Bus number would be used to direct a read or write to the proper device. Any request made with a bad Bus number is ignored and the client will respond with all '0's and a 'passing' completion code.

Figure 30-8. PCI Configuration Address Format

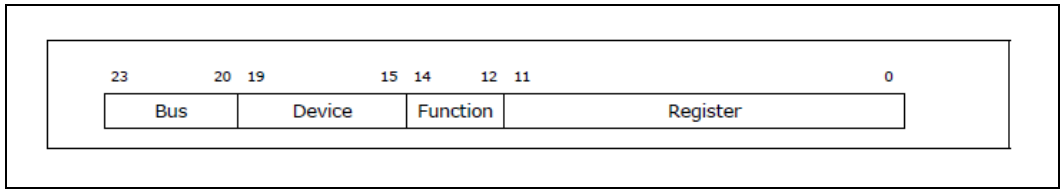

Table 30-21, "RdPCIConfigLocal() PECI Proxy Block Write" shows the RdPCIConfigLocal PECI proxy block write format and Table 30-22, "RdPCIConfigLocal() PECI Proxy Block Read" shows the RdPCIConfigLocal PECI proxy block read format. It is not possible to access PCI Express* B0, D0, F0 using the RdPCIConfigLocal command.

Table 30-21. RdPCIConfigLocal() PECI Proxy Block Write

SMBus	Function		Value	Data Source	Comment
Slave Address (Write)	Write Address	SMBus Command	0x4C	BMC	
Command Code	PECI Mode Command Code		0x62		
Byte Count	N	Control Data	0x09

Byte 6	PCI Data 3				
Byte 7	PCI Data 4 (MSB)				

30.7.8 WrPCILocalConfig()

The WrPCILocalConfig() command provides sideband write access to the PCI configuration space that resides within the processor. PECI originators can access this space even before BIOS enumeration of the system buses. The write accesses to registers that are locked will not take effect but will still return a completion code of 0x40. However, write accesses to registers that are hidden will return a completion code of 0x90.

Table 30-23, "WrPCILocalConfig() PECI Proxy Block Write" shows the WrPCILocalConfig PECI proxy block write format and Table 30-24, "WrPCILocalConfig() PECI Proxy Block Read" shows the WrPCILocalConfig PECI proxy block read format.

30.7.9 RdEndPointConfig()

The RdEndPointConfig() command provides sideband read access to the PCI configuration space that resides within the processor, as well as the SSA sideband configuration space of each agent. The exact listing of supported devices, functions, and registers is outside the scope of this document. PECI originators can access this space even before BIOS enumeration of the system busses. PECI originators may also conduct a device/function/register enumeration sweep of this space by issuing reads in the same manner that the BIOS would.

Table 30-25, "RdEndPointConfig() PECI Proxy Block Write" shows the RdEndPointConfig PECI proxy block write format and Table 30-26, "RdEndPointConfig() PECI Proxy Block Read" shows the RdEndPointConfig PECI proxy block read format.

30.8 DRAM Thermal Capabilities

Various DRAM component temperature data can be accessed using the RdPkgConfig() and WrPkgConfig() PECI commands addressed to the SoC.

See Section 30.7.4, "RdPkgConfig()" and Section 30.7.5, "WrPkgConfig()" for the format of the commands. The accessible data structures are given in Table 30-32, "Summary of DRAM Thermal and Power Optimization Services" which contains the values of the command index, parameter, and PECI data fields.

Table 30-32. Summary of DRAM Thermal and Power Optimization Services (Sheet 1 of 2)

Service	Index Field (Decimal)	Parameter Field (Word)	PECI Data Field (DWord)	Description	Alternate In-band MSR or CSR Access
RdPkgConfig() Accumulated DRAM Energy Read	04	0xFF	DRAM Energy consumed by the DIMMs	Read the DRAM energy consumed by all the DIMMS in all the channels	DDR_ENERGY_STATUS (CSR), MSR_DRAM_ENERGY_STATUS (MSR 619h)
RdPkgConfig() DIMM Temperature Reading (CLTT only)	14	Channel Index	Absolute temperature in degrees Celsius: [7:0] DIMM#0 [15:8] DIMM#1 [23:16] DIMM#2 [31:24] DIMM#3 For OLTT, will return 0	Read the temperature of each DIMM within a channel	C[0/1]TEMPSTS[0/1]
WrPkgConfig() DRAM Rank Temperature Write	18	Channel Index and DIMM Index	Absolute temperature in degrees Celsius for ranks 0-3	Write the temperature for each rank within a single DIMM	None
RdPkgConfig() DRAM Channel Temperature Read (CLTT only)	22	0x0000	Absolute temperatures in degrees Celsius [7:0] Channel#0 [15:8] Channel#2 [31:16] Reserved For OLTT, will return 0	Read the maximum DRAM channel temperature	None
WrPkgConfig() RdPkgConfig() DRAM Power Limit Data	34	0x0000	DRAM Plane Power Limit Data	Write/Read DRAM Power Limit Data	DDR_RAPL_LIMIT (CSR), MSR_DRAM_POWER_LIMIT (MSR 618h)

Table 30-32. Summary of DRAM Thermal and Power Optimization Services (Sheet 2 of 2)

Service	Index Field (Decimal)	Parameter Field (Word)	PECI Data Field (DWord)	Description	Alternate In-band MSR or CSR Access
RdPkgConfig() DRAM Power Info Read	35	0x0000	Maximum DRAM power settings & maximum time window	Read DRAM power settings info to be used by power limiting entity	DRAM_POWER_INFO[63:32] (CSR) , MSR_DRAM_POWER_INFO[63:32] (MSR 61Ch)
RdPkgConfig() DRAM Power Info Read	36	0x0000	Typical and minimum DRAM power settings	Read DRAM power settings info to be used by power limiting entity	DRAM_POWER_INFO[31:0] (CSR) , MSR_DRAM_POWER_INFO[31:0] (MSR 61Ch)
RdPkgConfig() DRAM Power Limit Performance Status Read	38	0x0000	Accumulated DRAM throttle time	Read sum of all time durations for which each DRAM has been throttled	DDR_RAPL_PERF_STATUS (CSR), MSR_DRAM_PERF_STATUS (MSR 61Bh)

Figure 30-9. Channel Index and DIMM Index Parameter Word

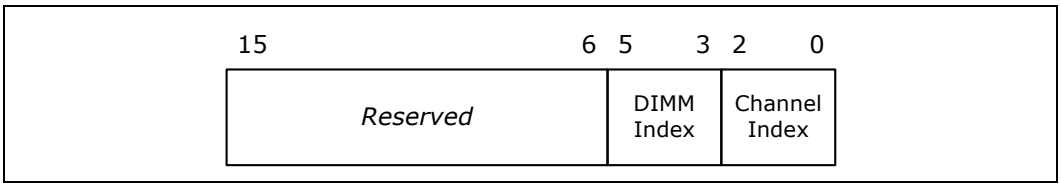

Table 30-33. Channel Index and DIMM Index

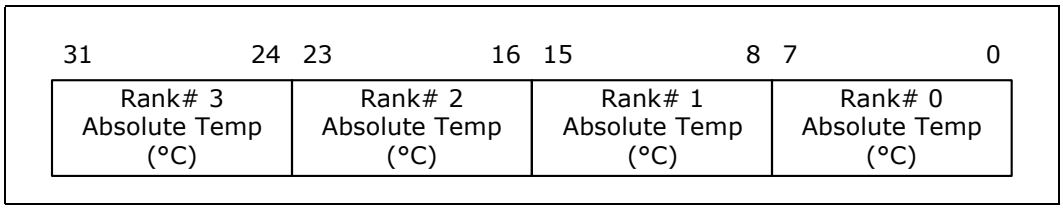
Index Encoding	Physical Channel Number	Physical DIMM Number
000	0	0
001	1	1
010	Reserved	Reserved
011	Reserved	Reserved

30.8.1 DRAM Rank Temperature Write (Index = 18)

See Table 30-32, "Summary of DRAM Thermal and Power Optimization Services." The DRAM rank temperature write allows the PECI host to program the processor with the temperature for all the ranks within a DIMM up to a maximum of four ranks. The programming data structure is defined in Figure 30-10, "Write DRAM Rank Temperature Data Dword."

Figure 30-10.Write DRAM Rank Temperature Data Dword

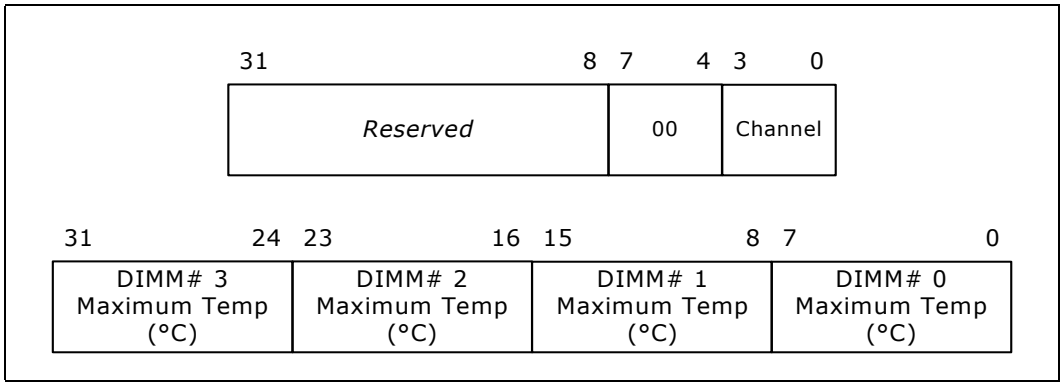


The DIMM index and channel index are specified through the parameter field as shown in Figure 30-9, "Channel Index and DIMM Index Parameter Word" and Table 30-33, "Channel Index and DIMM Index." This write is relevant to platforms that do not have on-die or on-board DIMM thermal sensors to provide memory temperature information or if the processor does not have direct access to the DIMM thermal sensors. This temperature information is used by the processor in conjunction with the activity-based DRAM temperature estimations. With this SoC product family, while temperature values are accepted on a per-rank basis, the SoC uses the average temperature over a given channel for throttling decisions.

30.8.2 DIMM Temperature Read (Index = 14)

See Table 30-32, "Summary of DRAM Thermal and Power Optimization Services." This feature allows the PECI host to read the maximum temperature of all the DIMMs within a channel. If CLTT is disabled, the values returned will be 0. The SoC does not support activity-based temperature estimations. The returned data structure is shown in Figure 30-11, "Read DIMM Temperature Data Dword."

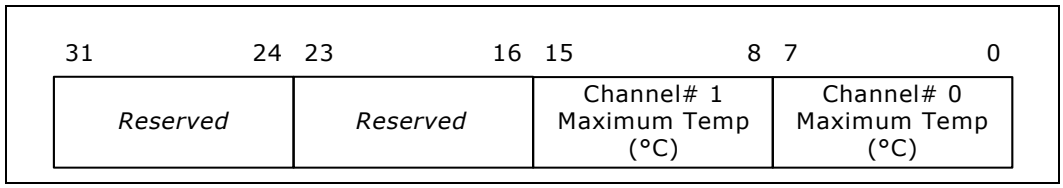
Figure 30-11.Read DIMM Temperature Data Dword



30.8.3 DRAM Channel Temperature Read (Index = 22)

See Table 30-32, "Summary of DRAM Thermal and Power Optimization Services." This feature enables a PECI host read of the maximum temperature of each memory controller channel of the given product SKU. This includes all of the DIMMs within the channel and all the ranks within each of the DIMMs. If CLTT is disabled, the values returned will be 0 See the returned data structure as shown in Figure 30-12, "Read DRAM Channel Temperature Data Dword."

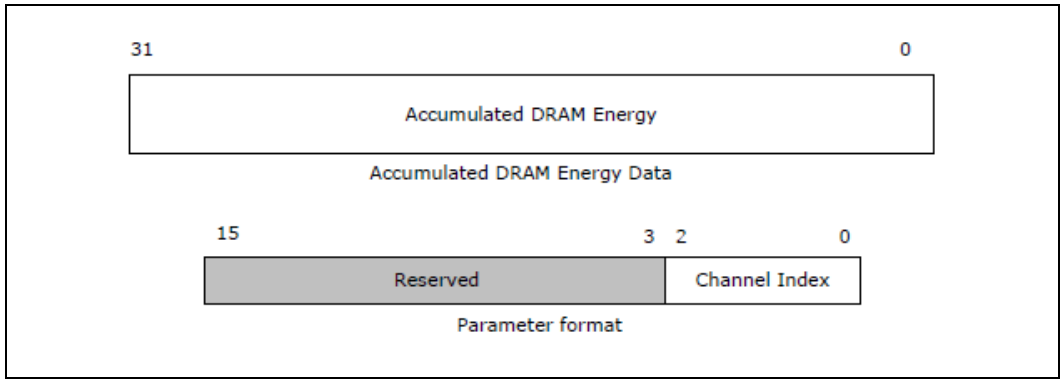
Figure 30-12.Read DRAM Channel Temperature Data Dword



30.8.4 DRAM Accumulated Energy Read (Index = 4)

See Table 30-32, "Summary of DRAM Thermal and Power Optimization Services." This feature allows the PECI host to read the DRAM energy consumed by all the DIMMs in all the channels or all the DIMMs within just a specified channel. The channel index are specified through the parameter field. Units used are defined as per the Package Power SKU Unit read described in Section 30.9.2, "Package Power SKU Unit Read (Index = 30)." The data is tracked by a 32-bit counter that wraps around. The channel index in Figure 30-14, "Read DRAM Power Info Data Dword" is specified as per the index encoding described in Figure 30-25, "Temperature Target Read." While Intel requires reading the accumulated energy data at least once every 16 seconds to ensure functional correctness, a more realistic polling rate recommendation is once every 100 mS for better accuracy. This feature assumes a 200W memory capacity. In general, as the power capability decreases, so will the minimum polling rate requirement.

Figure 30-13.Read DRAM Accumulated Energy Data Dword



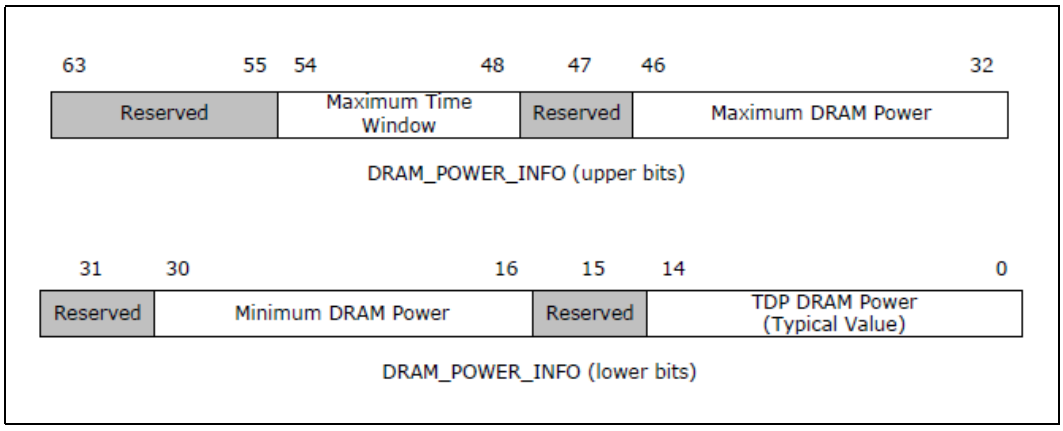
30.8.5 DRAM Power Info Read (Index = 35/36)

See Table 30-32, "Summary of DRAM Thermal and Power Optimization Services." This read returns the minimum, typical and maximum DRAM power settings and the maximum time window over which the power can be sustained for the entire DRAM domain and is inclusive of all the DIMMs within all the memory channels. Any power values specified by the power limiting entity that is outside of the range specified through these settings cannot be guaranteed. Since this data is 64 bits wide, PECI facilitates access to this register by allowing two requests to read the lower 32 bits and upper 32 bits separately. Power and time units for this read are defined as per the Package Power SKU Unit settings described in Section 30.9, "CPU Thermal and Power Optimization Capabilities."

The minimum DRAM power corresponds to a minimum bandwidth setting of the memory interface. It does 'not' correspond to a processor IDLE or memory self-refresh state. The 'time window' in Figure 30-14, "Read DRAM Power Info Data Dword" is representative of the rate at which the SoC Power Management Unit (PMU) samples the DRAM energy consumption information and reactively takes the necessary measures to meet the imposed power limits. Programming too small a time window may not give the PMU enough time to sample energy information and enforce the limit while too large a time window runs the risk of the PMU not being able to monitor and take timely action on energy excursions. While the DRAM power setting in Figure 30-14, "Read DRAM Power Info Data Dword" provides a maximum value for the 'time window' (typically a few seconds), the minimum value may be assumed to be ~100 mS.

The Power Management Controller (PMC) programs the DRAM power settings described in Figure 30-14, "Read DRAM Power Info Data Dword" when DRAM characterization has been completed by the memory reference code (MRC) during boot as indicated by the setting of the MC_BIOS_REQ register. The DRAM power settings will be programmed during boot independent of the 'DRAM Power Limit Enable' bit setting. In general, any tuning of the power settings is done by polling the voltage regulators supplying the DIMMs.

Figure 30-14.Read DRAM Power Info Data Dword



30.8.6 DRAM Power Limit Data Read/Write (Index = 34)

See Table 30-32, "Summary of DRAM Thermal and Power Optimization Services." This feature allows the PECI host to program the power limit over a specified time or control window for the entire DRAM domain covering all the DIMMs within all the memory channels. Actual values are chosen based on DRAM power consumption characteristics. The units for the DRAM Power Limit and Control Time Window are determined as per the Package Power SKU Unit settings described in Table 30.9.2, "Package Power SKU Unit Read (Index = 30)." The DRAM Power Limit Enable bit should be set to activate this feature. Exact DRAM power limit values are largely determined by platform memory configuration. As such, this feature is disabled by default and there are no defaults associated with the DRAM power limit values. The PECI host may be used to enable and initialize the power limit fields for the purposes of DRAM power budgeting. Alternatively, this can also be accomplished through inband writes to the appropriate registers. Both power limit enabling and initialization of power limit values can be done in the same command cycle. All RAPL parameter values including the power limit value, control time window, and enable bit will have to be specified correctly even if the intent is to change just one parameter value when programming over PECI.

The following conversion formula should be used for encoding or programming the 'Control Time Window' in bits [23:17].

Control Time Window (in seconds) = ([1 + 0.25 * 'x'] * $2^{'y'}$) * 'z' where

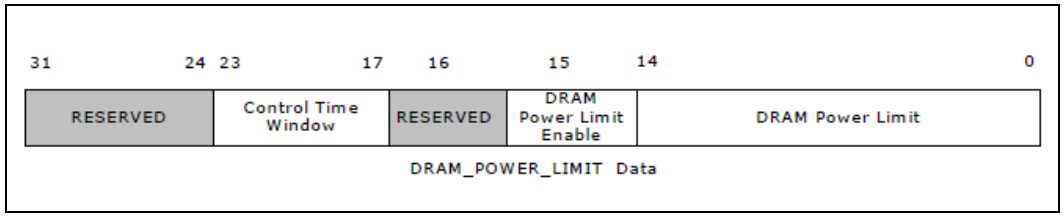
'x' = integer value of bits[23:22]

'y' = integer value of bits[21:17]

'z' = Package Power SKU Time Unit[19:16] (see Table 30.9.2, "Package Power SKU Unit Read (Index = 30)" for details on Package Power SKU Unit)

For example, using this formula, a control time value of 0x0A will correspond to a '1-second' time window.

Figure 30-15.DRAM Power Limit Data

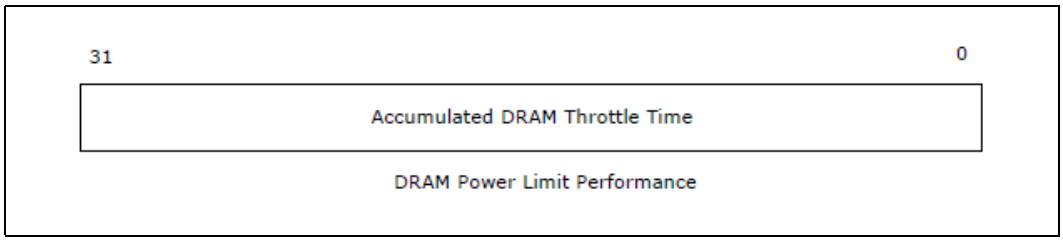


From a DRAM power management standpoint, all post-boot DRAM power management activities (also referred to as 'DRAM RAPL' or 'DRAM Running Average Power Limit') should be managed exclusively through a single interface like PECI or alternatively an inband mechanism. If PECI is being used to manage DRAM power budgeting activities, BIOS should lock out all subsequent inband DRAM power limiting accesses by setting bit 31 of the DRAM_POWER_LIMIT MSR or DRAM_PLANE_POWER_LIMIT CSR to '1'.

30.8.7 DRAM Power Limit Performance Status Read

See Table 30-32, "Summary of DRAM Thermal and Power Optimization Services." This feature allows the PECI host to assess the performance impact of the currently active DRAM power limiting modes. The read return data contains the sum of all the time durations for which each of the DIMMs has been operating in a low power state. This information is tracked by a 32-bit counter that wraps around. The unit for time is determined as per the Package Power SKU Unit settings described in Section 30.9.2, "Package Power SKU Unit Read (Index = 30)" The DRAM performance data does not account for stalls on the memory interface.

Figure 30-16.DRAM Power Limit Performance Data



In general, for the purposes of DRAM RAPL, the DRAM power management entity should use PECI accesses to DRAM energy and performance status in conjunction with the power limiting feature to budget power between the various memory sub-systems in the server system.

30.9 CPU Thermal and Power Optimization Capabilities

Table 30-34, "Summary of CPU Thermal and Power Optimization Services" provides a summary of the power and thermal optimization capabilities that can be accessed over PECI for this SoC product family. Twenty-three services are shown and each is described in the subsections following the table.

Note: The index field values are referenced as decimal numbers.

Table 30-34, "Summary of CPU Thermal and Power Optimization Services" also shows alternate in-band mechanisms to access similar or equivalent information where applicable for register read and write services.

The BIOS is required to populate CPUID, PlatformID and the CPU microcode update revision.

Table 30-34. Summary of CPU Thermal and Power Optimization Services (Sheet 1 of 7)

Service	Index Field (Decimal)	Parameter Field (Word)	PECI Data Field (DWord)	Description	Alternate In-band MSR or CSR Access
RdPkgConfig() Package Identifier Read Section 30.9.1, on page 848	00	0x0000	CPU ID Information	Returns processor-specific information including CPU family, model and stepping information.	Execute the CPUID instruction to get the processor signature.
		0x0001	Platform ID	Used to ensure microcode update compatibility with the processor.	IA32_PLATFORM_ID (MSR 17h)
		0x0002	PCU Device ID	Returns the device ID information for the processor PMU.	
		0x0003	Max Thread ID	Returns the maximum thread ID value supported by the processor.	
		0x0004	CPU Microcode Update Revision	Returns the processor microcode and internal power control-unit firmware revision information.	IA32_BIOS_SIGN_ID (MSR 8Bh)
		0x0005	MCA Error Source Log	Returns the MCA error source log.	MCA_ERR_SRC_LOG (CSR)

Table 30-34. Summary of CPU Thermal and Power Optimization Services (Sheet 2 of 7)

Service	Index Field (Decimal)	Parameter Field (Word)	PECI Data Field (DWord)	Description	Alternate In-band MSR or CSR Access
WrPkgConfig() VR Debug Interface	01	0x0000	[03:00] VR ID. 00h Vcc 01h Vnn 03h VccSram 02h Memory 06h [08:04] VR command. GetReg (0x07) supported. For illegal commands, return ILLEGAL_CMD completion code. [15:09] Reserved. Fail with ILLEGAL_DATA if non-zero. [23:16] VR register address or VID data. [31:24] Reserved. Fail with ILLEGAL_DATA if non-zero.	Read VR Register data through the VR12.x GetReg command. Data is returned in WrPkgConfig() response	
RdPkgConfig() Package Temperature Read Section 30.9.5, "Package Temperature Read (Index = 2)"	02		[15:0] Reserved [22:16] Processor package Temperature relative to PROCHOT	Returns the maximum processor die temperature (average) in PECI format.	P_CR_PACKAGE_THERM_STATUS (CSR)
RdPkgConfig() Accumulated Energy Status Read Section 30.9.11, "Accumulated Energy Status Read (Index = 3)"	03	0x0 = Vcc Energy 0xFF = SoC (Total Pkg Energy)	Accumulated CPU energy	Returns the value of the energy consumed by just the VCC power plane or the entire SoC.	PACKAGE_ENERGY_STATUS (CSR), MSR_PKG_ENERGY_STATUS (MSR 611h)
RdPkgConfig() Efficient Performance Indication (EPI)	06	0x0000	Number of productive processor cycles	Read number of productive cycles for power budgeting purpose	None

Table 30-34. Summary of CPU Thermal and Power Optimization Services (Sheet 3 of 7)

Service	Index Field (Decimal)	Parameter Field (Word)	PECI Data Field (DWord)	Description	Alternate In-band MSR or CSR Access
RdPkgConfig() Package Power Limit Performance Status Read Section 30.9.13, "Package Power Limit Performance Status Read (Index = 8)"	08	0x00FF: CPU package	Accumulated CPU throttle time	Read the total time for which the processor package was throttled due to power limiting.	PACKAGE_RAPL_PERF_STATUS (CSR), MSR_PKG_PERF_STATUS (MSR 613h)
RdPkgConfig() Per Core DTS Temperature Read Section 30.9.6, "Per Core DTS Temperature Read (Index = 9)"	09	0x0000 *through* 0x0017: Cores 0 *through* 15 **0xfd**: SoC temperature sensor 0 **0xfe**: SoC temperature sensor 1 **0xff**: SoC temperature sensor 2	Per core DTS maximum temperature [15:0] Module MAX temperature (same format as in Package Temperature) [32:16] Reserved	Read the maximum DTS temperature of a particular core or the system agent within the processor die in the relative PECI temperature format.	IA32_THERM_STATUS (MSR 19C)
THERM_MARGIN	10	0x10	N/A	Format S16.7.8 Read the thermal margin to spec (DTS 2.0) Margin offset relative to T-Control.	P_CR_PACKAGE_THERM_MARGIN_0_0_0_MCHBAR (CSR) PACKAGE_THERM_MARGIN (MSR 1A1h)
RdPkgConfig() Socket Power Throttled Duration	11	0x0000	Duration of the SoC operating condition	Returns the duration for which RAPL power limit determined the operating condition	None
WrPkgConfig() Configure Current Limit	15	0x0000	Current Limit	Configure the maximum current to limit the SoC power	MSR_VR_CURRENT_CONFIG (MSR 601h)

Table 30-34. Summary of CPU Thermal and Power Optimization Services (Sheet 4 of 7)

Service	Index Field (Decimal)	Parameter Field (Word)	PECI Data Field (DWord)	Description	Alternate In-band MSR or CSR Access
RdPkgConfig() Temperature Target Read Section 30.9.7, "Temperature Target Read (Index = 16)"	16	0x0000	[7:0] Reserved [15:8] TCONTROL value which indicates the relative offset from PROCHOT [23:16] PROCHOT temperature where the Thermal Monitor is activated. [27:24] Temperature offset in degrees (C) from the PROCHOT. If offset is set the Thermal Monitor will occur at lower than PROCHOT.	Returns the maximum processor junction temperature, PROCHOT and processor $T_{CONTROL}$.	TEMPERATURE TARGET (CSR), MSR_TEMPERATURE_TARGET (MSR 1A2h)
RdPkgConfig() Current Limit Read Section 30.9.10, "Current Limit Read (Index = 17)"	17	0x00FF	Current Limit	Reads the current limit on the VCC power plane	MSR_VR_CURRENT_CONFIG[31:0] (MSR 601h)
RdPkgConfig() Package Thermal Status	20	0x0000	Thermal Status Register	Read the thermal status register and optionally clear any log bits.The register includes status and log bits for TCC activation, PROCHOT_N assertion & critical temperature	IA32_PACKAGE_THERM_STATUS (MSR 1B1H)
WrPkgConfig() Package Power limits For multiple Turbo Modes Section 30.9.12, "Package Power Limits For Multiple Turbo Modes (Index = 26 and 27)"	26	0x0000	Power Limit 1 Data	Write power limit 1 data in multiple turbo mode.	PACKAGE_RAPL_LIMIT (CSR), MSR_PKG_POWER_LIMIT (MSR 610h)

Table 30-34. Summary of CPU Thermal and Power Optimization Services (Sheet 5 of 7)

Service	Index Field (Decimal)	Parameter Field (Word)	PECI Data Field (DWord)	Description	Alternate In-band MSR or CSR Access
RdPkgConfig() Package Power Limits For multiple Turbo Modes Section 30.9.12, "Package Power Limits For Multiple Turbo Modes (Index = 26 and 27)"	27	0x0000	Power Limit 2 Data	Read power limit 2 data in multiple turbo mode.	PACKAGE_RAPL_LIMIT (CSR), MSR_PKG_POWER_LIMIT (MSR 610h)
RdPkgConfig() Package Power SKU Read Section 30.9.3, "Package Power SKU Read (Index = 28 and 29)"	28	0x0000	Package Power SKU [31:0]	Returns Thermal Design Power (TDP) and minimum package power for the SoC product SKU.	PACKAGE_POWER_SKU (CSR), MSR_PKG_POWER_INFO (MSR 614h)
RdPkgConfig() Package Power SKU Read Section 30.9.3, "Package Power SKU Read (Index = 28 and 29)"	29	0x0000	Package Power SKU[64:32]	Returns the maximum package power value for the SoC product SKU and the maximum time interval for which it can be sustained.	PACKAGE_POWER_SKU (CSR), MSR_PKG_POWER_INFO (MSR 614h)
RdPkgConfig() Package Power SKU Unit Read Section 30.9.2, "Package Power SKU Unit Read (Index = 30)"	30	0x0000	Time, Energy and Power Units	Read units for power, energy and time used in the power control registers.	PACKAGE_POWER_SKU_UNIT (CSR), MSR_RAPL_POWER_UNIT (MSR 606h)
RdPkgConfig() Total Time Section 30.9.4, "Accumulated Run Time Read (Index = 31)"	31	0x0000	Elapsed time	Returns the total run time in ms. Total accumulated run time reported in IO_TSC_LOW. 31:0 - lower 32 bits of the UNCORE Time Stamp Counter.	IA32_TIME_STAMP_COUNTER (MSR 10h)
		0x00FE	64-bit counter indicating the aggregate of C0 residency count from all cores		
		0x00FF	32 MSBs of 64-bit counter indicating the aggregate of C0 residency count from all cores

Max value of 100% [31:31] Lock bit. If set, this command is locked out from future writes and all other data in this command is ignored	
GetCrashDumpDetails	51	Get Crash dump details		Get the details of the Crash Dump.	
GetCrashDumpFrame	52	Get Frame		Gets a particular frame in the specified crash dump	

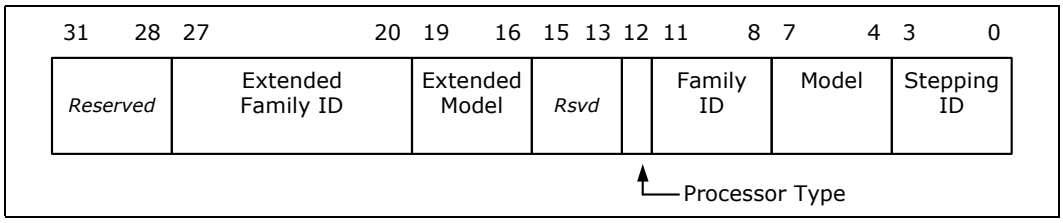
30.9.1 Package Identifier Read (Index = 0)

This feature enables the PECI host to uniquely identify the PECI client processor. The parameter field encodings shown in Table 30-34, "Summary of CPU Thermal and Power Optimization Services" allow the PECI host, typically the BMC, to access the relevant processor information as described below.

30.9.1.1 CPU ID Information

This is data field contains the equivalent information that can be accessed through executing the Intel® architecture CPUID instruction. It contains the processor type, stepping, model, and family ID information as shown in Figure 30-17, "CPU ID Data."

Figure 30-17.CPU ID Data



30.9.1.2 Platform ID

This data field can be used to ensure processor microcode updates are compatible with the processor.

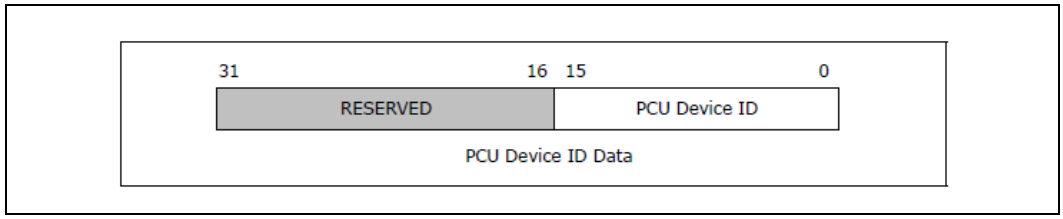
Note: The value of the platform ID or processor flag[2:0] as shown in Figure 30-18, "Platform ID Data" is typically unique to the platform type and processor stepping.

Figure 30-18.Platform ID Data

30.9.1.3 PCU Device ID

This information can be used to uniquely identify the processor power control unit (PCU) device when combined with the Vendor Identification register content and remains constant across all SKUs. Refer to the appropriate register description for the exact processor PCU Device ID value.

Figure 30-19.PCU Device ID Data

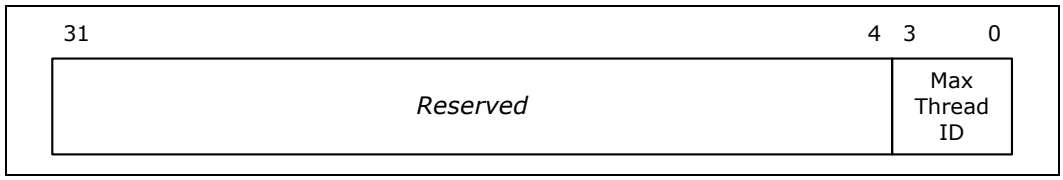


30.9.1.4 Maximum Thread ID

This is data field provides the number of supported processor threads.

Note: This value is dependent on the number of cores within the processor as determined by the processor SKU and is independent of whether certain cores or corresponding threads are enabled or disabled. See Figure 30-20, "Maximum Thread ID Data."

Figure 30-20.Maximum Thread ID Data

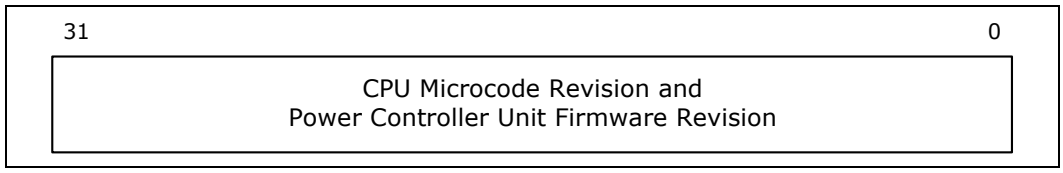


30.9.1.5 CPU Microcode Update Revision

This data field reflects the revision number for the microcode update and power control unit firmware updates on the processor sample.

Note: The revision data is a unique 32-bit identifier that reflects a combination of specific versions of the processor microcode and power control unit firmware. See Figure 30-21, "Processor Microcode Revision."

Figure 30-21.Processor Microcode Revision



30.9.1.6 MCA Error Source Log

This is data field contains contents of the Machine-Check Architecture (MCA) Error Source Log register. See Figure 30-22, "Package Power SKU Unit Data" for details. The register indicates the value as defined when IERR and/or MCERR are indicated by the SoC.

30.9.2 Package Power SKU Unit Read (Index = 30)

This feature enables the PECI host to read the units of time, energy, and power used in the processor and DRAM power control registers for calculating power and timing parameters. In Figure 30-22, "Package Power SKU Unit Data," the default values are:

- Power unit field [3:0] = 0011b
- Energy unit field [12:8] = 10000b
- Time unit field [19:16] = 1010b

Actual unit values are calculated as shown in Table 30-35, "Power Control Register Unit Calculations."

Figure 30-22. Package Power SKU Unit Data

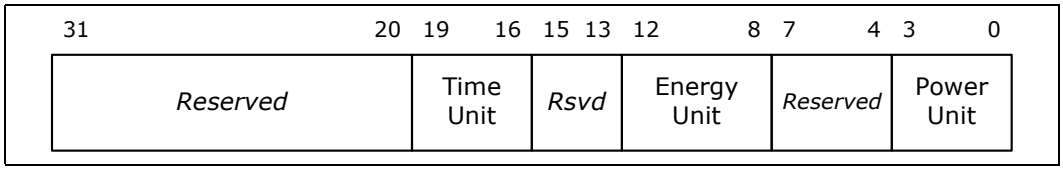


Table 30-35. Power Control Register Unit Calculations

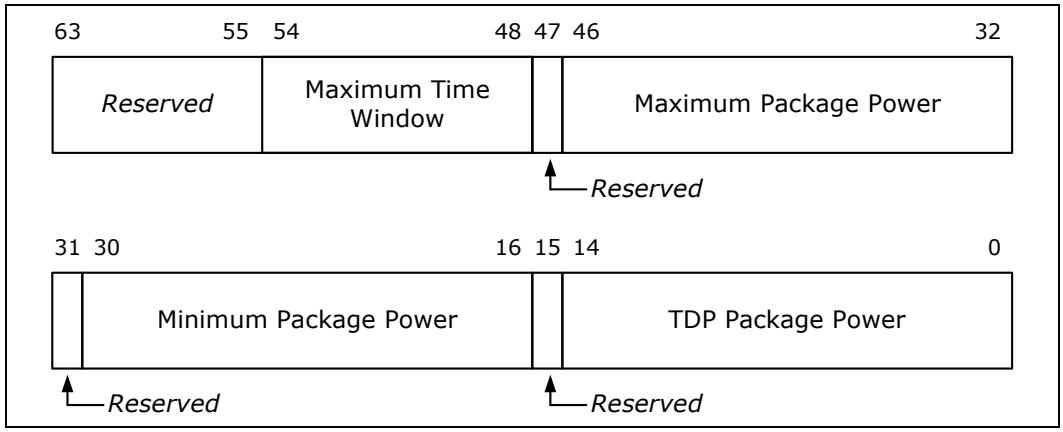
Unit Field	Value Calculation	Default Value
Time	1s / 2^TIME UNIT	1s / 2^10 = 976 µs
Energy	1J/2^ENERGY UNIT	1J/2^16 = 15.3 µJ
Power	1W/2^POWER UNIT	1W/2^3 = 1/8 W

30.9.3 Package Power SKU Read (Index = 28 and 29)

This read allows the PECI host to access the minimum, Thermal Design Power (TDP) and maximum power settings for the processor package SKU. It also returns the maximum time interval or window over which the power can be sustained. If the power limiting entity specifies a power limit value outside of the range specified through these settings, power regulation cannot be guaranteed. Since this data is 64-bits wide, PECI facilitates access to this register by allowing two requests to read the lower 32 bits and upper 32 bits separately as shown in Figure 30-23, "Package Power SKU Data." Power units for this read are determined as per the package power SKU unit settings described in Section 30.9.2, "Package Power SKU Unit Read (Index = 30)."

Figure 30-23.Package Power SKU Data



The package power SKU data is programmed by the SoC internal Power Control Unit (PCU) firmware during boot time based on SKU dependent power-on default values set during SoC manufacturing. The TDP package power specified through bits [14:0] in Figure 30-23, "Package Power SKU Data" is the maximum value of the Power Limit1 field described in Section 30.9.12, "Package Power Limits For Multiple Turbo Modes (Index = 26 and 27)" while the maximum package power in bits [46:32] is the maximum value of the Power Limit2 field which is also described in Section 30.9.12, "Package Power Limits For Multiple Turbo Modes (Index = 26 and 27)."

The minimum package power in bits [30:16] is applicable to both the Power Limit1 and Power Limit2 fields and corresponds to a mode when all the cores are operational and in their lowest frequency mode. Attempts to program the power limit below the minimum power value may not be effective since the BIOS/OS, and not the integrated PCU, controls disabling of cores and core activity.

Maximum time window in bits [54:48] is representative of the maximum rate at which the internal PCU can sample the package energy consumption and reactively take the necessary measures to meet the imposed power limits. Programming too-large of a time window runs the risk of the PCU not being able to monitor and take timely action on package energy excursions. On the other hand, programming too-small of a time window may not give the PCU enough time to sample energy information and enforce the limit. The minimum value of the "time window" can be obtained by reading bits [21:15] of the PWR_LIMIT_MISC_INFO CSR using the PECI RdPCIConfigLocal() command.

30.9.4 Accumulated Run Time Read (Index = 31)

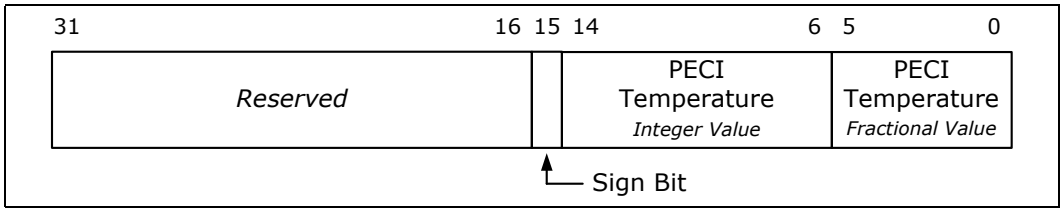
This services provides support for 2 accumulated runtime reads.

- 0x0000: This read returns the total time for which the processor has been executing with a resolution of 1 ms per count. This is tracked by a 32-bit counter that rolls over on reaching the maximum value. This counter activates and starts counting for the first time when the SoC desserts the active-low CPU_RESET_N output signal pin.
- 0x00FE: This read returns the total time for which the processor has been in C0 with a resolution of 1 ms per count. This is tracked by a 32-bit counter that rolls over on reaching the maximum value. This counter activates and starts counting for the first time when the SoC deasserts the active-low CPU_RESET_N output signal pin.

30.9.5 Package Temperature Read (Index = 2)

This read returns the maximum processor die temperature in a 16-bit PECI format. The upper 16 bits of the response data are reserved. See Figure 30-24, "Package Temperature Read Data." The PECI temperature data returned by this read is the instantaneous value and not the average value as is returned by the PECI GetTemp() described in Section 30.6.4, "PECI Proxy Command Trigger."

Figure 30-24.Package Temperature Read Data



30.9.6 Per Core DTS Temperature Read (Index = 9)

This feature enables the PECI host to read the maximum value of the Digital Thermal Sensor (DTS) temperature for any specific core within the processor. Alternatively, this service can be used to read the internal SoC System Agent (SSA) temperature. The temperature is returned in the same data format as described in Section 30.9.5, "Package Temperature Read (Index = 2)." Data is returned in a relative PECI temperature format.

Reads to a parameter value outside the supported range return an error as indicated by a completion code of 0x90. The supported range of parameter values can vary depending on the number of processor cores within the SoC. The temperature data returned through this feature is the instantaneous value and not the average value. It is updated once every 1 ms.

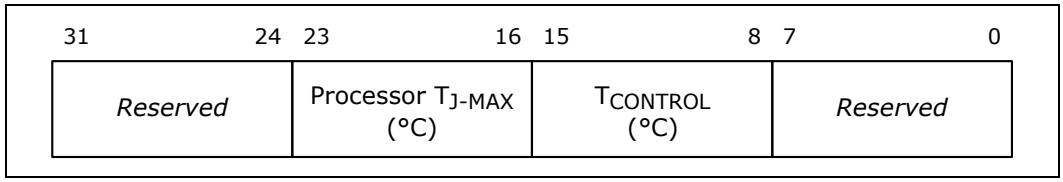
30.9.7 Temperature Target Read (Index = 16)

The temperature target read allows the PECI host to access the maximum processor junction temperature (T_{J-MAX}) in degrees Celsius. This is also the default temperature value at which the processor thermal control circuit activates. The T_{J-MAX} value may vary from processor part to part to reflect manufacturing process variations.

The temperature target read also returns the processor $T_{CONTROL}$ value. The $T_{CONTROL}$ is returned in a standard PECI temperature format and represents the threshold temperature used by the thermal management system for a fan speed control.

See Figure 30-27.

Figure 30-25.Temperature Target Read



30.9.8 Package Thermal Status Read / Clear (Index = 20)

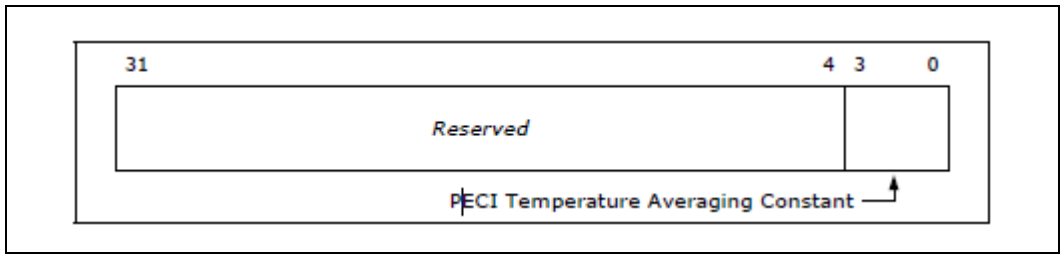
The Thermal Status Read provides information on package level thermal status. Data includes:

- Thermal Control Circuit (TCC) activation
- Bidirectional PROCHOT_N signal assertion
- Critical Temperature

Both status and sticky log bits are managed in this status word. All sticky log bits are set upon a rising edge of the associated status bit and the log bits are cleared only by Thermal Status reads or a processor reset. A read of the Thermal Status word always includes a log bit clear mask that allows the host to clear any or all of the log bits that it is interested in tracking.

A bit set to '0' in the log bit clear mask will result in clearing the associated log bit. If a mask bit is set to '0' and that bit is not a legal mask, a failing completion code will be returned. A bit set to '1' is ignored and results in no change to any sticky log bits. For example, to clear the TCC Activation Log bit and retain all other log bits, the Thermal Status Read should send a mask of 0xFFFFFFFD.

Figure 30-26.Package Thermal Status Read/Clear



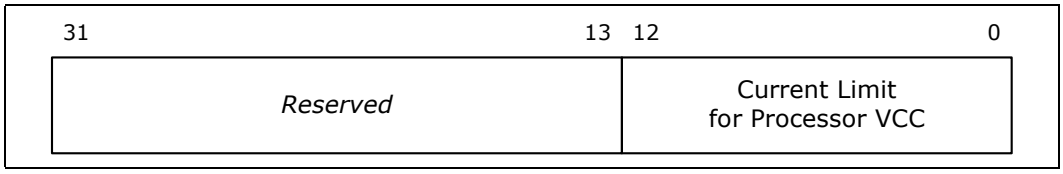
30.9.9 Thermally Constrained Time Read (Index = 32)

This feature allows the PECI host to access the total time for which the processor has been operating in a lowered power state due to Thermal Control Circuit (TCC) activation. The returned data includes the time required to ramp back up to the original P-State target after the TCC activation expires. This timer does not include TCC activation as a result of an external assertion of the SoC PROCHOT_N signal pin. This is tracked by a 32-bit counter with a resolution of 1 ms per count that rolls over or wraps around. Concerning the processor PECI clients, the only logic that can be thermally constrained are those which are supplied by VCC.

30.9.10 Current Limit Read (Index = 17)

This read returns the current limit for the processor VCC power plane in 1/8-ampere increments. Actual current limit data is contained only in the lower 13 bits of the response data. The default return value of 0x140 corresponds to a current limit value of 40 amperes. Bit 31 is a lock bit indicating that the IccMax has been locked to the returned value in bits 0-12.See Figure 30-27, "Current Limit Read Data."

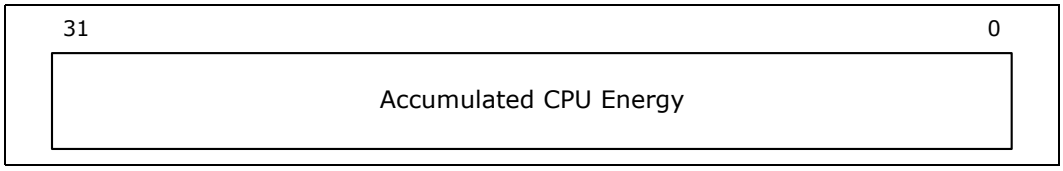
Figure 30-27.Current Limit Read Data



30.9.11 Accumulated Energy Status Read (Index = 3)

This service can return the value of the total energy consumed by the entire processor package or just the logic supplied by the VCC power plane as specified through the parameter field in Table 30-34, "Summary of CPU Thermal and Power Optimization Services." This information is tracked by a 32-bit counter that wraps around and continues counting on reaching its limit. See Figure 30-28, "Accumulated Energy Read Data." Energy units for this read are determined as per the package power SKU unit settings described in Section 30.9.2, "Package Power SKU Unit Read (Index = 30)."

Figure 30-28.Accumulated Energy Read Data

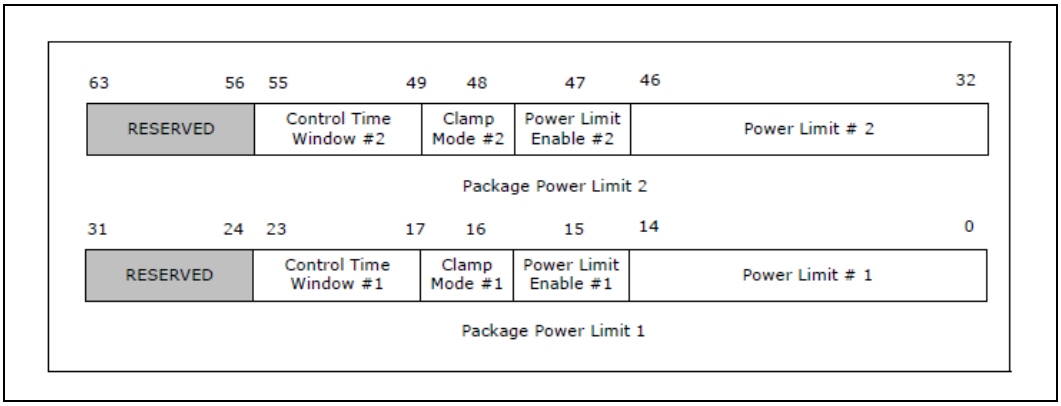


While Intel requires reading the accumulated energy data at least once every 16 seconds to ensure functional correctness, a more realistic polling rate recommendation is once every 100 ms for better accuracy. In general, as the power capability decreases, so will the minimum polling rate requirement. Intel recommends to tune the polling rate to reduce the potential impact on other power management features.

30.9.12 Package Power Limits For Multiple Turbo Modes (Index = 26 and 27)

This feature allows the PECI host to program two power limit values to support multiple turbo modes. The operating systems and drivers can balance the power budget using these two limits. Two separate PECI requests are available to program the lower and upper 32 bits of the power limit data shown in Figure 30-29, "Package Turbo Power Limit Data."

Figure 30-29.Package Turbo Power Limit Data



The units for the power limit and control time window are determined as per the package power SKU unit settings described in Section 30.9.2, "Package Power SKU Unit Read (Index = 30)," while the valid range for the power limit values are determined by the package power SKU settings described in Section 30.9.2, "Package Power SKU Unit Read (Index = 30)" and Section 30.9.3, "Package Power SKU Read (Index = 28 and 29)."

Setting the Clamp Mode bits is required to allow the cores to go into power states below what the operating system originally requested. The Power Limit Enable bits should be set to enable the power limiting function. Power limit values, Enable, and Clamp Mode bits can all be set in the same command cycle.

Intel recommends exclusive use of just one entity or interface, PECI for instance, to manage all processor package power limiting and budgeting needs. If PECI is being used to manage package power limiting activities, the BIOS should lock out all subsequent in-band package power limiting accesses by setting bit 31 of the MSR_PKG_POWER_LIMIT (MSR 610h) or TURBO_POWER_LIMIT (SoC sideband Port 04h, offset 7 and 8) register to 1.

Power Limit #1 is intended to limit processor power consumption to any reasonable value below TDP and defaults to TDP. Power Limit #1 values may be impacted by the processor heat sinks and system air flow. Processor Power Limit #2 can be used as appropriate to limit the current drawn by the processor to prevent any external power supply unit issues. Power Limit #2 should always be programmed to a value (typically 20%) higher than Power Limit #1 and has no default value associated with it.

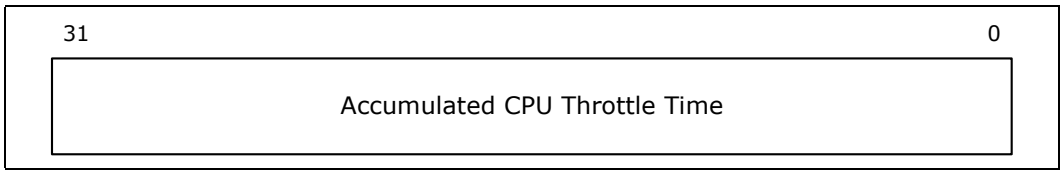
Though this feature is disabled by default and external programming is required to enable, initialize, and control the package power limit values and time windows, the processor package will still turbo to TDP if Power Limit #1 is not enabled or initialized. Control Time Window #1 values may be programmed to be within a range of 100 ms-10 seconds. Control Time Window #2 values should be in the range 40 ns to 10 ms.

The same conversion formula used for the DRAM Power Limiting feature (see Section DRAM Power Limit Data Read/Write) should be applied when programming the 'Control Time Window' in bits [23:17] and [55:49].

30.9.13 Package Power Limit Performance Status Read (Index = 8)

This service allows the PECI host to assess the performance impact of the currently active power limiting modes. The read return data contains the total amount of time for which the entire processor package has been operating in a power state that is lower than what the operating system originally requested. This information is tracked by a 32-bit counter that wraps around. See Figure 30-30, "Package Power Limit Performance Data." The unit for time is determined as per the package power SKU unit settings described in Section 30.9.2, "Package Power SKU Unit Read (Index = 30)."

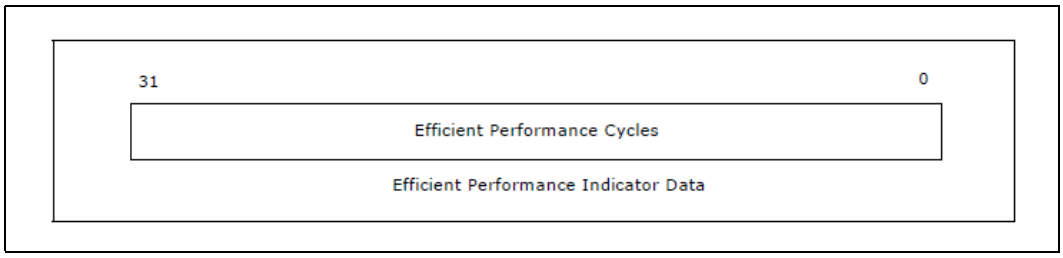
Figure 30-30.Package Power Limit Performance Data



30.9.14 Efficient Performance Indicator Read (Index = 6)

The Efficient Performance Indicator (EPI) Read provides an indication of the total number of productive cycles. Specifically, these are the cycles when the processor is engaged in any activity to retire instructions and as a result, consuming energy. Any power management entity monitoring this indicator should sample it at least once every 4 seconds to enable detection of wraparounds.

Figure 30-31.Efficient Performance Indicator Data



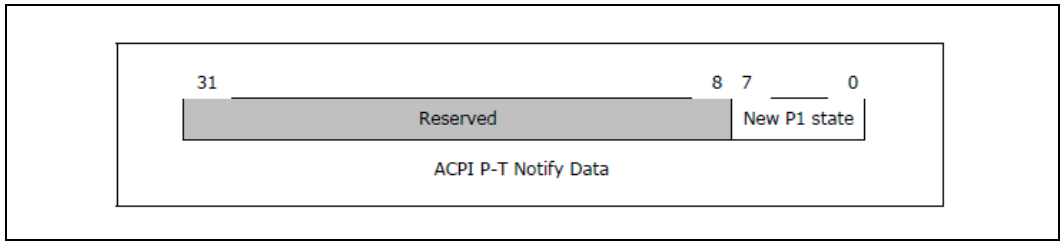
30.9.15 ACPI P-T Notify Write and Read (Index = 33)

This feature enables the processor turbo capability when used in conjunction with the PECI package RAPL or power limit. When the BMC sets the package power limit to a value below TDP, it also determines a new corresponding turbo frequency and notifies the OS using the 'ACPI Notify' mechanism as supported by the _PPC or performance present capabilities object. The BMC then notifies the processor PCU using the PECI 'ACPI P-T Notify' service by programming a new state that is one p-state below the turbo frequency sent to the OS via the _PPC method.

When the OS requests a p-state higher than what is specified in bits [7:0] of the PECI ACPI P-T Notify data field, the CPU will treat it as request for P0 or turbo. The PCU will use the IA32_ENERGY_PERFORMANCE_BIAS register settings to determine the exact extent of turbo. Any OS p-state request that is equal to or below what is specified in the PECI ACPI P-T Notify will be granted as long as the RAPL power limit does not impose a lower p-state. However, turbo will not be enabled in this instance even if there is headroom between the processor energy consumption and the RAPL power limit.

This feature does not affect the Thermal Monitor behavior of the processor nor is it impacted by the setting of the power limit clamp mode bit.

Figure 30-32.ACPI P-T Notify Data



30.9.16 Package PL3 (Index = 53)

PL3 is a package limit that is defined for the overall SoC in support of a PSU requirement of a strict duty cycle enforcement for points above PL2. This allows the PSU to be designed for application power draw, rather than virus.

Figure 30-33.PL2 and PL3

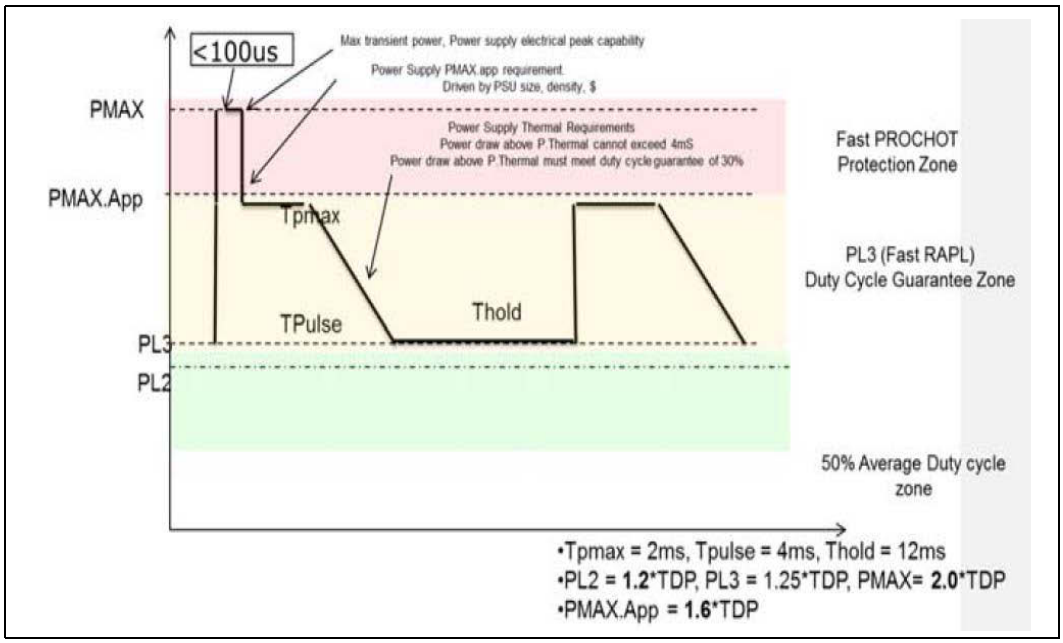


Figure 30-34.PL3 Register Definition

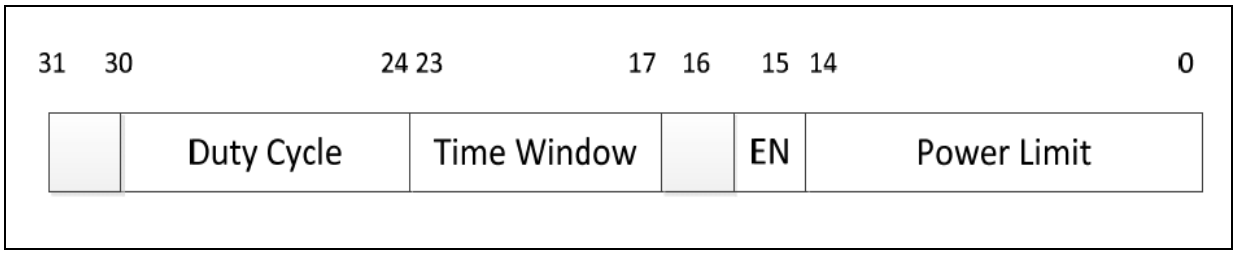


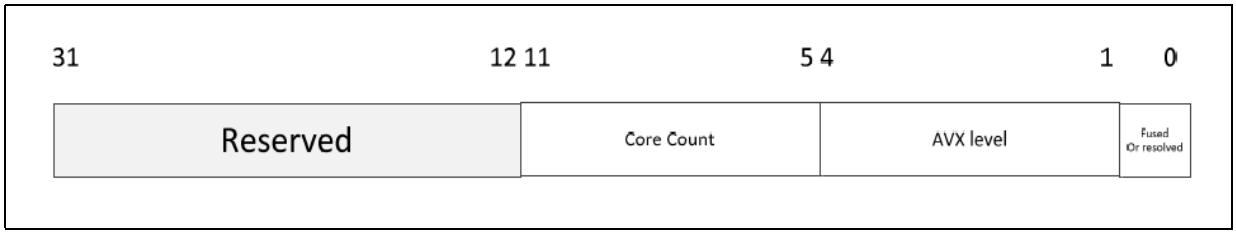
The defaults values are:

Power Limit: 1.25 TDP
Enable: Always set
Time Window: 8 ms
Duty-Cycle: 25%

30.9.17 Read Ratio Constraints (Index = 49)

Read constraints takes a single parameter that indicates the desired information

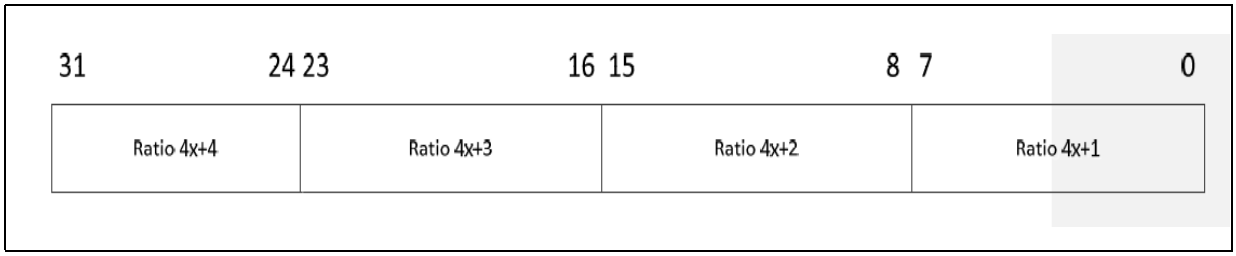
Figure 30-35.Read Ratio Constraints Parameter



Bit [0] indicates fused or resolved. 0:fused, 1: resolved.
Bit [4:1] indicate AVX level. 0h: non-AVX, 1h: AVX, 2h: AVX3.
Bits [11:5] indicate core count input x (0h - 7Fh).

The return value is shown in Figure 30-36, "Read Ratio Constraints Return Value."

Figure 30-36.Read Ratio Constraints Return Value

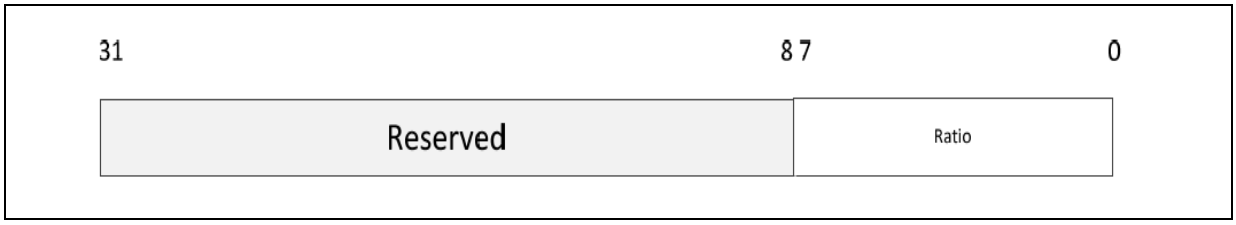


- If 4x + y, y = {1,2,3,4} is not a valid core count, returns ffh as the limit.

30.9.18 Read Ratio Limit

This read returns the ratio limit.

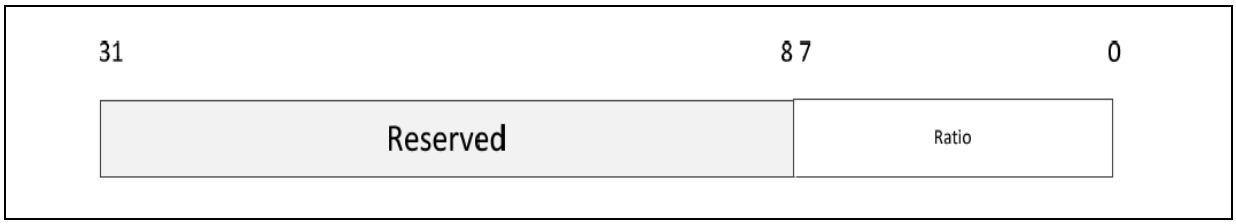
Figure 30-37.Read Ratio Limit



30.9.19 Write Ratio Limit

The ratio limit is defined in the data field.

Figure 30-38.Write Ratio Limit



30.10 Crash Dump

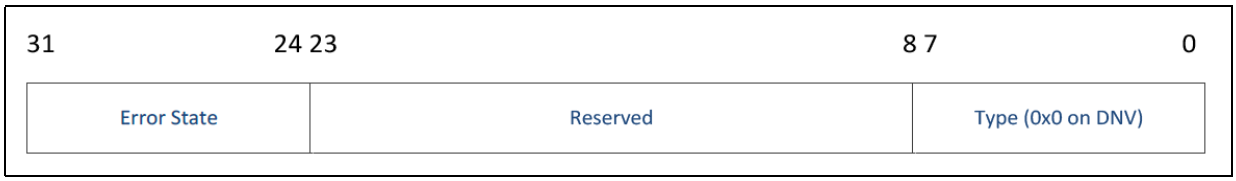
Crash Dump is implemented as a RdPkgConfig Command.

30.10.1 GetCrashDumpCapabilities (Index=51)

This feature returns the details of a crash dump. When parameter#0 is:

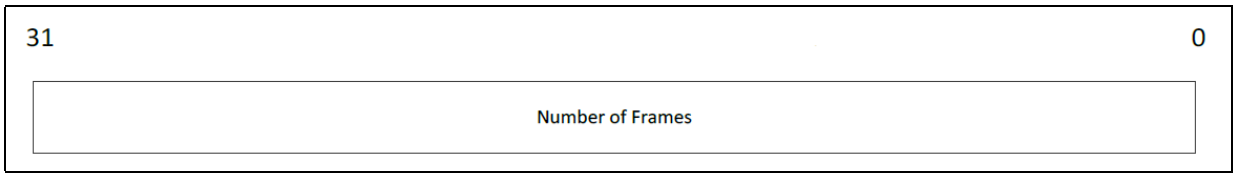
0x0 - returns the size info:

Figure 30-39.Crash Dump Capabilities Details



0x1 - returns the number of frames:

Figure 30-40.Crash Dump Capabilities (Parameter0 = 0x1)



30.10.2 GetCrashDumpFrame (Index = 52)

This feature gets a particular frame in the specified crash dump. When requesting the frame, the frame# is passed as a parameter. A maximum of 2^16 frames is only supported, starting at frame '0'.

Figure 30-41.Request Parameters

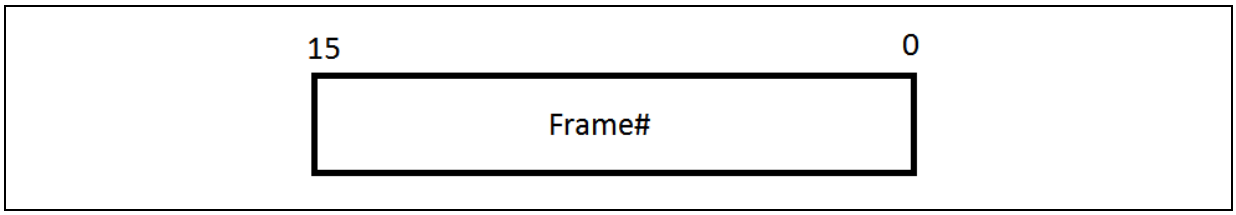


Figure 30-42.Response Data for Requested Frame

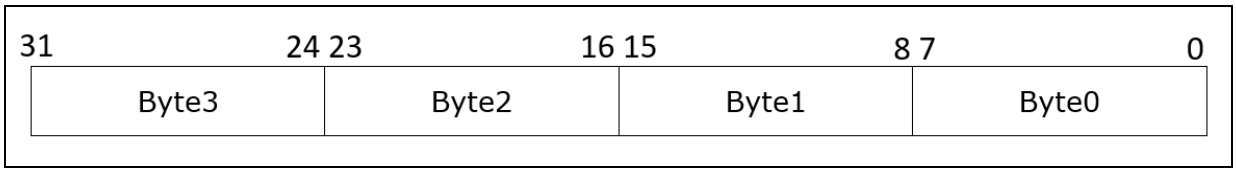

30.10.3 UnCore and PM Crash Dump Registers

The following are the registers visible in crash dump. The purpose of these registers is to enable customers to gather important system information when a crash happens in their system and to provide the information contained in these registers to Intel for analysis.

30.10.4 Core Crash Dump

30.10.4.1 Overview

Core crash dump provides the SoC with the ability to dump the core registers (including the SQ) when a 3-strike crash takes place. To provide this capability, RdPkgConfig has been implemented to access the core crash dump.

30.10.4.2 PECI Command Structure

RdPkgCOnfig is used with index 0x51. The parameter field is divided into 2 bytes. Byte0 is always 0x2 and Byte1 is the coreindex.

Table 30-37. RdPkgConfig() PECI Proxy Block Write

SMBus	Function		Value	Data Source	Comment
Slave Address (Write)	Write Address	SMBus Command	0x4C	BMC	
Command Code	PECI Mode command code		0x62		
Byte Count	N	Control Data	0x09		
Byte 1	SMBus-PECI Handshake Control		0x00		Value = 0x00 No AW FCS Required
Byte 2	PECI Client Address	PECI Command	0x30		Socket ID. Always 0x30 for the SoC.
Byte 3	PECI Write Length		0x05		
Byte 4	PECI Read Length		{0x02, 0x3, 0x5}		
Byte 5	RdPkgConfig() Command Code		0xA1

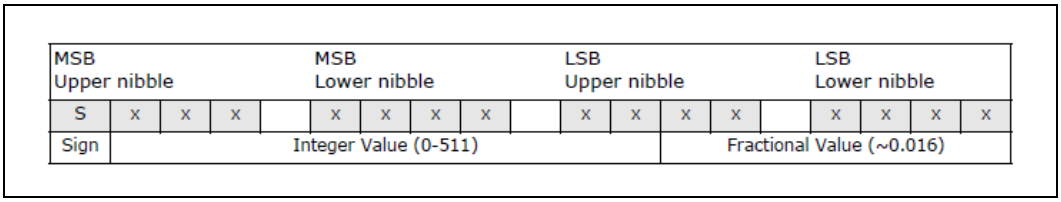
30.11 DTS Temperature Data

30.11.1 PECI Device Temp Data

When accessed using the PECI GetTemp() command, the temperature is formatted in a 16-bit, 2s complement value representing a number of 1/64 °C.

See Figure 30-43, "PECI Device Temp [15:0] Format - Temperature Sensor Data." This format allows temperatures in a range of +/-512 °C to be reported to approximately a 0.016 °C resolution.

Figure 30-43.PECI Device Temp [15:0] Format - Temperature Sensor Data



30.11.2 Interpretation

The resolution of the processor Digital Thermal Sensor (DTS) is approximately 1 °C, which can be confirmed by a performing a Read Model-Specific Register (RDMSR) Intel® architecture instruction to the IA32_THERM_STATUS MSR (19Ch) where it is architecturally defined.

Note: The MSR read will return only bits [13:6] of the PECI temperature sensor data defined in Figure 30-43, "PECI Device Temp [15:0] Format - Temperature Sensor Data." PECI temperatures are sent through a configurable low-pass filter prior to delivery in the GetTemp() response data. The output of this filter produces temperatures at the full 1/64 °C resolution even though the DTS itself is not this accurate.

Temperature readings from the processor are always negative in a 2s complement format, and imply an offset from the processor $T_{J\text{-}MAX}$ (PECI = 0). For example, if the processor $T_{J\text{-}MAX}$ is 100 °C, a PECI thermal reading of -10 implies that the processor is running at approximately 10 °C below $T_{J\text{-}MAX}$ which would be 90 °C. PECI temperature readings are not reliable at temperatures above $T_{J\text{-}MAX}$ since the processor is outside its operating range; therefore, the PECI temperature readings are never positive.

The changes in PECI data counts are approximately linear in relation to changes in temperature in degrees Celsius. A change of 1 in the PECI count represents roughly a temperature change of 1 °C. This linearity is approximate and cannot be guaranteed over the entire range of PECI temperatures, especially as the offset from the maximum PECI temperature (zero) increases.

30.11.3 Temperature Filtering

The processor Digital Thermal Sensor (DTS) provides an improved capability to monitor device hot spots, which inherently leads to more varying temperature readings over short time intervals. Coupled with the fact that typical fan speed controllers may only read temperatures at 4 Hz, the thermal readings need to reflect the thermal trends and not instantaneous readings. Therefore, PECI supports a configurable low-pass temperature filtering function that is expressed by the equation:

$$T_N = (1-\alpha) * T_{N-1} + \alpha * T_{SAMPLE}$$

where T_N and T_{N-1} are the current and previous averaged PECI temperature values respectively, T_{SAMPLE} is the current PECI temperature sample value and the variable "α" = $1/2^X$, where *X* is the Thermal Averaging Constant that is programmable as described in Section 30.9.8, "Package Thermal Status Read / Clear (Index = 20)."

30.11.4 Reserved Values

Several values well out of the operational range are reserved to signal temperature sensor errors. These are shown in Table 30-40, "Error Codes."

Table 30-40. Error Codes

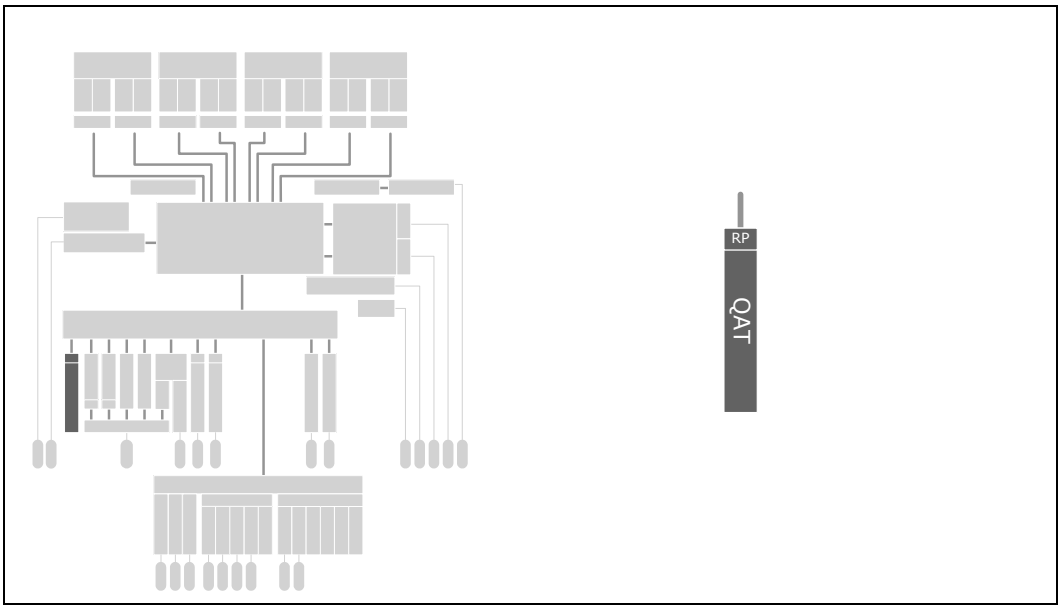
Error Codes	Description
0x8000	General sensor error
0x8001	Reserved
0x8002	Sensor is operational, but has detected a temperature below its operational range.
0x8003	Sensor is operational, but has detected a temperature above its operational range.
0x8004 – 0x81FF	Reserved

§ §

31 Intel® QuickAssist Technology (Intel® QAT)

The integrated Intel® QuickAssist Technology (Intel® QAT) provides acceleration functions that can be used by the IA cores. The acceleration services can be accessed by a standard PCIe* driver. To enhance communication between the IA and the Intel® QAT, the Intel® QAT implements rings via the Ring controller to route messages between them.

Figure 31-1. What is Covered in This Chapter



Applications running on the IA core(s) can make use of the acceleration by calling the Intel® QuickAssist Technology Application Programming Interfaces (APIs). The APIs communicate with the Intel® QuickAssist Technology hardware via PCI configuration space access and assisted rings stored in system memory.

Refer to the *Intel® QuickAssist Technology API Programmer's Guide, incorporated herein by reference, and available at:*

- https://01.org/packet-processing/intel%C2%AE-quickassist-technology-drivers-and-patches.

31.1 Signal Descriptions

There are no signal pins or signal names associated with this chapter.

31.2 Features

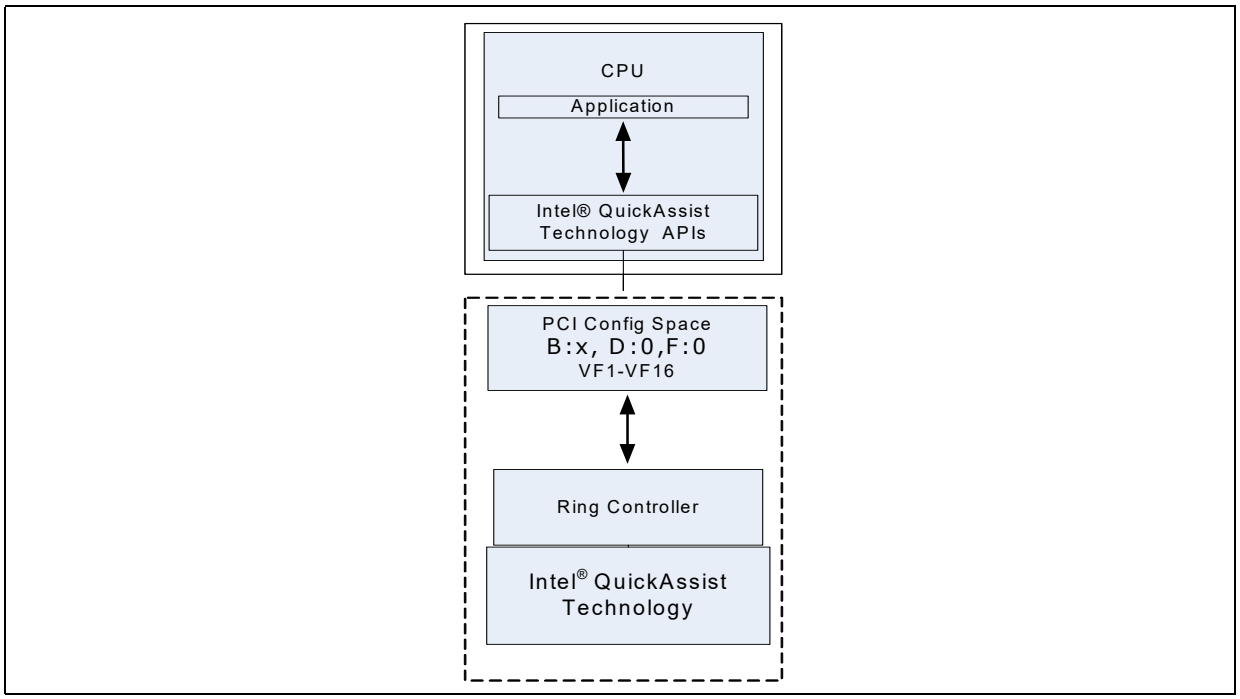
This product contains Intel® QuickAssist Technology hardware version 1.7.

- Symmetric cryptographic functions
  - Cipher operation
  - Hash/authenticate operation
  - Cipher-hash combined operation
  - Key derivation operation
- Public key functions
  - RSA operation
  - Diffie-Helman operation
  - Digital signature standard operation
  - Key derivation operation
  - Elliptic curve cryptography: ECDSA and ECDH
- Compression/Decompression
  - Deflate

31.3 Usage Model

Intel® QAT is used by applications running on the IA cores to accelerate and offload processing. Intel® QAT appears to software as a PCIe endpoint and is used as a look-aside co-processor.

Figure 31-2. Intel® QAT Usage Block Diagram



The following steps list a high-level overview of the usage.

1. The application requires Intel® QAT service (e.g., decrypting a packet using AES). It requests service by calling an API with appropriate parameters.
2. The Intel® QAT device driver formats a request message and places it onto ring-in-host memory, then notifies the Intel® QAT.
3. The Intel® QAT reads the request message from the Ring controller.
4. The Intel® QAT carries out the request.
5. When the process is done, write response message to the ring-in-host memory.
6. Interrupt the CPU via a Message Signaled Interrupt (MSI), or a user application can poll for completions.

Note: Refer to the *Intel® QuickAssist Technology API Programmer's Guide* for information on the Intel® QuickAssist Technology APIs available at:

- https://01.org/packet-processing/intel%C2%AE-quickassist-technology-drivers-and-patches.

31.3.1 Ring Controller

The Ring controller provides communication between the IA cores and the Intel® QuickAssist Integrated Accelerator.

- Implements 256 rings for communications between the CPU and the Intel® QAT.
- Organized in 16 bundles of 16 rings each.
- Each bundle supports one interrupt to the endpoint (EP).

31.3.2 Single-Root I/O Virtualization (SR-IOV)

A virtualized platform enables system hardware resources to be shared among multiple guest operating systems (OS). Each guest OS on the virtual platform operates under the assumption that it has complete control of all platform hardware resources. An I/O device that supports I/O virtualization provides the ability for it to be shared simultaneously among multiple guest operating systems.

The Intel® QAT EP implements support for single-root I/O virtualization for function 0 and enables a usage model that allows up to 16 guest operating systems simultaneous access to its resources.

SR-IOV is a PCI-SIG* I/O Virtualization (IOV) specification which in conjunction with system virtualization technologies like VT-d and VT-x, allows multiple guest operating systems running simultaneously within a single platform to natively share PCIe devices.

The SR-IOV capability structure is discovered and configured using the well-defined standard PCI enumeration process.

- Implements an SR-IOV extended capability record.
- One Physical Function (PF): Supports INTx, MSI, and MSI-X.
- 16 Virtual Functions (VF): Supports ARI. Implements MSI only. Does not support INTx messages or MSI-X.
- EP does not support the following optional IOV features:
  - Multi-root IOV
  - VF migration
- Ring access:
  - PF can access all 16 ring bundles.
  - Each VF can access one bundle.

Note: ARI must be enabled to use any Virtual Functions (VF).

31.3.2.1 I/O Virtualization Models

An I/O device such as the Intel® QAT can be shared amongst multiple guest operating systems in a virtual platform using several different hardware, software, and a combination of software and hardware techniques.

31.3.2.2 Sharing via Virtual Machine Monitor (VMM)

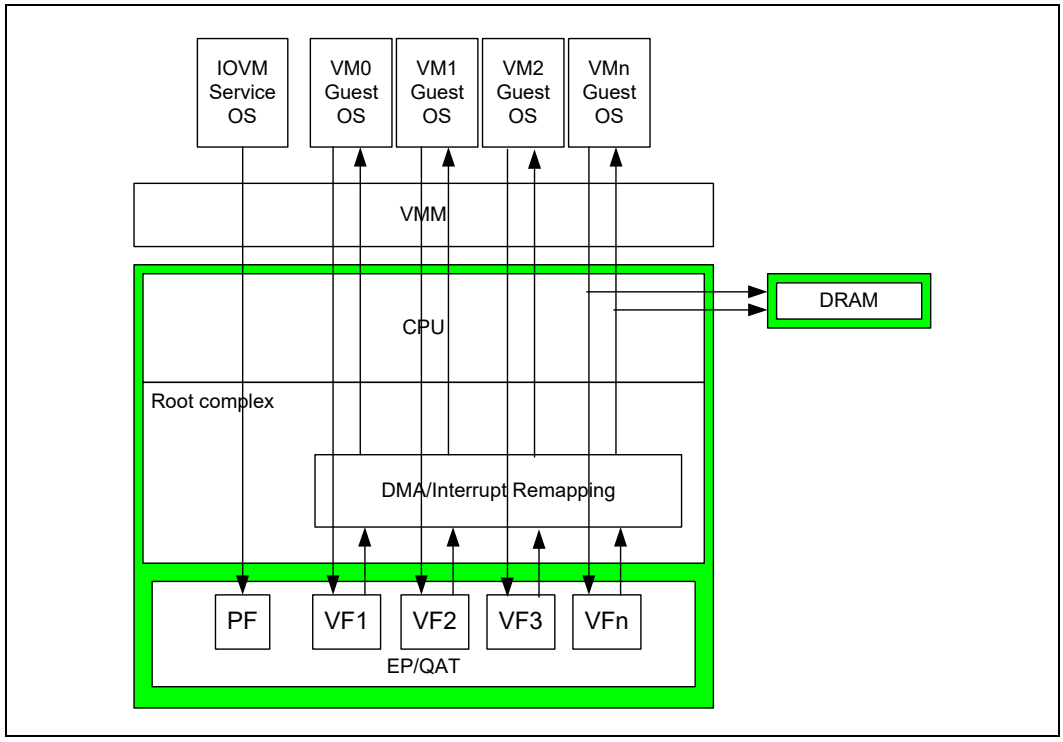
The I/O devices in this mode are assigned to the VMM/hypervisor. The VMM will expose a synthetic device to the Virtual Machines (VMs) and could provide a paravirtualized driver that will run in VM. All accesses from the VM using the paravirtualized driver are intercepted by the VMM. The VMM will then use the device driver to access the I/O device on behalf of the VM. In this form of I/O sharing, there is little or no hardware support in the root complex or I/O device for virtualization.

31.3.2.3 Direct Assignment of EP with SR-IOV

The VMM can take advantage of the Intel® QAT EP with SR-IOV support in the hardware and directly assign up to 16 VMs to the 16 VFs as shown in Figure 31-3, "Direct I/O Assignment Model with IOV Support." Each VM can independently access the services of the Intel® QAT.

Configuration and initialization of the Intel® QAT will be through the I/O Virtual Machine (IOVM). All error messages and interrupts not related to the ring status will be directed towards the IOVM (i.e., serviced by the IOVM).

Figure 31-3. Direct I/O Assignment Model with IOV Support



31.3.3 Ring Bundle Mapping

Each VF will be statically allocated one bundle (16 rings). A guest OS that is directly assigned to a VF will have access to only the rings associated with the bundle the VF is assigned to as shown in Table 31-1, "Ring Assignment to Intel® QAT Virtual Functions."

All errors and interrupts generated by the rings will use the Ring ID (RID) associated with that bundle.

Table 31-1. Ring Assignment to Intel® QAT Virtual Functions

Ring	Virtual Function Assignment	Function Number	Ring CSR PCI Offset Begin
Bundle 0	VF1	8	00000h
Bundle 1	VF2	9	01000h
Bundle 2	VF3	10	02000h
Bundle 3	VF4	11	03000h
Bundle 4	VF5	12	04000h
Bundle 5	VF6	13	05000h
Bundle 6	VF7	14	06000h
Bundle 7	VF8	15	07000h
Bundle 8	VF9	16	08000h
Bundle 9	VF10	17	09000h
Bundle 10	VF11	18	0A000h
Bundle 11	VF12	19	0B000h
Bundle 12	VF13	20	0C000h
Bundle 13	VF14	21	0D000h
Bundle 14	VF15	22	0E000h
Bundle 15	VF16	23	0F000h

Notes:
1. The PF can view and access all bundles.
2. Interrupts and memory accesses generated by each of the bundles via ring commands will use the associated bundle's RID.

31.3.3.1 VF Interrupts

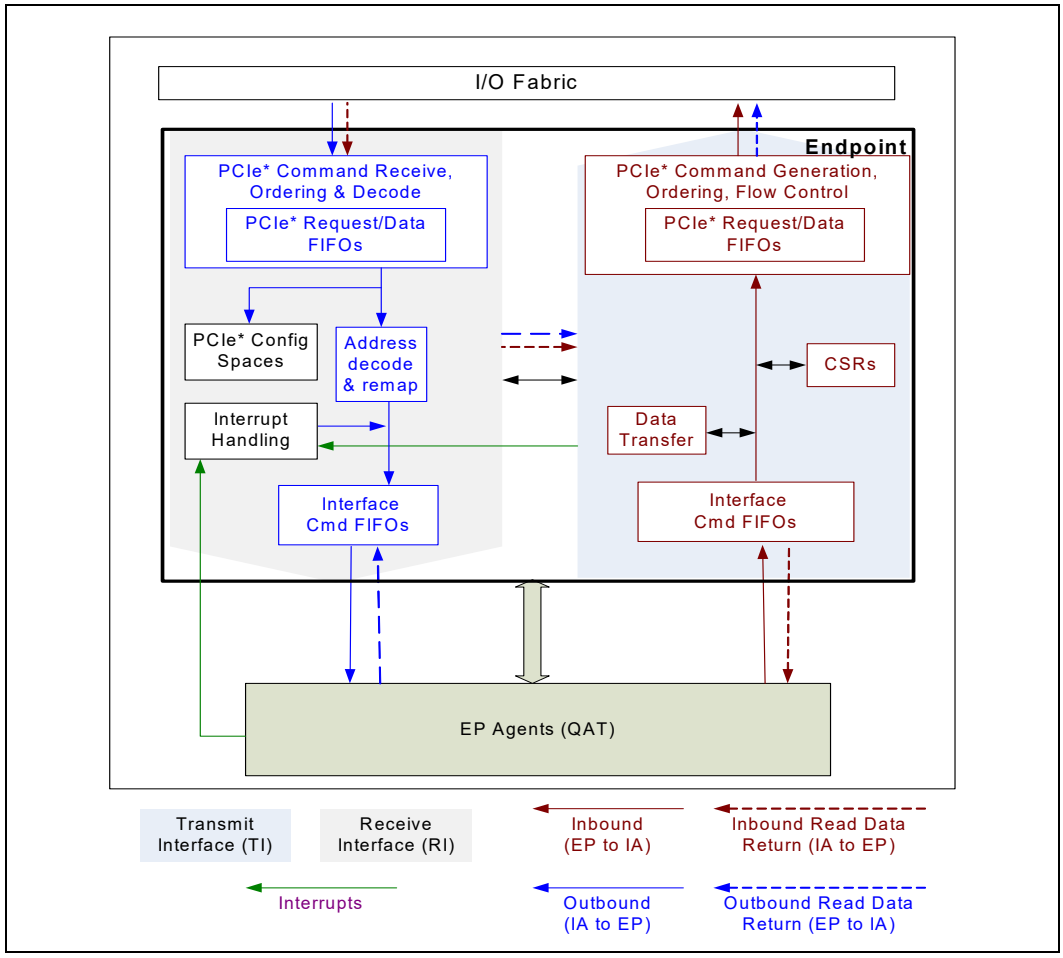
Each VF will support only MSI (one vector). A VF supports functional interrupts generated by the Ring controller. INTx is not applicable for VF per the PCI Express* SR-IOV specification.

31.3.4 PCIe Endpoint (EP) Function

The Intel® QAT will show up as a PCIe device to the software running on the IA cores. The Intel® QAT is an Endpoint Device/Function that is integrated in the SoC and connected to a dedicated Root Port.

Figure 31-4, "EP Functional Description Block Diagram" shows the functional description block diagram of the PCIe EP interface.

Figure 31-4. EP Functional Description Block Diagram



31.3.4.1 Transmit Interface (TI)

TI is responsible for converting EP agent commands toward system memory and Outbound (OB) completions into the PCIe transactions. The TI connects to the inbound port of the PCIe root complex.

31.3.4.2 Receive Interface (RI)

The Receive Interface (RI) is responsible for converting OB PCIe commands from the IA cores into the EP agents' commands. Downstream read completions for PCIe commands initiated by the TI are also received by the RI.

31.3.4.3 PCIe EP Functions

RI connects to the OB port of the PCIe root complex. Table 31-2, "PCIe Commands Supported by RI" lists the RI supported PCIe transactions. The EP only supports requests that are aligned on Dword address boundaries.

Table 31-2. PCIe Commands Supported by RI

PCIe* Command	Description	Source	EP Attributes	Comments
MRd32/MRd64	Memory Read	IA reading EP MMIO region, PCIe* extended configuration space	4B	
MWr32/MWr64	Memory Write	IA writing to EP MMIO region, PCIe extended configuration space	4-8B	Note 2
CfgRd0	Type 0 Configuration Read	IA reading EP Configuration register	1-4B	
CfgWr0	Type 0 Configuration Write	Non-Posted IA writing to EP Configuration register	1-4B	Note 2
CmplD	Completion with Data	Read completion with data for a read command initiated by TI	4B-256B	

Notes:
1. Although the EP is capable of handling 8B requests, Intel® QAT does not support any target that supports 8B requests. Therefore, software should not attempt any 8B requests.
2. This is a non-posted transaction. RI will generate a completion without data after the configuration write is completed. The completion will be routed via a RI-TI private bus to the TI. The TI will initiate the PCIe completion packet.
3. The RI will generate an Unsupported Request (UR) completion if it receives any PCIe commands from IA that are not listed in this table.

31.3.4.4 EP Function Mapping

The EP RI implements a single PCIe device with SR-IOV, and Table 31-3, "PCIe EP Function Mapping" shows the mapping of the EP functionality. When SR-IOV is enabled, the RI exposes additional virtual functions.

Table 31-3. PCIe EP Function Mapping

EP	Functional Blocks	PCIe* Function Number	BARs	Interrupt Capability	PCIe Extended/PCI Capabilities
Intel® QuickAssist Technology	Intel® QAT	0	PMISCBAR, PETRINGCSRBAR	MSI, MSI-X with 16 vectors, INTA	MSI, MSI-X, PM, PCIe, AER, SR-IOV, ARI
VF[1:16]		8-23 Note 1	SRIOVBAR0, SRIOVBAR1	MSI only	MSI, PCIe, AER, ARI, ACS

Notes:
1. ARI must be enabled to view function numbers > 7.
2. When ARI is disabled, the bus and device number is captured by the RI on every type 0 configuration write. When ARI is enabled, the device number is implicitly assumed to be 0 and only the bus number is captured by RI on every type 0 configuration write.
3. PPETRINGCSRBAR is used for access to registers that configure and access Ring. PMISCBAR is used for accessing EP and the MSI-X table.

31.3.4.5 EP Mapping of BARs to MMIO

Table 31-4, "EP Mapping of BARs to MMIOs" shows the mapping of the EP MMIO regions to the BARs. See each PCIe function BAR definition for more details.

Table 31-4. EP Mapping of BARs to MMIOs

Function #	BAR Name (Size)	Region Size	Functionality	Comments
0	PMISCBAR (256 KB)	248 KB	EP, Intel® QAT	This region is mapped to the EP and Intel® QAT CSRs.
0		4 KB	EP MMIO CSRs	The EP CSRs are located in the EP.
0		4 KB	MSI-X Tables	The MSI-X tables are located in the EP.
0	PETRINGCSRBAR	256 KB	16 Bundles of Ring CSRs	128 KB for all 16 bundles of CSRs and Intel® QAT CSRs. ***Note:*** This space is allocated for 32 bundles. Only the lower 16 bundles are used and the upper 16 are memory holes in this region.
8-23 (VF[1-16])	SRIOVBAR0	MIN (4 KB, System Page Size) (Note_2)	1 ETR Bundle per VF[x] (RAM)	Each bundle requires 512B, but are mapped in a 4 KB window by default or the system page size.
	SRIOVBAR1	MIN (4 KB, System Page Size) (Note_3)	VF Messaging Registers	There is only one register per VF but is mapped in a 4 KB window by default or the system page size.

Notes:
1. Accesses to the MMIO region that are not implemented within the regions defined in this table will return 0s. Accesses to MMIO regions that are not claimed by any of the BARs will return UR.
2. The SRIOVBAR0 size is dependent on the value programmed in the system.
3. The SRIOVBAR1 size is dependent on the value programmed in the system page size.

31.3.4.6 Alternative Routing-ID Interpretation (ARI)

Receive Interface (RI) provides support for the Alternative Routing-ID Interpretation (ARI). When enabled, ARI allows the PCIe device to implement more than 8 functions.

An ARI device interprets the Routing, Requester, and Completer IDs as having an 8-bit function number instead of the traditional 3-bit function number. An ARI device has its associated device number implied to be 0 rather than specified by an ID field.

Note: ARI must be enabled to use all of the VF Intel® QAT supports.

Table 31-5. Bus, Device and Function Interpretation

ARI Disabled	**Bus Number**	**Device Number**	**Function Number**
	[7:0]	[4:0]	[2:0]
ARI Enabled	**Bus Number**	**Function Number**	
	[7:0]	[7:0]	

RI supports ARI for function 0 when SR-IOV is enabled.

31.3.5 Interrupts

RI is responsible for collating interrupts and errors from the endpoint and taking the appropriate actions based on the PCIe configurations status.

Interrupts from EP can be configured in the RI to be routed to the IA cores. The interrupts can be sent upstream as either an MSI, MSI-X, or by using INTx virtual wire interrupt signaling mechanism (which are messages on PCIe).

31.3.5.1 INTx

PCIe supports devices that need to use the PCI compatible legacy interrupt signaling: INT[A, B, C, D]. Instead of dedicated pins for this functionality, PCIe supports inband virtual wires.

The EP supports the generation of INTx virtual wire interrupt signaling based on internal generated interrupts. The INTx notification is accomplished using PCIe messages.

RI is responsible for collating interrupt sources from the EP agents and generating the transaction that is translated to a PCIe interrupt message to the IA. Upon detecting an interrupt from an internal source, the RI first determines whether to generate an MSI, MSI-X, or INTx message.

31.3.5.2 Message Signaled Interrupt (MSI)

Message Signaled Interrupts (MSI) are an optional feature that enables a device function to request service by writing a system-specified data value to a system-specified address (using a PCI Dword memory write transaction). System software initializes the message address and message data during device configuration. Each function in the EP supports the MSI capability. All the interrupts per function share one vector.

31.3.5.3 MSI-X

MSI-X defines a separate optional extension to the basic MSI functionality. Compared to MSI, MSI-X supports a larger number of vectors per function, the ability for the OS to program independent address and data values for each vector. The address and data values for each vector are specified by a table that resides in the memory space. MSI-X is supported only for the physical function.

Once an MSI has been generated using MSI-X, its characteristics are similar to an MSI that was generated using an MSI capability record. However, MSI-X supports per-vector masking that is optional for MSI. MSI-X also supports a Function Mask bit, which when set, masks all of the vectors associated with a function. Per-vector masking is managed through a Mask and Pending bit pair per the MSI vector or MSI-X table entry. An MSI-X vector is masked when its associated MSI-X Table Entry Mask bit or the MSI-X Function Mask bit is set. While a vector is masked, the function is prohibited from sending the associated message, and the function must set the associated Pending bit whenever the function would otherwise send the message. When software unmasks a vector whose associated Pending bit is set, the function must schedule sending the associated message, and clear the Pending bit as soon as the message has been sent.

When MSI-X is enabled, EP generates an interrupt using a PCIe posted memory write transaction. The address and data of that transaction are determined by the system and programmed in the PCI MSI-X table entry.

31.3.6 EP Errors

There are two classes of errors that the EP will encounter:

- Errors that occur due to PCIe transactions
  - PCIe error management defines the scope of these kinds of errors including how they are reported and handled.
- Other errors not directly related to PCIe transactions
  - This class of errors is reported via interrupts and does not fall under the scope of PCIe error management mechanisms.

31.3.6.1 PCIe Error Management

PCIe error management focuses on errors associated with the PCIe interface and the transactions between the transaction layers of the transmitting and the receiving PCIe ports.

31.3.6.2 PCIe Error Reporting Mechanisms

The PCIe specification provides three mechanisms for reporting errors that occur while servicing PCIe transactions.

1. PCI
   a. This mechanism provides backward compatibility with legacy PCI compatible software and is required per the PCIe specification. Legacy compatible PCI software will use this mechanism and control this feature via the PCI configuration Command register. When this mechanism is enabled, EP will also log error status information in the PCI Configuration Status register.
   b. EP will support the legacy PCI compatible error mechanism.
2. PCIe
   a. This is the baseline PCIe mechanism for software that understands PCIe devices. The mechanism can be enabled via the PCIe Device Control register. Error status is logged in the PCIe Device Status register.
   b. Supported error classifications: unsupported request type, fatal error, non-fatal error, and correctable error
3. PCIe Advanced Error Reporting (AER)
   a. The optional advanced error reporting registers can be implemented by PCIe devices. This mechanism is defined using a PCIe extended capability structure.
   b. All EP Functions will support AER.

31.3.6.3 PCIe Error Handling and Signaling

The EP will classify errors in the following three PCIe specification-defined buckets:

1. Correctable errors: These errors are handled by the Hardware (HW).
2. Uncorrectable errors (non-fatal): These errors are handled by device-specific software.
3. Uncorrectable errors (fatal): These errors are handled by system software.

EP will use three different mechanisms to signal errors that occur when processing PCIe commands.

1. Completion status
2. Error forwarding or data poisoning
3. Error messages

31.3.6.4 PCIe Error Sources

Table 31-6, "PCIe Error Sources" defines the standard PCIe defined error sources. The following sections describe each of the PCIe error types, and describe how the EP handles the PCIe errors.

Table 31-6. PCIe Error Sources

	Type of Error	Reported Using	Comment
TL	ECRC Check	Uncorrectable Non-Fatal Message	
	Malformed TLP	Uncorrectable Fatal Message	RI will perform checks on the PCIe* transactions received from IA.
	Completion Timeout	Uncorrectable Non-Fatal Message	RI will generate these split transaction errors. Completer abort is supported in RI.
	Unsupported Requests	Completion Status	
	Completer Abort (optional)		
	Unexpected Completion	Uncorrectable Non-Fatal Message	
	Data Corruption/Poisoning	PCIe Header	TI will set the EP bit in the header based on the internal bus data error. Writes that terminate in RI get dropped and the status logged. Writes that target an EP function will be sent with a data error and logged in RI.

31.3.6.4.1 Role-Based Error Reporting

In earlier versions of the PCI Express Specification, errors were reported by the agent that detected the error. The *PCI Express Base Specification Revision 3.0* implements a role-based error reporting where the response to the errors is based on the component's role in the transaction. In general, errors detected in non-posted transactions are handled by the initial requester and the completer may optionally send an advisory message to the root complex as an ERR_COR message. Errors in posted transactions are still logged and reported by the target device.

Note: If the severity for the error is programmed to fatal in the PCI Express Uncorrectable Error Severity register, then it is not an advisory non-fatal error and is signaled with an ERR_FATAL message. A fatal severity overrides all other Advisory Error Control bits.

The following errors are considered advisory non-fatal error cases and have different handling depending on the transaction type.

- ECRC check failed
- Unsupported Request (UR)
- Completer Abort (CA)
- Unexpected completion
- Poisoned TLP received
- Completion timeout

31.3.6.4.2 Malformed Packets

The following checks are made to detect malformed TLPs.

- Data payload exceeds the length specified by the value in the Max_Payload_Size field of the Device Control register.

When a malformed packet is detected, the packet is dropped and the error is logged. No flow control information is updated for malformed packets.

31.3.6.4.3 ECRC Check Failed

EP does not calculate for ECRC but will report the ecrc_error signal that it receives. EP reports by sending an ERR_NONFATAL message to the root complex.

31.3.6.4.4 Unsupported Request

Unsupported requests are detected by the address decode and translation logic. A TLP is treated as unsupported in the following cases:

- The TLP fails to match any of the active memory or I/O windows.
- A configuration TLP that targets an invalid function number.
- A receipt of a Vendor_Defined Type 0 message.
- A message request with an undefined or unsupported message code.
- A poisoned I/O or configuration request.
- A receipt of a memory or I/O transaction while in a non-D0 power state.
- A receipt of a Memory Read Lock (MRdLk).

No checks are made for the address plus the length crossing a window boundary.

For posted transactions, this is **not** an advisory error, and an ERR_NONFATAL is sent to the root complex.

For non-posted transactions, this is considered an advisory error. An ERR_COR is sent to the root complex and a completion with UR status is returned to the requester.

Note: If the severity setting in the PCI Express Uncorrectable Error Severity register is fatal, this is not an advisory error, and an ERR_FATAL will be sent to the root complex.

31.3.6.4.5 Completer Abort (CA)

Requests that target abort or master abort on the internal bus are treated as a completer abort.

These requests must have passed the malformed TLP checks as well as the unsupported request checks before they are issued on the internal bus.

For posted transactions, an ERR_NONFATAL is sent to the root complex.

For non-posted transactions, an ERR_COR is sent to the root complex and a completion with CA status is returned to the requester.

Note: If the severity setting in the PCI Express Uncorrectable Error Severity register is fatal this is not an advisory error and an ERR_FATAL will be sent to the root complex.

31.3.6.4.6 Unexpected Completions

Unexpected completions occur when a completion transaction ID does not match a outstanding request. If the Requester ID of the completion matches a valid function, the error will get logged in that function. Otherwise, the error will get logged against all functions.

This is an advisory non-fatal error and an ERR_COR will be sent to the root complex.

Note: If the severity setting in the PCI Express Uncorrectable Error Severity register is fatal, this is not an advisory error and an ERR_FATAL will be sent to the root complex.

31.3.6.4.7 Poisoned TLP Received

Poisoned TLPs can be received for both inbound posted (write/message) and inbound completions. The two TLP types can be handled differently.

Poisoned completions are passed through to the target agent with the error bit set. The error is logged in the corresponding function. This is an advisory error and an ERR_COR will be issued.

Poisoned memory writes that are MMIO-mapped are passed through to the intended target. Depending on the register target, the MMIO-mapped register may get updated with the poisoned data, whereas in some cases the register will not be updated as the byte-enable signals will be disabled. The error is logged in the corresponding function. This is a non-fatal error and an ERR_NONFATAL will be issued.

Writes to configuration registers will not complete to the target. Since configuration writes are non-posted writes, a completion with UR is returned to the host.

Note: If the severity setting in the PCI Express Uncorrectable Error Severity register is fatal, this is not a non-fatal error, and an ERR_FATAL will be sent to the root complex. Auto-recovery is discouraged as the ERR_FATAL message will likely bring down the hierarchy.

31.3.6.4.8 Completion Timeout

When an out-bound, non-posted request results in a completion timeout, the advanced error registers are updated in the corresponding function. This will be treated as an advisory error, and an ERR_COR will be sent to the root complex.

Note: If the severity setting in the PCI Express Uncorrectable Error Severity register is fatal, this is not an advisory error, and an ERR_FATAL will be sent to the root complex. Auto-recovery is discouraged as the ERR_FATAL message will likely bring down the hierarchy.

31.3.6.4.9 Non-Function Specific Errors

The PCI Express Specification lists the following errors as non-function specific:

- Transaction layer errors
  - — ECRC fail
  - — UR, when caused by no function claiming a TLP
  - — Receiver overflow
  - — Flow control protocol error
  - — Malformed TLP
  - — Unexpected completion, when caused by a no function claiming a completion

On the detection of one of these errors, a multi-function device should generate at most one error reporting message of a given severity, where the message must report the Requester ID of a function of the device that is enabled to report that specific type of error. If no function is enabled to send a reporting message, the device does not send a reporting message. If all reporting-enabled functions have the same severity level set for the error, only one error message is sent. If all reporting-enabled functions do not have the same severity level set for the error, one error message for each severity level is sent. Software is responsible for scanning all functions in a multi-function device when it detects one of those errors.

31.3.7 Device-Specific Error Management

EP will report device-specific errors using interrupts—INTx or MSI based on the PCIe configuration settings.

Table 31-7. Device-Specific Errors

Function	Description
Function 0	EP Implements error source and mask registers. When detecting an assertion on an unmasked error, RI will generate either an INTA or MSI.

31.3.7.1 Memory Error Poisoning

The TI also tracks data errors for all transactions that flow through the TI, including accesses to PCIe and CSRs.

31.3.7.1.1 Memory Write Poisoning

For a PCIe memory write (including memory writes triggered by the Ring Controller), the TI pulls data from the EP master. If the internal bus indicates an error, then the TI logs the error, but it does not abort the write transaction. Instead, the TI passes along the data error notification along with the data. On PCIe, the TI will set the EP bit in the header of the packet.

31.3.8 Error Handling with SR-IOV

EP ring-related errors that are associated with a given VF are handled by the given VF itself. For example, the VF would report and log the errors. Each VF supports the legacy PCI (PCI Command and Status registers) and PCIe reporting mechanism (ERR_COR, ERR_NONFATAL, ERR_FATAL messages). The VF also supports PCIe extended capability - AER. Errors that are not directly related to the ring associated with a given VF are handled by the PF. For example, errors such as EP parity errors, etc.

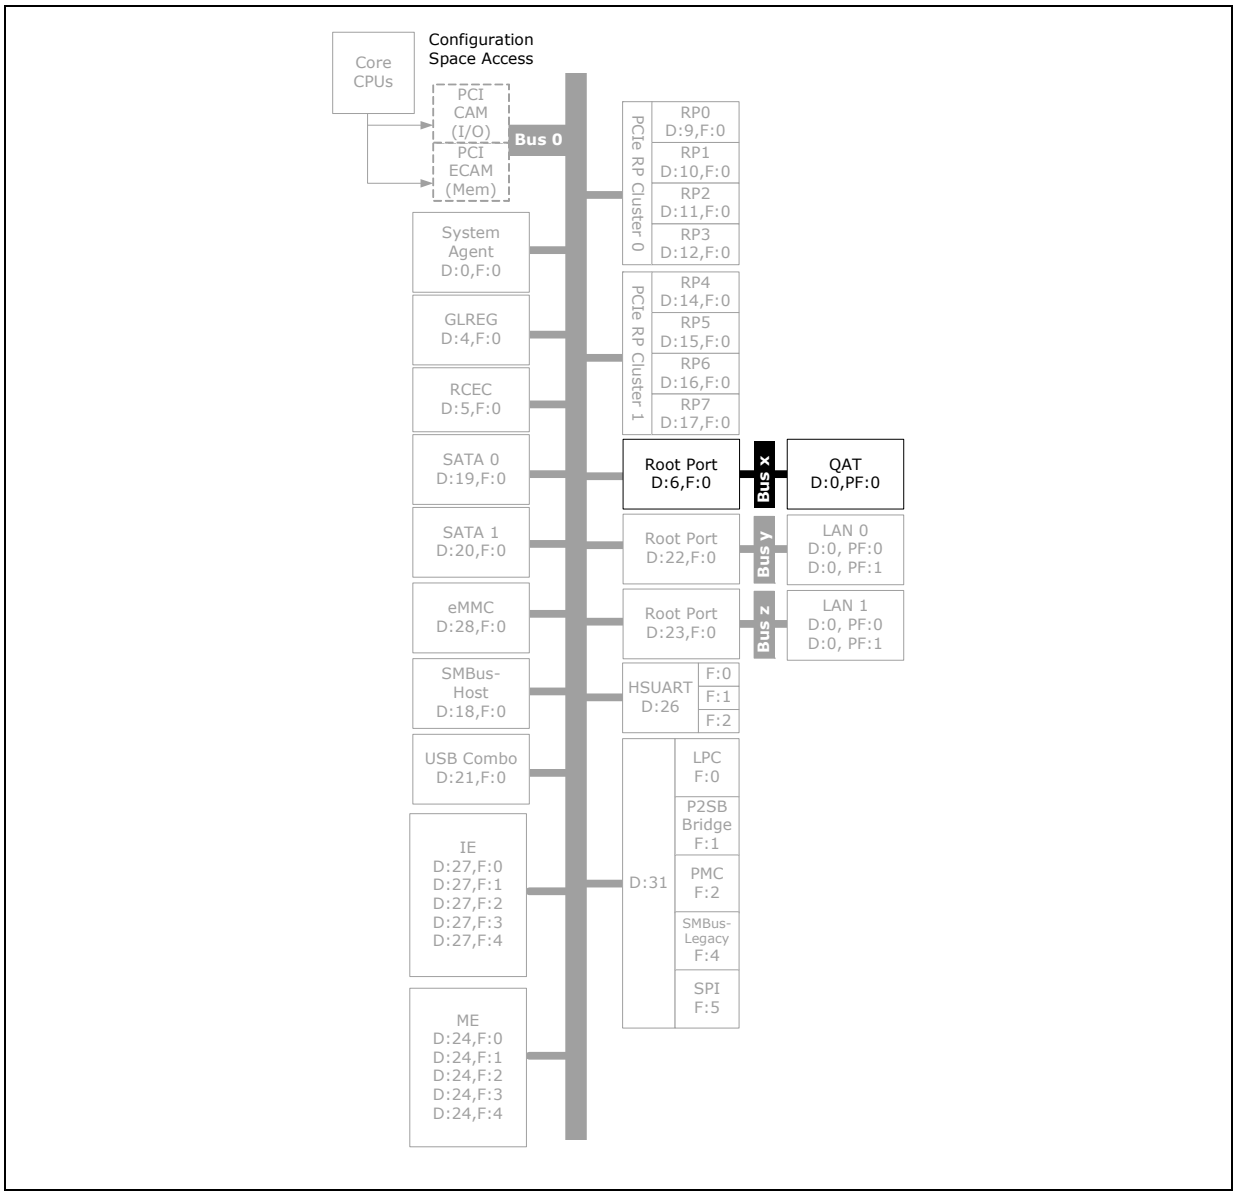
31.4 PCI Configuration Space Map

Figure 31-5, "Register Map" shows the associated PCI configuration space from a system software viewpoint. Refer to the *Intel® QuickAssist Technology API Programmer's Guide* for information on the Intel® QuickAssist Technology APIs to program the Intel® QAT available at:

- https://01.org/packet-processing/intel%C2%AE-quickassist-technology-drivers-and-patches.

The APIs communicate with the Intel® QuickAssist Technology hardware via PCI configuration space access and assisted rings stored in system memory.

Figure 31-5. Register Map



§ §

32 SoC Voltage Rails

This chapter lists and describes all of the power supplies that directly connect to the SoC, as well as signals that directly connect to the SoC and are related to the power supplies.

This chapter does NOT discuss the complete set of platform (the printed wiring board containing the SoC as well as all other associated components) power supplies, those that do not connect to the SoC. A complete platform requires additional voltages, beyond what is directly connected to the SoC.

32.1 SoC Voltage (And Related Signals) Descriptions

The signal descriptions are shown in Table 32-1, "Signal Descriptions." The "Direction" column of Table 32-1, "Signal Descriptions" is interpreted as follows:

- I = Input signal.
- O = Output signal.

The "Voltage Regulator Group" column of Table 32-1, "Signal Descriptions" is used as an aid in categorizing the signal type; implying a particular voltage supply level, class of voltage supply, if the signal is a reference voltage, if the signal is used for Voltage Regulator (VR) sensing (SENSE), Observation (OBS), or a VR return (VSS).

Two signals that are of the same "Voltage Regulator Group" should not necessarily be directly interconnected. While many signals are supplied by the same VR, they may have differing specific filtering and/or isolation requirements. For example, a signal may require a ferrite bead, an inductor, or some other R/C filtering circuit. The Platform Design Guide should be referenced when determining how to interconnect signals for a successful platform design.

For pin numbers and other information for these signals and voltage sources, see Table 39-5, "Package Rotation (ROT) Pins" and Table 39-6, "Directory of Signal and Voltage Pins - Sorted by Pin Number."

Table 32-1. Signal Descriptions (Sheet 1 of 2)

Signal Name	Direction	Voltage Regulator Group	Description
OBS_VCCCPUVIDSI0GT_MOD1	O	OBS	Used to observe the die voltage being delivered to Atom CPU core #0.
OBS_VCCCPUVIDSI0GT_MOD4	O	OBS	Used to observe the die voltage being delivered to Atom CPU core #1.
OBS_VCCBIUVIDSI0GT_MOD1	O	OBS	Used to observe the die voltage being delivered to the BIU.
OBS_VCCRAMCPUSI1GT_ MOD0	O	OBS	Used to observe the die voltage being delivered to the Atom CPU core L2 caches.
SENSE_VCCCPUVIDSI0	O	SENSE	Voltage sense signal that provides feedback to the voltage regulator that supplies the voltage to the Atom CPU cores via the VCCCPU_SVID_S0 set of pins.
SENSE_VSSCPUVIDSI0	O	SENSE	Voltage sense return signal for the voltage sense signal SENSE_VCCCPUVIDSI0 that provides feedback to the voltage regulator that supplies the voltage to the Atom CPU cores via the VCCCPU_SVID_S0 set of pins.
SENSE_VSSRAMCPU_S0	O	SENSE	Voltage sense return signal for the voltage sense signal SENSE_VCCRAMCPU_S0 that provides feedback to the voltage regulator that supplies the voltage to the Atom CPU core L2 caches via the VCCRAM_S0 set of pins.
SENSE_VCCRAMCPU_S0	O	SENSE	Voltage sense signal that provides feedback to the voltage regulator that supplies the voltage to the Atom CPU core L2 caches via the VCCRAM_S0 set of pins.
VCCFHVSIO_1P05	I	V1P05	Power supply for an on-die voltage regulator.
VCCACKDDR_1P05	I	V1P05	Power supply pins for the DDR digital clock.
VCCADDR_1P05	I	V1P05	Power supply pins for the DDR I/O.
VCCAON_HSIO_1P05	I	V1P05	Power supply pins that feeds the logic which controls the LDO/PG within the HSIO PCIe3, SATA 3.1, and USB3 PHYs.
VCCCL_HSIO_1P05	I	V1P05	Power supply pins that power the PLLs within the HSIO PCIe3, SATA 3.1, and USB3 PHYs.
VCCDIGICKSI0_1P05	I	V1P05	Power supply pins for the SoC internal integrated digital clock circuit, requires on-board filtering.
VCCDIGXXXSI0_1P05	I	V1P05	Power supply pins for multiple digital IP block.
VCCFHVSI0_GROUP0_1P05	I	V1P05	Power supply for an on-die voltage regulator.
VCCFHVSI0_GROUP1_1P05	I	V1P05	Power supply for an on-die voltage regulator.
VCCFHVSI0_GROUP2_1P05	I	V1P05	Power supply for an on-die voltage regulator.
VCCKRA_LV	I	V1P05	Power supply pins feeding 10GE IP block.
VCCKRLCPLL	I	V1P05	Power supply pins for the 10GE PLL, requires on-board filtering.
VCCPLLEBB_HSIO_1P05	I	V1P05	Power supply pin that powers T-Line drivers within the HSIO PHYs.
VCCUSB_1P05	I	V1P05	Power supply pins that power the USB2 PHY.
VCCFHVIFPSI0_1P8	I	V1P80	Power supply for an on-die voltage regulator.
VCCPADXXXSI0_1P8	I	V1P80	Power supply pins that power the 1.8V GPIOs.

Table 32-1. Signal Descriptions (Sheet 2 of 2)

Signal Name	Direction	Voltage Regulator Group	Description
VCCUSBSUS_1P8	I	V1P80	Power supply pins that power the 1.8V suspend supply for the USB2 PHY.
VCCFHVIFPSI0_3P3	I	V3P30	Power supply for an on-die voltage regulator.
VCCPADXXXSI0_3P3	I	V3P30	Power supply pins that power the 3.3V GPIOs, and RTC.
VCCUSBSUS_3P3	I	V3P30	Power supply pins that power the 3.3V suspend supply for the USB2 PHY.
VCC_LPC_ESPI_3P3_1P8	I	V3P30	Power supply for the LPC 3.3V.
VCCCPU_SVID_S0	I	VCC	Power supply pins that power the Atom cores, actual voltage is dependent on SoC request to the VR.
VCCRAM_S0	I	VCCRAM	Power supply pins that power the Atom L2 caches, actual voltage is dependent on SoC request to the VR.
VCCKR_HV	I	V1P80	Voltage reference used by the LAN IP block, requires on-board filtering.
VCCREF_SFRXXXSI0_N	I	VCCREF	Voltage reference for the North side Atom core LDOs, requires on-board filtering.
VCCREF_SFRXXXSI0_S	I	VCCREF	Voltage reference for the South side Atom core LDOs, requires on-board filtering.
VCCUSB_1P24	I	VCCREF	Voltage reference for the USB2 SFR LDO.
VCCCKDDR_VDDQ	I	VDDQ	Power supply pins that drive the DDR clock signals to the DDR memory devices, actual voltage is dependent on SoC request to the VR.
VCCDDR_VDDQ	I	VDDQ	Power supply pins that drive the DDR data signals to the DDR memory devices, actual voltage is dependent on SoC request to the VR.
VCCDDRSFR_VDDQ	I	VDDQ	Power supply for the SFR LDO feeding the DDR PLL, requires on-board filtering, actual voltage is dependent on SoC request to the VR.
VNN_SVID	I	VNN	Power supply pins that power portions of several IPs and level shifters within the UnCore, actual voltage is dependent on SoC request to the VR
VCCRTC_3P3_G3	I	VRTC	Battery backed power supply for the RTC IP block.
VSS	O	VSS	SoC common power supply return signal. Check the Platform Design Guide to see if any of the VSS pins have unique routing or isolation requirements.

§ §

33 Resets and Voltage Sequencing

This chapter discusses the requirements for resetting the SoC and the power-up/power-down voltage sequencing requirements for the SoC. This chapter discusses only the requirements of the SoC, not the entire platform (Printed Wiring Board (PWB) containing the SoC and all associated components).

Table 33-1. References

Reference	Revision	Date	Document Title
ACPI Specification	5.0 A	November 2013	*Advanced Configuration and Power Interface Specification Version 5.0, Errata A*

33.1 Signal Descriptions

The signal descriptions are shown in Table 33-2, "Signal Names and Descriptions."

For additional signal information, including whether a signal is assigned to shared-function pin or can be used as a Customer GPIO signals see Chapter 39, "Signal Pin Names and Signal MUXing."

The Direction/Type column of Table 33-2, "Signal Names and Descriptions" is interpreted as follows:

- I = Input signal. The SoC has receiver circuit.
- O = Output signal. The SoC has driver circuit.

Table 33-2. Signal Names and Descriptions

Signal Names	Direction	Shared	Description
PMU_PLTRST_N	O	Yes	See Chapter 16, "Power Management Controller (PMC)" for details.
PMU_SLP_S3_N	O	Yes	See Chapter 16, "Power Management Controller (PMC)" for details.
PMU_SLP_S45_N	O	Yes	See Chapter 16, "Power Management Controller (PMC)" for details.
PMU_SUSCLK	O	Yes	See Chapter 16, "Power Management Controller (PMC)" for details.
SUS_STAT_N	O	Yes	See Chapter 16, "Power Management Controller (PMC)" for details.
SUSPWRDNACK	O	Yes	See Chapter 16, "Power Management Controller (PMC)" for details.
COREPWROK	I	No	See Chapter 24, "Real Time Clock (RTC)" for details.
RSMRST_N	I	No	See Chapter 24, "Real Time Clock (RTC)" for details.
RTEST_N	I	No	See Chapter 24, "Real Time Clock (RTC)" for details.
SRTCRST_N	I	No	See Chapter 24, "Real Time Clock (RTC)" for details.

Nine separate power supplies are required to power the SoC. This chapter does not detail how the nine power supplies connect to the SoC, see Chapter 32, "SoC Voltage Rails."

For convenience, Table 33-3, "SoC Required Power Supplies" lists the reference names of the SoC required power supplies, and their nominal voltages:

Table 33-3. SoC Required Power Supplies

PS Name	Nominal Voltage (V)	Comment
VRTC	2.0-3.3	Tied to battery or 3.3V
VCC	0.52-1.24	Dynamic Range (SVID address 00h)
VNN	0.65-1.24	Dynamic Range (SVID address 01h)
VDDQ	1.20	DDR4 (SVID address 02h)
VCCRAM	0.75-1.20	Dynamic Range (SVID address 03h)
VCCREF	1.24	Static (SVID address 015h)
V1P05	1.05	Static (SVID address 015h)
V1P80	1.80	Static (SVID address 015h)
V3P30	3.3	Static (SVID address 015h)

Table 33-4, "SoC Power Supply for each Supported Power State" lists the states of each SoC power supply for each supported power state:

Table 33-4. SoC Power Supply for each Supported Power State

PS Name	G3	S5	S4	S0
VRTC	With Battery: On Without Battery: OFF	ON	ON	ON
VCC	OFF	OFF	OFF	ON
VNN	OFF	ON	ON	ON
VDDQ	OFF	OFF	OFF	ON
VCCRAM	OFF	OFF	OFF	ON
VCCREF	OFF	OFF	OFF	ON
V1P05	OFF	ON	ON	ON
V1P80	OFF	ON	ON	ON
V3P30	OFF	ON	ON	ON

33.2 Architectural Overview

The SoC device configuration and power management complies with the *Advanced Configuration and Power Interface Specification Version 5.0, Errata A*. However, not all the states defined by ACPI are supported.

The supported ACPI Global (G) States are listed below:

- G0
- G1
- G2
- G3

The supported ACPI System (S) States are listed below:

- S0
- S4
- S5

ACPI terms are used in this chapter for the SoC Reset and Voltage Sequencing requirements.

Table 33-5, "Supported ACPI Transitions And Definitions" lists the supported ACPI Power State transitions along with the term used throughout this chapter in describing each event:

Table 33-5. Supported ACPI Transitions And Definitions

ACPI Transition	SoC
From G3 To G0.S0	Cold Boot
From G0.S0 To G3	Shutdown
From G0.S0 To G1.S4	Deep Sleep
From G1.S4 To G0.S0	Deep Sleep Wake
From G0.S0 To G2.S5	Soft Off
From G2.S5 To G0.S0	Soft Off Wake
From Gx.Sx To G3	Power Failure

The sequencing/reset requirements for each ACPI Transition listed in Table 33-5 is detailed in the sections below.

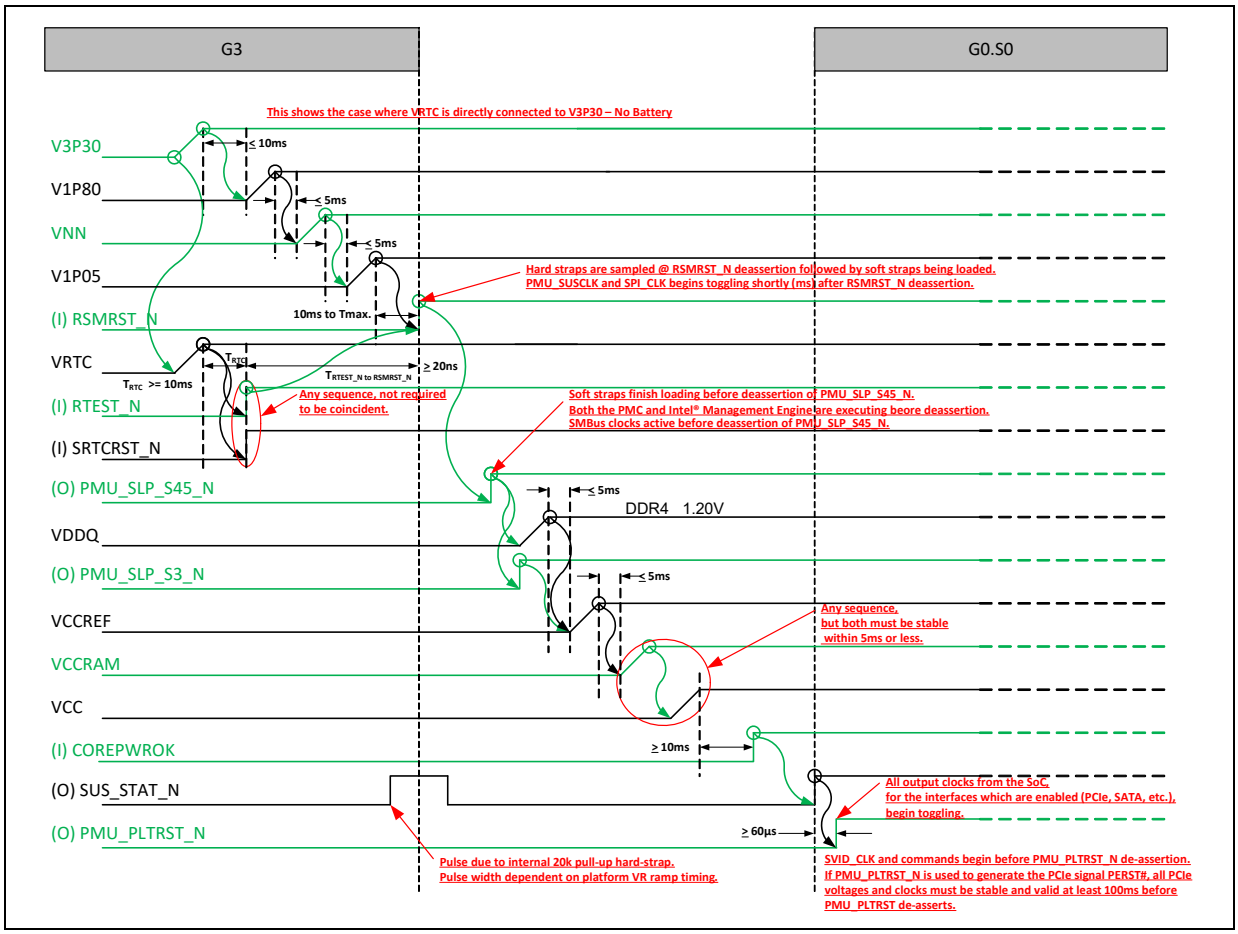
33.3 Cold Boot: From G3 To G0.S0

Figure 33-1, "ACPI Cold Boot Sequence" illustrates the ACPI timing sequence in going from G3 to G0.S0. The arrows in the timing diagram show the sequences that must be followed. In some cases a delay is shown, in other cases, no specific timing delay is given. For cases where no specific timing delay is given, only the sequence is of significance.

The arrows showing the transition of one signal/voltage causing the transition of another signal/voltage occur when the signal/voltage causing the transition reaches its specified valid level. For example, in Figure 33-1, "ACPI Cold Boot Sequence," when V3P30 reaches the level specified as the operating range for V3P30, this is when V1P80 can begin to reach its specified valid level. And for this example, V1P80 must begin ramping within 10ms or less after V3P30 has reached its valid operating range.

Figure 33-2, "Non-ACPI Cold Boot Sequence" is similar to Figure 33-1, "ACPI Cold Boot Sequence," but illustrates the Non-ACPI sequence, where the PMU_SLP_S45_N and PMU_SLP_S3_N signals may be ignored.

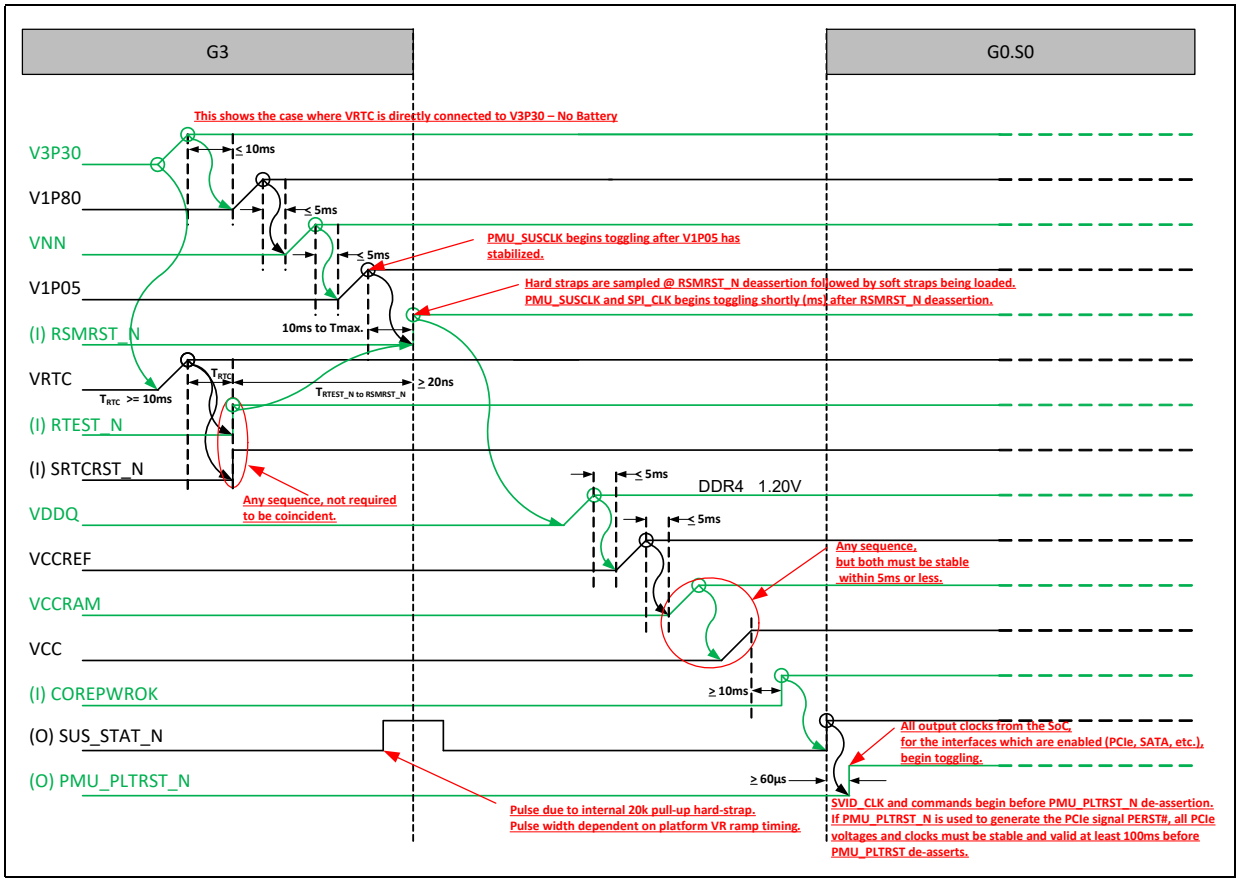
Figure 33-1. ACPI Cold Boot Sequence



Notes:

1. After RSMRST_N de-asserts the Hard straps are sampled. PMU_SLP_S45 will not de-assert until PMU_SUSCLK starts and the Soft straps are loaded from flash.
2. Before PMU_SLP_S45_N de-asserts the PMC and Intel® Management Engine are running.
3. TMAX = 10s: RSMRST should not be asserted indefinitely while the uncore supplies are powered. Specifically, a maximum delay of 10s from V1P05 to RSMRST deassertion should be enforced.

Figure 33-2. Non-ACPI Cold Boot Sequence



Notes:
1. After RSMRST_N de-asserts the Hard straps are sampled. PMU_SLP_S45 will not de-assert until PMU_SUSCLK starts and the Soft straps are loaded from flash.
2. Before PMU_SLP_S45_N de-asserts the PMC and Intel® Management Engine are running.
3. TMAX = 10s: RSMRST should not be asserted indefinitely while the uncore supplies are powered. Specifically, a maximum delay of 10s from V1P05 to RSMRST deassertion should be enforced.

Figure 33-1, Figure 33-2, Figure 33-3, and Figure 33-4 show the configuration where there is no battery connected to VRTC, and instead optionally connected only to V3P30. However, if the battery backed option is selected, then VRTC would always be at the battery voltage and ramp up to V3P30 after the V3P30 VR comes up. When the battery backed option is selected, then the battery and V3P30 are both connected to the VRTC pin through diodes.

The signals RTEST_N and SRTCRST_N are normally held high to VRTC through an external RC circuit, causing a delay in the signals becoming inactive sometime after VRTC has ramped. On a typical system, a jumper is used to force these signals active for testing purposes.

Note: In certain user cases, the core power rails (VCC/VCCRAM/VCCREF/VDDQ) do not need to be cycled during cold reset, but COREPWROK must be cycled during cold reset. If this certain user cases is using non-ACPI code boot sequence, SLP_Sx still are signals to be monitored to be de-asserted before COREPWROK asserted.

33.4 Shutdown: From G0.S0 To G3

Figure 33-3, "ACPI Shutdown Sequence" illustrates the ACPI timing sequence in going from G0.S0 to G3. The arrows in the timing diagram show the sequences that must be followed. In some cases a delay is shown, in other cases, no specific timing delay is given. For cases where no specific timing delay is given, only the sequence is of significance.

The arrows showing the transition of one signal/voltage causing the transition of another signal/voltage occur when the signal/voltage causing the transition falls out of its specified valid level. For example, in Figure 33-3, "ACPI Shutdown Sequence," when V1P05 falls below its valid operating level, this is when the timer begins for T_D. Where T_D is defined as the required time delay before VNN can begin ramping down.

Figure 33-4, "Non-ACPI Shutdown Sequence" is similar to Figure 33-3, "ACPI Shutdown Sequence," but illustrates the Non-ACPI sequence, where the PMU_SLP_S45_N and PMU_SLP_S3_N signals may be ignored.

Figure 33-3. ACPI Shutdown Sequence

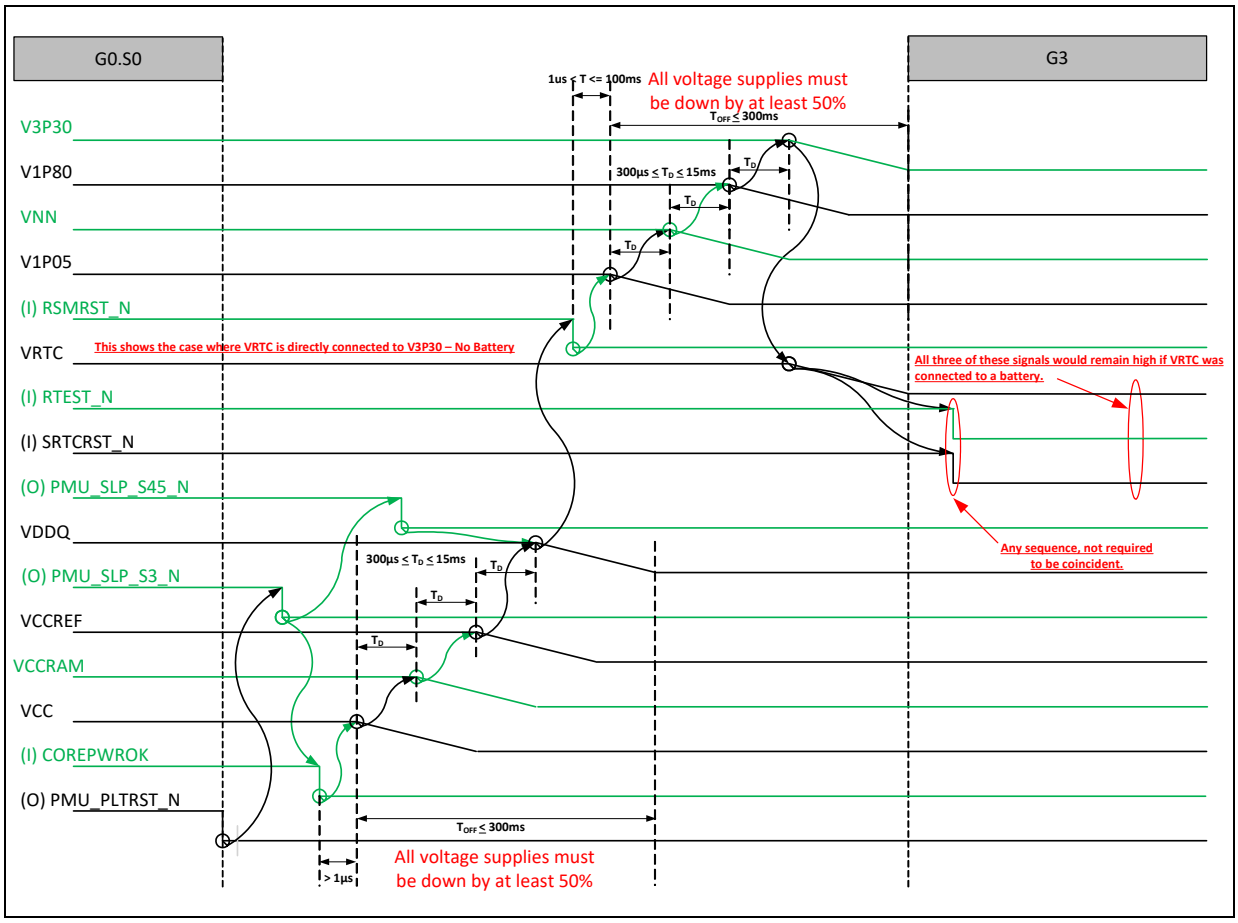


Figure 33-4. Non-ACPI Shutdown Sequence

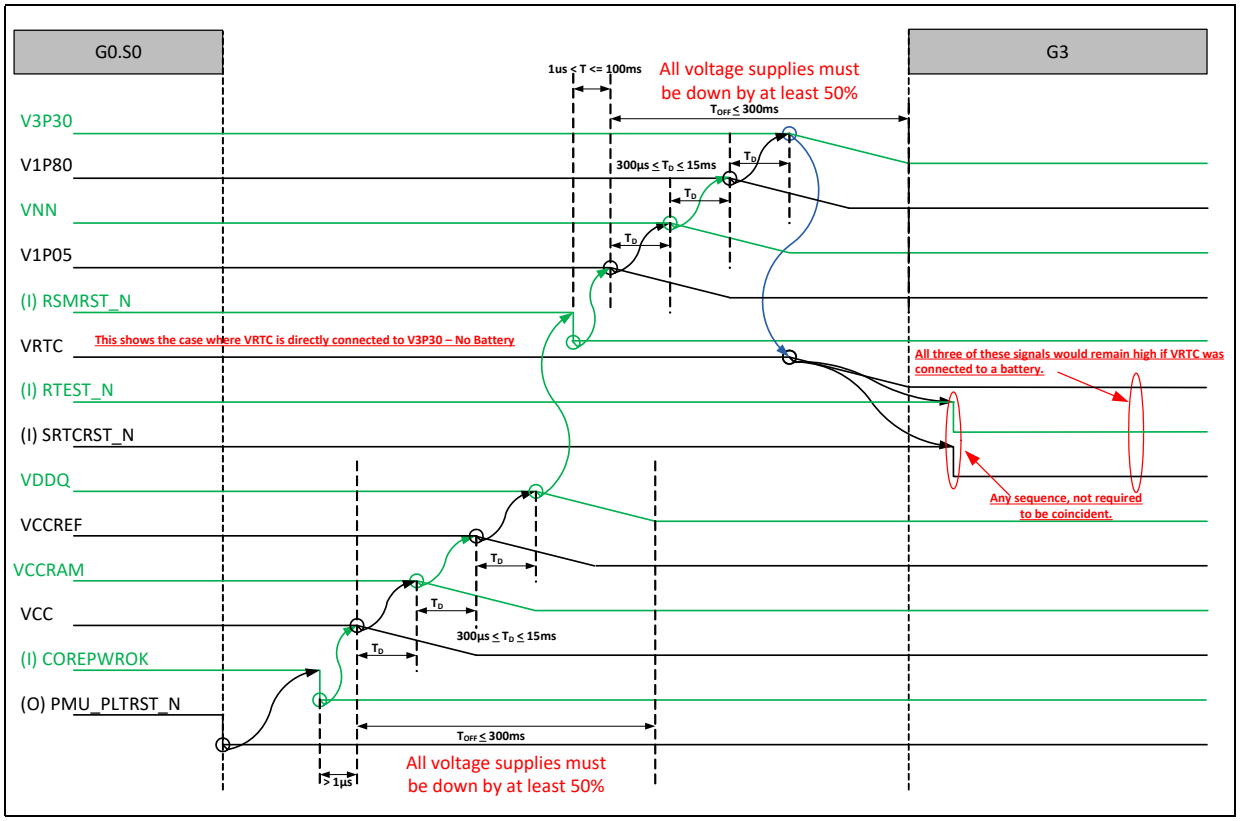


33.5 Deep Sleep: From G0.S0 To G1.S4

Going from G0.S0 to G1.S4 is depicted by the sequence shown in Figure 33-3, "ACPI Shutdown Sequence," and stopping after the VDDQ power supply is turned off. There is no way to discern the G1.S4 state from the G2.S5 state from merely observing the SoC signals.

33.6 Deep Sleep Wake: From G1.S4 To G0.S0

Going from G1.S4 to G0.S0 to is depicted by the sequence shown in Figure 33-1, "ACPI Cold Boot Sequence," beginning in the G1.S4 state. There is no way to discern the G1.S4 state from the G2.S5 state from merely observing the SoC signals.

33.7 Soft Off: From G0.S0 To G2.S5

Going from G0.S0 to G2.S5 is depicted by the sequence shown in Figure 33-3, "ACPI Shutdown Sequence," and stopping after the VDDQ power supply is turned off. There is no way to discern the G1.S4 state from the G2.S5 state from merely observing the SoC signals.

33.8 Soft Off Wake: From G2.S5 To G0.S0

Going from G2.S4 to G0.S0 to is depicted by the sequence shown in Figure 33-1, "ACPI Cold Boot Sequence," beginning in the G2.S5 state. There is no way to discern the G1.S4 state from the G2.S5 state from merely observing the SoC signals.

33.9 Power Failure: From Gx.Sx To G3

While the SoC is capable of withstanding uncontrolled shutdowns due to a power failure, designs should adhere to the specified controlled power shutdown sequencing in order to avoid potential shortened component life expectancies. Intel does not specify or validate the number of power failure cycles a component may withstand before expected component life is affected.

In order to ensure that a power failure does not damage the SoC, the RSMRST_N signal must be asserted (must go low - from a 1 to a 0) at least 1µs before the main power supply that is used to derive all the SoC voltage rails falls 5% below its nominal value. With this sequence, initial testing has shown that components which have experienced 2000 uncontrolled shutdowns (power failures) have not experienced any failures or suffered shortened life expectancies.

33.10 Special Considerations for Platform Voltages

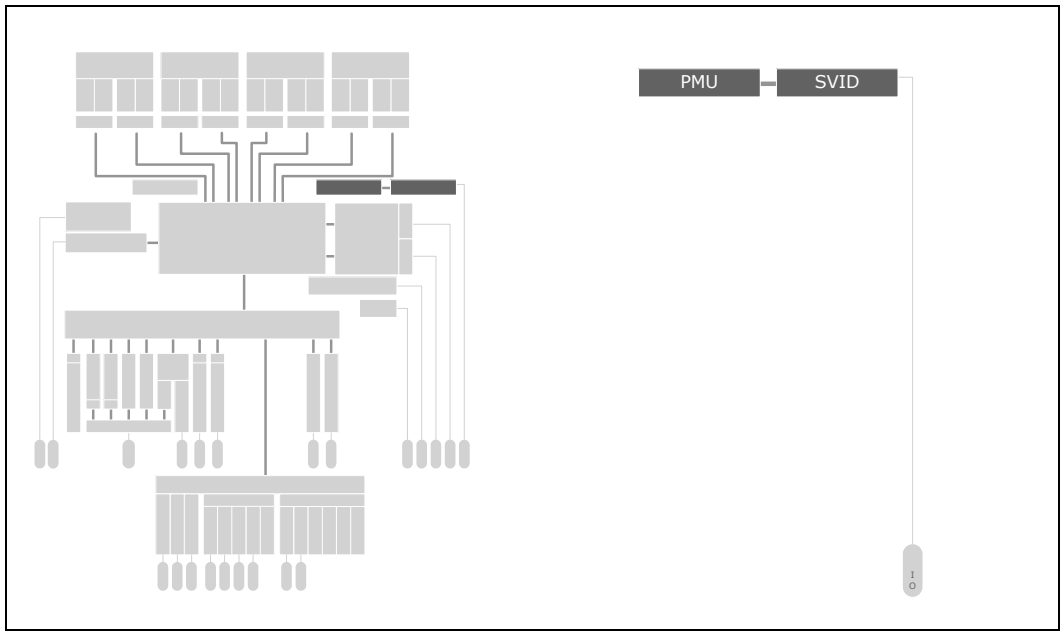
Voltages that do not directly connect to the SoC, but power other platform devices which connect to the SoC, must be isolated (to prevent leakage into SoC), until the SoC has powered up. The 5VDC supply which is provided to a USB interface is an example of a voltage that is not required by the SoC.

§ §

34 Power Management

The SoC provides dynamic power management that fits a number of usages like Microserver, Cloud Storage and Communication Infrastructure. As the technology changes and the number of cores per node and per module change, a better approach is required to manage optimal power of the node/module with respect to the power budget.

Figure 34-1. What is Covered in This Chapter



34.1 Signal Descriptions

The signal descriptions are shown in Table 34-1, "sVID Controller Signals." For additional signal information, including whether a signal is assigned to shared-function pin or can be used as a customer GPIO signal, see Chapter 39, "Signal Pin Names and Signal MUXing." The Direction/Type column of Table 34-1, "sVID Controller Signals" is interpreted as follows:

- I = Input signal. The SoC has receiver circuitry.
- O-OD = Open-Drain Output. SoC output circuit uses an open-drain driver.

Table 34-1. sVID Controller Signals

Signal Name	Direction/ Type	Shared	Description
SVID_DATA	I,O-OD	Yes	**sVID Data:** Used by the SoC to send requests and data to the external Voltage Regulator (VR) and then by the VR to respond.
SVID_CLK	O-OD	Yes	**sVID Clock:** sVID requests driven on SVID_DATA by the SoC use this clock. The VR uses this clock to register-capture the requests. When the VR responds with data on SVID_DATA, the VR uses this SoC-driven clock.
SVID_ALERT_N	I	Yes	**sVID Alert:** Used by the VR to signal to the SoC that the prior request has not reached the requested operating point.

34.2 Overview

The power management control is comprised of a number of Intel proprietary mechanisms. The power management signal interface to the rest of the platform is through the Power Management Controller (PMC) block. This chapter refers to this distributed function as the SoC Power Management Unit (PMU).

To take advantage of all power management capabilities an external, board-level Baseboard Management Controller (BMC) or some other embedded controller, is required to manage the platform power planes, power-on, sleep states, and reset signaling. This chapter refers to the BMC or Embedded Controller (EC). The EC interfaces with the SoC internal fabric to perform its management functions.

The SoC power management is responsible for the following tasks:

- Communicating with the EC and the Intel® Management Engine (Intel® ME)
- Reset sequencing
- Managing processor C-states and P-states
- Managing Sleep-state entry sequences
- Managing DDR4 power management
- Controlling Low Pin Count (LPC) interface clock
- Directing processor thermal management and memory
- Interfacing with the BIOS and the operating system software
- Managing Intel® Turbo Boost Technology, SoC RAPL control, and DRAM RAPL control

Table 34-2. References

Description	Document ID / Location
Advanced Configuration and Power Interface Specification Version 5.0, Errata A	http://uefi.org/specifications

34.3 Power Management Features

The power management features are:

- ACPI system power states supported: G0 (S0), G1 (S4), G2 (S5), G3 (Mechanical Off)
  - S1, S2, S3 are not supported.
- ACPI processor (CPU) C-states: C0, C1, C2, and C3.
- ACPI device states: D0, D3
- ADR (Asynchronous DRAM Refresh)
- Enhanced Intel SpeedStep® Technology
- Clock and Power gating
- Thermal throttling
- Dynamic I/O, memory, and SoC power reductions
- Running Average Power Limiter (RAPL)
- DDR4 SDRAM memory controller and PHY:
  - CKE active power-down (APD) and pre-charge power-down (PPD).
  - Self-Refresh
  - DDR PHY optimization to reduce SoC power.
  - DLL master/slave shut down based on CPU state.

34.3.1 Asynchronous DRAM Refresh (ADR)

ADR provides an early warning to the SoC of an impending reset or power failure so that it can save critical RAID information to the system memory DIMMs that remain powered by a dedicated battery while the reset is in progress.

See Section 16.15, “Asynchronous DRAM Refresh (ADR)” in this document.

34.4 Power Wells

The SoC circuitry is powered by three power wells:

- Core power well
- SUS power well
- RTC power well

34.4.1 Core Power Well

This power group includes all voltage rails and associated power wells that are on only when the system is in the S0 state (system is fully powered-on). The core power well contains the MAIN and cache power rails. These voltage rails are turned off when the system transitions to one of the other low-power system sleep states. See Figure 34-2, "Global System Power States and Transitions" for the ACPI states flow diagram.

34.4.2 SUS Power Well

The register-description chapters of the EDS use the terminology "Primary" and "DSW" for this power well instead of SUS Power Well.

This power group includes voltage rails and associated power wells that are on when the system is in the S0 and S5 states. These voltage rails are turned off when the system transitions from S5 to the G3 (mechanically off) state.

Most of the power management signal pins have their drivers/receivers in the SUS power well.

34.4.3 RTC Power Well

This power group includes all internal voltage rails and associated power wells that are always on, even when the system is in the G3 (mechanical off) state. This group is supplied its 3.3V from the SUS power supply, when the system is in S0 and S5. When the system is in the G3 state, the optional RTC power well is powered from an external battery source, typically a 3.0V lithium-type coin cell.

If a complete power failure (no AC power and no battery back-up supply) occurs, this voltage rail does not provide any power if there is no functioning battery providing its power. In the G3 state (mechanical off), it is permissible for designs not to have an external coin-cell battery if the design does not need to preserve information when the system power is turned off.

34.5 Supply Voltage Rails

The SoC is a highly integrated component where many traditional subsystems are contained on one die.

A total of nine external unique rails need to be supplied. Table 34-3, "SoC Voltage Rails" shows each voltage rail level and a list of internal units associated with the voltage rail.

See Table 33-3, "SoC Required Power Supplies" for voltage values for VCC, VNN,VCCRAM, and VCCREF.

Table 34-3. SoC Voltage Rails

Voltage Rail	VR Rail	SoC Internal Units	S0	S5	RTC
Coin Cell Battery	VRTC	Real Time Clock (RTC)	On	On	On
sVID VCC VR	VCC	CPU Core	On	-	-
sVID VNN VR	VNN	UnCore	On	On	-
P1V05	P1V05	• GPIOSUS signal pins • GbE control and I/O • Power Management Controller (PMC)	On	On	-
VCCRAM	VCCSRAM	• Core L2 Cache	On	-	-
P1V8	V1P8	• GPIO SUS • USB 2.0 SUS • GbE Biasing	On	On	-
VDDQ	VDDQ	DDR I/O	On	-	-
VCCREF			On	-	
V3P3	V3P3	• GPIO SUS-Well High-Voltage signal pins • USB 2.0 SUS signal pins • Thermal Sensor • USB2 I/O	On	On	-

Note: S3 and S4 are part of the state machine and are included in Table 33-4, "SoC Power Supply for each Supported Power State." These states, however, are passed through on the way to S0 or S5.

RTC - In the G3 (mechanically off) state remains on when the RTC battery is present.

34.6 Serial Voltage Identification (sVID) Controller

The three signals provided by the SoC are in Table 34-1, "sVID Controller Signals."

34.6.1 SVID VR Requirements

It is required that the voltage rails for the cores (VCC), L2 SRAM (VCCRAM), and fabric (VNN) support IMON as defined by the Serial VID (SVID) Protocol Specification, Revision 1.7 which covers VR13.0.

The VDDQ VR, if used, must support IMON for DRAM RAPL and DRAM Energy Reporting to function. It is not, however, required for silicon functionality.

Failure to support IMON for the core voltage rails and VDDQ (if the VR is used) may result in one or more of the following:

- System fails to boot
- Power management features fail to work (e.g. RAPL)
- SoC reliability may be compromised
- SoC may show instability at varied temperatures

Note: Voltage control, VCC, VNN, and VCCSRAM, using the SVID feature is required for the silicon to function. Voltage control for VDDQ is supported but not required.

34.6.1.1 sVID Commands

The sVID commands are shown in Table 34-4, "sVID Commands."

Table 34-4. sVID Commands

Command	Command Code	Send Payload	Receive Payload	Description
Not Supported Reserved	00h	(Extended Command)		
SetVID_Fast	01h	VID	n/a	Sets the new VID target. VR Jumps to the new VID target with controlled (up or down) slew rate programmed by the VR. When the VR receives a VID Moving Up command it exits all low-power states to the normal state to ensure the fastest slew to the new voltage. VR sets VR_settled bit and issues alert when VR has reached new VID target.
SetVID_Slow	02h	VID	n/a	Sets the VID target. VR Jumps to new VID target with controlled slew rate (up or down) programmed by the VR. SetVID-Slow is 4x slower than SetVID-fast. When VR receives a VID Moving Up command it exits all low-power states to the normal state to ensure the fastest slew to the new voltage. VR sets VR_settled and issues alert when VR has reached new VID target.
SetVID_Decay	03h	VID	n/a	Sets the VID target. VR jumps to new VID target, but does not control the slew rate, the output voltage decays at a rate proportional to the load current. SetVID_Decay is only used in VID down direction. VR sets VR_settled bit is set, but alert line is not asserted for SetVID-decay.
SetRegADR	05h	VR Register Address	n/a	Sets the address pointer in the data register table. Typically the Next command SetRegDAT is the payload that gets loaded into this address. However, for multiple writes to the same address, only one SetRegADR is needed.
SetRegDAT	06h	VR Register Data	n/a	Writes the contents to the data register that was previously identified by the address pointer with SetRegADR.
GetReg	07h	VR Register Address	VR Register Data	Slave returns the specified register contents as the payload. The majority of the VR monitoring data is accessed through the GetReg command.
Test_Mode	08h			Vendor Defined
Reserved	08h through 1Fh			

34.7 Core Power Management Overview

The SoC supports the hardware C0, C1, C1e, and C6 C-states. C3 is not supported. For C-states deeper than C6, the SoC will be automatically demoted to C6.

All cores in the C0, C1, or C1e C-state operate at the same voltage and frequency. The target frequency is typically the maximum requested frequency for all threads.

The SoC may or may not provide the requested frequency. Many factors can constrain the resolved frequency including but not limited to the following.

- Temperature
- Power constraints
- SKU constraints

The SoC determines a “resolved” frequency based on the OS requests and these constraints. The SoC autonomously manages the voltage based on the resolved frequency and various additional constraints.

The upper and lower bounds of these targets are weighed and prioritized to come up with a final ratio resolution for each core and the sections.

34.8 System Global Power States

Figure 34-2, "Global System Power States and Transitions" shows the system Global Power States as defined by the *Advanced Configuration and Power Interface Specification Version 5.0, Errata A*.

Table 34-5, "ACPI Power States" provides an overview of the power states defined for platforms based on the SoC. For design details on the power states definition and initiation see Chapter 33, "Resets and Voltage Sequencing."

Figure 34-2. Global System Power States and Transitions

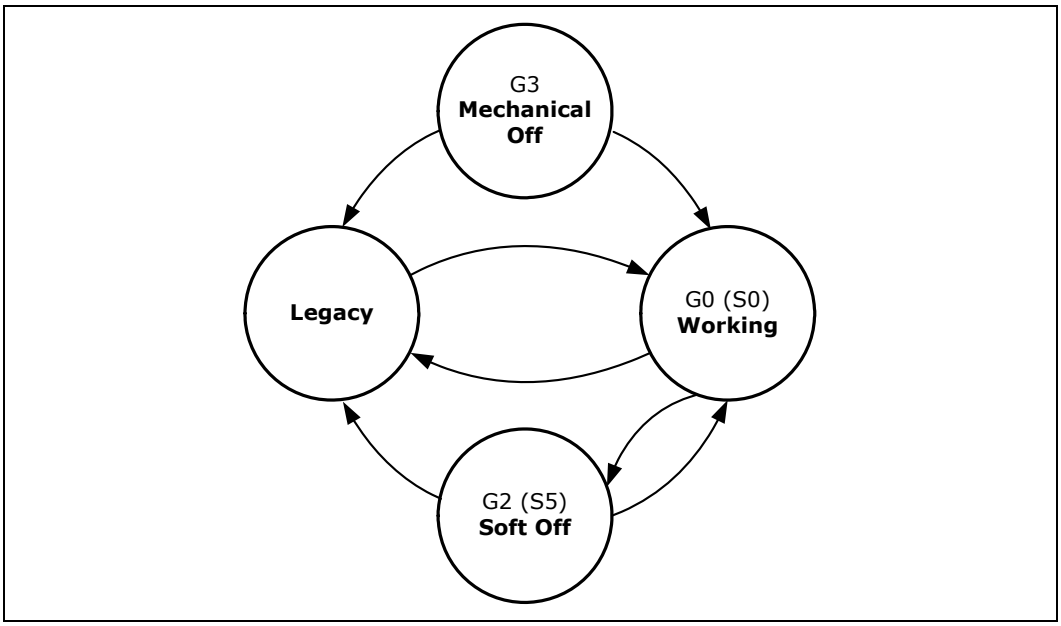


Table 34-5. ACPI Power States

State (Global/Sleep/CPU)	APCI Name	Description
G0/S0/C0	Working (Full On)	CPU operating. Individual devices are shut-off to save power.
G0/S0/C1 G0/S0	Working with CPU Power Management	The different CPU operating levels are defined by Cx states.
G2/S5	Soft Off	System context not maintained. All main power is shut off except for the logic required to wake system. A full boot is required when waking.
G3	Mechanical Off	• System context not maintained. • All main power shut off except for the RTC. • No Wake events occur, because the system does not have any power. This state occurs if user removes the batteries, turns off a mechanical switch, or if the system power supply is at a level that is insufficient to power the waking logic. When system power returns, transition depends on the state before entry to G3.

Table 34-6. ACPI Power State Transitions for the SoC

State (Global/Sleep/CPU)	Transition Trigger	Next State
G0/S0/C0	Executing the MWAIT instruction or LVL Rd	G0/S0/Cx
	Sleep Enable (SLP_EN) bit written to 1 by the software in the Power Management 1 Control (PM1_CNT) register	Specified by the 3-bit code Sleep Type (SLP_TYP) field of the PM1_CNT register: • 000 G0/S0 - Working (Full On) • 001 G1/S1 - Not supported by the SoC • 010 Reserved • 011 Reserved • 100 Reserved • 101 G1/S3 - Suspend-To-RAM - Not supported by the SoC • 10 G1/S4 - Suspend-To-Disk S4 • 111 G2/S5 - Soft Off
	Power Button Override	G2/S5
	Mechanical Off/Power Failure	G3
G0/S0/C1 G0/S0/C3	C-State break events including: • CPU Snoop • MSI • Legacy Interrupt • Always-On (AONT) Timer expires	G0/S0/C0
	Power Button Override	G2/S5
	SUS Well Power Failure	G3
G2/S5	Any Enabled Wake Event	G0/S0/C0
	SUS Well Power Failure	G3
G3	Power Returns	Option to go to: • S0/C0 (Reboot) • G2/S5 (Stays off until the power button is pressed or other enabled wake event)
S0/G3/S0	Surprise Power Loss	ADR (Automatic DIMM Refresh) asserts if the appropriate battery back-up design is in place.

34.8.1 Idle Power Optimizations

The SoC does not use the G1/S1 sleep state. Instead, as other recent server processors do, it enters the G1/S1 sleep state is not used. The processor now enters low power states (package C-states) while staying in the S0 state. This method provides low latency wake-ups. Alternatively, the S4 (sleep) or S5 (soft off) may be used to put the system into its lowest idle power states. Note the exit latency between S4 and S5 are OS and platform configurations dependent. In certain cases, S4 latency is not necessarily faster than S5.

34.9 Processor Power States - C-States

There are three types of C-states which are frequently mixed up:

- ACPI C-states
- Core C-states
- Package C-states

ACPI C-states are C0, C1, C2, and C3. These states are mapped to the actual hardware C-states (C0, C1, C1e, C6) through BIOS tables.

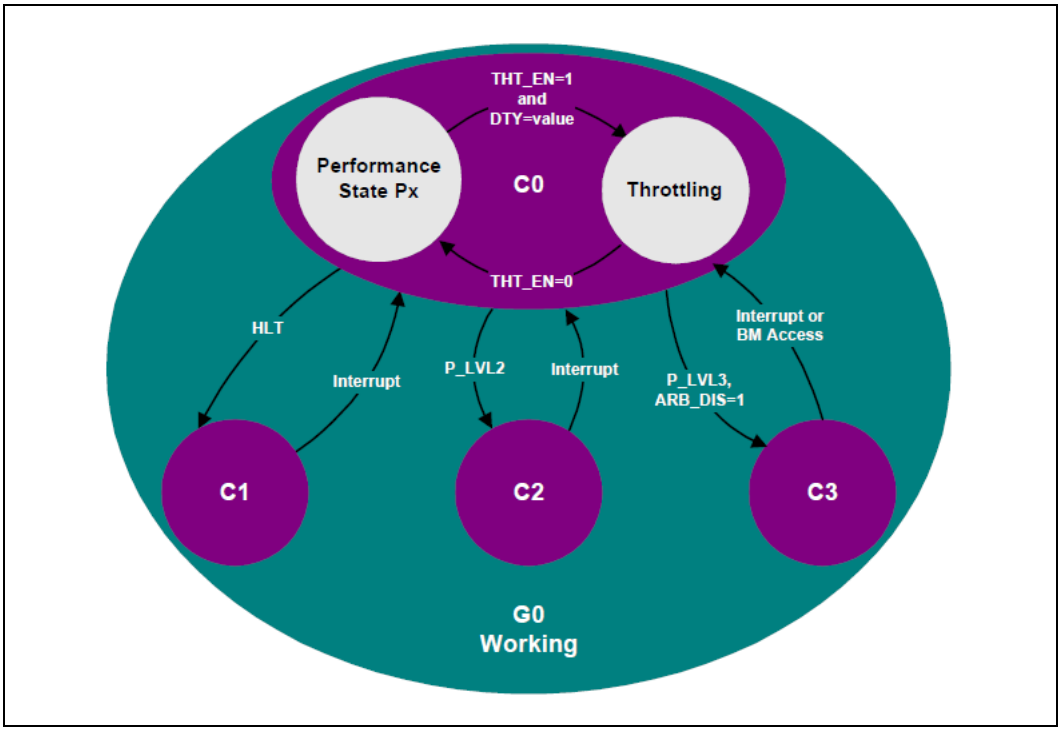
When all cores go into certain Core C-states, the SoC has the option to enter a deeper package C-state and take additional power saving actions in the package and/or on the platform.

Note: Linux and the mainline kernel have moved away from ACPI C-states with the intel_idle driver. This driver will be updated to support this SoC at launch.

Figure 34-3 shows the Processor Power States described in the *Advanced Configuration and Power Interface Specification Version 5.0, Errata A*.

The processor Performance States (P-States) are described later in Section 34.10.1, "Processor Performance States - P-States."

Figure 34-3. Processor Power States



Concerning the SoC CMP Module and its interface to the System Agent, the SoC has three types of C-States:

- Core C-States. See Table 34-7, "Core C-States."
- Package C-States. See Table 34-8, "Package C-States."

Table 34-7. Core C-States

HW Core C-State	Typical Mapped ACPI C-State	Description
CC0	C0 | ACPI C0	Active State
CC1	C1 | ACPI C1	Some core clocks gated. L1 Data Cache Snoops are serviced.
CC1e	C1e | N/A	Some core clocks gated. L1 Data Cache Snoops are serviced. Provides a hint to reduce voltage and frequency.
CC6	C6| ACPI C2	Core power gated and clock gated L1 Data cache is flushed

Table 34-8. Package C-States

Core C-State	Package C-State	When Entered
C0	PC0	• Active States • When at least one core is in CC0
C1e	PC1e	• Reduce voltage and frequency for C1e • When no cores are in CC0 or CC1 and at least 1 core is in C1e
CC6	PC2	• All cores in CC6 • Some package actions allowed

34.10 Performance States

This section describes the concept of processor and device performance states. Processor and device performance states (Px states) are power consumption and capability states within the active/executing states, C0 for processors and D0 for devices. Performance states allow the Operating System Power Management (OSPM) to make trade-offs between performance and energy conservation. Processor and device performance states have the greatest impact when the states invoke different device and processor efficiency levels as opposed to a linear scaling of performance and energy consumption. Since performance state transitions occur in the active/executing device states, ensure that performance state transitions do not adversely impact the system.

34.10.1 Processor Performance States - P-States

The SoC supports P-States for every dual-core pair within a module. Based on power performance analysis, the SoC only supports Package Level P-States. The Power Management Unit will select the highest P-state from all requests across all modules and apply that state to all cores.

Note: Hardware Power Management and Hardware P-states are not supported.

34.10.1.1 Frequency/Voltage Scaling

P-state frequency and voltage are resolved at the package level and not by the individual cores or modules.

Table 34-9. ACPI P-State Mappings

P-State	ACPI Meaning	Frequency Mapping
P0	Performance is preferred over power efficiency	Greater-than or equal-to the Maximum Non-Turbo Limit Ratio. This is set based on thermal/electrical limits, platform constraints, and other parameters.
P1	Maximum performance/efficiency is desired	Maximum Non-Turbo Limit Ratio (base frequency)
P2 through PN	Intermediate performance/efficiency is desired	Less-than the Maximum Non-Turbo Limit Ratio, Greater-than the Maximum Efficiency Ratio
PN	Frequency at the minimum voltage	Maximum Efficiency Ratio correlates to minimum operational voltage (LFM_RATIO)

The OS requests a P-State based on application performance needs. A desired P-State is requested via IA32_PERF_CTL (CLOCK_CR_GEYSIII_CONTROL). The SoC supports the Enhanced Intel SpeedStep® Technology.

34.10.2 Software P-State Requests

ACPI enumerates the base frequency at P1 and the maximum turbo frequency at P0. There are multiple ratios/frequencies between these two points. The SoC supports requests to intermediate ratios and will attempt to provide those ratios (under all normal constraints).

34.11 Power Management Technologies

34.11.1 Intel® Turb Boost Technology

Intel® Turbo Boost Technology enables higher performance through the availability of increased core frequency under certain configurations and workloads. Turbo allows processor cores to run faster than the specified operating frequency if the processor is operating below rated power, temperature, and current specification limits of the system. Turbo is engaged with any number of cores or logical processors enabled and active, enabling increased performance of both multi- and single-threaded workloads.

The BIOS may disable turbo features on turbo-enabled SKUs. If Reset = 1, then the SKU does not support turbo and it is disabled. If RESET = 0, then the SKU does support turbo and it is enabled by default. BIOS can set the bit to disable it.

The Operating System (OS) and applications must use CPUID.06H:EAX[1] to detect whether the BIOS has enabled turbo features. If IA32_MISC_ENABLES[38] is set, CPUID.06H:EAX[1] returns 0. Turbo features have been enabled by BIOS.

Because IA32_MISC_ENABLES[38] is defined per-package, CPUID has to read from the UnCore to get MISC_ENABLES[38]. The OS or BIOS manages read-modify-write conflicts cross-core. Setting IA32_MISC_ENABLES[38] on any core causes the SoC to disable turbo operation for ALL cores.

Certain software workloads may not be able to tolerate the non-deterministic aspects of turbo operation. The software temporarily disables turbo operation by setting CLOCK_CR_GEYSIII_CONTROL[32] bit of the IA32_PERF_CTL Model-Specific Register (MSR) [MSR 0199h]. As previously mentioned, disabling turbo on any core causes turbo to be disabled for ALL cores.

Two MSRs (MSRs 0x1AE and 0x1AD) can be used to limit the maximum amount of turbo that is granted based on the number of active cores. At reset these registers are populated based on the SKU limits. Software (either BIS or Ring-O) can reprogram these limits at boot or runtime. Configuring frequencies larger than the SKU limits will be silently clipped.

34.11.2 Voltage Regulator Constraints

For some platforms, the voltage regulator for the shared VCC voltage rail has some maximum current limits. A typical voltage regulator for a platform using the SoC has a Thermal Design Current (Icctdc) specification and a Maximum Current (Iccmax) limit.

Icctdc represents the current which is sustained indefinitely by the voltage regulator (i.e., able to sustain a TDP workload on all processors running at base frequency), whereas the Iccmax is the peak current which the voltage regulator does source without tripping any protective circuitry. Any current greater than Icctdc is only sustained for a short duration. Iccmax is sustained typically for approximately 10 ms.

Such voltage-regulator specifications must be taken into account when configuring the aggressiveness of turbo operation for the device. Turbo operating points are limited based on the number of active cores to keep the current drawn within the Iccmax limit.

See Section 35.2, "Feature Summary" for Thermal Management Features.

34.11.3 Thermal Design Power Constraints

The Thermal Design Power (TDP) represents the power consumed by the device when running a realistic worst-case workload at $T_{J\text{-}MAX}$ temperature. The realistic-worst-case workload is determined based on knowledge of the target application and realistic usage scenarios. The system thermal solution must be designed to dissipate the heat generated during a sustained period of activity with all cores running at TDP at guaranteed maximum frequency.

See Section 35.2, "Feature Summary" for Thermal Management Features.

34.11.4 FAST PROCHOT

Fast PROCHOT provides a mechanism for the platform to trigger a very quick and heavy throttling (decreasing the clock frequency) of the SoC processor cores. This description is an overview of the functionality. For design details for PROCHOT and Fast PROCHOT see Section 35.4, "Thermal Management (TM)."

Fast PROCHOT is typically used by the power supply unit (PSU) to trigger an immediate throttle to protect against unexpected current spikes or thermal conditions. Other customer platform innovation is possible.

Benefits:

- Enables PSU cost reduction without excessive guard banding lowering cost.
- Enables Processor performance without excessive guard banding enhancing performance.

High-Level Flow:

- Via a comparator at the PSU PROCHOT_N is asserted.
- The SoC Power Management Unit (PMU) utilizes the new fast throttle mechanism. Power is reduced quickly via core instruction throttling.

A frequency transition occurs later and is used to provide more power/performance efficient throttling.

34.11.5 Running Average Power Limiting (RAPL)

The SoC contains proprietary power monitors and Running Average Power Limit (RAPL) algorithms that calculate an energy budget and convert the budget into voltage/frequency working points. This section provides an overview of RAPL. For details see Section 35.6, "Run Average Power Limit (RAPL)."

The SoC supports RAPL control through these interfaces:

- MMIO. Recommended usage is BIOS and platform limits.
- MSR. Recommended usage is runtime limits through ring-0 software).
- PECI. Recommended usage is through an external Baseboard Management Controller (BMC) or other platform circuitry via the SoC PECI/SMBus interface.

RAPL is used in mobile devices to conserve battery power, but the SoC is not typically used in applications where battery is the main source of power. The SoC uses RAPL to deal with the SoC Package and DRAM thermal management in the high-density platform environment of Microserver, Storage, and Communication applications. See Section 35.2, "Feature Summary" for Thermal Management Features.

34.11.6 Always-On Timers (AONT)

Always-On Timers run while the SoC is in the S0 state and are used to periodically wake-up the cores from sleeping. They do not run when the SoC transitions out of S0.

34.11.7 I/O Device Controller Enable/Disable

Table 34-10. I/O Power Management Summary

Integrated I/O Device	I/O Feature Not Used by Customer	Nothing Connected to Interface at Boot Time
PCIe* Root Ports	The BIOS disables the circuitry and power on a per-lane basis.	The BIOS disables the circuitry and power on a per-lane basis.
SATA 3.1	The BIOS disables the circuitry and power-on a per-port basis.	Disabled at power-on unless explicitly enabled by the software.
LAN	The BIOS disables the circuitry and power-on a per-port basis.	Ports not WOL-enabled are in P2. Ports with WOL are in P0. If all ports are WOL-disabled, internal clocks off.
USB	The BIOS disables the circuitry and power.	Idle State with internal clocks off.

§ §

35 Thermal Management

The SoC implements configurable forms of thermal management for itself, memory, and the system. The architecture implements various proven methods of maintaining maximum performance while remaining within thermal specifications. Thermal Control Circuit (TCC) mechanisms are used to reduce power consumption when thermal device limits are exceeded, and the system is notified of this condition via interrupts or thermal signaling pins.

35.1 Signal Descriptions

The signal descriptions are shown in Table 35-1, "Signal Names and Descriptions". For additional signal information including whether a signal is assigned to shared-function pin or can be used as a Customer GPIO signals see Chapter 39, "Signal Pin Names and Signal MUXing." The Direction/Type column of Table 35-1, "Signal Names and Descriptions" is interpreted as follows:

- I = Input signal. The SoC has receiver circuit.
- O-OD = Open-Drain Output. SoC output circuit uses an open-drain driver.

Table 35-1. Signal Names and Descriptions

Signal Names	Direction	Shared	Description
MEMHOT_N	I	Yes	**Memory Hot:** Active-low input signal from the platform board indicating memory exceeds temperature limits. When this signal is active, the SoC can perform memory throttling in an attempt to cool the memory devices.
PROCHOT_N	I,O-OD	Yes	**Processor Hot:** Active low. As an input, the platform board External Circuitry (EC) chooses to drive this signal low to reduce SoC current consumption if the EC detects overheating in the board or system. Also as an input, the power supply asserts this signal to trigger the SoC Fast PROCHOT feature in the event of a maximum power excursion. As an output, the signal is asserted if any SoC thermal sensor indicates the component is operating above temperature limits. The platform board must ignore this SoC output signal while PMU_PLTRST_N (active-low SoC output) is asserted. ***Note:*** PROCHOT_N can be configured to be an output or an input signal pin. It cannot be configured to be bi-directional.
THERMTRIP_N	O-OD	Yes	**Catastrophic Thermal Trip:** Active-low, open-drain output signal indicating the SoC has reached an operating temperature that may damage the component. Once THERMTRIP_N is asserted, the platform must remove power by shutting down the power regulators. The platform board must ignore this SoC output signal while PMU_PLTRST_N (active-low SoC output) is asserted. See Section 35.4.5, "THERMTRIP_N" for additional details on THERMTRIP_N. Even though this open-drain output has an internal 20-kΩ pull-up resistor, an external 51-Ω pull-up resistor tied to V1P05 is recommended for open-drain operation.

35.2 Feature Summary

Thermal management features include:

- Up to 13 Digital Thermal Sensors (DTS):
  - Eight sensors, one for each L2 Cache in the processor core area.
  - Five sensors not in the processor core area.
- Thermal Control Circuit (TCC) mechanisms:
  - Configurable PROCHOT_N.
  - Intel® Thermal Monitor 1.
  - Intel® Thermal Monitor 2.
- Catastrophic temperature protection (THERMTRIP_N) and memory temperature protection (MEM_THERMTRIP).
- Two programmable thermal interrupt thresholds per DTS.
- Memory Temperature Management control modes:
  - OLTT - Open Loop Thermal Throttling.
  - CLTT - Closed Loop Thermal Throttling via SMBus-Legacy interface.
  - CLTT Pass-through via SMBus-PECI interface.
- Thermal status/trigger signal pins:
  - MEMHOT_N input-only signal.
  - PROCHOT_N configurable as an input-only signal or as an output-only signal.
  - THERMTRIP_N output-only signal.
- Fan Speed Control (FSC) parameter ($T_{CONTROL}$ and margin to $T_{CONTROL}$)
- Fast PROCHOT_N input signal pin driven by the platform or power supply that triggers a rapid Intel® Thermal Monitor 2 (TM2) throttling response:
  - Available only when PROCHOT_N pin is configured as input-only signal.
- Inverse Temperature Dependence (ITD) function for maintaining processor performance at low temperatures.
- Platform Voltage Regulator Hot Alert to lower voltage needs when a VR is approaching its thermal limits.

35.3 Registers with Multiple Access Methods

Many of the Thermal Management registers mentioned in this chapter are accessible in more than one way. Even so, the type of access used may have unique Read/Write access capabilities. In some cases of access via the PECI SMBus, the temperature values may have a different format or bit length. For details see Chapter 30, "SMBus Controller - Platform Environment Control Interface."

35.4 Thermal Management (TM)

The IA-32 architecture provides mechanisms for monitoring temperature and controlling thermal power. These are presented in sub-section 14.7 of Volume 3 of the *Intel® 64 and IA-32 Architectures Software Developer's Manual* and are listed below along with the section in this document:

- Catastrophic Shutdown detector
  See Section 35.4.5, "THERMTRIP_N."
- Automatic and Adaptive Thermal Monitoring mechanisms
  See Section 35.4.4, "Thermal Throttling."
- Software-Controlled Clock Modulation mechanism
  See Section 35.4.4.4, "Software-Controlled Clock Modulation."
- On-die Digital Thermal Sensor (DTS) and interrupt mechanisms
  See Section 35.4.1, "Digital Thermal Sensor (DTS)."

35.4.1 Digital Thermal Sensor (DTS)

Each of the 13 on-die Digital Thermal Sensor (DTS) reports the temperature of the associated processor core pair or other portions of the SoC circuitry as a temperature relative to the factory-configured Thermal Control Circuit (TCC) Activation Temperature which is also known as DTS_{MAX}.

- There is one DTS for each two-core processor. Here two cores share an L2 cache and a Bus Interface Unit (BIU). Some SoC product SKUs provide only one core processor per L2 cache and BIU and contain one DTS per core processor.
- There are five additional DTSs located in the remaining SoC circuitry.

Each core-related DTS produces a 7-bit temperature value in the TEMPERATURE field of its IA32_THERM_STATUS register (MSR 19Ch). The TEMPERATURE value is reported as a negative offset from the eight-bit REF_TEMP field of the TEMPERATURE_TARGET register. REF_TEMP is the Thermal Monitor Activation Temperature, also called the PROCHOT_N Temperature, TCC Activation Temperature, and DTS_{MAX}. The REF_TEMP value is the maximum temperature at which the silicon is capable of operating.

Example: If TEMPERATURE_TARGET.REF_TEMP indicates 90 °C, a IA32_THERM_STATUS.TEMPERATURE value of 10 decimal implies that this domain is currently operating at 80 °C.

The SoC Package temperature is based on all 13 DTSs and is in the TEMPERATURE field of the IA32_PACKAGE_THERM_STATUS register (MSR 1B1Ch). The TEMPERATURE value is reported as a negative offset from the aforementioned REF_TEMP field of the TEMPERATURE_TARGET register.

The registers associated with DTS configuration and target values are shown here. The core-related and SoC Package Status registers are mentioned in Section 35.5.3, "Thermal Status and Interrupts":

TEMPERATURE_TARGET

MSR_TEMPERATURE_TARGET (MSR 1A2h)
P_CR_TEMPERATURE_TARGET_0_0_0_MCHBAR (MMIO MCHBAR + 7074h)
Temperature Target Read Data (PECI RdPkgConfig(), Index 16)

This 32-bit register contains information about the Fan Speed Control (FSC) target temperature as well as details on the reference temperature for core-pair DTS relative temperature reading. The register contains the TJ_MAX_TCC_OFFSET. It also contains the Read-Only REF_TEMP (also known as DTS_{MAX}) and FAN_TEMP_TARGET_OFFSET (also known as $T_{CONTROL}$) fields which are set at the Intel factory.

DTS_CONFIG3_CFG

P_CR_DTS_CONFIG3_CFG_0_0_0_MCHBAR (MMIO MCHBAR + 7118h)

This 32-bit register contains an offset value to modify $T_{CONTROL}$. This register contains the legacy TCONTROL_OFFSET and OFFSET_PROGRAMMED fields.

35.4.2 Fan Speed Control (FSC)

Note: This chapter deals with software-controlled and BMC-controlled platform fan speed control. While the SoC has the FAN_PWM[3:0] and FAN_TACH[3:0] signal pins, the pins are exclusively controlled by the customer-programmed Innovation Engine (IE) and are not discussed here. See Chapter 37, "Innovation Engine."

While the SoC does not support the DTS 2.0 Fan Speed Control (FSC) feature, it does support the FSC as used on many Intel® Xeon® processor products that are multi-chip packages (MCP) even though the SoC is not an MCP.

The MCP FSC feature reports "Thermal Margin" as the temperature margin relative to the TEMPERATURE_TARGET.FAN_TEMP_TARGET_OFFSET. The FAN_TEMP_TARGET_OFFSET value is also known as $T_{CONTROL}$. It uses the same Thermal Margin access methods as DTS 2.0 FSC, but the underlying calculations are different and the overall algorithm is much simpler.

The Thermal Margin value simply reflects whether or not the SoC is meeting the TEMPERATURE_TARGET.FAN_TEMP_TARGET_OFFSET ($T_{CONTROL}$) specification; negative margin means the platform needs to increase fan speed. At high power levels, Thermal Margin becomes negative because of the thermal load line, but

TEMPERATURE_TARGET.REF_TEMP (DTS_{MAX}) is set at the Intel factory so that the SoC does not throttle when running a TDP workload and meeting the SoC T_{CASE_MAX} specification.

Thermal Margin is calculated as:

PACKAGE_THERM_STATUS.TEMPERATURE
minus the
TEMPERATURE_TARGET.FAN_TEMP_TARGET_OFFSET
where FAN_TEMP_TARGET_OFFSET is a positive value

Software can read the value of Thermal Margin by PECI command or by the THERM_MARGIN field of an MSR or an MMIO register:

PACKAGE_THERM_MARGIN

MSR_PLATFORM_BRV (MSR 1A1h)
P_CR_PACKAGE_THERM_MARGIN_0_0_0_MCHBAR (MMIO MCHBAR + 703Ch)
THERM_MARGIN Read Data (PECI RdPkgConfig(), Index 10)

Bits 15:0 (of the MSR and MMIO) is the THERM_MARGIN: This product does not support DTS 2.0 and margin to the thermal loadline. This register reports margin to the T_CONTROL temperature in 2's compliment format (S16.7.8). Negative margin implies that the temperature is operating above the (static) T_CONTROL temperature, and that thermal controls (fans, etc.) should be attempting to cool the silicon. Positive margin implies that the silicon is operating at a temperature below the T_CONTROL point and that a reduction in cooling may provide better power efficiency. Unlike Intel products that support DTS 2.0, sustained negative margin is expected and acceptable when the SoC is operating with high power consumption.

35.4.3 PROCHOT_N Signal Pin

The SoC PROCHOT_N signal pin can be configured to be an output or an input signal pin. It cannot be configured to be bi-directional. Bits 0, 21, 22 and 23 of the MSR_POWER_CTL register, MSR 1FCh, provide this configuration.

See Table 35-2, "MSR_POWER_CTL (MSR 1FCh)."

Table 35-2. MSR_POWER_CTL (MSR 1FCh)

Bits	Access Type	Default	Description
31:25	-	-	*Reserved*
24	RW	0	**VR_THERM_ALERT_DISABLE**: When set to 1, disables the VR_THERMAL_ALERT signaling.
23	RW	0	**PROCHOT_LOCK**: When set to 1, locks bits 0, 21, 22 and 23 of this MSR. Once set, a reset is required to clear this bit.
22	RW	0	**PROCHOT_RESPONSE**: PROCHOT_N signal pin configurable response enable. 0 = Go to Pn on incoming asserted PROCHOT_N signal. 1 = Go to a state lower than Pn on incoming asserted PROCHOT_N signal. Go to Pm on incoming PROCHOT_N. ***Note:*** PROCHOT_OUTPUT_MODE_DISABLE must be 1 (input-only signal pin) for this bit to function.
21	RW	1	**PROCHOT_OUTPUT_MODE_DISABLE**: PROCHOT_N signal pin output disable. 0 = PROCHOT_N is an output-only signal pin. 1 = PROCHOT_N output is disabled and the PROCHOT_N signal pin is input-only.
20:19	-	-	*Reserved*
18	RW	0	**PWR_PERF_PLTFRM_OVR**: When set to 0 (default), this bit disables access to IA32_ENERGY_PERF_BIAS (MSR 1B0h), causing a GP# fault on access. CPUID.(EAX=6):ECX[3] will read 0.
17:2	-	-	*Reserved*
1	RW	1	**C1E_ENABLE**: Used to enable C1E behavior on every C1 entry (even if MWAIT C1E sub-state bit was not set or when using HLT). When this package-visible bit is set, it causes the CPU to switch to minimum GV point when all cores have entered C1.
0	RO	0	*Reserved*

The PROCHOT_N signal direction and how the SoC reacts are shown in Table 35-3, "PROCHOT_N Signal Direction and Function."

Table 35-3. PROCHOT_N Signal Direction and Function

MSR_POWER_CTL Bit 21 PROCHOT_OUTPUT_MODE_DISABLE	MSR_POWER_CTL Bit 22 PROCHOT_RESPONSE	Resulting PROCHOT_N Signal Pin
0	x	Output-Only Signal
1	0	Input-Only Signal, go to Pn (the default mode)
1	1	Input-Only Signal, go to Pm

- Pn - Use-frequency scaling and voltage scaling to attain PROCHOT relief. Pn is the lowest frequency of operation, also called the Low Frequency Mode (LFM) frequency.
- Pm - Provides more PROCHOT relief than Pn mode does.

The default mode for PROCHOT_N provides the Fast PROCHOT capability. Customers can use the Input-Only, Pm mode to get some additional power savings on PROCHOT, but this will be mostly frequency-only scaling and not voltage scaling.

Generally, Pm provides a small amount of additional PROCHOT relief versus Pn. Even so, the Pm mode can help a bit more on SoC product SKUs that have small dynamic range from throttling.

Fast PROCHOT is enabled when the MSR (1FCh) MSR_POWER_CTL field PROCHOT_OUTPUT_DISABLE (bit 21) is set. When Fast PROCHOT enabled the processor responds to platform requests to operate within the platform power budget, when rapidly exercised by non-ideal workloads. The PROCHOT_N input time response has been improved on the SoC from 3ms to 80us (from PROCHOT_N pin assertion), when FAST PROCHOT is enabled. Additional time is required for the platform to detect a Pmax condition and assert the PROCHOT_N pin (typically around 20 uS). If a rise in power at or above 1.6x TDP for the processor is detected by platform logic, a PROCHOT_N input by the platform or power supply triggers this rapid Intel® Thermal Monitor 2 (TM2) throttling response. Platform logic is required to detect the power level within 20µs and assert PROCHOT_N for this feature usage. It is recommended that PROCHOT_N be configured for input-only mode to take advantage of this reduced response time. The platform is required to use DTS to check for over temperature conditions, when Fast PROCHOT is enabled as the primary means of temperature monitoring for thermal control, as the PROCHOT_N signal output is disabled.

The Output-Only mode can be useful on systems that want to use PROCHOT_N for fan speed control. While this is not the recommended usage model, it can be used on very-low-cost platform designs. PROCHOT_N is asserted by the SoC when a thermal sensor indicates the component is operating above temperature limits.

35.4.4 Thermal Throttling

The SoC has only one thermal-control domain—the processor cores. No uncore throttling is supported. When an over-temperature event occurs based on the Throttle Threshold Temperature (see Section 35.4.4.1, "Throttle Threshold Temperature"), all processor cores are throttled regardless of which of the 13 DTS within the SoC is reporting the over-temperature event.

Note: The SoC does not throttle the processor when DRAM Memory is hot. Memory Thermal Management (see Section 35.5, "Memory Thermal Management (MTM)") is managed independently of Thermal Management.

Two Thermal Throttling mechanisms are implemented to reduce temperature by reducing power consumption in response to temperatures exceeding the Throttle Threshold Temperature:

- Intel® Thermal Monitor 2 (TM2) - Thermal throttling based on voltage and frequency reductions. See Section 35.4.4.2, "Core Frequency/Voltage Reduction (Intel® Thermal Monitor 2)."
- Intel® Thermal Monitor 1 (TM1) - Thermal throttling via core clock modulation using the processor's eHALT feature. See Section 35.4.4.3, "Clock Modulation (Intel® Thermal Monitor 1)."

Note: IA32_MISC_ENABLE (MSR 1A0h), bit 3, is the Automatic Thermal Control Circuit (TCC) Enable. The SoC ignores the setting of this MSR bit, even if it is 0 and the SoC always invokes TM2 and TM1 (automatic TCC).

The SoC invokes TM2 when the SoC package temperature (the highest temperature of the 13 DTSs) has met or has exceeded the Throttle Threshold Temperature defined in the next sub-section.

The SoC only invokes TM1 if TM2 has reached its Maximum Throttle Point of Pm and the SoC is still over temperature.

35.4.4.1 Throttle Threshold Temperature

The Throttle Threshold Temperature is determined from the following equation:

TEMPERATURE_TARGET.REF_TEMP — TEMPERATURE_TARGET.TJ_MAX_TCC_OFFSET

TJ_MAX_TCC_OFFSET can be set by software in 1°C increments. The register default value is 0 offset. If set to 0, the SoC uses an internally-set guardband offset of approximately 0.5°C, making the Throttle Threshold Temperature about 0.5°C below the REF_TEMP value (REF_TEMP is also known as the DTS_{MAX} temperature or the PROCHOT temperature).

35.4.4.2 Core Frequency/Voltage Reduction (Intel® Thermal Monitor 2)

Intel® Thermal Monitor 2 (TM2) refers to thermal throttling based on voltage and frequency. The SoC attempts to lower the temperature by transitioning to a lower operating frequency and lower operating voltage. An internal algorithm attempts to select the highest possible frequency while staying within thermal constraints. If enabled, TM2 is automatically selected as the primary thermal control mechanism and cannot be disabled by the Operating System software.

Since the SoC does not support per-core Px states, all processor core modules of the SoC package throttle together based on the Throttle Threshold Temperature.

When TM2 starts it steps-down the frequency/voltage until the Maximum Efficiency Throttle Point (Pn) is achieved. If the SoC package temperature is still equal-to or above the Throttle Threshold Temperature, it continues to step-down to the Maximum Throttle Point of Pm. If the package temperature is still not below the Throttle Threshold Temperature, TM1 is invoked.

35.4.4.3 Clock Modulation (Intel® Thermal Monitor 1)

Intel® Thermal Monitor 1 (TM1) is activated as a secondary control mechanism when TM2 (see Section 35.4.4.2, "Core Frequency/Voltage Reduction (Intel® Thermal Monitor 2)") is unsuccessful at reducing processor temperatures, and the SoC is still over temperature. TM1 cannot be disabled by the Operating System software.

Figure 35-1. TM1 Use of Processor Clock Duty Cycle Modulation

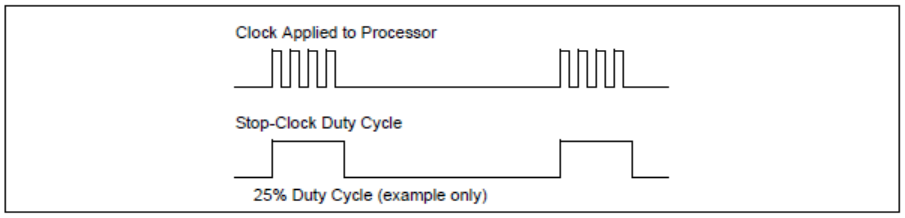


Figure 14-21. Processor Modulation Through Stop-Clock Mechanism

TM1 works by periodically stopping (gating) the processor clock for a period of time (microseconds), preventing all execution and reducing power. The "duty cycle" of TM1 refers to the percentage of time the clock is running and not gated off.

When TM1 throttling is invoked, the core clock duty-cycle modulation starts stepping down from the clock's maximum "on" duty-cycle ratio until the clock's minimum "on" duty-cycle ratio (1/8) is reached. During pre-throttle, it steps-down the "on" duty cycle 12.5% once every 8 ms. During throttle it does this more often: once every 1 ms.

When TM1 throttling is reduced during throttle the clock "on" duty-cycle ratio goes back to every 8 ms (pre-throttle). If throttling is further reduced, the "on duty-cycle ratio returns to the maximum.

The stop-clock time duration is clock-frequency dependent. Higher frequencies stop the clock for shorter time durations for a given "on" duty-cycle configuration.

35.4.4.4 Software-Controlled Clock Modulation

This mechanism permits Operating Systems (OS) to implement power-management policies that reduce power consumption. This is in addition to the reduction offered by automatic thermal monitoring mechanisms TM2 and TM1.

The SoC supports the "Extension of the software controlled clock modulation" described in sub-section 14.7 of Volume 3 of the *Intel® 64 and IA-32 Architectures Software Developer's Manual*.

The mechanism is accessible to software through the IA32_CLOCK_MODULATION register (MSR 19Ah).

The register fields are:

— THROTTLE_ACTIVE (bit 4) enables the Software-Controlled Processor Clock Modulation mechanism.

— T_STATE_REQ (bits 3:0), when THROTTLE_ACTIVE is set, this 4-bit field selects the clock modulation duty cycle in 6.25% increments.

For multiple processor cores in a physical package, each processor core can modulate to a programmed duty cycle independently.

This mechanism functions much like the automatic hardware-controlled TM1 mechanism in reducing SoC power consumption.

35.4.5 THERMTRIP_N

The THERMTRIP_N feature provides SoC protection in the event of a catastrophic thermal event, i.e., temperatures are reached which may damage the SoC silicon. The temperature to trigger THERMTRIP_N is set at the factory and is higher than the temperature that invokes TM2 and TM1. The protection is accomplished by reducing SoC power as fast as possible. Dynamic power is largely eliminated by the SoC within microseconds by means of shutting down as many internal clocks as possible.

The SoC asynchronously signals the platform with PMU_SLP_S45_N indicating the SoC has entered the low power S5 state and logs an error in the SoC circuitry in the RTC Power Well.

Note: THERMTRIP is one of the Power Button Override Events. These events cause an unconditional transition to the S5 state and the Power Button Override (PWRBTNOR_STS) bit of the Power Management 1 Enables and Status (PM1_EN_STS) register is set by the SoC and saved by the SoC RTC power well. This bit is not affected by hard resets via CF9h I/O writes and is not reset by the internal POWERGOOD reset. The THERMTRIP indication is preserved through power failures. This bit is still asserted when the global SCI_EN is set to '1' in which case a System Control Interrupt (SCI) will be generated. The BIOS or SCI handler software clears this bit by writing a 1 to it.

The SoC also indicates a THERMTRIP_N event via the active-low THERMTRIP_N output signal pin. When CLTT is enabled for Memory Thermal Management (Section 35.5.1.2, "Close Loop Thermal Throttling (CLTT)"), the MEM_THERMTRIP can be configured to generate the THERMTRIP event.

Overall power to the SoC is eliminated fully once the VRs on the motherboard are shut down within milliseconds. The platform must remove all power (except battery power) to the SoC within 500 ms of a THERMTRIP_N signal assertion. A cold reset is required to recover from a THERMTRIP_N event.

35.4.6 Thermal Status and Interrupts

35.4.6.1 Thermal Status and Interrupts — Processor

The Operating System (OS) can manage both Core processor and SoC package thermal conditions natively without relying on BIOS or other system board components. The SoC can be programmed to generate interrupts for various thermal events. These interrupts are typically handled either by the OS or System Management Mode (SMM) software.

The thermal interrupt Delivery Mode, Interrupt Mask and the Interrupt Vector for this interrupt, can be programmed through the Thermal Monitor Register entry in the local core's APIC Local Vector Table (LVT), or optional modes may be configured that allow the thermal interrupt notification to be routed to a master core for processing. For more information on the APIC LVT Thermal Monitor Register, see Volume 3, Section 10.5 of the *Intel® 64 and IA-32 Architectures Software Developer's Manual*.

There are two programmable thermal thresholds per core plus two per package. There is no direct mapping to the number of DTS instances, as interrupts are implemented by the SoC power management mechanism, not in the DTS.

The per-core Thermal Status and per-core Thermal Interrupt use the temperature value of the DTS located near the shared L2-cache. This is important to know when accessing the Model-Specific Registers (MSRs).

The SoC Package Thermal Status and Interrupt uses the Maximum Package Temperature value which is defined as the maximum temperature of the 13 SoC DTSes. All DTS sensors are simultaneously monitored for catastrophic thermal conditions. If such a condition occurs, the CPU will perform an immediate shutdown.

THERM_INTERRUPT
IA32_THERM_INTERRUPT (MSR 19Bh)

There are six processor Thermal Interrupts that can be enabled:

- HIGH_TEMP_INT_ENABLE - This bit allows software to enable thermal interrupt delivery upon the rising edge of the Thermal Monitor Status of this core as it crosses the Thermal Monitor Activation Temperature to a temperature above it.
- LOW_TEMP_INT_ENABLE - This bit allows software to enable thermal interrupt delivery upon the falling edge of the Thermal Monitor Status of this core as it crosses the Thermal Monitor Activation Temperature to a temperature below it.
- PROCHOT_INT_ENABLE - Assertion or de-assertion of PROCHOT_N.
- OUT_OF_SPEC_INT_ENABLE - This bit allows software to enable thermal interrupt delivery upon observation that the processor is operating out of its thermal specification. This interrupt is designed as an early warning of thermal runaway in the silicon and shutdown is recommended.
- THRESHOLD_1_INT_ENABLE - This bit allows software to enable thermal interrupt delivery upon observation of any rising or falling detection of the core temperature crossing the THRESHOLD_1_REL_TEMP temperature.
- THRESHOLD_2_INT_ENABLE - This bit allows software to enable thermal interrupt delivery upon observation of any rising or falling detection of the core temperature crossing the THRESHOLD_2_REL_TEMP temperature.
- THRESHOLD_1_REL_TEMP and THRESHOLD_2_REL_TEMP - Each is a seven-bit value that represents a negative offset from the reference maximum junction temperature defined in TEMPERATURE_TARGET.REF_TEMP. These temperature thresholds are compared against the corresponding Thermal Status Relative Temperature reading for this core.

THERM_STATUS
IA32_THERM_STATUS (MSR 19Ch)
Per-Core DTS Temperature Read Data (PECI RdPkgConfig(), Index 9)

This register is typically used to inspect the thermal status of a specific core as well as to discover the sources of core thermal-interrupt events. There are seven types of processor Thermal Status each with a sticky monitor bit (Log bit) to let software know if a new status bit has been posted. Each status bit is Read-Only.

- POWER_LIMITATION_STATUS - Indicates that the processors are performance limited due to power constraints.
- THERMAL_MONITOR_STATUS - Indicates that any of the Thermal Monitors has tripped and that the SoC processors are currently thermally throttling.
- PROCHOT_STATUS - Indicates PROCHOT is currently asserted.
- OUT_OF_SPEC_STATUS - Indicates that a processor is operating out of its thermal specification.
- THRESHOLD1_STATUS - Indicates that the actual processor temperature is currently higher than or equal to the value set in Thermal Threshold 1.
- THRESHOLD2_STATUS - Indicates that the actual processor temperature is currently higher than or equal to the value set in Thermal Threshold 2.
- TEMPERATURE - Processor DTS temperature (DTS near shared L2 cache) reported as a negative offset in °C from the factory-set TEMPERATURE_TARGET.REF_TEMP.

Note: Because TEMPERATURE and the two temperature threshold values shown above are defined as negative offsets, a higher number means a lower temperature.

Note: The GetTemp() command via the PECI SMBus returns a temperature value which is different than the TEMPERATURE field shown here. See Chapter 30, “GetTemp()” and Chapter 30, “DTS Temperature Data.”

35.4.6.2 Thermal Status and Interrupts — SoC Package

The SoC package thermal status and interrupt are reported the same way the core status and interrupt is reported. See Section 35.4.6.1, "Thermal Status and Interrupts — Processor." The Thermal Monitor Register entry in the core APIC Local Vector Table (LVT) for package-scoped interrupts is identical to entries of core-scoped interrupts. Software is responsible for determining the origin of the interrupt.

PACKAGE_THERM_INTERRUPT
IA32_PACKAGE_THERM_INTERRUPT (MSR 1B2h)

There are seven package-level Thermal Interrupts that can be enabled:

- POWER_INT_ENABLE - When this bit is set a thermal interrupt will be sent upon detection of a rising-edge assertion of the Power Limit Status bit in the IA32_PACKAGE_THERM_STATUS (MSR 1B1h) register.
- HIGH_TEMP_INT_ENABLE - Rising edge of the Thermal Monitor Status of the virtual maximum package temperature.
- LOW_TEMP_INT_ENABLE - Falling edge of the Thermal Monitor Status of the virtual maximum package temperature.
- OUT_OF_SPEC_INT_ENABLE - This bit allows software to enable thermal interrupt delivery upon observation that a processor or un-core DTS is operating out of its thermal specification. This interrupt is designed as an early warning of thermal runaway in the silicon and shutdown is recommended.
- PROCHOT_INT_ENABLE - Assertion or de-assertion of PROCHOT_N.
- THRESHOLD_1_INT_ENABLE - This bit allows software to enable thermal interrupt delivery upon observation of any rising or falling detection of the SoC package maximum temperature crossing the Threshold 1 temperature.
- THRESHOLD_2_INT_ENABLE - This bit allows software to enable thermal interrupt delivery upon observation of any rising or falling detection of the SoC package maximum temperature crossing the Threshold 2 temperature.

Threshold 1 and Threshold 2 are 7-bit values in IA32_PACKAGE_THERM_INTERRUPT that represent a negative offset from the reference maximum junction temperature defined in MSR_TEMPERATURE_TARGET.REF_TEMP. These temperature thresholds are compared against the corresponding Thermal Status Relative Temperature reading for the "virtual package max temperature." The possible interrupts and associated enable bis are mentioned above.

PACKAGE_THERM_STATUS

IA32_PACKAGE_THERM_STATUS (MSR 1B1h)
Package Thermal Status Data (PECI RdPkgConfig(), Index 20)

There are seven types of package-level Thermal Status, each with a sticky monitor bit (Log bit) to let software know if a new status bit has been posted. Each status bit is Read-Only.

- POWER_LIMITATION_STATUS - Indicates that the processors are performance limited due to power constraints.
- THERMAL_MONITOR_STATUS - Indicates that any of the package Thermal Monitors has tripped and that the package is currently thermally throttling.
- PROCHOT_STATUS - Indicates PROCHOT is currently asserted.
- OUT_OF_SPEC_STATUS - Indicates that a processor is operating out of its thermal specification.
- THRESHOLD1_STATUS - Indicates that the actual package temperature is currently higher than or equal to the value set in Thermal Threshold 1.
- THRESHOLD2_STATUS - Indicates that the actual package temperature is currently higher than or equal to the value set in Thermal Threshold 2.
- TEMPERATURE - Package temperature reported as a negative offset in °C from the factory-set TEMPERATURE_TARGET.REF_TEMP.

Note: Because TEMPERATURE and the two temperature thresholds shown above are defined as negative offsets, a higher number means a lower temperature.

35.5 Memory Thermal Management (MTM)

The SoC can provide thermal management of the DIMM components of the platform board that are connected to the SoC Memory Controllers. After the SoC memory subsystem has been setup by BIOS the BIOS needs to indicate how memory thermals are to be managed by the SoC. The SoC-internal registers written by BIOS at boot time must remain statically configured.

Note: The Memory Thermal Management registers are not accessible as SoC Model-Specific Registers (MSRs).

35.5.1 Thermal Throttling

Three Memory Thermal Management (MTM) methods are available: Open Loop Thermal Throttling (OLTT); Closed Loop Thermal Throttling (CLTT); CLTT Pass-Through. The MTM mode is selected via the P_CR_MEM_THERM_CTRL_0_0_0_MCHBAR register. Memory throttling can be configured to generate an SMI.

There are no Model-Specific Registers (MSRs) associated with MTM.

The SoC does not support the reading of the DRAM device's Mode Register 4 (MR4). Because of this, memory subsystems that do not read the DIMM temperature sensors via Serial Presence Detect (SPD) and the SoC Legacy SMBus, or have the ability to provide the SoC the DIMM temperature via the PECI SMBus, need to use OLTT for Memory Thermal Management.

The SoC has a dedicated Memory Hot input indicator pin, named MEMHOT_N, to allow the platform to indicate when memory thermal throttling is required. It is a fast-responding event to the SoC power-management control, approximately 100 µs. The amount of thermal throttling can be programmed during the setup at boot time.

The SoC response to the MEMHOT_N input signal pin can be enabled and configured in the P_CR_MEMHOT_THERM_CONFIG_0_0_0_MCHBAR register. The three bandwidth throttle levels of P_CR_MEM_THERM_THROT_CONFIG_0_0_0_MCHBAR are used in the P_CR_MEM_THERM_CTRL_0_0_0_MCHBAR register.

The state of the MEMHOT_N signal pin is provided in the P_CR_MEMHOT_THERM_STATUS_0_0_0_MCHBAR register.

35.5.1.1 Open Loop Thermal Throttling (OLTT)

The OLTT mode provides a fixed level of memory thermal throttle via a bandwidth limit mechanism programmed by BIOS during boot time. The bandwidth throttle level used is programmable in the two-bit OLTT_THROT_LVL field of the P_CR_MEM_THERM_CTRL_0_0_0_MCHBAR register. The throttle level values are the same as the values programmed for CLTT mode and explained in Section 35.5.1.3, "CLTT Throttle Levels." The throttle-level values can be altered at runtime.

The memory bandwidth limits work by limiting the number of memory reads/writes within a given interval. BIOS programs the bandwidth percentage and the SoC converts that bandwidth percentage into the number of reads and writes for a particular interval.

Note: Even though the P_CR_MEM_THERM_THROT_CONFIG_0_0_0_MCHBAR register is associated with CLTT mode, its three throttling level values are used for OLTT mode and for the MEMHOT_N input signal pin mechanism.

35.5.1.2 Close Loop Thermal Throttling (CLTT)

In CLTT mode the SoC provides three configurable levels of memory bandwidth throttling that are triggered in response to temperature data sent from the DIMMs to the SoC. The SoC can be programmed to use one of two ways to receive this temperature data:

- Normal: DIMM temperature readings are periodically obtained via SPD by the SoC using the Legacy SMBus interface.
- Pass-through: Temperature readings are provided to the SoC from the platform Baseboard Management Controller (BMC) via the SMBus PECI interface.

DIMM temperature data are provided by a “Temperature Sensor On DIMM” (TSOD).

For normal CLTT the temperature readings are provided directly from the Legacy SMBus interface.

For pass-through CLTT the BMC is required to acquire TSOD temperature measurements from the DIMM or obtain DIMM temperature information by some other means or mechanism, and write the measurements to the SoC using PECI commands via the SoC PECI SMBus. The BMC, or other means is expected to update the DIMM temperature values via the PECI SMBus every 5-10 ms.

The SoC supports dynamic CLTT which allows the platform to make run-time updates to MTM configuration values that adjusts the temperature dynamic range in response to memory subsystem environmental changes detected by the platform.

35.5.1.3 CLTT Throttle Levels

In CLTT normal mode the MTM throttle level is based on the threshold crossed by the highest, adjusted DIMM temperature value the SoC receives via SPD over the SoC Legacy SMBus interface. The throttle levels are programmed by BIOS in the P_CR_MEM_THERM_THROT_CONFIG_0_0_0_MCHBAR register:

00 = no throttle
01 = THRT_MID (default is 0% throttled)
10 = THRT_HI (default is 90% throttled)
11 = THRT_CRIT (default is 99% throttled)

The % values of throttling are interpreted as shown in the following example:

If the value is 25% throttled then 75% of the maximum memory bandwidth will be available.

In CLTT mode, the throttle-level values in the P_CR_MEM_THERM_THROT_CONFIG_0_0_0_MCHBAR register can be adjusted after BIOS boot time.

The memory bandwidth limits work by limiting the number of memory reads/writes within a given interval. BIOS programs the bandwidth percentage, and the SoC converts that bandwidth percentage into the number of reads and writes for a particular interval.

35.5.1.4 CLTT Temperature Threshold Values

In CLTT mode, there are three programmable temperature threshold values which trigger MTM responses. They are programmed by BIOS. Their names, location in the P_CR_MEM_THERM_TEMP_CONFIG_0_0_0_MCHBAR register, default values, and MTM response are:

- TEMP_LO (bit 1), TSOD = 84 °C, Initiate 2x refresh rate and THRT_MID.
- TEMP_MID (bit 10), TSOD= 93 °C, Initiate THRT_HI, continue 2x refresh rate.
- TEMP_HI (bit 11), TSOD = 100 °C, Initiate THRT_CRIT, continue 2x refresh rate, assert MEM_THERMTRIP.

The P_CR_MEM_THERM_TEMP_CONFIG_0_0_0_MCHBAR register also contains a three-bit TEMP_THROT_HYST field that provides a programmable, negative-going threshold hysteresis value that is programmable by BIOS.

To account for offsets between DIMM hot-spot temperature and the reported TSOD values, per-DIMM temperature offsets can be programmed in the P_CR_MEM_THERM_TEMP_OFST_0_0_0_MCHBAR register.

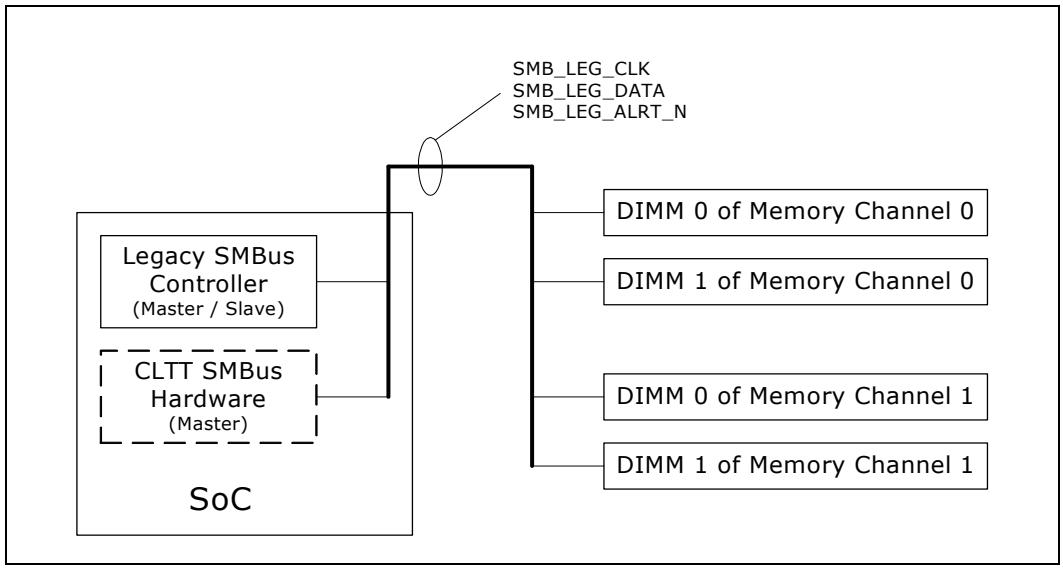
Note: It is the responsibility of the platform to ensure that current, accurate temperature data is provided. The SoC Memory Thermal Management algorithms have no mechanism to detect if temperature data is stale or invalid. If TSODs malfunction, it is recommended that the platform utilize the MEMHOT_N input signal pin as a backup mechanism to control DIMM temperature.

The offset temperature values in the P_CR_MEM_THERM_TEMP_OFST_0_0_0_MCHBAR register and the throttle thresholds in the P_CR_MEM_THERM_TEMP_CONFIG_0_0_0_MCHBAR register that the SoC uses to create variable MTM throttle thresholds, can be based on system information such as airflow. These registers can be written by the BMC via the PECI WrEndPointConfig() command over the SoC PECI SMBus interface. This PECI command writes the appropriate register located within the SoC sideband registers. See Chapter 30, "WrEndPointConfig()."

35.5.1.5 Legacy SMBus Used for Accessing Information for CLTT

When in CLTT Normal mode, the SoC uses a special internal connection to the Legacy SMBus interface as an SMBus Master to acquire DIMM-related CLTT information from the system DIMMs. See Figure 35-2, "CLTT SMBus Connection to DIMMs."

Figure 35-2. CLTT SMBus Connection to DIMMs



SoC commands to the SMBus slave (one of the installed DIMMs) are initiated through SoC-internal messages to the SoC SMBus interface hardware by the SoC power-management controller. As an SMBus bus master, the CLTT-based SoC SMBus hardware issues the particular transaction on the SMBus. Only a limited set of SMBus transactions are supported for this purpose.

Once the transaction over the SMBus interface has been completed, the SoC SMBus hardware places the data in SoC-internal registers and responds to the SoC power-management controller that the SMBus operation has been completed.

The CLTT SMBus operations do not support the SMBus Alert option (SMB_LEG_ALRT_N signal). The Legacy SMBus controller does support SMBus Alert.

The Temperature Sensor On DIMM (TSOD) information acquired by this SMBus mechanism is available to software and BIOS through the SoC Sideband registers:

- C0TEMPSTS0 - DIMM 0 of Memory Channel 0
- C0TEMPSTS1 - DIMM 1 of Memory Channel 0
- C1TEMPSTS0 - DIMM 0 of Memory Channel 1
- C1TEMPSTS1 - DIMM 1 of Memory Channel 1

35.5.1.6 PECI SMBus Used for Accessing Information for CLTT

When in CLTT Pass-Through mode, the BMC or some other external management agent writes temperature measurements periodically to the SoC using a PECI write command via the SoC PECI SMBus interface. See Chapter 30, "DRAM Rank Temperature Write (Index = 18)" in the PECI SMBus chapter.

35.5.2 MEM_THERMTRIP

Internal to the SoC, MEM_THERMTRIP indicates that a DIMM temperature has exceeded the highest temperature threshold and memory is considered to be in a state of catastrophic thermal failure. The MEM_THERMTRIP state is determined by the Memory Thermal Management (MTM) throttling algorithm but initiates an additional configurable response that can trigger a processor THERMTRIP_N event.

The SoC-generated P_CR_MEM_THERM_STATUS_0_0_0_MCHBAR register bits are used by the SoC to generate and internal MEM_THERMTRIP indication.

If configured to do so, MEM_THERMTRIP can generate the SoC-internal THERMTRIP event indication and assert the SoC THERMTRIP_N signal pin. This is configured by the EN_MEMTRIP field of the P_CR_MEM_THERM_STATUS_0_0_0_MCHBAR register.

35.5.3 Thermal Status and Interrupts

While the SoC does not generate interrupts for Memory Thermal Management events, it does provide various CLTT and customer-configurable status and logs available through the P_CR_MEM_THERM_INT_STATUS_0_0_0_MCHBAR register:

- "CLTT SMBus is hung" status and log
- "CLTT SMBus is reset" status and log
- DIMM temperature is at or above the point to cause SoC memory throttling. Status and log.

Each log is one bit that is set to 1 the first time the particular status is set and remains sticky until cleared via software or by reset.

When in CLTT mode, either in Normal or Pass-Through mode, the SoC provides thermal status and a log for each of the DIMMs of the memory subsystem. These can be read by software in the P_CR_MEM_THERM_STATUS_0_0_0_MCHBAR register. Each DIMM has a two-bit field:

- 00 = Memory temperature < TEMP_LO
- 01 = TEMP_LO ≤ Memory temperature < TEMP_MID
- 10 = TEMP_MID ≤ Memory temperature < TEMP_HI
- 11 = Memory temperature ≥ TEMP_HI (MEM_THERMTRIP condition)

For TEMP_HI, TEMP_MID, and TEMP_LO, see Section 35.5.1.4, "CLTT Temperature Threshold Values."

Each DIMM has a two-bit Thermal Throttle log in the P_CR_MEM_THERM_STATUS_0_0_0_MCHBAR register. The logs are sticky bits set to highest throttle level achieved (same encoding as P_CR_MEM_THERM_THROT_CONFIG_0_0_0_MCHBAR register fields) when CLTT memory throttling is initiated by the particular DIMM. The logs remain set until cleared when software writes a 1 value to the log field or the SoC is reset. For more information about memory throttle levels, see Section 35.5.1.3, "CLTT Throttle Levels."

35.6 Run Average Power Limit (RAPL)

RAPL provides platform software the ability to monitor, control, and get notifications about SoC power consumption. The SoC provides RAPL for managing platform thermals.

The Thermal Design Power (TDP) specified for the SoC represents the maximum amount of power the platform cooling system required to dissipate in order for the SoC to operate. But it is possible for the processor to consume more than the TDP power for a short period of time without it being thermally significant. The primary use case of RAPL is providing software the ability of setting per-package, hardware-enforced, power limits. In addition, RAPL provides a very accurate power meter capable of supporting core and non-core devices.

The SoC supports two RAPL domains of power rationing:

- SoC Package domain which includes everything on the die
- DRAM domain which includes the directly-attached DRAM

The PKG_POWER_LIMIT and DRAM_POWER_LIMIT registers are used to configure which RAPL domain is to be enabled. Having both SoC Package RAPL and DRAM RAPL combined into a single RAPL limit called Super-Domain RAPL is not supported.

The SoC supports external access to the RAPL domain interfaces three ways:

- Non-architectural Model-Specific Registers (MSRs) using RDMSR and WRMSR instructions
- Memory-Mapped I/O (MMIO) registers in Host Root Space
- By the BMC, or equivalent, through PECI SMBus commands to access the RAPL registers.

The following set of capabilities are supported through the interfaces:

- Power Limit - Specify power limit, time window, and other controls. RAPL provides a way to set short-term and longer-term averaging windows for Power Limits. Platform thermal control software is advised to dynamically update the RAPL Power Limits and the averaging windows to meet SoC system requirements.
- Energy Status -Access the power-metering interface providing energy consumption information.
- Perf Status - Access to information on the performance effects (regression) due to Power Limits. It is defined as a duration metric that measures the Power Limit effect in the respective domain.
- Power Info - Interface providing information on the range of parameters for a given domain.

The SoC provides the Read-Only RAPL_POWER_UNIT register for software to discover the basic units of time, energy and power defined for SoC Package RAPL and DRAM RAPL.

For additional details about RAPL, see Volume 3, Chapter 14 of the *Intel® 64 and IA-32 Architectures Software Developer's Manual*.

35.6.1 RAPL — SoC Package

For SoC Package RAPL, both Power Limit 1 (PL1) and PL2 Power/Time tuples are supported.

PL1 is typically used for long thermal-time constants, defaulting to Thermal Design Power (TDP) Power/Time. PL2 is typically programmed for a shorter Power/Time tuple to manage Dynamic Turbo where power is allowed to exceed TDP for short, thermal time constants, thus allowing burst performance. To mitigate power, the SoC manages internal power-management mechanisms if required to meet the power tuples. Both PL1 and PL2 have their own control systems which operate concurrently.

The SoC also provides what is called “Fast RAPL” which is a special duty-cycle protection to control excursions past PL2 to limit the duty-cycle of power transients greater than PL2. The purpose of this protection is to avoid thermal over-design of the platform Voltage Regulator (VR). The protection allows the guaranteed VR duty-cycle specifications to be greater than PL2 alone would allow. The SoC uses the SVID interface to read the output current of VCC, VNN and VCCRAM VRs to calculate power to provide this special protection. The VR needs to be capable of being sampled at 100-µs intervals for output current as well using its internal A/D converter to provide a 200-µs anti-aliasing filter prior to digital conversion.

The registers associated with SoC Package RAPL are accessible by RDMSR/WRMSR instructions, through Memory-Mapped I/O (MMIO), or using PECI commands via the PECI SMBus interface. In some cases the PECI information has a different format:

RAPL_POWER_UNIT

MSR_RAPL_POWER_UNIT (MSR 606h)
P_CR_PACKAGE_POWER_SKU_UNIT_0_0_0_MCHBAR (MMIO MCHBAR + 7068h)
Package Power SKU Unit Read Data (PECI RdPkgConfig(), Index 30)

This register defines the units for calculating all SoC Package RAPL and DRAM RAPL RAPL power, current, energy, resistance and timing parameters.

PKG_POWER_LIMIT

MSR_PKG_POWER_LIMIT (MSR 610h)
P_CR_PACKAGE_RAPL_LIMIT_0_0_0_MCHBAR (MMIO MCHBAR + 70A8h)
Package Power Limits for Multiple Turbo Modes (PECI WrPkgConfig(), Index 26)
Package Power Limits for Multiple Turbo Modes (PECI RdPkgConfig(), Index 27)

This register allows software to define power limitation for the SoC Package RAPL domain. PL1 and PL2 power limits and associated time windows can be specified. The values are expressed in units defined by the RAPL_POWER_UNIT register.

PKG_ENERGY_STATUS

MSR_PKG_ENERGY_STATUS (MSR 611h)
P_CR_PACKAGE_ENERGY_STATUS_0_0_0_MCHBAR (MMIO MCHBAR + 706Ch)
Accumulated Energy Status Read Data (PECI RdPkgConfig(), Index 03)

This 32-bit Read-Only register contains an accumulated value of the energy consumed by the entire SoC package. The value of this register is updated by the SoC approximately once every 1 ms. The units are proportional to Joules and are defined by the RAPL_POWER_UNIT register. The SoC uses this value for PL1 and PL2 RAPL algorithms.

PKG_PERF_STATUS

MSR_PKG_PERF_STATUS (MSR 613h)
P_CR_PACKAGE_RAPL_PERF_STATUS_0_0_0_MCHBAR (MMIO MCHBAR + 7050h)
Package Power Limit Performance Status Read Data (PECI RdPkgConfig(), Index 08)

Measures the time that any core in the SoC package is performance-throttled below what the Operating System requested and below the core's base frequency because of Power Limits PL1 or PL2. The time value is expressed in units defined by the RAPL_POWER_UNIT register.

PKG_POWER_INFO

MSR_PKG_POWER_INFO (MSR 614h)
P_CR_PACKAGE_POWER_SKU_0_0_0_MCHBAR (MMIO MCHBAR + 70A0h)
Package Power SKU Read Data (PECI RdPkgConfig(), Index 28 and 29)

This register provides the factory-defined limits for the configurable PL1 and PL2 SoC Package Power Limits and Time Windows in the PKG_POWER_LIMIT register. The values are expressed in units defined by the RAPL_POWER_UNIT register.

PP0_ENERGY_STATUS

MSR_PP0_ENERGY_STATUS (MSR 639h)
P_CR_PRIMARY_PLANE_ENERGY_STATUS_0_0_0_MCHBAR (MMIO MCHBAR + 705Ch)

This register contains an accumulated value of the energy consumed in the primary power plane across all cores of the SoC. The value is expressed in units defined by the RAPL_POWER_UNIT register. The value of this register is updated approximately once every 1 ms.

PP1_ENERGY_STATUS

MSR_PP1_ENERGY_STATUS (MSR 641h)
P_CR_SECONDARY_PLANE_ENERGY_STATUS_0_0_0_MCHBAR (MMIO MCHBAR + 7060h)

This register contains an accumulated value of the energy consumed in the secondary power plane across all cores of the SoC. The value is expressed in units defined by the RAPL_POWER_UNIT register. The value of this register is updated approximately once every 1 ms.

TURBO_ACTIVATION_RATIO

MSR_TURBO_ACTIVATION_RATIO (MSR 64Ch)

P_CR_TURBO_ACTIVATION_RATIO_0_0_0_MCHBAR (MMIO MCHBAR + 70F0h)

ACPI P-T Notify Write Data (PECI WrPkgConfig(), Index 33)
ACPI P-T Notify Read Data (PECI RdPkgConfig(), Index 33)

This register is used by software to configure the Performance State (P-State) at which Turbo activates. Turbo activation starts at clock ratios above the eight-bit Turbo Activation Ratio Threshold (MAX_NON_TURBO_RATIO field) configured in this register. This feature is disabled when the threshold is set to zero.

IA_PERF_LIMIT_REASONS

MSR_IA_PERF_LIMIT_REASONS (MSR 64Fh)

P_CR_IA_PERF_LIMIT_REASONS_0_0_0_MCHBAR (MMIO MCHBAR + 70B0h)

This register reports reasons for performance limitations on the processor cores. Status bits are an instantaneous indication of an active constraint. Log bits indicate that a constraint was enforced since the log bit was last cleared.

CORE_PERF_LIMIT_REASONS

MSR_CORE_PERF_LIMIT_REASONS (MSR 690h)

Indicator of Frequency Clipping in Processor Cores (R/W). Frequency refers to processor core frequency. I see 11 status fields and 11 associated logs.

PL3_CONTROL

Official MSR Name is TBD (MSR 615h)
P_CR_PL3_CONTROL (Sideband Port P47h, offset 4790h)

Control Power Limit 3 (PL3) and Power Limit 4 (PL4) using this register.

This limit control is physically different from the same control in the IA core MSR space.

— PL3 is designed to clamp peak sustained power to levels supported by the battery or input power supply and as such manage lifetime degradation of that power delivery element. With PL3, peak power excursions above the limit are allowed so long as they do not exceed the configured duty cycle constraint in this register.

— PL4 is designed to clamp peak instantaneous power to levels below the max supported by the battery or input power supply. These clamps are implemented a priori and the SoC is guaranteed to constrain itself below the PL4 limit always.

35.6.2 RAPL — DRAM

Note: DRAM RAPL is not supported when Non-Volatile DIMMs (NVDIMMs) are used.

Note: Both Memory Thermal Management (MTM) and RAPL are capable of throttling memory bandwidth. When both MTM and RAPL are in effect, the memory bandwidth limit will be set to the more restrictive limit between MTM and RAPL. When either condition (MTM or RAPL) is removed, the remaining memory bandwidth limit will be invoked until conditions change such that a different limit, or no limit, is required.

DRAM RAPL is a SoC feature that manages the DRAM power budget to a programmable value. The SoC only supports DRAM RAPL Power Level 1 (PL1) Limit Power/Time tuple. RAPL manages the DRAM domain power which comprises the summation of all the DIMMs populated on the two Memory Controller channels: Two DIMMs per channel; Two ranks per DIMM. To keep within the set Power/Window values, the DIMM power consumption is mitigated by the SoC controlling the memory-access bandwidth by using bandwidth throttling.

The registers associated with DRAM RAPL are accessible by either RDMSR/WRMSR instructions, through Memory-Mapped I/O (MMIO), or using PECI commands via the PECI SMBus interface. In some cases the PECI information has a different format:

DRAM_POWER_LIMIT
MSR_DRAM_POWER_LIMIT (MSR 618h)
P_CR_DDR_RAPL_LIMIT_0_0_0_MCHBAR (MMIO MCHBAR + 7040h)
DRAM Power Limit Data (PECI RdPkgConfig()/WrPkgConfig(), Index 34)

This register is written by the platform software and read by the SoC approximately once every 1 ms. It contains the DRAM Power Limit enable, the DRAM Power Limit value, and the Time Window value. The values are expressed in units defined by the RAPL_POWER_UNIT register.

DRAM_ENERGY_STATUS
MSR_DRAM_ENERGY_STATUS (MSR 619h)
P_CR_DDR_ENERGY_STATUS_0_0_0_MCHBAR (MMIO MCHBAR + 7048h)
Accumulated DRAM Energy Read Data (PECI RdPkgConfig(), Index 04)

This 32-bit Read-Only register contains the Joules of energy consumed by all DIMMs. The value of this register is updated by the SoC approximately once every 1 ms. The units are proportional to Joules and are defined by the RAPL_POWER_UNIT register.

DRAM_PERF_STATUS
MSR_DRAM_PERF_STATUS (MSR 61Bh)
P_CR_DDR_RAPL_PERF_STATUS_0_0_0_MCHBAR (MMIO MCHBAR + 704Ch)
DRAM Power Limit Performance Status Read Data (PECI RdPkgConfig(), Index 38)

Memory RAPL performance throttling counter. This counter accumulates time that any channel in the memory controller is bandwidth-throttled due to memory RAPL constraints. The time values are expressed in units defined by the RAPL_POWER_UNIT register.

DRAM_POWER_INFO
MSR_DRAM_POWER_INFO (MSR 61Ch)
P_CR_DRAM_POWER_INFO_0_0_0_MCHBAR (MMIO MCHBAR + 7130h)
DRAM Power Info Read Data (PECI RdPkgConfig(), Index 35 and 36)

Various DRAM RAPL power and time-window information.

35.7 Inverse Temperature Dependence (ITD)

Inverse Temperature Dependence (ITD) is a SoC feature where internal circuitry requests the platform board VRs to increase SoC voltages at cold temperatures to compensate for timing-path slowdown when cold. The ITD feature is provided on all SoC product SKUs for the VCC, VCCSRAM, and VNN voltage groups. The temperature values and voltage offsets are set at the Intel factory.

Note: ITD is also known as Low Temperature Effect Compensation (LTEC).

35.8 Platform Voltage Regulator Thermal Alert

The SoC supports VR_THERMALERT. The SoC polls the SVID status message for the bit that indicates the platform board Voltage Regulator (VR) is approaching its maximum operating temperature. The VR asserts the VR_THERMALERT bit in the SVID message at a VR temperature lower than the one it uses to assert its VR-hot# pin. The pin is used to drive the SoC PROCHOT_N signal pin if PROCHOT_N is configured as a SoC input.

In response to the VR_THERMALERT indication the SoC reduces all cores in Turbo Mode (P0 Performance State) directly to the P1 Performance State, and clamps it there, but does not throttle (lower the SoC voltage and clock-frequency) any further. Cores in lower P-states remain in those states. No interrupt is generated.

Turbo is then disallowed until the VR_THERMALERT condition is removed.

The VR_THERMALERT signaling is disabled when VR_THERM_ALERT_DISABLE, bit 24 of the MSR_POWER_CTL register (MSR 1FCh), is set to 1.

There are three ways software can access the access the VR_THERMALERT status:

PERF_LIMIT_REASONS

MSR_IA_PERF_LIMIT_REASONS (MSR 64Fh)

P_CR_IA_PERF_LIMIT_REASONS_0_0_0_MCHBAR (MMIO MCHBAR + 70B0h)

The fields are:

VR_THERMALERT_STATUS (bit 10) - Read-Only. Clock frequency is limited due to a VR thermal excursion.

VR_THERMALERT_LOG (bit 26) - Logged indication that frequency was clamped due to a VR thermal excursion. This bit is set by the SoC and can be cleared by software.

35.9 Model-Specific Registers (MSR)

Table 35-4. MSR Registers

MSR Address (hex)	Register Name	Register Name (Basic Name)
199	IA32_PERF_CTL	PERF_CTL
19A	IA32_CLOCK_MODULATION	CLOCK_MODULATION
19B	IA32_THERM_INTERRUPT	THERM_INTERRUPT
19C	IA32_THERM_STATUS	THERM_STATUS
1A0	IA32_MISC_ENABLE	MISC_ENABLE
1A1	MSR_PLATFORM_BRV	PLATFORM_BRV
1A2	MSR_TEMPERATURE_TARGET	TEMPERATURE_TARGET
1AA	MSR_MISC_PWR_MGMT	MISC_PWR_MGMT
1B1	IA32_PACKAGE_THERM_STATUS	PACKAGE_THERM_STATUS
1B2	IA32_PACKAGE_THERM_INTERRUPT	PACKAGE_THERM_INTERRUPT
1FC	MSR_POWER_CTL	POWER_CTL
606	MSR_RAPL_POWER_UNIT	RAPL_POWER_UNIT
610	MSR_PKG_POWER_LIMIT	PKG_POWER_LIMIT
611	MSR_PKG_ENERGY_STATUS	PKG_ENERGY_STATUS
613	MSR_PKG_PERF_STATUS	PKG_PERF_STATUS
614	MSR_PKG_POWER_INFO	PKG_POWER_INFO
618	MSR_DRAM_POWER_LIMIT	DRAM_POWER_LIMIT
619	MSR_DRAM_ENERGY_STATUS	DRAM_ENERGY_STATUS
61B	MSR_DRAM_PERF_STATUS	DRAM_PERF_STATUS
61C	MSR_DRAM_POWER_INFO	DRAM_POWER_INFO
64F	MSR_IA_PERF_LIMIT_REASONS	IA_PERF_LIMIT_REASONS

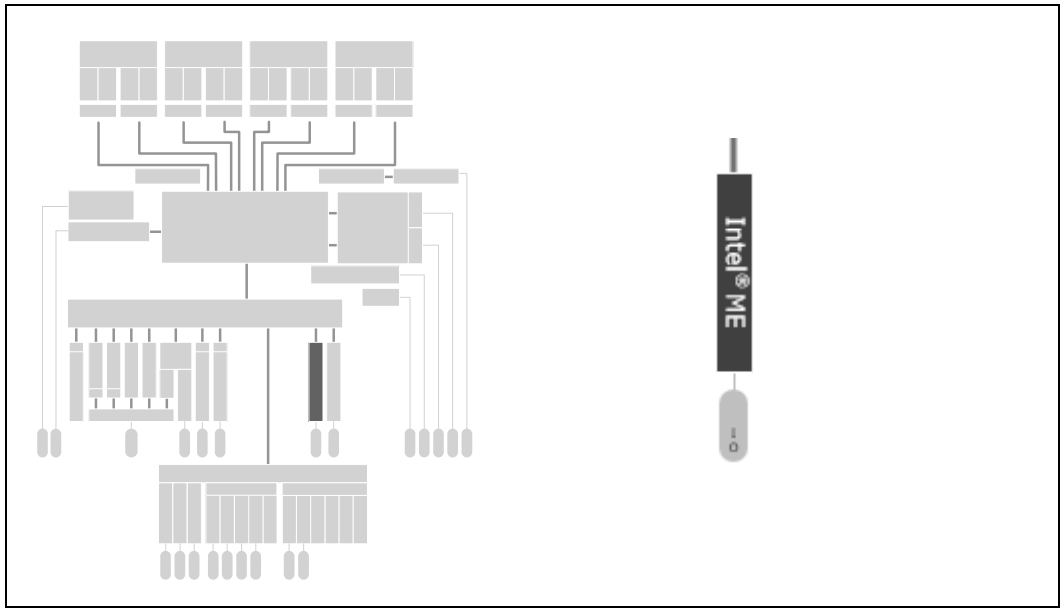
§ §

36 System Management

The Intel® Management Engine (Intel® ME) is a subsystem that provides the system management. The Intel® ME firmware is provided and developed by Intel.

The Innovation Engine (IE) is an optional feature through which SoC customers can create a custom system-management subsystem. See Chapter 37, "Innovation Engine."

Figure 36-1. What is Covered in This Chapter



36.1 Signal Descriptions

The Intel® ME has three SMBus controllers that tie into the SoC SMBus interfaces. The signals for these SMBus controllers are shown in Chapter 27, "System Management Bus (SMBus) Controller - Overview."

For additional signal information, including whether a signal is assigned to shared-function pin or can be used as a Customer GPIO signals see Chapter 39, "Signal Pin Names and Signal MUXing." The Direction/Type column of Table 36-1, "Signal Names and Descriptions" is interpreted as follows:

- I = Input signal. The SoC has receiver circuit.
- O-OD = Open-Drain Output. SoC output circuit uses an open-drain driver.

Table 36-1. Signal Names and Descriptions

Signal Names	Direction	Shared	Description
SMB_ME_SMT0_CLK	I,O-OD	Yes	**SMBus Clock:** (SMBCLK) for System Management Transport 0 of the Intel® ME
SMB_ME_SMT0_DATA	I,O-OD	Yes	**SMBus Data:** (SMBDAT) for System Management Transport 0 of the Intel® ME.
SMB_ME_SMT0_ALRT_N	I,O-OD	Yes	**SMBus Alert:** (SMBALERT#) for System Management Transport 0 of the Intel® ME.
SMB_ME_SMT1_CLK	I,O-OD	Yes	**SMBus Clock:** (SMBCLK) for System Management Transport 1 of the Intel® ME.
SMB_ME_SMT1_DATA	I,O-OD	Yes	**SMBus Data:** (SMBDAT) for System Management Transport 1 of the Intel® ME.
SMB_ME_SMT2_CLK	I,O-OD	Yes	**SMBus Clock:** (SMBCLK) for System Management Transport 2 of the Intel® ME.
SMB_ME_SMT2_DATA	I,O-OD	Yes	**SMBus Data:** (SMBDAT) for System Management Transport 2 of the Intel® ME.

36.2 Intel® ME and Intel Server Platform Services Firmware

36.2.1 Key Properties of Intel® ME

- Connectivity:
  - Delivery of advanced I/O functions.
- Security:
  - More secure and isolated execution.
- Modularity and Partitioning:
  - OSV, VMM and SW independence.
- Power:
  - When in S0, the SoC can be configured by BIOS to completely shut down Intel® ME power.
  - The SoC has a power-disable policy that can be set to shut down the Intel® ME and all its contents are lost.
  - Advanced functions in low power S5 operation.
  - OS independent PM and thermal heuristics.

36.2.2 Intel® ME Requirements

The following list of components composes the Intel® ME hardware infrastructure.

- The Intel® ME is the general purpose controller that resides in the SoC. It operates in parallel to, and is resource-isolated from, the host processor.
- The SPI flash device stores Intel Server Platform Services (SPS) FW code that is executed by the Intel® ME for its operations. The SoC controls the flash device through the SPI interface and internal logic.
- The Intel® ME interacts with the SoC BIOS/UEFI to make sure the Flexible I/O Adapter (FIA) and associated High-Speed I/O (HSIO) lanes are properly configured. See Chapter 10, “Flexible I/O Adapter (FIA) Overview.”

36.3 Register Map

The Intel® ME is accessible through the Host Root Space as shown in Figure 36-2, "Register Map."

This device has no Sideband Registers.

§ §

37 Innovation Engine

The Innovation Engine (IE) is an optional, complete, embedded engine intended to enable SoC customers to provide their own custom system management. This chapter provides a brief overview of the IE. It is reserved for system-builder code, not for Intel firmware since Intel supplies IE hardware only. IE activation is not required for normal system operation.

Note: Intel recommends that customers perform the IE manufacturing lock step described, even if not using the Innovation Engine, to eliminate any in field security risk.

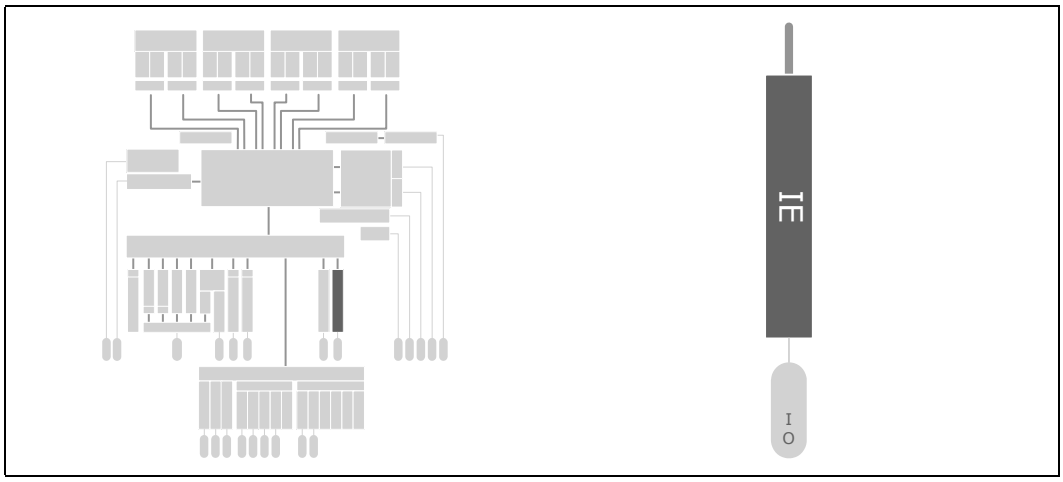
IE is a completely optional feature, and is disabled by default in the silicon. It can be enabled by system builders and OEMs to run signed firmware created by the system builder or a third party software vendor. IE is not like the Intel® Management Engine (Intel® ME) where Intel provides the HW plus a complete FW solution. Intel only provides IE hardware (along with collateral and tools enabling). If the IE is configured to be enabled, the IE ROM brings up the system in real mode and then hands off to the system builder's firmware to continue.

To use IE, the OEM enables the IE in Soft Straps, in the SPI descriptor region (using the Flash Image Tool).

Customers should be resourced and able to develop their own firmware for the IE, or work with a third party vendor to develop IE firmware solutions.

Note: If the OEM has enabled IE Verified Boot, then the IE will always be started, and the IE Soft Strap Enable/Disable is ignored.

Figure 37-1. What is Covered in This Chapter



The signal descriptions are shown in Table 37-1, "Signal Names and Descriptions." For additional signal information, including whether a signal is assigned to shared-function pin or can be used as a Customer GPIO signals see Section 39.1, "Directory of Signal Names and Pin Names."

The Direction/Type column of Table 37-1, "Signal Names and Descriptions" is interpreted as follows:

- I = Input signal. The SoC has receiver circuit.
- O = Output signal. The SoC has driver circuit.
- O-OD = Open-Drain Output. SoC output circuit uses an open-drain driver.

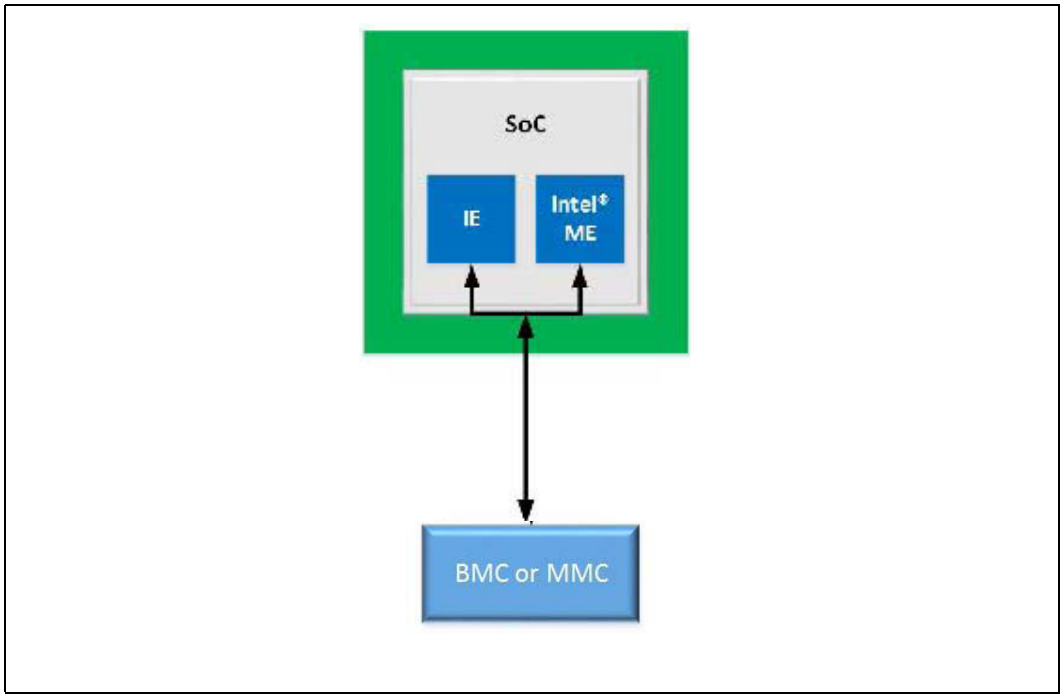
Table 37-1. Signal Names and Descriptions

Signal Names	Direction	Shared	Description
UART_IE_RXD	I		UART_IE Receive Data: Active-high input. See Table 18-2, "Signal Names and Descriptions" on page 566.
UART_IE_TXD	O		UART_IE Transmit Data: Active-high output. See Table 18-2, "Signal Names and Descriptions" on page 566.
UART_IE_CTS	I		UART_IE Clear to Send: Active-high input. See Table 18-2, "Signal Names and Descriptions" on page 566.
UART_IE_RTS	O		UART_IE Request to Send: Active-high output. See Table 18-2, "Signal Names and Descriptions" on page 566.
SMB_IE_SMT0_CLK	I,O-OD	Yes	**SMBus Clock:** (SMBCLK) for System Management Transport 0 of the IE.
SMB_IE_SMT0_DATA	I,O-OD	Yes	**SMBus Data:** (SMBDAT) for System Management Transport 0 of the IE.
SMB_IE_SMT0_ALRT_N	I,O-OD	Yes	**SMBus Alert:** (SMBALERT#) for System Management Transport 0 of the IE.
SMB_IE_SMT1_CLK	I,O-OD	Yes	**SMBus Clock:** (SMBCLK) for System Management Transport 1 of the IE.
SMB_IE_SMT1_DATA	I,O-OD	Yes	**SMBus Data:** (SMBDAT) for System Management Transport 1 of the IE.
SMB_IE_SMT2_CLK	I,O-OD	Yes	**SMBus Clock:** (SMBCLK) for System Management Transport 2 of the IE.
SMB_IE_SMT2_DATA	I,O-OD	Yes	**SMBus Data:** (SMBDAT) for System Management Transport 2 of the IE.
FAN_PWM[3:0]	O-OD	Yes	**Fan Pulse-Width Modulation (PWM):** These open-drain output signals produce a PWM duty cycle that is used for fan-speed control. When controlling a 3-wire-controlled fan, this signal controls a power transistor that, in turn, controls power to the fan. When controlling a 4-wire-controlled fan, this signal is connected to the "Control" signal on the fan. The polarity of this signal is programmable. The fan controller is part of the IE.
FAN_TACH[3:0]	I	Yes	**Fan Tachometer:** This pulsed input signal is used by the IE to measure fan speed. This signal is connected to the "Sense" signal on the fan. This signal is driven by the fan in an open-drain configuration.

37.1 Feature Summary

- IE is an embedded sub-system in the SoC:
  - Includes a small, 32-bit IA core.
- Reserved for system-builder's code, not for Intel firmware:
  - Intel supplies IE hardware only.
  - IE code is cryptographically signed by the system builder using a private key.
  - IE code that doesn't authenticate with the system builder public key will not load.
- IE activation is not required for normal system operation:
  - Completely optional feature.
- Power:
  - When in S0, the SoC can be configured by BIOS to completely shut down the IE power.
  - The SoC has a power-disable policy that can be set to shut down the IE and all its contents are lost.

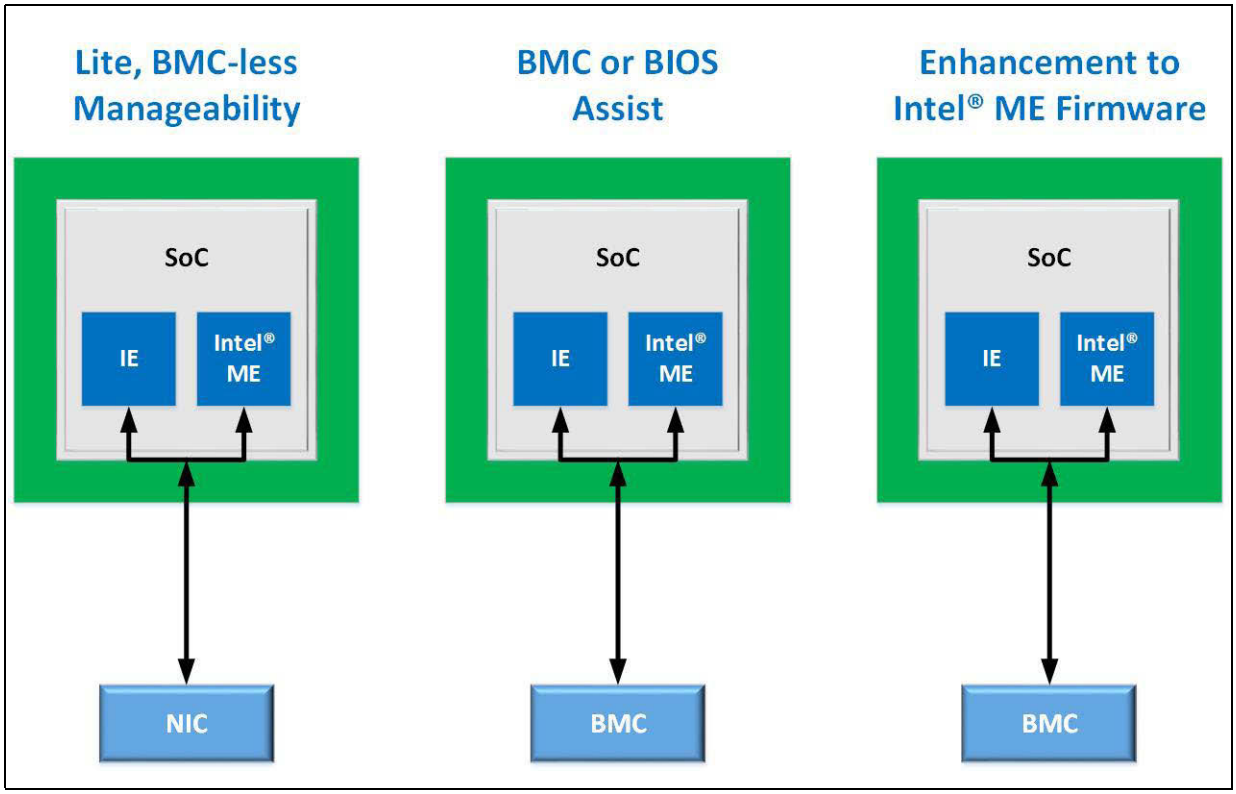
Figure 37-2. Intel Atom® Processor C3000 Product Family Embedded Sub-System



37.2 Sample IE Usages

- Lightweight Management/BMC-less platforms. IE takes role of BMC and can do lightweight BMC functions including log SEL events, serial over LAN, basic sensor monitoring. Can also do an IPMI 2.0 compliant implementation.
- BMC or BIOS assist – Enterprise segment likes video redirection and higher BMC capabilities. BMC can respond to network packets and present a nice GUI over network, offload tight loop code to IE
- Enhancements to Intel® ME FW – to optimize or customize for specific usages.
- IE Verified Boot – IE code signed by the system builder is authenticated. The system builder code then authenticates the BIOS image.

Figure 37-3. Sample IE Usages



37.3 Architectural Overview

The Innovation Engine (IE) is an integrated SoC subsystem that is based on a custom Intel® Architecture Processor. This subsystem has dedicated general purpose DMA and Crypto accelerator engines. The PCI Express Message Transport subsystem is comprised of I/O devices, based on standard PCI architecture. This subsystem is connected to the rest of the system via internal fabric, if required. This subsystem maintains its own system space and exposes some of its interface to the Host space, as described below.

The IE ROM holds boot code and is responsible for initialization of the IE subsystem. The subsystem authenticates the OEM IE image and initiates the start up process. SPI Flash is used to store OEM IE images.

IE Memory Subsystem – (SRAM and ROM) – completely independent from Host and Intel® ME.

- IE SRAM – 1.4MB available for IE to run FW.
- IE ROM – 128KB of dedicated ROM embedded in silicon (hard-coded, read-only).

The shared SPI Flash – dedicated IE region for customer FW storage (4-8MB). Regions are defined for all masters accessing the shared SPI flash. Those regions can be as big as the overall SPI flash size (so full flexibility). But in most cases, would be a 4-8MB range allocated for IE in typical platforms.

Depending on what application is running, SPI flash could be used for storing additional data, or holding a small image that could be exposed through IE. We also support paging from SPI flash. Code and data can be bigger than on-die SRAM and can page out of SPI flash. This paging would be managed as a kernel function (have to support page fault handling in kernel), plus DMA driver to load a 4K page from SPI flash into SRAM.

The devices exposed by the IE subsystem to the Host Root Space are:

- HECI (1, 2 and 3) – These functions define the mechanism for host software and IE firmware to communicate. This device exposes three PCI functions to the host during PCI bus enumeration. The message format is OEM dependent and communication between host and IE subsystem takes place via circular buffers and control/status registers. This function supports host MSI, SMI and SCI# interrupt generation mechanisms.
- PTIO – This exposes two PCI functions to the host.
  - Keyboard Text (KT) – The Innovation Engine provides a Keyboard Transfer (KT) interface to redirect virtual keyboard input to the host. The interface is visible to the Innovation Engine as a PCI device.
  - IDE-Redirect (IDER) - The IE provides an IDE-redirection mechanism that performs the basic functions. It provides the capability to boot from a remote IDE drive.

Some of Host Root Space devices are also part of IE root space. A partial list of devices parts of the IE root space are:

- HECI devices/clients
  - HECI specification uses term “HECI client” to refer to software endpoints that send and receive messages via HECI.
  - Examples of Host HECI clients are System BIOS module, OS Services & Applications that interface with HECI.
  - FW HECI Clients are IE FW modules that use HECI to communicate with Host Clients.
  - Each endpoint supports many connections established by the clients at the same time as each client is identified by a unique address assigned while establishing the connection. Both host client address and FW client address are contained by the HECI message header to enable dispatch of the message. HECI Protocol doesn't enforce any restrictions on the format of the message data between HECI Clients.

Note: IE HSUART and IE SMT are exclusively IE Root Space devices. They are not discovered or addressable in Host Root Space.

- HSUART - UART primary fabric interface only supports single channel and 32-bit data/addressing. The register space is not mapped into the prefetchable address space, and the primary target interface does not support more than one DWord access per I/O fabric request.

  In the downstream direction, a register access of more than one DWord could result in undefined behavior and will be treated as an unsupported request. Any unsupported downstream Posted request will be dropped and unsupported, Non-Posted request will be completed with the appropriate unsuccessful completion status. The first 2 DWs of each UART CSR are IO as well as memory mapped. The UART I/O fabric is a PCI device and supports configuration read and write requests at the primary target.

  In the upstream direction, the primary interface makes 32-bit memory read and write requests for DMA transfers. UART primary fabric also supports single MSI vector per function which will be sent as a Posted Write request in upstream direction.

  UART only supports 64 bytes I/O fabric Max Payload Size and Max Read Request Size.

  All upstream memory requests will be split at 64byte block boundary. As no read request will cross the 64bytes RCB, the UART I/O fabric accepts only single completions for each upstream memory read request.

- SMBus Message Transport (SMT): There are three SMBus devices in the IE root space. The SMT provides a mechanism to the IE for sending OOB manageability messages to managed devices or management controllers over SMBus.

37.4 Inter-Processor Communication (IPC)

The IE communicates with the Intel® Management Engine using an IPC Interface over the sideband fabric. The IPC Interface is intended for transferring small messages directly between cores. IPC messages from the IE core are routed to the sideband fabric.

37.4.1 IE Root Space Devices

In addition to the devices that are visible to both the Host address space and the IE root space, the following devices are only visible internally to the IE root space.

37.4.1.1 PECI

In-band PECI is restricted to Intel® ME. PECI over SMBus is also supported through an external wire.

37.4.1.2 SMBus Message Transport (SMT)

The SoC provides a number of virtual SMBus interfaces that are visible to the IE Root Space as PCI devices. Externally, these interfaces conform to the I2C specification as physical SMBus devices. The configuration of the SMT interfaces is determined at manufacturing time, and can be configured to the Intel® Management Engine (Intel® ME), or the Innovation Engine. The requirements vary depending on which Intel® ME features are desired by the system builder.

Bus speed can be configured by Soft Straps to run I2C Fast-mode Plus (Fm+) timings (up to 1MHz) if all devices on the segment support the higher speed.

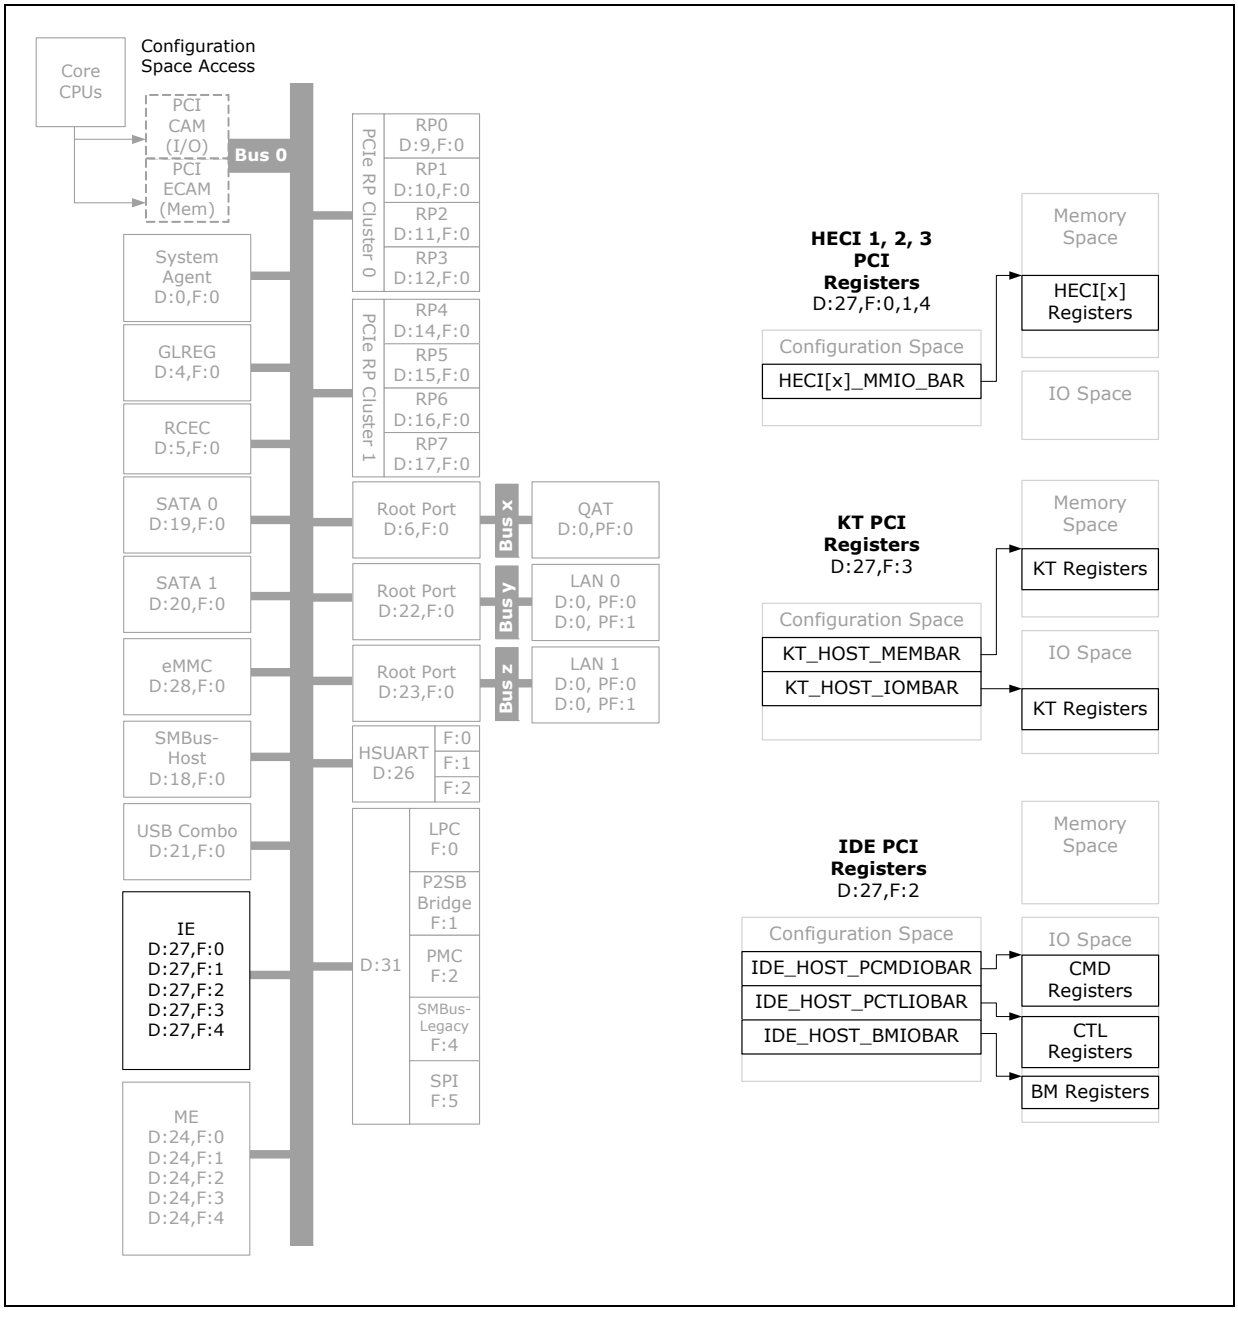
37.4.1.3 UART

The Innovation Engine supports a serial UART for communication between the Innovation Engine and an external interface, such as an OEM Chassis Management Module. Additionally, this interface can be used for debug purposes.

37.5 Register Map

The IE is accessible through the Host Root Space as shown in Figure 37-4, "Register Map."

Figure 37-4. Register Map



37.5.1 Host Root Space - IE HECI1

37.5.1.1 PCI Configuration and Capabilities

37.5.5.4 Sideband Registers

This device has no Sideband Registers.

§ §

38 JTAG and Debug Ports

This chapter describes the SoC debug mechanisms available to customers. This includes the Intel® Direct Connect Interface (Intel® DCI) and Joint Test Action Group (JTAG) interface.

Figure 38-1. What is Covered in This Chapter

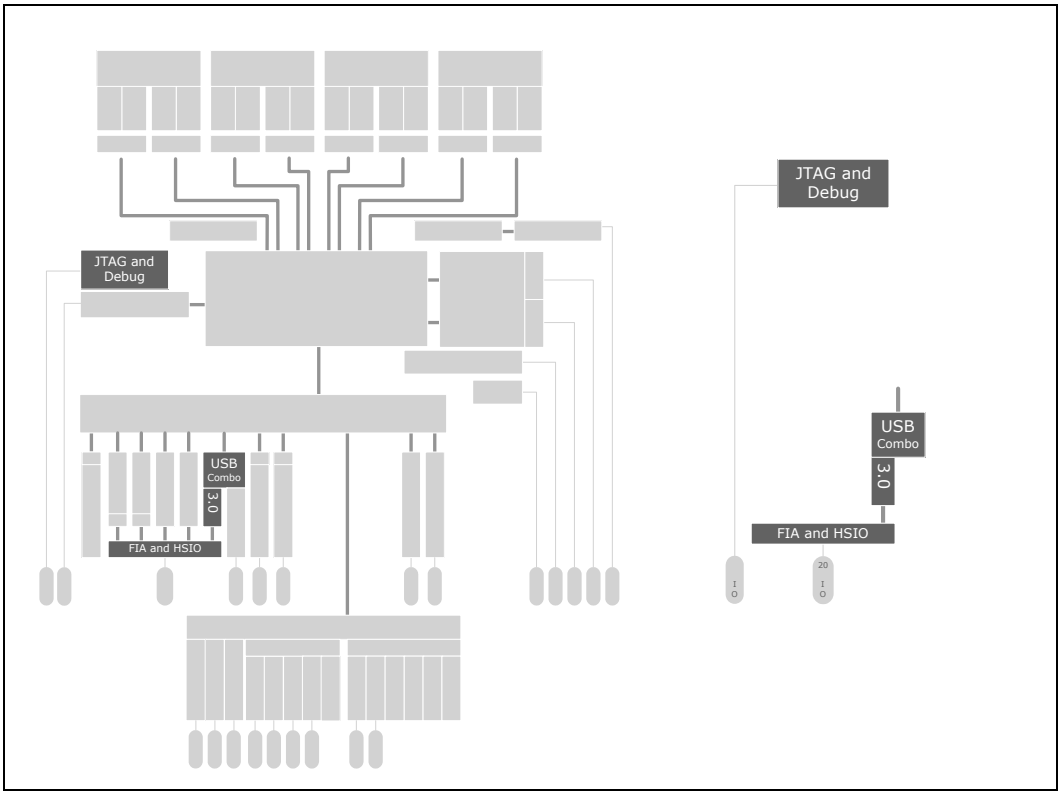

Table 38-1. References

Reference	Revision	Date	Document Title
IEEE Std 1149.1*-2001	-	June 14, 2001	*IEEE Standard Test Access Port and Boundary-Scan Architecture*, 1149.1-2001
IEEE Std 1149.7*-2009	-	Dec. 9, 2009	*IEEE Standard for Reduced-Pin and Enhanced-Functionality Test Access Port and Boundary-Scan Architecture*, 1149.7-2009
USB xHCI Specification	1.1	Dec. 20, 2013	*eXtensible Host Controller Interface for Universal Serial Bus (xHCI) Specification*, Revision 1.1

38.1 Signal Descriptions

The signal descriptions are shown in Table 38-2, "Signal Names and Descriptions." For additional signal information, including whether a signal is assigned to shared-function pin or can be used as a Customer GPIO signals see Chapter 39, "Signal Pin Names and Signal MUXing." The Direction/Type column of Table 38-2, "Signal Names and Descriptions" is interpreted as follows:

- I = Input signal. The SoC has receiver circuit.
- O = Output signal. The SoC has driver circuit.
- O-OD = Open-Drain Output. SoC output circuit uses an open-drain driver.

Table 38-2. Signal Names and Descriptions

Signal Names	Direction	Shared	Description
CTBTRIGINOUT	I,O	Yes	**CTB Trigger:** Signals for triggering an external logic analyzer based on internal SoC events.
CTBTRIGOUT	O	Yes	
CX_PRDY_N	O-OD	Yes	**Debug Port Signals:** For connection to a MIPI-60 header on the board.
CX_PREQ_N	I	Yes	
DFX_PORT[15:0]	O	Yes	
DFX_PORT_CLK[1:0]	O	Yes	
Test Access Port 0 - for Debug Port MIPI-60 Header on Board			
TCK	I	No	**Test Clock:** For debug-capable platform board, an external 51-Ω +/- 5% resistor tied to VSS is required. Otherwise, no external resistor is required.
TDI	I	No	**Test Data Input:** For debug-capable platform board, an external 51-Ω +/- 5% resistor tied to V1P05 is required. Otherwise, no external resistor is required.
TDO	I,O-OD	No	**Test Data Output:** For debug-capable platform board, an external 51-Ω +/- 5% resistor tied to V1P05 is required. Otherwise, no external resistor is required.
TMS	I	No	**Test Mode Select:** For debug-capable platform board, an external 51-Ω +/- 5% resistor tied to V1P05 is required. Otherwise, no external resistor is required.
TRST_N	I	No	**Test Reset:** For debug-capable platform board, an external resistor within the range of 500-Ω to 1kΩ tied to VSS is required. Otherwise, no external resistor is required.

38.2 Feature List

- Intel® Direct Connect Interface (Intel® DCI)
  - Debug Capability (DbC)
  - Intel® DCI-OOB (Out of Band)
- MIPI Parallel Trace Interface (PTI) capability
- IEEE Test Access Port (TAP)
- Intel® Trace Hub (Intel® TH)

38.3 Signals after Reset

- Following Power-up Reset, Warm Reset, and Cold Reset, all of the signals listed in Table 38-2, "Signal Names and Descriptions" are available at the SoC pins except for:
  - CTBTRIGINOUT
  - CTBTRIGOUT

To make these signals available, software must reconfigure these pins. The pin configuration mechanism is explained in Chapter 26, "Customer General-Purpose I/O (GPIO)."

38.4 Intel® Direct Connect Interface (Intel® DCI)

Intel® DCI provides a USB 3.0 path to debug features that can replace the traditional Test Access Port (TAP) pins and GPIO. Intel® DCI is being developed as an industry standard through the Mobile Industry Processor Interface Alliance (MIPI* Alliance) standards group. USB-hosted Intel® DCI provides TAP Access, Trace Extraction and Trace Capture.

Depending on the product SKU, lanes 19:16 are set to be either SATA or USB 3.0. For lane configurations, see Chapter 10, "Flexible I/O Adapter (FIA) Overview" For Intel® DCI to work correctly, the Intel® ME programs the Intel® DCI registers to indicate which lanes are SATA and which are USB 3.0 for the particular SoC product SKU.

Debug Capability (DbC) and Intel® DCI-OOB (Out of Band) are part of Intel® DCI. Any USB 3.0 lane (port) can be used for DbC or Intel® DCI-OOB. Two lanes are the maximum that can be used, only if they are in different modes (one lane for DbC and one lane for Intel® DCI-OOB) and used at different times. Intel® DCI does not support dual-mode (simultaneous) operation.

Whichever USB 3.0 port receives an external DbC request switches into the DbC mode and that is the only USB 3.0 port allowed to be in DbC mode until the port goes out of DbC mode.

38.4.1 Debug Capability (DbC)

The USB Debug Capability is a hosting transport that a debugger can use to control a platform. It is provided by the SoC USB eXtensible Host Controller (xHC). DbC is an optional USB functionality that enables low-level system debug over USB. The xHC Interface (xHCI) debugging capability provides a means of connecting two systems where one system is a Debug Host and the other a Debug Target (System Under Test).

The Host Memory Space range from 0xFED6_0000 to 0xFED6_0FFF is reserved for traffic targeting the SoC xHCI DbC subsystem. The Operating System must be informed that this address range is reserved. No other Memory-Mapped I/O (MMIO) in Host Memory Space must overlap with this address range. DbC is never a memory target. It always reads data from elsewhere and transfers in/out through the SoC USB 3.0 port.

See the section on DbC in the *eXtensible Host Controller Interface for Universal Serial Bus (xHCI), Revision 1.1*.

38.4.2 Intel® DCI-OOB (Out of Band)

Intel® DCI-OOB (Out of Band) is a hosting transport that a debugger can use to control a platform. Intel® DCI-OOB is supported by the SoC but requires a special USB 3.0 to Intel® DCI-OOB adapter. Intel® DCI-OOB gives the SoC customer the ability to do the same debug capabilities as DbC, but without the restriction of running it while the operating system (OS) is running on the target. It can run at any time, even during reset.

Intel® DCI-OOB has lower bandwidth when compared to DbC and only supports two of three main operations. Intel® DCI-OOB supports TAP control and Trace Streaming from Intel® Trace Hub, but it does not support memory extraction from main memory. Only DbC supports memory extraction from main memory.

38.5 Intel® Trace Hub

While Intel® Direct Connect Interface (Intel® DCI) is for closed chassis debug, the Intel® Trace Hub (Intel® TH) is an integrated PCI device for system tracing debug. It is discovered as Bus 0, Device 31 (decimal), Function 7.

The Intel® TH is an integrated trace analyzer and a set of silicon features allowing the user to perform system-level debug. It provides hardware-software co-debug. Intel is enabling third-party debug-software vendors to use the integrated Intel® TH in their products to unify software and hardware visibility and internal tracing capabilities.

An Intel® TH viewer is bundled with the Intel® System Studio product to allow the user one common viewer for hardware and software co-development.

The Intel® TH allows the user to trigger sources and capture the events into system memory (DRAM). The user can retrieve the events stored in memory for viewing with the software compiler debug tool (ISS) or retrieve the events from system memory through a third-party vendor JTAG tool using industry-standard MIPI (STPv2) interface and the Parallel Trace Interface (PTI).

38.6 On-Board Debug Port Connector

The SoC provides debug-related signals that can be accessed by a 60-pin Mobile Industry Processor Interface (MIPI) connector. MIPI calls this the Parallel Trace Interface (PTI).

39 Signal Pin Names and Signal MUXing

Warning: The information in this chapter is preliminary and is subject to change.

The SoC pin numbers, signal-pin names, and associated signals are listed in Table 39-1, "Signal Pin Name Directory - Sorted by Name" in alphabetical order by signal-pin name. Some pins shown in the table have multiple uses and are shared by multiple signals.

The voltage supply pins and voltage sense pins are in a separate list, Table 39-4, "Voltage Pins Sorted by Platform VR and SoC Voltage Group."

Table 39-6, "Directory of Signal and Voltage Pins - Sorted by Pin Number" lists all of the SoC pins sorted by pin number.

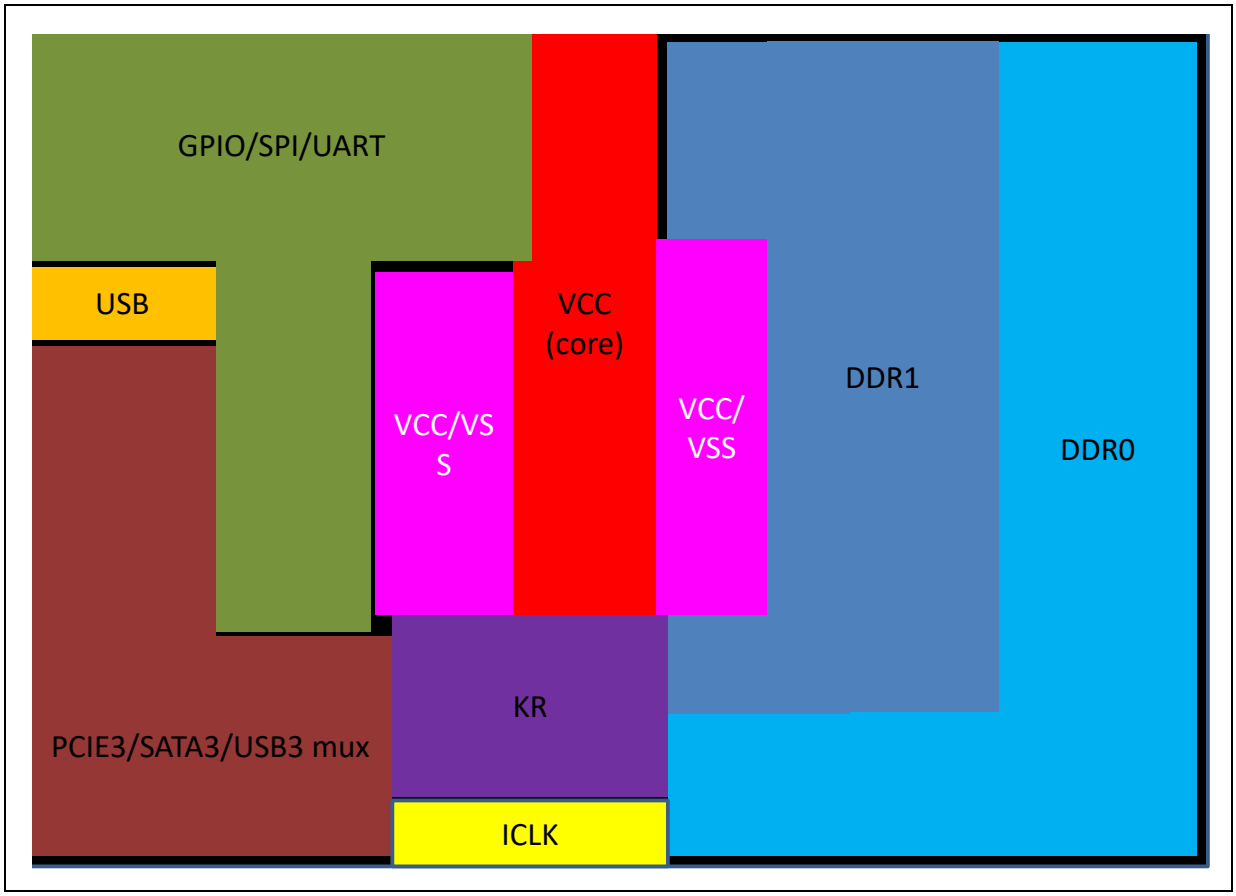
The Transmit and Receive differential interface signals for the lanes of the integrated PCI Express* Root Ports, SATA controller ports, and USB 3.0 ports share up to 20 High-Speed I/O (HSIO) lanes of the SoC. These are shown in Table 39-3, "Signals that Share the Twenty HSIO Lanes."

See also Chapter 10, "Flexible I/O Adapter (FIA) Overview."

Note: All signal descriptions are in the functional sections of this document. Readers of the electronic version of this document can navigate to the signal descriptions by clicking on the blue-lettered "D" in the Description column of the following tables:

- Table 39-1, "Signal Pin Name Directory - Sorted by Name"
- Table 39-3, "Signals that Share the Twenty HSIO Lanes."

Figure 39-1. Ball Quadrant Map



39.1 Directory of Signal Names and Pin Names

The table headers for Table 39-1, "Signal Pin Name Directory - Sorted by Name":

- Pin - SoC Pin/Ball matrix number
- Pin Name - Signal Name assigned to the SoC Pin/Ball
- Buffer Type - The type of driver/receiver circuitry used by the signals associated with the SoC Pin/Ball.
- V Group - SoC Voltage Group that supplies power to the driver/receiver circuitry.
- Pin States - Shows the possible states of what is connected to the pin:
  - Not Shared: The signal is not shared. None of the pin states listed below apply to the pin.
  - Strap Sampling: Shown if the pin serves as a Hard Strap during the SoC Hard-Strap pin sampling period. The sampling period is described in Section 4.1, "SoC Hard (Pin) Straps."
  - GPIO Mode: Also known as Func 0, is shown if the pin is capable of being programmed to be a Customer GPIO.
  - Default: The default internal signal connection to the pin after reset. In some cases, the pin's default setting is the Customer GPIO for the pin. Also, in some cases, The LAN Controller firmware can alter a signal-pin's default setting just before BIOS starts.
  - Func x: For pins that are shared by multiple signals, the Function number (Func 1, Func 2,..., Func 7) is programmable by BIOS. There can be up to seven different functional signals per shared pin, but in most cases, less than seven are used. The default pin-MUX setting is the pin's signal after a reset and is not necessarily Func 1. In some cases the default is a reset-configured Customer GPIO for the pin.
- Signal Name - The name of the signal internally connected to the pin for the given Pin State.
- Dir - The direction of the signal and whether the signal is an open-drain, tri-state, differential, or analog circuit:
  - I: SoC Input
  - O: SoC Output
  - O-OD: SoC Open-Drain Output
  - O-Tri: SoC Tri-State Output (logic 0, logic 1, and Hi-Z states)
  - Diff: Differential circuit
  - Analog: Not a digital-logic signal. Typically associated with pins for external compensation circuits or pins connected to internal thermal-sensing diodes.
  - SW: The PU/PD is programmed by BIOS. Typically, this is meant for Customer GPIOs.

- Internal PU/PD - Shown where the SoC has an internal Pull-Up (PU) resistor, Pull-Down (PD) resistor, or both, connected to the pin.
  - The Internal PU/PD shown for the default setting (As BIOS Starts state) remains intact even after BIOS alters the Func 1, Func 2, etc. setting.
  - The internal termination can be altered by BIOS which can program a new PU and/or PD for the pin buffer circuitry or remove all internal resistor connections to the pin.
  - For pins designated as Hard Straps, the SoC applies a special PU/PD arrangement that is active only during the strap-sensing period. After this sampling period, the default Internal PU/PD is applied to the pin.
- Signal Descriptions - Readers of the electronic version of this document can navigate to the chapter containing the signal description by clicking on the blue-colored "D" in the Description column of Table 39-1, "Signal Pin Name Directory - Sorted by Name."

39.1.1 Reserved (RSVD_xxx) Pins

A number of the SoC pins are reserved for Intel. Table 39-2 lists these pins and provides recommendations for the platform board design.

Table 39-2. Treatment of Reserved Pins (Sheet 1 of 2)

Pin	Pin Name	Dir	Shared-Function Pin?	Voltage Rail	SoC Has Internal Resistor	Board Design Recommendation
H35	RSVD_H35	O	No	n/a	n/a	Make no connection to this pin.
H42	RSVD_H42	O	No	n/a	n/a	Make no connection to this pin.
K35	RSVD_K35	O	No	n/a	n/a	Make no connection to this pin.
K42	RSVD_K42	O	No	n/a	n/a	Make no connection to this pin.
P33	RSVD_P33	I,O	No	n/a	n/a	Make no connection to this pin.
R31	RSVD_R31	O	No	n/a	n/a	Make no connection to this pin.
R50	RSVD_R50	I	No	VSS	No	Use Pull-Down Resistor with a value ranging from 0 to 1 kΩ, ±5%
R54	RSVD_R54	O, Diff	No	n/a	n/a	Make no connection to this pin.
R58	RSVD_R58	O, Diff	No	n/a	n/a	Make no connection to this pin.
T33	RSVD_T33	I,O	No	n/a	n/a	Make no connection to this pin.
T56	RSVD_T56	O, Diff	No	n/a	n/a	Make no connection to this pin.
T59	RSVD_T59	O, Diff	No	n/a	n/a	Make no connection to this pin.
U31	RSVD_U31	O	No	n/a	n/a	Make no connection to this pin.
W50	RSVD_W50	I,O	No	n/a	n/a	Make no connection to this pin.
Y48	RSVD_Y48	I,O	No	n/a	n/a	Make no connection to this pin.
AA29	RSVD_AA29	O	No	n/a	n/a	Make no connection to this pin.
AD58	RSVD_AD58	I,O	No	n/a	n/a	Make no connection to this pin.
AH20	RSVD_AH20	O, Diff	No	n/a	n/a	Make no connection to this pin.
AH54	RSVD_AH54	I	No	VSS	No	Use Pull-Down Resistor with a value ranging from 0 to 1 kΩ, ±5%
AJ22	RSVD_AJ22	O, Diff	No	n/a	n/a	Make no connection to this pin.
AK20	RSVD_AK20	O, Diff	No	n/a	n/a	Make no connection to this pin.
AL22	RSVD_AL22	O, Diff	No	n/a	n/a	Make no connection to this pin.
AL59	RSVD_AL59	I	No	VSS	No	Use Pull-Down Resistor with a value ranging from 0 to 1 kΩ, ±5%
AN20	RSVD_AN20	O	No	n/a	n/a	Make no connection to this pin.
AP22	RSVD_AP22	O	No	n/a	n/a	Make no connection to this pin.
AW30	RSVD_AW30	O	No	n/a	n/a	Make no connection to this pin.
BA24	RSVD_BA24	I,O	No	n/a	n/a	Make no connection to this pin.
BA26	RSVD_BA26	I,O	No	n/a	n/a	Make no connection to this pin.
BA29	RSVD_BA29	O	No	n/a	n/a	Make no connection to this pin.
BB29	RSVD_BB29	O	No	n/a	n/a	Make no connection to this pin.
BF38	RSVD_BF38	O	No	n/a	n/a	Make no connection to this pin.
BG40	RSVD_BG40	I	No	VSS	No	Use Pull-Down Resistor with a value ranging from 0 to 1 kΩ, ±5%

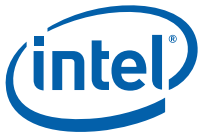

Table 39-2. Treatment of Reserved Pins (Sheet 2 of 2)

Pin	Pin Name	Dir	Shared-Function Pin?	Voltage Rail	SoC Has Internal Resistor	Board Design Recommendation
BH38	RSVD_BH38	I,O	No	n/a	n/a	Make no connection to this pin.
BK38	RSVD_BK38	I,O	No	n/a	n/a	Make no connection to this pin.
BY58	RSVD_BY58	O	Yes	V3P30	No	Can be programmed to be used as Customer GPIO[89] signal pin. If not used as a GPIO, make no connection to this pin.

39.2 Directory of Signals that Share the HSIO Pins

The High-Speed I/O (HSIO) signals listed in Table 39-1, "Signal Pin Name Directory - Sorted by Name" are shared with PCI Express*, SATA, and USB 3.0 signal pins.

Table 39-1, "Signal Pin Name Directory - Sorted by Name" lists these shared signal names.

The individual shared signals are described in the following chapters:

- Chapter 11, "PCI Express Root Ports (RP)"
- Chapter 12, "SATA Controller"
- Chapter 14, "USB Combo Controller"

Readers of the electronic version of this document can navigate to these description chapters by clicking on the blue-colored "D" in the Description column of Table 39-3, "Signals that Share the Twenty HSIO Lanes."

The association of the Signals in Table 39-3, "Signals that Share the Twenty HSIO Lanes" with the 20 HSIO Lanes, the supported shared patterns, and the HSIO configuration control, are described in Chapter 10, "Flexible I/O Adapter (FIA) Overview."

Table 39-3. Signals that Share the Twenty HSIO Lanes

Signal Name	Direction	Link to Signal Description
PCI Express Root Port Cluster 0 (RP0, RP1, RP2, RP3) - 8 Lanes		
PCIE0_RP_3_0_TX_DP[7:0] PCIE0_RP_3_0_TX_DN[7:0]	O, Differential	D
PCIE0_RP_3_0_RX_DP[7:0] PCIE0_RP_3_0_RX_DN[7:0]	I, Differential	D
PCI Express Root Port Cluster 1 (RP4, RP5, RP6, RP7) - 8 Lanes		
PCIE1_RP_7_4_TX_DP[7:0] PCIE1_RP_7_4_TX_DN[7:0]	O, Differential	D
PCIE1_RP_7_4_RX_DP[7:0] PCIE1_RP_7_4_RX_DN[7:0]	I, Differential	D
SATA0 Controller - 8 Lanes		
SATA0_TX_DP[7:0] SATA0_TX_DN[7:0]	O, Differential	D
SATA0_RX_DP[7:0] SATA0_RX_DN[7:0]	I, Differential	D
SATA1 Controller - 8 Lanes		
SATA1_TX_DP[7:0] SATA1_TX_DN[7:0]	O, Differential	D
SATA1_RX_DP[7:0] SATA1_RX_DN[7:0]	I, Differential	D
USB 3.0 Interface of the USB Combo Controller - 4 Lanes		
USB3_TX_DP[3:0] USB3_TX_DN[3:0]	O, Differential	D
USB3_RX_DP[3:0] USB3_RX_DN[3:0]	I, Differential	D

39.3 Directory of Voltage Supply and Sense Pin Names

Special on-board filtering is required.

Table 39-4. Voltage Pins Sorted by Platform VR and SoC Voltage Group (Sheet 1 of 3)

Platform VR	SoC Voltage Group	Pin Number(s)	Power Delivery Notes
Voltage Observe Output Pins	OBS_VCCRAMCPUSI1GT_MOD0	AA37	
	OBS_VCCCPUVIDSI0GT_MOD0	Y36	
	OBS_VCCCPUVIDSI0GT_MOD4	BA36	
	OBS_VCCBIUVIDSI0GT_MOD0	AA36	
Voltage Sense Output Pins	SENSE_VCCRAMCPU_S0	AW36	
	SENSE_VSSRAMCPU_S0	AW37	
	SENSE_VCCCPUVIDSI0	AE37

39.4 Directory of Rotation-Detect Pins

Table 39-5. Package Rotation (ROT) Pins

Pin Name	Pin Number(s)	Description
NC_ROT	A70	**Package Rotation (ROT) Detect**: For Intel use on special validation boards with a socket for the SoC package. NC_ROT has no connection inside the SoC package. VSS_ROT is connected to VSS power plane of the SoC package. For customer board designs, these pins can be left as no-connects or can be tied to VSS on the board.
VSS_ROT	CA3	

39.5 Directory of All Signal and Voltage Pins - Sorted by Pin Number

§ §

40 Signal Electrical and Timing Characteristics

This chapter is organized by signal interface. Each sub-chapter contains the interface DC, AC, and signal timing requirements and characteristics. Some of these requirements and characteristics are based on industry and Intel standards. When the SoC interface complies to a standard, the reader is referred to the standard for the requirements and characteristics. SoC exceptions to the standard, if any, are shown as well as any of the standard's optional interface characteristics as implemented by the SoC design.

Most of the information presented here is in Table and Figure form. In some cases, the reader is referred to one of the functional-description chapters where additional interface-related information is available.

40.1 DDR Memory Interface

The SoC supports up to two channels of DDR4, depending on configuration and product SKU.

40.1.1 DDR4

DDR4 SDRAM is the successor to DDR3 SDRAM. It was revealed at the Intel Developer Forum in San Francisco in 2008, samples were announced in early 2011. DDR4 is expected to reach mass market adoption around 2015.

Published in September 2012, the initial JEDEC DDR4 standard has been defined to provide higher performance, with improved reliability and reduced power, thereby representing a significant achievement relative to previous DRAM memory technologies.

The SoC DDR4 interface was designed to the DDR4 (JESD79-4) standard, and is available for free download from the JEDEC website.

The SoC supports DDR4 voltage of 1.2V. The DDR4 standard supports various options, see the Memory Controller Section 9.3, "Feature List" on page 353 of this document for the DDR4 options supported by this SoC.

This SoC was designed to the DDR4 standard, aside from the deviations listed below.

40.1.1.1 Deviations From The DDR4 Standard

While there are no known deviations, DDR4 is very sensitive to board layout, and only the configurations listed in the SoC Platform Design Guide have been simulated and validated by Intel. It is up to the customer to simulate and validate memory configurations not listed within the SoC Platform Design Guide.

40.1.1.2 Supplementary DDR4 Signals Not Covered By The DDR4 Standard

No supplementary signals.

40.2 PCI Express Root Port Interface

The SoC has up to 16 PCI Express 3.0 lanes, depending on configuration and product SKU, see the PCI Express Section 11.2, "Feature List" on page 372 section of this document for the PCI Express options supported by this SoC.

The SoC PCI Express interface was designed to the PCI Express 3.0 Base specification revision 3.0, made available in November 2010. In August 2007, PCI-SIG announced that PCI Express 3.0 would carry a bit rate of 8 gigatransfers per second (GT/s), and that it would be backward compatible with existing PCI Express implementations. New features for the PCI Express 3.0 specification include a number of optimizations for enhanced signaling and data integrity, including transmitter and receiver equalization, PLL improvements, clock data recovery, and channel enhancements for currently supported topologies.

PCI Express 3.0 upgrades the encoding scheme to 128b/130b from the previous 8b/10b encoding, reducing the overhead to approximately 1.54% ((130–128)/130), as opposed to the 20% overhead of PCI Express 2.0. This is achieved by a technique called "scrambling" that applies a known binary polynomial to a data stream in a feedback topology. Because the scrambling polynomial is known, the data can be recovered by running it through a feedback topology using the inverse polynomial. PCI Express 3.0's 8 GT/s bit rate effectively delivers 985 MB/s per lane, practically doubling the lane bandwidth relative to PCI Express 2.0.

On November 18, 2010, the PCI Special Interest Group officially published the finalized PCI Express 3.0 specification to its members to build devices based on this new version of PCI Express.

PCI Express 3.1 was released in 2014, making various tweaks to the published standard.

40.2.1 Deviations From The PCI Express 3.0 Standard

No known deviations.

40.2.2 Supplementary PCI Express Signals Not Covered By The PCI Express 3.0 Standard

No supplementary signals.

40.3 SATA Interface

The SoC has up to 16 SATA 3.1 lanes, depending on configuration and product SKU, see Chapter 12, "SATA Controller" of this document for the SATA options supported by this SoC.

The Serial ATA International Organization presented the draft specification of SATA 6 Gbit/s physical layer in July 2008, and ratified its physical layer specification on August 18, 2008. The SoC SATA interface was designed to this standard.

The full 3.0 standard was released on May 27, 2009. It runs with a native transfer rate of 6.0 Gbit/s, and taking 8b/10b encoding into account, the maximum uncoded transfer rate is 4.8 Gbit/s (600 MB/s). The theoretical burst throughput of SATA 6.0 Gbit/s is double that of SATA 2.0. SATA 3.1 was released July 2011, introducing new features, supporting the same transfer rate as SATA 3.0, both being backward compatible with SATA 2.0.

40.3.1 Deviations From The SATA 3.1 Standard

No known deviations.

40.3.2 Supplementary SATA Signals Not Covered By The SATA 3.1 Standard

No supplementary signals.

40.4 USB Interface

The SoC has up to four USB 3.0 ports, depending on configuration and product SKU, see the USB Section 14.2, "Feature List" on page 495 of this document for the USB options supported by this SoC.

The SoC USB interface was designed to the USB 3.0 standard released in November 2008. The standard defines a new SuperSpeed mode with a signaling speed of 5 Gbit/s and, due to encoding overhead, usable data rate of up to 4 Gbit/s (500 MB/s). A USB 3.0 port is usually colored blue, and is backwards compatible with USB 2.0.

While the SoC does NOT support USB 3.1, the Universal Serial Bus Revision 3.1 Specification was released July, 2013. The USB 3.1 specification introduces a faster transfer mode called "SuperSpeed USB 10 Gbps"; its logo features a SuperSpeed+ (stylized as SUPERSPEED+) caption. The USB 3.1 standard increases the signaling rate to 10 Gbit/s, double that of USB 3.0, and reduces line encoding overhead to just 3% by changing the encoding scheme to 128b/132b.

The USB 3.1 standard is backward compatible with USB 3.0, and USB 3.0 is backward compatible with USB 2.0.

A USB 3.0 port makes use of SuperSpeed PHYs, in addition to USB 2.0 PHYs. The SoC USB controller supports using just the USB 2.0 PHYs, to implement USB 2.0 ports, or combine the USB 2.0 PHYs with the SuperSpeed PHYs to implement a fully compliant USB 3.0 port; up to a total of four USB ports, depending on configuration and product SKU.

40.4.1 Deviations From The USB 3.0 Standard

No known deviations.

40.4.2 Supplementary USB Signals Not Covered By The USB 3.0 Standard

No supplementary signals.

40.4.3 USB 2.0 Standard

Refer to the *Universal Serial Bus Specification, Revision 2.0*.

40.5 SMBus Interface

The SoC has several SMBus controllers, depending on configuration and product SKU, see the SMBus Section 27.2, "Feature List" on page 709 of this document for the SMBus options supported by this SoC.

The SoC SMBus interface is designed to the SMBus 3.0 standard.

40.5.1 Deviations From The SMBus 2.0 Standard

SMBus/I2C Characteristics of the SDA and SCL Bus Do Not Meet Specification with minor deviation:

SMBus/I2C tSU;STA (set-up time for a repeated START condition) and tSU;STO (set-up time for STOP condition) show certain level violation for 100KHz speed, 400KHz speed and 1MHz Speed.

- For 100KHz tsusta min spec 4.7us vs 4.62 measured, 1.59%
- For 100KHz tsusto min spec 4.0us vs 3.96 measured, 0.847%
- For 400KHz tsusta min spec 0.6us vs 0.529 measured, 11.8%
- For 1MHz tsusta min spec 0.26us vs 0.202 measured, 22%
- For 1MHz tsusto min spec 0.26us vs 0.240 measured, 7.58%

SMBus/I2C tHIght (High period of the SCL clock) shows certain level violation for 400KHz speed and 1MHz Speed.

- For 400KHz tHight min spec 0.6us vs 0.59us measured, 0.7%
- For 1MHz tHight min spec 0.26us vs 0.2us measured, 0.847%

40.5.2 Supplementary SMBus Signals Not Covered By The SMBus 2.0 Standard

No supplementary signals.

40.6 LPC Interface

The SoC LPC interface was designed to the LPC Specification 1.1, August 2000, see the LPC Section 20.2, "Feature List" on page 628 of this document for the LPC options supported by this SoC.

40.6.1 Deviations From The LPC 1.1 Standard

No known deviations.

40.6.2 Supplementary LPC Signals Not Covered By The LPC 1.1 Standard

No supplementary signals.

40.7 eMMC Interface

The SoC eMMC interface was designed to the JEDEC Standard Embedded Multi-Media Card (eMMC) Electrical Standard (5.0), JESD84-B50 (Revision of JESD84-B451, June 2012) September 2013, see the eMMC Section 17.2, "Feature List" on page 558 of this document for the eMMC options supported by this SoC.

The eMMC standard specifies the electrical characteristics at the device end, and not the host. The electrical characteristics at the device end are greatly affected by the physical routing between the host and device. See the SoC Platform Design Guide for routing guidelines that meet the eMMC electrical characteristics at the device end of the channel.

40.7.1 Deviations From The eMMC 5.0 Standard

Given the electrical characteristics of our eMMC I/Os, and the SoC routing guidelines provided by the SoC Platform Design Guide for the eMMC signals, smaller overshoot/undershoot excursions than what the eMMC standard allows will be seen at the device end of the channel. This does not mean we deviate from the eMMC standard, rather we more strictly control overshoot/undershoot than is required by the eMMC standard.

40.7.2 Supplementary eMMC Signals Not Covered By The eMMC 5.0 Standard

No supplementary signals.

40.8 HSUART Interface

The SoC HSUARTs are compatible with the Texas Instruments* PC16550D HSUART specification. See the HSUART Section 18.2, "Feature List" on page 568 of this document for the HSUART options supported by this SoC.

40.8.1 Deviations From Texas Instruments PC16550D Standard

The I/Os of the original Texas Instruments PC16550D used 5.0V signaling. The HSUARTs within the SoC deviate from the Texas Instruments PC16550D standard in that the SoC HSUART I/Os are implemented using the 3.3V GPIO buffers, see Section 40.13.3, "3.3V GPIO (CMOS-HV Buffer Type) Electrical Characteristics" on page 1066 for the Electrical Characteristics.

40.8.2 Supplementary HSUART Signals Not Covered By The Texas Instruments PC16550D Standard

No supplementary signals.

40.9 Serial Peripheral Interface (SPI)

See Chapter 19, "Serial Peripheral Interface (SPI)" of this document for the SPI options supported by this SoC.

There is no industry standard for the SPI bus. The electrical and timing characteristics for this interface are described below.

40.9.1 Interface Timing Parameters and Waveforms

Table 40-1, Table 40-2, and Table 40-3 contain the timing specifications for the SPI interface signals.

Table 40-1. SPI (17.14MHz) Signal Timing Specifications

Symbol	Parameter	Min	Typical	Maximum	Unit
t180	Serial Clock Frequency	16.9	-	17.4	MHz
t183	T_{CO} of SPI_MOSI_IO[0] with respect to serial clock falling edge at the host.	-5	-	13	ns
t184	Setup of SPI_MISO_IO[1] with respect to serial clock falling edge at the host.	16	-	-	ns
t185	Hold of SPI_MISO _IO[1] with respect to serial clock falling edge at the host.	0	-	-	ns
t186	Setup of SPI_CS_N[1:0] assertion with respect to serial clock rising at the host.	30	-	-	ns
t187	Hold of SPI_CS_N[1:0] deassertion with respect to serial clock falling at the host.	30	-	-	ns
t188	SPI_CLK High Time	26.37	-	-	ns
t189	SPI_CLK Low Time	26.82	-	-	ns

Table 40-2. SPI (30MHz) Signal Timing Specifications

Symbol	Parameter	Minimum	Typical	Maximum	Unit
t180	Serial Clock Frequency	29.83	-	30.6	MHz
t183	T_{CO} of SPI_MOSI _IO[0] with respect to serial clock falling edge at the host.	-5	-	5	ns
t184	Setup of SPI_MISO_IO[1] with respect to serial clock falling edge at the host.	8	-	-	ns
t185	Hold of SPI_MISO_IO[1] with respect to serial clock falling edge at the host.	0	-	-	ns
t186	Setup of SPI_CS_N[1:0] assertion with respect to serial clock rising at the host.	30	-	-	ns
t187	Hold of SPI_CS_N[1:0] deassertion with respect to serial clock falling at the host.	30	-	-	ns
t188	SPI_CLK High Time	14.88	-	-	ns
t189	SPI_CLK Low Time	15.18	-	-	ns

Table 40-3. SPI (48MHz) Signal Timing Specifications

Symbol	Parameter	Minimum	Typical	Maximum	Unit
t180	Serial Clock Frequency	47	-	49	MHz
t183	T_{CO} of SPI_MOSI_IO[0] with respect to serial clock falling edge at the host.	-3	-	4.5	ns
t184	Setup of SPI_MISO_IO[1] with respect to serial clock falling edge at the host.	5	-	-	ns
t185	Hold of SPI_MISO_IO[1] with respect to serial clock falling edge at the host.	0	-	-	ns
t186	Setup of SPI_CS_N[1:0] assertion with respect to serial clock rising at the host.	30	-	-	ns
t187	Hold of SPI_CS_N[1:0] deassertion with respect to serial clock falling at the host.	30	-	-	ns
t188	SPI_CLK High Time	5	-	-	ns
t189	SPI_CLK Low Time	10.8	-	-	ns

Figure 40-1. SPI Timing Diagram

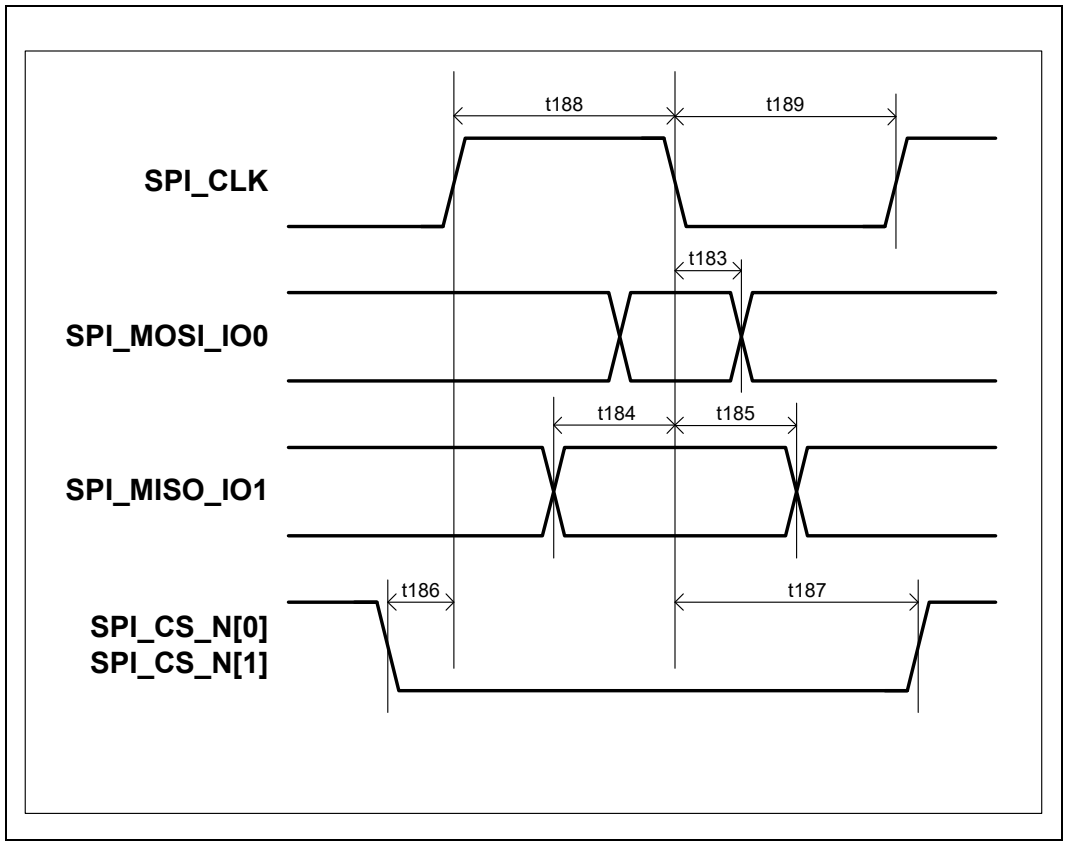

Table 40-4. CS# Setup and CS# Hold

Parameter	Value	Description
CS# Setup	2.5 ns (min)	SPI_CS# low to SPI_CLK high
CS# Hold	2.5 ns (min)	SPI_CLK low to SPI_CS# low

Figure 40-2. Dual-Output Fast Read Timing with 24-bit Addressing

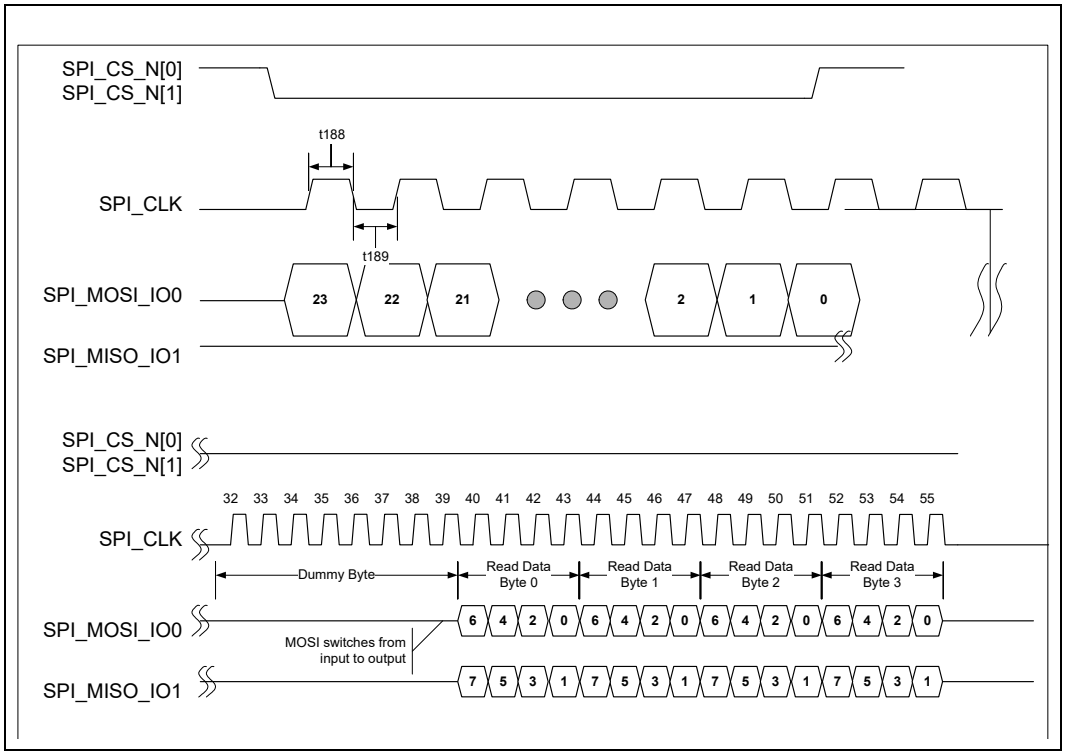

Figure 40-3. Dual I/O Fast Read Timing with 24-bit Addressing

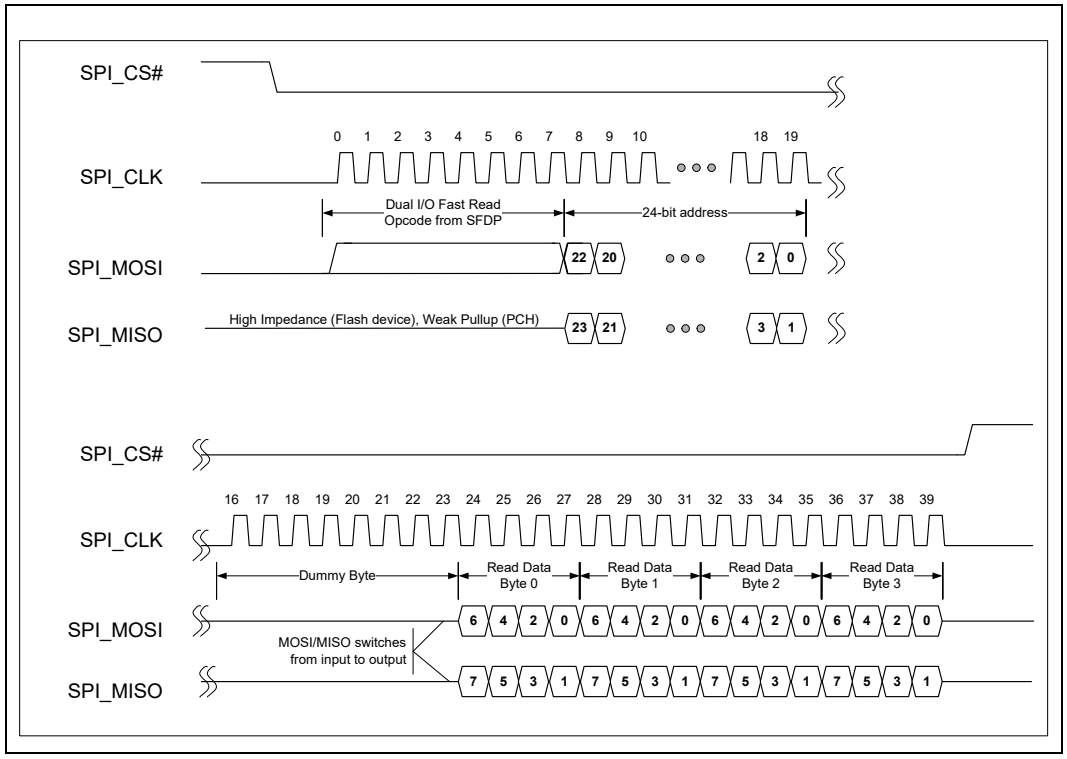

Figure 40-4. Quad Output Fast Read Timing with 24-bit Addressing

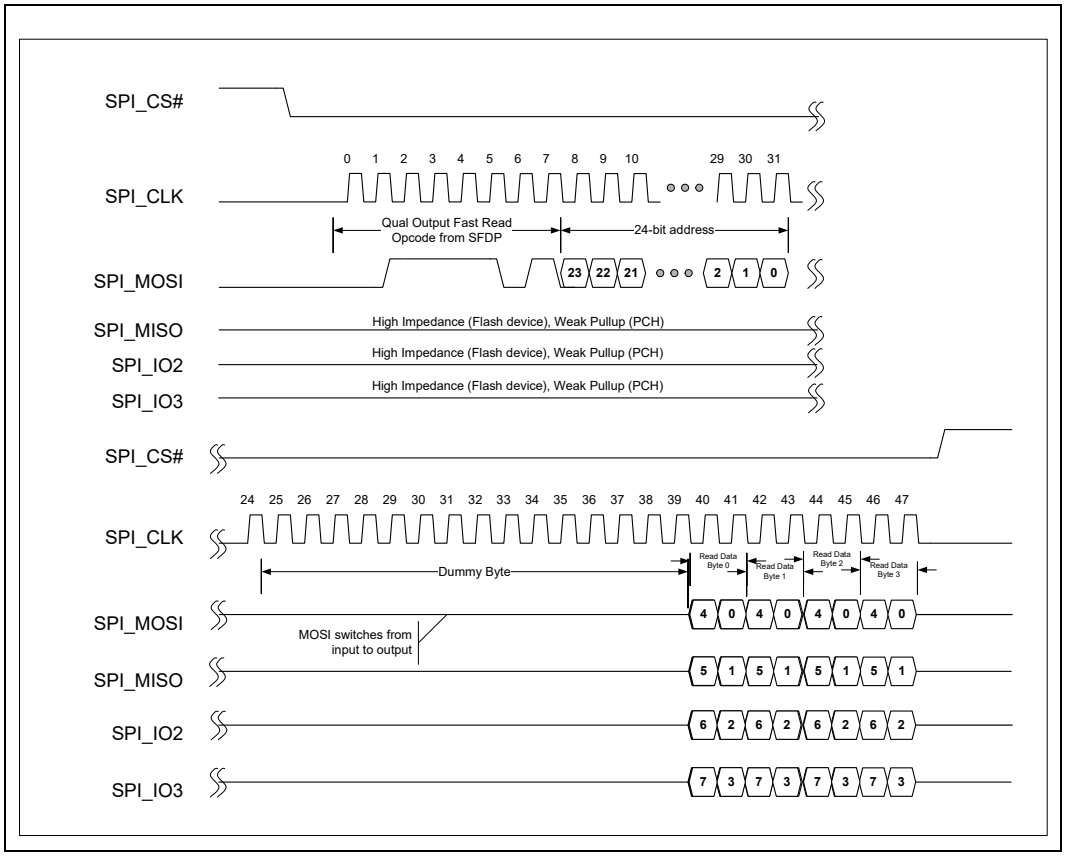

Figure 40-5. Quad I/O Fast Read Timing with 24-bit Addressing

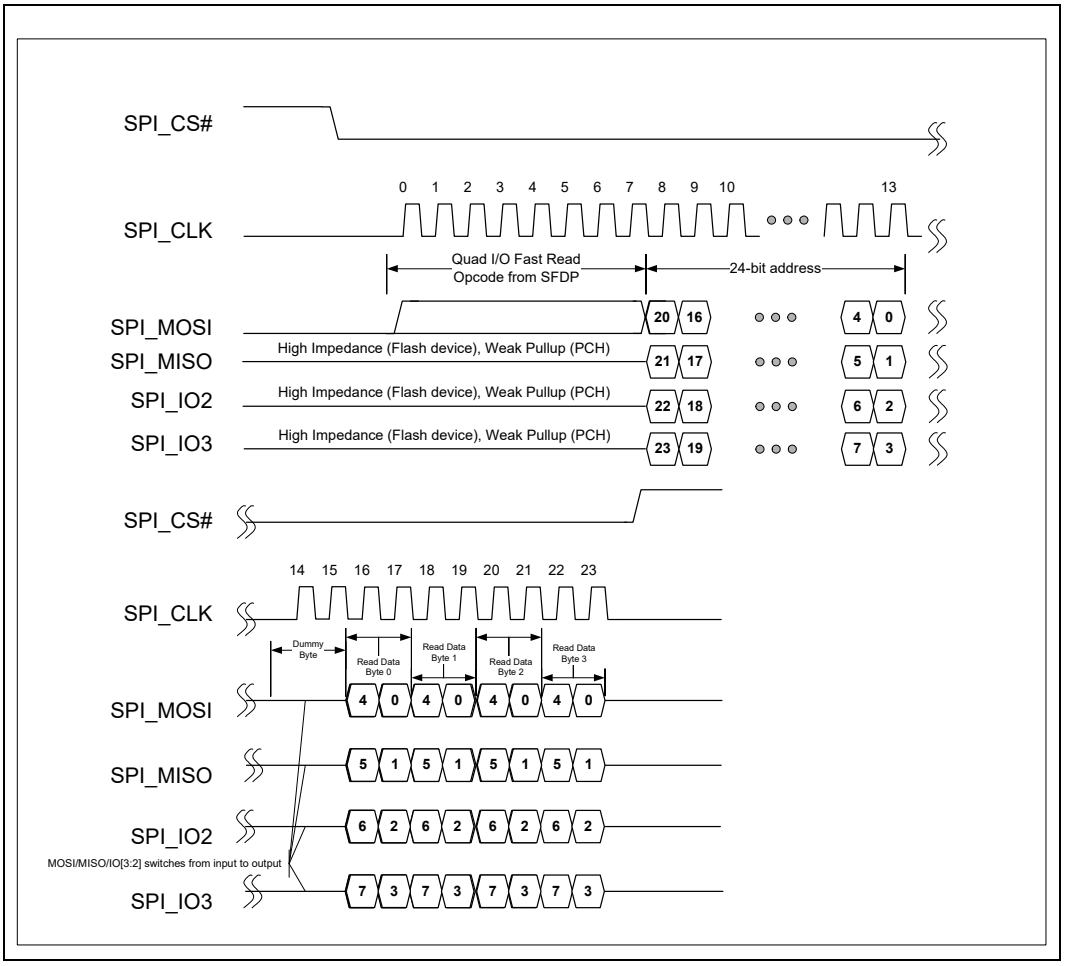


40.9.2 SPI Electrical Characteristics

The I/O buffers used for the SPI interface are the 3.3V GPIO (CMOS-HV Buffer Type) buffers, see Section 40.13.3, "3.3V GPIO (CMOS-HV Buffer Type) Electrical Characteristics" on page 1066 for the Electrical Characteristics.

40.10 LAN Interface

The SoC includes up to two integrated LAN controllers, with up to two LAN ports each, depending on configuration and product SKU. See the LAN Section 13.3, "Feature List" on page 417 of this document for the LAN options supported by this SoC.

Each LAN port is configurable, supporting various electrical interfaces, depending on configuration and product SKU. Each type of supported electrical interface is listed separately in the sections below.

40.10.1 10GBASE-KR Interface

The SoC 10GBASE-KR interface was designed to the IEEE802.3 Standard.

40.10.1.1 Deviations From The IEEE802.3 10GBASE-KR Standard

No known deviations.

40.10.1.2 Supplementary 10GBASE-KR Signals Not Covered By The IEEE802.3 10GBASE-KR Standard

No supplementary signals.

40.10.2 SFI Interface

The SoC SFI interface was designed to the SFF-8431 Revision 4.1 Standard.

40.10.2.1 Deviations From The SFF-8431 SFI Standard

The SoC supports only SFP+ DA (Direct Attach; i.e., passive twin-ax cable assembly) and limiting optical modules. It will not support linear optical modules.

Linear modules are modules which contain a linear receiver, whereas limiting modules contain a limiting receiver.

40.10.2.2 Supplementary SFI Signals Not Covered By The SFF-8431 SFI Standard

No supplementary signals.

40.10.3 2500BASE-X Interface

2500BASE-X is not an IEEE standard, but leverages the electricals from IEEE802.3ae-2002 (XAUI). 2500BASE-X is term used by Broadcom to describe 2.5Gbit/s (3.125GBd) operation.

40.10.3.1 Deviations From The 2500BASE-X Industry Convention

No known deviations.

40.10.3.2 Supplementary 2500BASE-X Signals Not Covered By The 2500BASE-X Industry Convention

No supplementary signals.

40.10.4 1000BASE-KX Interface

The SoC 1000BASE-KX interface was designed to the IEEE802.3 Standard.

40.10.4.1 Deviations From The IEEE802.3 1000BASE-KX Standard

No known deviations.

40.10.4.2 Supplementary 1000BASE-KX Signals Not Covered By The IEEE802.3 1000BASE-KX Standard

No supplementary signals.

40.10.5 SGMII Interface

The SoC SGMII interface was designed to the Cisco Systems* SGMII Industry Standard, Revision 1.7.

40.10.5.1 Deviations From The Cisco Systems SGMII Industry Standard

No known deviations, other than Half Duplex mode is not supported, only Full Duplex mode is supported.

40.10.5.2 Supplementary SGMII Signals Not Covered By The Cisco Systems SGMII Industry Standard

No supplementary signals.

40.10.6 Management Data Input/Output (MDIO)

The MDIO interface is also known as Serial Management Interface (SMI) or Media Independent Interface Management (MIIM). The MDIO interface connects Media Access Control (MAC) devices with Ethernet physical layer (PHY) circuits.

The MDIO interface is defined by Clause 22 of IEEE 802.3, and is augmented by Clause 45.

The SoC MDIO interface supports both Clause 22 and Clause 45. However, the only I/O voltage supported is the 3.3V option.

40.10.6.1 Deviations From IEEE 802.3

Clause 22 and Clause 45 of IEEE 802.3 support multiple voltage options for the I/O buffers. The only I/O voltage option supported by the SoC is 3.3V, and the specific I/O buffers used for the MDIO interface are the 3.3V GPIO (CMOS-HV Buffer Type) buffers, see Section 40.13.3, "3.3V GPIO (CMOS-HV Buffer Type) Electrical Characteristics" on page 1066 for the Electrical Characteristics.

40.10.6.2 Supplementary MDIO Signals Not Covered By Clause 22 and Clause 45 of IEEE 802.3

No supplementary signals.

40.10.7 Slave ("Target") Network Controller Sideband Interface (NC-SI)

The SoC NC-SI Slave interface was designed to the *DMTF Network Controller Sideband Interface (NC-SI) Specification, Document Number: DSP0222, Version 1.0.0.*

40.10.7.1 Deviations From The NC-SI Standard

No known deviations.

40.10.7.2 Supplementary NC-SI Signals Not Covered By The NC-SI Standard

No supplementary signals.

40.11 SoC Serial Voltage Identification (SVID) Interface

It consists of three signals. See Section 34.6, "Serial Voltage Identification (sVID) Controller" on page 908 of this document for the options supported by this SoC.

40.11.1 SoC SVID Timing Deviates from the VR13.0 Specification

The SoC SVID timing deviates from the VR13.0 specification for the following parameters:

- Tco_max_CPU Clock to data delay @bump = 5µs versus the 0.65µs listed in the VR13.0 specification
- Tco_min_CPU Clock to data delay @bump = 1µs versus the -3.6µs listed in the VR13.0 specification
- Tsu_CPU - Setup time of signal VDIO at CPU side = 15µs versus the 1µs listed in the VR13.0 specification.

40.11.2 Supplementary Signals Not Covered By The SVID Standard

No supplementary signals.

40.12 SoC JTAG and Debug Interfaces

The SoC JTAG/Debug interface was designed to the IEEE Std 1149.1 Standard. See Chapter 38, "JTAG and Debug Ports" of this document for the options supported by this SoC.

The IEEE standard for JTAG does not specify the electrical characteristics of the interface signals, only the functional requirements. The intent is to not limit JTAG by the electrical characteristics of any existing device or I/O technology, but to support any device with existing and future I/O technologies. The JTAG specifications include guidance for interconnecting multiple devices using disparate I/O technologies.

As is the case, the I/O technology used to design the SoC JTAG/Debug I/Os are implemented using the 1.05V GPIO buffers, see Section 40.13.1, "1.05V GPIO (CMOS-LV Buffer Type) Electrical Characteristics" on page 1062 for the Electrical Characteristics.

40.12.1 Deviations From The JTAG Standard

No known deviations.

40.12.2 Supplementary Signals Not Covered By The JTAG Standard

No supplementary signals.

40.13 Customer General Purpose I/O (GPIO) Interface

The SoC has several pins that are configurable as GPIO. See the GPIO Section 26.1, "GPIO Ball and Signal Names" on page 686 of this document for the GPIO options supported by this SoC.

GPIO transceivers are Intel custom circuit designs, and do not comply to any public specifications. There are three classes (types) of GPIO transceivers used in this SoC: 1.05V GPIO, 1.8V GPIO, and 3.3V GPIO.

Many SoC signals make use of the same buffers as the GPIO signals. All SoC signals are listed in Table 39-1. SoC signals which are implemented using the GPIO buffers contain either CMOS-LV, CMOS-MV, or CMOS-HV in the column "Buffer Type" of Table 39-1.

The electrical characteristics for each class of GPIO is listed below in separate sections.

40.13.1 1.05V GPIO (CMOS-LV Buffer Type) Electrical Characteristics

40.13.1.1 Receiver Electrical Characteristics

The tables below list the DC and AC Characteristics of the receiver.

Table 40-5. 1.05V GPIO Receiver DC Characteristics

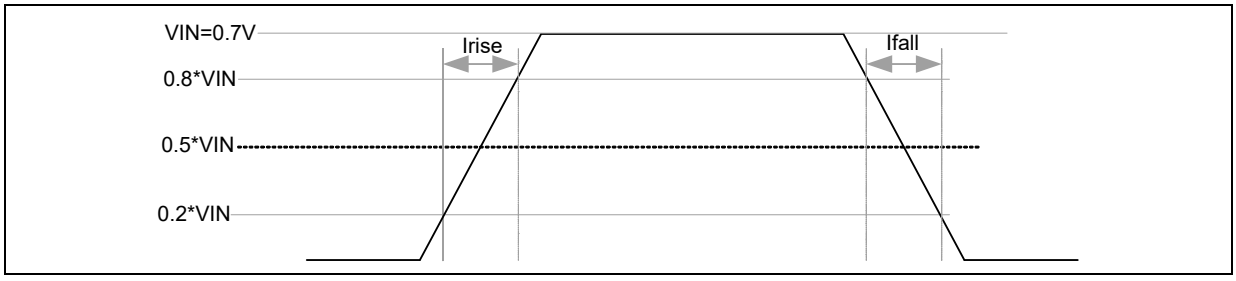
Parameter	Symbol	Minimum	Nominal	Maximum	Test Condition	Unit	Notes
Power Supply	V1P05		1.05		N/A	V	+/- 5%
High-Level Input Voltage	Vih	0.65*V1P05			N/A	V	
Low-Level Input Voltage	Vil			0.35*V1P05	N/A	V	
Input Hysteresis	Vhys	50			N/A	mV	
Input Leakage	Lin	-50		50	V1P05/GND	uA	
Input Capacitance	Cin			5	N/A	pF	

Table 40-6. 1.05V GPIO Receiver AC Characteristics

Parameter	Symbol	Minimum	Nominal	Maximum	Unit	Notes
Input Frequency	Fin	N/A		533	MHz	
Input Rise/Fall	Irise/Ifall	N/A		6	ns	

The figure below depicts the receiver timing.

Figure 40-6. 1.05V GPIO Receiver Timing



40.13.1.2 Driver Electrical Characteristics

The tables below list the DC and AC Characteristics of the driver.

Table 40-7. 1.05V GPIO Driver DC Characteristics

Parameter	Symbol	Minimum	Nominal	Maximum	Test Condition	Unit	Notes
Power Supply	V1P05		1.05		N/A	V	+/- 5%
Driver Pullup Impedance	Zup	30	50	90	N/A	Ohm	
Driver Pulldown Impedance	Zdn	12	20	28	N/A	Ohm	
High-Level Output Voltage	Voh	V1P05-0.3			-2mA	V	
Low-Level Output Voltage	Vol			0.2	3mA	V	

Table 40-8. 1.05V GPIO Driver AC Characteristics

Parameter	Symbol	Minimum	Nominal	Maximum	Test Condition (Cap to GND)	Unit	Notes
Output Frequency	Fout	N/A		533	0.15pF	MHz	
Output Rise / Fall Rate	Orise/Ofall	N/A	N/A	0.2	0.15pF	ns	Output Rise Rate = -(Output Fall Rate)

The figure below depicts the driver timing.

The figure below depicts the driver timing.

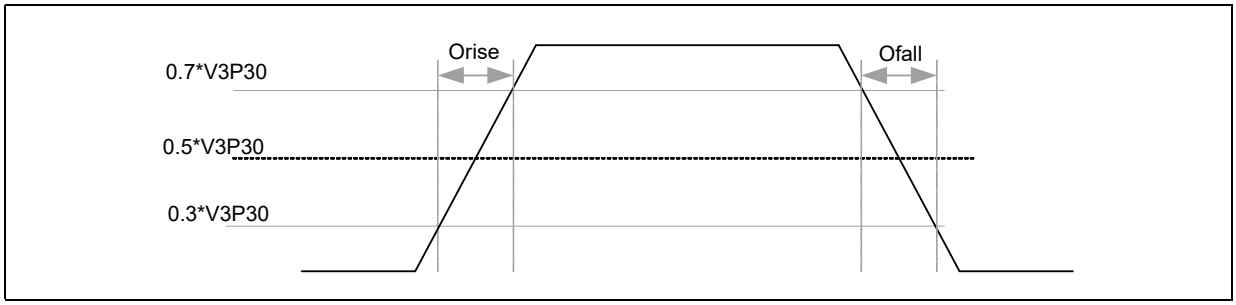
Figure 40-9. 3.3V GPIO Driver Timing



40.14 Miscellaneous Interfaces

Miscellaneous signals not included in the sections above, are not defined by any industry standard, and are custom SoC signals defined by Intel. Three different types of Intel custom electrical interfaces were used in implementing these interfaces.

Many SoC signals make use of the same buffers as the GPIO signals. All SoC signals are listed in Table 39-1, "Signal Pin Name Directory - Sorted by Name" on page 995. SoC signals which are implemented using the GPIO buffers contain either CMOS-LV, CMOS-MV, or CMOS-HV in the column "Buffer Type" of Table 39-1.

Chapter 39, "Signal Pin Names and Signal MUXing" lists all of the SoC signals along with their "V Group" (Voltage Group).

See the subsections below for the electrical characteristics of each "V Group".

40.14.1 Signals of "V Group V1P05" (CMOS-LV Buffer Type)

See Section 40.13.1, "1.05V GPIO (CMOS-LV Buffer Type) Electrical Characteristics" on page 1062 for the Electrical Characteristics of signals within this group.

40.14.2 Signals of "V Group V1P80" (CMOS-MV Buffer Type)

See Section 40.13.2, "1.8V GPIO (CMOS-MV Buffer Type) Electrical Characteristics" on page 1064 for the Electrical Characteristics of signals within this group.

40.14.3 Signals of "V Group V3P30" (CMOS-HV Buffer Type)

See Section 40.13.3, "3.3V GPIO (CMOS-HV Buffer Type) Electrical Characteristics" on page 1066 for the Electrical Characteristics of signals within this group.

§ §

41 Operating Conditions and Power Requirements

41.1 Absolute Maximum and Minimum Ratings

For proper functional operation, all processor electrical and thermal requirements must be satisfied. These are shown starting with Section 41.2, "Normal Operating Conditions" on page 1070.

When the device is subjected to conditions outside the functional operation condition limits, but within absolute maximum and minimum ratings, neither functionality nor long-term reliability can be expected. If a device is returned to conditions within functional operation limits after having been subjected to conditions outside these limits, but within the absolute maximum and minimum ratings, the device may be functional, but with its lifetime degraded depending on exposure to conditions exceeding the functional operation condition limits.

At conditions exceeding absolute maximum and minimum ratings, neither functionality nor long-term reliability is expected. Moreover, devices that are subjected to these conditions for any length of time, will either not function or its reliability will be severely degraded when returned to conditions within the functional operating condition limits.

41.1.1 Component Storage Conditions Specification

This section applies to component-level storage prior to board attach. Environmental storage condition limits define temperature and relative humidity to which the device is exposed to while being stored in the applicable Intel shipping media trays, reels, and moisture barrier bags and boxes, and the component is not electrically connected.

41.1.1.1 Prior to Board-Attach

Table 41-1 specifies absolute maximum and minimum storage temperature and humidity limits for given time durations. Failure to adhere to specified limits can result in physical damage to the component. If this is suspected, Intel recommends a visual inspection to determine possible physical damage to the silicon or surface components.

Table 41-1. Storage Condition Ratings - Prior to Board-Attach

Symbol	Parameter	Minimum	Maximum	Unit
$T_{ABSOLUTE\ STORAGE}$	Device storage temperature when exceeded for any length of time.	-25	125	°C
$T_{SUSTAINED\ STORAGE\ TIME\ AND\ TEMPERATURE}$	The minimum/maximum device storage temperature for a sustained period of time.	-5	40	°C
$T_{SHORT\ TERM\ STORAGE}$	The ambient storage temperature and time for up to 72 hours.	-25	85	°C
$RH_{SUSTAINED\ STORAGE}$	The maximum device storage relative humidity for up to 30 months.		60% at 24 °C	

Notes:
1. Specified temperatures are not to exceed values based on data collected. Exceptions for surface mount re-flow are specified by the applicable JEDEC standard. Non-adherence may affect processor reliability.
2. Component product device storage temperature qualification methods may follow JESD22-A119 (low temperature) and JESD22-A103 (high temperature) standards when applicable for volatile memory.
3. Component stress testing is conducted in conformance with JESD22-A104.
4. The JEDEC J-JSTD-020 moisture level rating and associated handling practices apply to all moisture sensitive devices removed from the moisture barrier bag.

41.1.1.2 Post Board-Attach

The storage condition limits for the component once attached to the application board are not specified.

Intel does not conduct component-level certification assessments post board-attach given the multitude of attach methods and board types used by customers.

Provided as general guidance only, board-level Intel-branded products are specified and certified to meet the following temperature and humidity limits:

- Non-Operating Temperature Limit: -40 °C to 70 °C
- Humidity: 50% to 90%, non-condensing with a maximum wet-bulb of 28 °C

41.2 Normal Operating Conditions

41.2.1 Component Temperature

Table 41-2 specifies the normal operating temperature range for product SKUs that feature Commercial Temperature Range and for product SKUs that feature Extended Temperature Range. The list of product SKUs is in Chapter 1, "Introduction and Product Offerings."

All supply voltage requirements, input signal requirements, and output signal characteristics are specified for the normal operating temperature range of the device. The temperature range is specified in terms of the Package Junction Temperature (Tj) which is the temperature of the die active surface. For a platform board and chassis using the device, the design must maintain an operational Tj within the specified range.

Table 41-2. Component Temperature Range

Parameter	Symbol	Minimum	Maximum	Unit	SoC Product SKU Feature
Package Junction Temperature	Tj[1]	0	100	°C	Commercial Temperature
		-40[2]	100	°C	Extended Temperature

1. All SKU thermal values are based on maintaining Tj minimum and maximum. Based on product SKU, the SoC has its DTS_{MAX} value (also called REF_TEMP) set at the Intel factory so that the SoC does not throttle when running a TDP workload and meet the SoC T_{CASE_MAX} specification. DTS_{MAX} is described in Chapter 35, "Thermal Management".
2. While this temperature is lower than the specified minimum $T_{ABSOLUTE\ STORAGE}$ value, the Package Junction Temperature value assumes the part will be powered-on and hence won't stay at the minimum junction temperature for a long time

41.2.2 Supply Voltage and Current Requirements

Table 41-3 specifies the device voltage supply requirements for each of the voltage supply groups. These groups are described in Table 32-1, "Signal Descriptions" on page 893.

For the table below, the following definitions apply:

- **DC VR Error**
  This is the difference between the constant load VR output voltage and the measured output voltage averaged over time (tens of ms).

- **DC Tolerance**
  This is the three sigma of "DC VR Error", over the range of conditions, load and lifetime.

- **VR Ripple**
  This is the variation in the output voltage of a regulator due to the switching/sampling characteristics of the regulator. This ripple can be most easily measured by looking at the supply output under a constant load, across the range of loads. The ripple frequency will be at the bandwidth of the regulator.

- **AC Tolerance**
  The response to transients (Istep divided by di/dt) generated by the SOC or other platform components (e.g., feed-through from the VR input supply, which may have other loads).

- **Total Tolerance** = DC Tolerance + VR Ripple + AC Tolerance

- **AVP Sense Tolerance**
  This is the tolerance of the load line sensing circuitry over the range of conditions, load, and lifetime.

- **Total Tolerance With Load Line** = (IxRll) + DC Tolerance + VR Ripple + AC Tolerance + AVP Sense Tolerance = (IxRll) + Total Tolerance
  Where Rll is the Load Line Resistance.

The measurement points for the SoC VR specifications are at the SoC (the load). If access at the SoC is not practical, the measurements may be taken at the input of the VR sense signals, which is nearly identical to what the SoC receives.

Table 41-3. Voltage Supply Requirements Under Normal Operating Conditions

Group	Parameter		Typical (V)	DC Tolerance	VR Ripple	Total Tolerance
VCC	Dynamic VID voltage for core circuitry (variable, switched internally)	SVID V_{BOOT}	1	± 6mV	N/A	Total Tolerance With Load Line ±50mV See Table 41-4, "SoC VCC Load Line"
		SVID	0.52 - 1.24			
		Nominal	1.15			
VNN	Dynamic VID voltage for un-core circuitry (variable, always-on voltage supply)	SVID V_{BOOT}	1	± 0.5%	N/A	± 6%
		SVID	0.65 - 1.24			
		Nominal	1.05			
VCCRAM	Dynamic VID for internal circuitry (variable, switched internally)	SVID V_{BOOT}	1	± 0.5%	N/A	± 7%
		SVID	0.75 - 1.20			
		Nominal	1.15			
VDDQ	Static VID for internal Standard DDR4 circuitry (static, switched internally). *See Note below table.*	SVID V_{BOOT}	1 or 1.20	± 8mV	N/A	+60mV, -38mV (1.260-1.162 V)
		Nominal	1.20			
VCCREF	VCC reference voltage		1.24	± 2.1%	N/A	± 50mV
V1P05	Device internal circuitry (always-on voltage supply, switched internally)		1.05	± 0.6%	± 3mV VR Ripple for frequencies less than 1MHz	± 25mV
V1P80	Device internal circuitry (always-on voltage supply, switched internally)		1.8	± 2.1%	N/A	± 72mV
V3P30	Device internal circuitry (always-on voltage supply, switched internally)		3.3	± 2%	N/A	± 165mV
VRTC	All power states other than G3 Mechanical-Off state		3.3	± 2%	N/A	± 165mV
VRTC	G3 State: From Real Time Clock (RTC) battery supply		2.0 - 3.0	± 2%	N/A	± 165mV

Note: DDR4 DRAM Activating Power (VPP) supply (2.5 V nominal, 2.375 V min, 2.75 V max) goes to the DIMM component only and not to the SoC.

Table 41-4. SoC VCC Load Line

Vcc Tolerance / Load Line / Power		Units
VCC_{MAX} =	VID (V) – 2.3 mΩ * ICC (A) + 50 mV	V
VCC_{TYP} =	VID (V) – 2.3 mΩ * ICC (A)	
VCC_{MIN} =	VID (V) – 2.3 mΩ * ICC (A) - 50 mV	
PVCC =	ICC (A) * VCC (V)	W
Total Tolerance	±50mV	V

Adequate supply current is required for each device voltage group to ensure proper operation. The current requirements vary by product SKU group. The tables below show the characteristics of the current draw for all the SKUs in each group, over the supply voltage ranges shown in Table 41-3.

ICC_{MAX} represents the worst-case transient current that the SoC draws from a given power supply. Platform board designers typically use this value to keep the board Voltage Regulator (VR) current below the VR Over-Current Protection (OCP) limit.

Thermal Design Current (TDC) represents the worst-case sustained current (DC equivalent) that the SoC draws from a given power supply. Platform board designers use this value for proper VR design including VR thermal design.

$DI/DT_{\mathbf{MAX}}$ represents the worst-case current change rate, with the worst-case current change step of $ICC_{\mathbf{STEP}}$.

These parameters determine the characteristics of each VR design, the copper layout connecting the VRs to the SoC; as well as determining the number, type, location, and size of capacitors for each VR.

Note: The ICC_{TDC} values shown in the Supply Current Required tables below are representative numbers. ICC_{TDC} values vary across parts and operating conditions. Only the ICC_{MAX} values are guaranteed when the SoC product has achieved production release.

For the supported features of each SKU, please refer to Chapter 1, "Introduction and Product Offerings."

Table 41-5. Supply Current Required - Server and Cloud Storage SKUs 0, 1, and 2 (See Table 1-1)

Group	Parameter	ICC_{TDC}	ICC_{MAX} in S0	ICC_{MAX} in S5	ICC_{STEP}	DI/DT_{MAX} [A/µs]

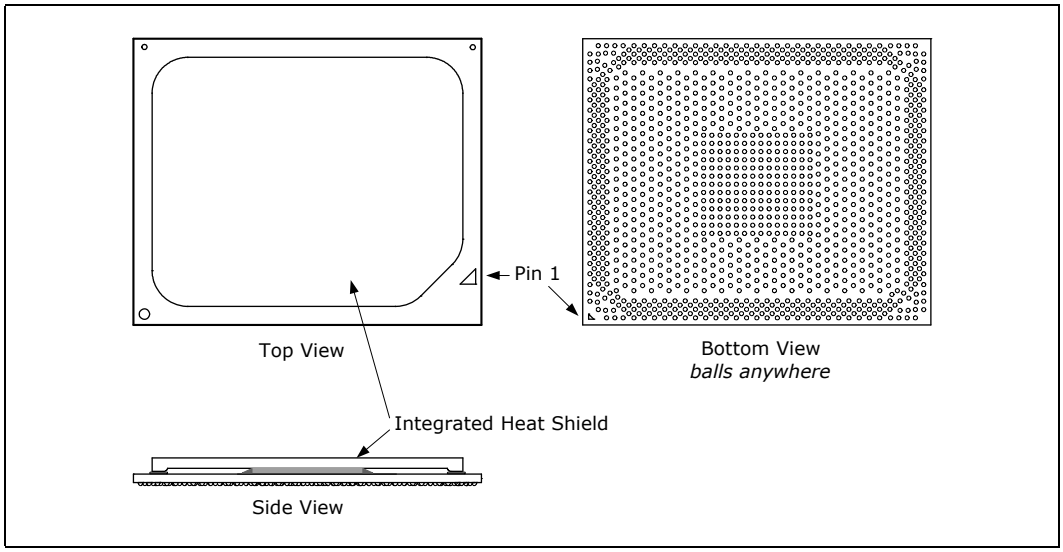
§ §

42 Package Mechanical Overview

The SoC is manufactured as a 34 mm x 28 mm Flip-Chip Ball Grid Array (FBGA15) package and consists of a silicon die mounted face down on an organic substrate populated with 1310 solder balls (the term "pins" is also used in this document) on the bottom side. The balls have a mixed pitch—minimum pitch is 0.65 mm. The package contains an integrated heat spreader that is 30.36 mm x 24.36 mm, 1 mm thick. See Figure 42-1 for a representation of the SoC package.

Figure 42-1. SoC Package Drawing



§ §

Volume 4: Registers

February 2018
Order Number: 337018-002

43 Introduction

This volume documents the registers accessible to software running in the IA Host Space. There is a register chapter for each PCI device/function in the Host Root Space. There are additional chapters for other SoC entities that have software-accessible registers. There is also a chapter for the SoC Model-Specific Registers (MSRs).

Note: Accessing unimplemented registers and/or writing reserved bits may result in undefined behavior on the platform.

43.1 Access to Registers in Host Root Space

The registers shown in this volume are those accessible in the SoC Host Root Configuration, Memory and I/O Spaces.

Details of the registers accessible in the Root Space of the Intel® Management Engine (Intel® ME) are not provided to SoC customers.

43.1.1 PCI Configuration Space

Access to the registers in PCI Configuration Space is performed through one of the two Configuration Access Methods (CAMs):

- I/O-indexed - PCI CAM (only the first 256 bytes of the function Configuration Space)
- Memory-mapped - PCI enhanced CAM (ECAM)

These two methods are explained in Section 3.3.1, "How to Access Registers in PCI Configuration Space" on page 185.

The descriptions for the Configuration Registers show the PCI Bus, Device, and Function numbers as Bbus#:Ddevice#:Ffunction#. An example is B0:D17:F0. All three of the numbers are decimal. The register offset address from the B:D:F: is also shown for each Configuration Register and is a hexadecimal value. The structure of the Configuration Registers are defined in the *PCI Local Bus Specification, Revision 3.0* and *PCI Express Base Specification Revision 3.0*.

Note: Some of the registers in Host Root Configuration Space can be accessed and altered through the SMBus-PECI interface by an external component such as a Baseboard Management Controller (BMC). See Chapter 30, "SMBus Controller - Platform Environment Control Interface".

43.1.1.1 Unimplemented Devices/Functions and Registers

Read accesses in the Configuration Space is to unimplemented PCI functions and so the devices return all ones, emulating a Master Abort response. Note that there is no asynchronous error reporting that happens when a configuration-read transaction Master Aborts.

Write accesses in the Configuration Space is to unimplemented PCI functions and so the devices return a normal response.

Software must not attempt, or rely on, reads or writes to unimplemented registers or register bits. Unimplemented registers return all zeros when read. Writes to unimplemented registers are ignored by the SoC. For configuration writes to these registers (requires a Completion), the Completion is returned with a normal completion status (not Master-Aborted).

43.1.2 Memory Space—Relocatable Address

Access to this kind of register requires a base memory address defined in a Base Address Register (BAR). The register is accessed using an offset address that is added to the memory BAR. Memory-Mapped I/O (MMIO) registers are accessed in this fashion. A list of most of the Memory BARs is in Section 3.1.2, "Host Memory Space—Relocatable Memory-Mapped I/O" on page 169.

The register description for this type of register shows the name of the BAR and a hexadecimal offset value.

43.1.3 Memory Space—Fixed Address

Fixed-address registers in the Host Root Memory Space are accessed by software and the SoC hardware. The register locations are not relocatable and a BAR is not associated with the register access. The Host Root address map of these registers is in Section 3.1.1, "Host Memory Space—Regions and Boundaries" on page 166.

The register description for this type of register shows the memory address as a hexadecimal value.

43.1.4 I/O Space—Relocatable Address

Access to this kind of register requires a base I/O-Space address defined in a Base Address Register (BAR). The register is accessed using an offset address that is added to the I/O BAR. A list of the I/O BARs is in Section 3.2.2, "Host I/O Space—Relocatable I/O Addresses" on page 180.

The register description for this type of register shows the name of the I/O BAR and a hexadecimal offset value.

43.1.5 I/O Space—Fixed Address

Fixed-address registers in Host Root I/O Space (also known as I/O Ports) are accessed by the CPU when software executes the following instructions:

- Read: IN, INS INSB, INSW, and INSD
- Write: OUT, OUTS, OUTSB, OUTSW, and OUTSD

The descriptions of these I/O Port instructions are in the *IA-32 Intel® Architecture Software Developer's Manual*, Volume 2. The SoC Host Root address map of these registers is in Section 3.2.1, "Host I/O Space—Fixed I/O Addresses" on page 175

The register description for this type of register shows the I/O Port address as a hexadecimal value.

43.1.6 Sideband Registers

The SoC has an internal messaging mechanism that is used by the internal circuitry. This mechanism includes registers called Sideband Registers that are accessible to BIOS so it can configure and tune the system before the Operating System is loaded. BIOS accesses these Sideband Registers in the Host Root Memory Space. They are located as an offset address from the memory BAR defined as SBREG_BAR. A few Sideband Registers are accessible to BIOS as offsets from the Memory Controller Hub Base Address Register (MCHBAR). For more information, see Section 3.4, "Host Root Space - Host Sideband Register Access" on page 187.

The register description for this type of register shows the name of the memory BAR (either SBREG_BAR or MCHBAR) and a hexadecimal offset value.

43.1.7 Model-Specific Registers (MSR)

These registers are accessed by the CPU when software executes the following instructions:

- RDMSR - Read MSR
- WRMSR - Write MSR

The descriptions of the RDMSR and WRMSR instructions are in the *IA-32 Intel® Architecture Software Developer's Manual*, Volume 2. The access to the SoC Machine Check Registers is through MSRs. The SoC MSRs are all described in Chapter 69, "Model-Specific Registers (MSR)".

43.2 Register Description Terminology

43.2.1 Default Values

Warning: BIOS must not rely on the register Default values provided in this document, and instead verify these values by first reading them.

Some Default values shown in the register-description tables vary by product SKU and are set to values at the factory that are different than published here. Generally, the Default values are set by hardware when the register or register fields are reset. During power-on situations, the original default values set by hardware may be written to different values before BIOS starts executing instructions. Things like Hard Pin Straps, customer-selected Soft Straps, the SoC power-management controller, the Intel® Management Engine (Intel® ME) and the Innovation Engine (IE) may alter the default values before BIOS starts executing instructions. By the time that the Operating System is loaded, BIOS could have also modified what was the Default value.

43.2.2 Software Access Attributes

Table 43-1 is a comprehensive list of software-access attributes used in the register descriptions.

Table 43-1. Register Attributes Definitions

Attribute	Description
RO	**Read Only:** These bits can only be read by software, writes have no effect. The value of the bits is determined by the hardware only which includes pin strapping, soft straps, and internal microcode.
RW	**Read / Write:** These bits can be read and written by software.
RO/C RO/C/V	**Read Clear Variant:** These bits can be read by software, and the act of reading them automatically clears them. Hardware is responsible for writing these bits, and therefore the / V modifier is implied.
WO/1S	**Write 1 to Set:** Writing a '1' to these bits will set them to '1.' Writing '0' will have no effect. Reading will return indeterminate values.
WO/1C	**Write 1 to Clear:** Writing a '1' to these bits will set them to '0.' Writing '1' will have no effect. Reading will return indeterminate values.
RW/O	**Read / Write Once:** These bits can be read by software. After reset, these bits can only be written by software once, after which the bits becomes "Read Only."
RW/L	**Read / Write Lock:** These bits can be read and written by software. The bits can be made to be "Read Only" via a separate configuration bit or other logic.
RW/1C	**Read / Write 1 to Clear:** These bits can be read and cleared by software. Writing a '1' to a bit clears it, while writing a '0' to a bit has no effect.
RW/0C	**Read / Write 0 to Clear:** These bits can be read and cleared by software. Writing a '0' to a bit clears it while writing a '1' has no effect.
RO/P	**RO Sticky:** These bits can only be read by software, writes have no effect. The value of the bits is determined by the hardware only. These bits are only re-initialized to their default value by a PWRGOOD reset.
RW/1S	**Read, Write 1 to Set:** These bits can be read. Writing a '1' to a given bit will set it to '1.' Writing a 0 to a given bit will have no effect. It is not possible for software to set a bit to '0.' The '1'-to-'0' transition can only be performed by hardware. These registers are implicitly /V modified.
RW/P	**R / W Sticky (Persistent):** These bits can be read and written by software. These bits are only re- initialized to their default value by a PWRGOOD reset.
RW/1C/P	**R / W1C Sticky:** These bits can be read and cleared by software. Writing a '1' to a bit clears it, while writing a '0' to a bit has no effect. These bits are only re-initialized to their default value by a PWRGOOD reset.
RW/O/P	If a register is both sticky (persistent) and "once," then the sticky value applies to both the register value and the "once" characteristic. Only a PWRGOOD reset will reset both the value and the "once" so that the register can be written to again.
RW/V RO/V	These bits may be modified by hardware. Software cannot expect the values to stay unchanged.
RW/V/P RO/V/P	These bits may be modified by hardware and are Sticky. Software cannot expect the values to stay unchanged. These bits are re-initialized to their default values by a PWRGOOD reset.
RW/P/L	If a register is both sticky and locked, then the sticky behavior only applies to the value. The sticky behavior of the lock is determined by the register that controls the lock.
RW/V/P/L	These bits can be read or written by software and may be modified by hardware. Software cannot expect the values to stay unchanged. These bits are re-initialized to their default values by a PWRGOOD reset. If a register is both sticky and locked, then the sticky behavior only applies to the value. The sticky behavior of the lock is determined by the register that controls the lock.
RSV	**Reserved:** These bits are reserved for future expansion and their value must not be modified by software. When writing these bits, software must preserve the value read.
NA	**No Access:** These bits are not accessible from the given source. Writes are dropped and Reads return '0.'

43.2.3 Hexadecimal, Binary and Decimal Numbers

Base 16 numbers are represented by a string of hexadecimal digits followed by the character “h” (for example, F82Eh). A hexadecimal digit is a character from the following set: 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, A, B, C, D, E, and F. Hexadecimal numbers can also be shown using an “x” character (for example 0x2A).

Base 2 (binary) numbers are represented by a string of 1s and 0s, sometimes followed by the character “b” (for example, 1010001b). The “b” designation is only used in situations where confusion as to the type of the number might arise.

Base 10 numbers are represented by a string of decimal digits followed by the character “d” (for example, 23d). The “d” designation is only used in situations where confusion as to the type of the number might arise.

§ §

44 System Agent - B0, D0, F0

44.1 Introduction and Index

The host-accessible registers for the System Agent are described here. The legend for the register access codes are described in Chapter 43, "Introduction."

44.1.1 Host Configuration Space

These registers are discovered in Host Configuration Space starting at Bus 0, Device 0 (decimal), Function 0. The offset addresses are listed.

Table 44-1. Summary of PCI Configuration Registers—0/0/0

Offset (hex)	Bytes	Default Value (hex)	Register Name (Register Symbol)
0	4	19908086	"Device ID and Vendor ID Register (DEVICE_ID_VENDOR_ID_0_0_0_PCI)—Offset 0h" on page 1103
4	4	00000007	"PCI Status and PCI Command Register (PCI_STATUS_COMMAND_0_0_0_PCI)—Offset 4h" on page 1103
8	4	06000000	"PCI Revision ID and PCI Class Code Register (REVISION_ID_CLASS_CODE_0_0_0_PCI)—Offset 8h" on page 1104
C	4	00800000	"Master Latency Timer and Header Type Register (MASTER_LATENCY_TIME_0_0_0_PCI)—Offset Ch" on page 1104
2C	4	00000000	"PCI Subsystem Vendor ID and PCI Subsystem ID (SVID_SID_0_0_0_PCI)—Offset 2Ch" on page 1105
34	4	000000E0	"Capability Register Pointer (CAPPTR_0_0_0_PCI)—Offset 34h" on page 1105
48	4	00000000	"Memory Controller Hub Base Address Register (MCHBAR_LO_0_0_0_PCI)—Offset 48h" on page 1106
4C	4	00000000	"Memory Controller Hub Base Address Register (MCHBAR_HI_0_0_0_PCI)—Offset 4Ch" on page 1106
54	4	00000033	"Device Enable Register (DEVEN_0_0_0_PCI)—Offset 54h" on page 1107
60	4	00000000	"PCI Express Enhanced Configuration Range Base Address Low (PCIEXBAR_LO_0_0_0_PCI)—Offset 60h" on page 1108
64	4	00000000	"PCI Express Enhanced Configuration Range Base Address High (PCIEXBAR_HI_0_0_0_PCI)—Offset 64h" on page 1109
A8	4	00000000	"Top of Upper Usable DRAM Low (TOUUD_LO_0_0_0_PCI)—Offset A8h" on page 1110
AC	4	00000000	"Top of Upper Usable DRAM High (TOUUD_HI_0_0_0_PCI)—Offset ACh" on page 1111
B0	4	00000000	"Base of Data Stolen Memory (BDSM_0_0_0_PCI)—Offset B0h" on page 1112
B4	4	00000000	"Base of Graphics Stolen Memory (BGSM_0_0_0_PCI)—Offset B4h" on page 1113
B8	4	00100000	"Top Segment Memory Base (TSEGMB_0_0_0_PCI)—Offset B8h" on page 1114
BC	4	00100000	"Top of Lower Usable DRAM (TOLUD_0_0_0_PCI)—Offset BCh" on page 1115
DC	4	00000000	"Scratchpad (SKPD_0_0_0_PCI)—Offset DCh" on page 1115
E0	4	010C0009	"Capability ID0 Capability Control (CAPID0_CAPCTRL0_0_0_0_PCI)—Offset E0h" on page 1116
E4	4	00000000	"Capability ID0 A (CAPID0_A_0_0_0_PCI)—Offset E4h" on page 1117
E8	4	00000000	"Capability ID0 B (CAPID0_B_0_0_0_PCI)—Offset E8h" on page 1118
F4	4	00000000	"Manufacturer ID Register (MANUFACTURER_ID_0_0_0_PCI)—Offset F4h" on page 1119

44.1.2 Host Memory Space—MCHBAR

An index of the registers that are accessible in Host Memory Space is shown here.

Table 44-2. Summary of Memory Mapped I/O Registers for C-Unit—MCHBAR

Offset (hex)	Bytes	Default Value (hex)	Register Name (Register Symbol)
C-Unit Registers			
6C80	8	0000000000000000	"Default VTd Base Address Register (DEFVTDBAR_0_0_0_MCHBAR_C)—Offset 6C80h" on page 1120

Table 44-3. Summary of Memory Mapped I/O Registers for A-Unit—MCHBAR

Offset (hex)	Bytes	Default Value (hex)	Register Name (Register Symbol)
647C	4	00000000	"Spare BIOS (A_CR_SPARE_BIOS_MCHBAR)—Offset 647Ch" on page 1121
6588	4	00000000	"Uncorrectable Error Status Register (A_CR_UNCERRSTS_0_0_0_MCHBAR)—Offset 6588h" on page 1122
658C	4	FFFFFFFF	"Uncorrectable Error Mask Register (A_CR_UNCERRMSK_0_0_0_MCHBAR)—Offset 658Ch" on page 1125
6590	4	00000000	"Uncorrectable Error Severity Register (A_CR_UNCERRSEV_0_0_0_MCHBAR)—Offset 6590h" on page 1127
6594	4	00000000	"First Uncorrectable Error Register (A_CR_UNCFERRSTS_0_0_0_MCHBAR)—Offset 6594h" on page 1129
6598	4	00000000	"Next Uncorrectable Error Register (A_CR_UNCNERRSTS_0_0_0_MCHBAR)—Offset 6598h" on page 1132
659C	4	00000000	"Uncorrectable Error Select Register (A_CR_UNCERRCNTSEL_0_0_0_MCHBAR)—Offset 659Ch" on page 1135
65A0	4	00000000	"Uncorrectable Error Count (A_CR_UNCERRCNT_0_0_0_MCHBAR)—Offset 65A0h" on page 1137
65A4	4	00000000	"Correctable Error Status Register (A_CR_CORERRSTS_0_0_0_MCHBAR)—Offset 65A4h" on page 1138
65A8	4	FFFFFFFF	"Correctable Error Mask Register (A_CR_CORERRMSK_0_0_0_MCHBAR)—Offset 65A8h" on page 1141
65AC	4	00000000	"First Correctable Error Register (A_CR_CORFERRSTS_0_0_0_MCHBAR)—Offset 65ACh" on page 1143
65B0	4	00000000	"Next Correctable Error Register (A_CR_CORNERRSTS_0_0_0_MCHBAR)—Offset 65B0h" on page 1146
65B4	4	FFFFFFFF	"Correctable Error Count Select (A_CR_CORERRCNTSEL_0_0_0_MCHBAR)—Offset 65B4h" on page 1149
65B8	4	00000000	"Correctable Error Count (A_CR_CORERRCNT_0_0_0_MCHBAR)—Offset 65B8h" on page 1151
65C0	8	0000000000000000	"Slice and Channel Hash (A_CR_SLICE_CHANNEL_HASH_0_0_0_MCHBAR)—Offset 65C0h" on page 1152
65D0	4	00000000	"A_CR_ASYM_MEM_REGION0_0_0_0_MCHBAR—Offset 65D0h" on page 1154
65D4	4	00000000	"A_CR_ASYM_MEM_REGION1_0_0_0_MCHBAR—Offset 65D4h" on page 1154

Table 44-4. Summary of Memory Mapped I/O Registers for B-Unit—MCHBAR (Sheet 1 of 6)

Offset (hex)	Bytes	Default Value (hex)	Register Name (Register Symbol)
6800	4	00000007	"B-Unit Miscellaneous Configuration (B_CR_BMISC_0_0_0_MCHBAR)—Offset 6800h" on page 1155
6868	4	00000000	"Slice 0 Memory Access Count (B_CR_MEM_ACCESS_COUNT_SLICE0)—Offset 6868h" on page 1155
686C	4	00000000	"Slice 1 Memory Access Count (B_CR_MEM_ACCESS_COUNT_SLICE1)—Offset 686Ch" on page 1155
6870	4	00000000	"IMR0 Base (B_CR_BIMR0BASE_0_0_0_MCHBAR)—Offset 6870h" on page 1156
6874	4	00000000	"IMR0 Mask (B_CR_BIMR0MASK_0_0_0_MCHBAR)—Offset 6874h" on page 1157
6878	8	00000C0061010202	"IMR0 Control Policy (B_CR_BIMR0CP_0_0_0_MCHBAR)—Offset 6878h" on page 1157
6880	8	0000000000000000	"IMR0 Read Access Policy (B_CR_BIMR0RAC_0_0_0_MCHBAR)—Offset 6880h" on page 1158
6888	8	0000000000000000	"IMR0 Write Access Policy (B_CR_BIMR0WAC_0_0_0_MCHBAR)—Offset 6888h" on page 1161
6890	4	00000000	"B_CR_BIMR1BASE_0_0_0_MCHBAR—Offset 6890h" on page 1164
6894	4	00000000	"IMR1 Mask (B_CR_BIMR1MASK_0_0_0_MCHBAR)—Offset 6894h" on page 1165
6898	8	00000C0061010202	"IMR1 Control Policy (B_CR_BIMR1CP_0_0_0_MCHBAR)—Offset 6898h" on page 1165
68A0	8	0000000000000000	"IMR1 Read Access Policy (B_CR_BIMR1RAC_0_0_0_MCHBAR)—Offset 68A0h" on page 1166
68A8	8	0000000000000000	"IMR1 Write Access Policy (B_CR_BIMR1WAC_0_0_0_MCHBAR)—Offset 68A8h" on page 1169
68B0	4	00000000	"Base 0 IMR2 Base (B_CR_BIMR2BASE_0_0_0_MCHBAR)—Offset 68B0h" on page 1172
68B4	4	00000000	"IMR2 Mask (B_CR_BIMR2MASK_0_0_0_MCHBAR)—Offset 68B4h" on page 1173
68B8	8	00000C0061010202	"IMR2 Control Policy (B_CR_BIMR2CP_0_0_0_MCHBAR)—Offset 68B8h" on page 1173
68C0	8	0000000000000000	"IMR2 Read Access Policy (B_CR_BIMR2RAC_0_0_0_MCHBAR)—Offset 68C0h" on page 1174
68C8	8	0000000000000000	"IMR2 Write Access Policy (B_CR_BIMR2WAC_0_0_0_MCHBAR)—Offset 68C8h" on page 1177

44.1.5 Sideband Registers

An index of the Sideband registers that are accessible to the Host are listed here. Each is accessible in Host Memory Space using the Sideband Base Address Register (BAR) DEFVTDBAR. It is located in Host Root Memory Space MCHBAR +offset 6C80h.

See Section 44.3.123, "Default VTd BAR (B_CR_DEFVTDBAR_0_0_0_MCHBAR)—Offset 6C80h" on page 1316. Also see Section 3.4.2, "Accessing System Agent Sideband Registers" on page 187.

The Sideband registers for Memory Controller 0 are shown in Table 44-8. For Memory Controller 1 see Table 44-9.

Table 44-8. Summary of Sideband Registers—0x10 (Memory Controller 0)

Offset from Sideband Port 10h (hex)	Memory-Mapped I/O offset from SBREG_BAR (hex)	Default Value (hex)	Register Name (Register Symbol)

Table 44-10. Summary of Sideband Registers—0x99

Offset from Sideband Port 99h (hex)	Memory-Mapped I/O offset from SBREG_BAR (hex)	Default Value (hex)	Register Name (Register Symbol)
220	99_0220	00042222	"ICLK_DWORD8—Port 99h, Offset 220h" on page 1480

44.2 Registers in Configuration Space

44.2.1 Device ID and Vendor ID Register (DEVICE_ID_VENDOR_ID_0_0_0_PCI)—Offset 0h

This register uniquely identifies any PCI device.

Type: PCI Configuration Register (Size: 32 bits)

Offset: [B:0, D:0, F:0] + 0h

Default: 19908086h

Bit Range	Default & Access	Field Name (ID): Description
31:16	0x1990 RO	**Device ID (DID):** This field identifies the particular function as allocated by Intel.
15:0	0x8086 RO	**Vendor ID (VENDOR_ID):** This field identifies Intel as the manufacturer of the device.

44.2.2 PCI Status and PCI Command Register (PCI_STATUS_COMMAND_0_0_0_PCI)—Offset 4h

PCI Status is used to record status information for PCI bus related events. PCI Command provides coarse control over a device's ability to generate and respond to PCI cycles.

Type: PCI Configuration Register (Size: 32 bits)

Offset: [B:0, D:0, F:0] + 4h

Default: 00000007h

Bit Range	Default & Access	Field Name (ID): Description
31:0	0x7 RO	**PCI Status and PCI Command (PCI_STATUS_AND_COMMAND):** Allowing this device to respond to I/O space and Memory Space accesses. This device is also allowed to behave as a bus master.

44.2.3 PCI Revision ID and PCI Class Code Register (REVISION_ID_CLASS_CODE_0_0_0_PCI)—Offset 8h

Revision ID contains the revision number of the device. Class Code identifies the basic function of the device.

Type: PCI Configuration Register (Size: 32 bits)

Offset: [B:0, D:0, F:0] + 8h

Default: 06000000h

Bit Range	Default & Access	Field Name (ID): Description
31:16	0x600 RO	**Class Code 1 (CLASS_CODE1):** This device is a Host Bridge.
15:8	0x0 RO	**Class Code 0 (CLASS_CODE0):** This device is a Host Bridge.
7:0	0x0 RW/V	**Revision ID (REVISION_ID):** Revision ID

44.2.4 Master Latency Timer and Header Type Register (MASTER_LATENCY_TIME_0_0_0_PCI)—Offset Ch

This register defines Latency Timer and layout of the device Configuration Space header.

Type: PCI Configuration Register (Size: 32 bits)

Offset: [B:0, D:0, F:0] + Ch

Default: 00800000h

Bit Range	Default & Access	Field Name (ID): Description
31:24	0x0 RO	**Reserved (RESERVED_1):** Reserved.
23:16	0x80 RO	**Header Type (HEADER_TYPE):** This is a multi-function device.
15:8	0x0 RO	**Master Latency Timer (MASTER_LATENCY_TIMER):** This field specifies, in units of PCI bus clocks, the value of the Latency Timer for this PCI bus master.
7:0	0x0 RO	**Reserved (RESERVED_0):** Reserved.

44.2.5 PCI Subsystem Vendor ID and PCI Subsystem ID (SVID_SID_0_0_0_PCI)—Offset 2Ch

This register is used to uniquely identify the subsystem where the PCI device resides.

Type: PCI Configuration Register (Size: 32 bits)

Offset: [B:0, D:0, F:0] + 2Ch

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:16	0x0 RW	**Subsystem ID (SUBSYSTEM_ID):** PCI Subsystem ID: This field should be programmed during BIOS initialization.
15:0	0x0 RW	**Subsystem Vendor ID (SUBSYSTEM_VENDOR_ID):** PCI Subsystem Vendor ID: This field should be programmed by BIOS during boot-up to indicate the vendor of the system board.

44.2.6 Capability Register Pointer (CAPPTR_0_0_0_PCI)—Offset 34h

This register contains a pointer to the first Capability Register in a linked list.

Type: PCI Configuration Register (Size: 32 bits)

Offset: [B:0, D:0, F:0] + 34h

Default: 000000E0h

Bit Range	Default & Access	Field Name (ID): Description
31:8	0x0 RO	**Reserved (RESERVED_0):** Reserved.
7:0	0xe0 RO	**Base Address of First Capability Register (BASE_ADDR):** This pointer is an 8-bit address to an offset within this device's Configuration Space that holds the first Capability Register (CAPID0_CAPCTRL).

44.2.7 Memory Controller Hub Base Address Register (MCHBAR_LO_0_0_0_PCI)—Offset 48h

This register contains the lower 32bits of the MCHBAR base address.

Type: PCI Configuration Register (Size: 32 bits)

Offset: [B:0, D:0, F:0] + 48h

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:15	0x0 RW	**Base Address of MCHBAR (BASE_ADDR):** Defines the base address of MCHBAR. MCHBAR[38:15] is MCHBAR_HI[6:0],MCHBAR_LO[31:15]. If incoming Request Address[38:15] matches MCHBAR[38:15] then the request hits and address in the MCHBAR range.
14:4	0x0 RO	**Reserved:** Reserved
3:1	0x0 RO	**Reserved:** Reserved
0	0x0 RW	**MCHBAR Enable (MCHBAREN):** • 0: MCHBAR is disabled and does not claim any memory • 1: MCHBAR memory mapped accesses are claimed and decoded appropriately

44.2.8 Memory Controller Hub Base Address Register (MCHBAR_HI_0_0_0_PCI)—Offset 4Ch

This register contains the upper 32bits of the MCHBAR base address.

Type: PCI Configuration Register (Size: 32 bits)

Offset: [B:0, D:0, F:0] + 4Ch

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:7	0x0 RO	**Reserved (RESERVED_0):** Reserved.
6:0	0x0 RW	**Base Address of MCHBAR (BASE_ADDR):** Defines the base address of the MCHBAR. If incoming Request Address[38:15] matches MCHBAR[38:15], then request hits an address in the MCHBAR range.

44.2.9 Device Enable Register (DEVEN_0_0_0_PCI)—Offset 54h

The DEVEN register allows for enabling/disabling of PCI devices and functions that are within the CPU package.

Type: PCI Configuration Register (Size: 32 bits)

Offset: [B:0, D:0, F:0] + 54h

Default: 00000033h

Bit Range	Default & Access	Field Name (ID): Description
31:6	0x0 RO	**Reserved (RESERVED_1):** Reserved.
5	0x1 RW/V	**Device 3 Function 0 Enable (D3F0EN):** • 0: Bus 0 Device 3 Function 0 is disabled and hidden • 1: Bus 0 Device 3 Function 0 is enabled and visible This bit will be set to 0b and remain 0b if Device 3 capability is disabled.
4	0x1 RW/V	**Device 2 Function 0 Enable (D2F0EN):** • 0: Bus 0 Device 2 Function 0 is disabled and hidden • 1: Bus 0 Device 2 Function 0 is enabled and visible This bit will be set to 0b and remain 0b if Device 2 capability is disabled.
3	0x0 RO	**RSVD0:** Reserved
2	0x0 RO	**Reserved (RESERVED_0):** Reserved.
1	0x1 RW/V	**Device 0 Function 1 Enable (D0F1EN):** • 0: Bus 0 Device 0 Function 1 is disabled and hidden • 1: Bus 0 Device 0 Function 1 is enabled and visible This bit will be set to 0b and remain 0b if Device 0/0/1 capability is disabled.
0	0x1 RO	**Device 0 Function 0 Enable (D0F0EN):** Bus 0 Device 0 Function 0 may not be disabled, and is therefore hardwired to 1.

44.2.10 PCI Express Enhanced Configuration Range Base Address Low (PCIEXBAR_LO_0_0_0_PCI)—Offset 60h

This register contains the lower 32bits of the base address of the PCI Express Enhanced Configuration region.

Type: PCI Configuration Register (Size: 32 bits)

Offset: [B:0, D:0, F:0] + 60h

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:28	0x0 RW	**PCI Express Base Address Register (PCIEXBAR):** PCIEXBAR[38:28] is PCIEXBAR_HI[6:0],PCIEXBAR_LO[31:28]. Describes bits [38:28] of the base address of the contiguous 256MB region for PCI Express Enhanced Configuration region. If bits [38:28] of the request address matches the PCIEXBAR[38:28] then the request targets the PCI Express Enhanced Configuration Space region. **Power Well:** prst
27	0x0 RO	**Address Mask for 128MB region (ADMSK128):** Reserved. **Power Well:** prst
26	0x0 RO	**Address Mask for 64MB region (ADMSK64):** Reserved. **Power Well:** prst
25:3	0x0 RO	**Reserved (RESERVED_0):** Reserved. **Power Well:** prst
2:1	0x0 RO	**Length of the Region (LENGTH):** Reserved. **Power Well:** prst
0	0x0 RW	**PCIEXBAR Range Enable (PCIEXBAREN):** • 0: The PCIEXBAR range is disabled. Address may target DRAM or MMIO, depending on other address decode rules. • 1: The PCIEXBAR range is enabled. Incoming request address must be compared with PCIEXBAR to determine whether the request targets PCI Express Enhanced Configuration region. **Power Well:** prst

44.2.11 PCI Express Enhanced Configuration Range Base Address High (PCIEXBAR_HI_0_0_0_PCI)—Offset 64h

This register contains the upper 32bits of the base address of the PCI Express Enhanced Configuration region.

Type: PCI Configuration Register (Size: 32 bits)

Offset: [B:0, D:0, F:0] + 64h

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:7	0x0 RO	**Reserved (RESERVED_0):** Reserved. **Power Well:** prst
6:0	0x0 RW	**PCI Express Base Address Register (PCIEXBAR_HI):** PCIEXBAR[38:28] is PCIEXBAR_HI[6:0],PCIEXBAR_LO[31:28]. Describes bits [38:28] of the base address of the contiguous 256MB region for PCI Express Enhanced Configuration region. If bits [38:28] of the request address matches the PCIEXBAR[38:28] then the request targets the PCI Express Enhanced Configuration Space region. **Power Well:** prst

44.2.12 Top of Upper Usable DRAM Low (TOUUD_LO_0_0_0_PCI)—Offset A8h

Defines the top of the upper usable DRAM range and start of the upper MMIO address range. Formerly defined in BMBOUND_HI. This register contains the lower 32 bits of TOUUD.

Type: PCI Configuration Register (Size: 32 bits)

Offset: [B:0, D:0, F:0] + A8h

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:20	0x0 RW	**Top of Upper Usable DRAM (TOUUD):** TOUUD[38:20] is TOUUD_HI[6:0],TOUUD_LO[31:20]. Upper usable DRAM address range ends at the preceding byte. Upper MMIO Range starts at this address and extends up to the maximum system addressable memory range. Bits 38:20 are compared with bits 38:20 of the incoming request address to determine whether the request targets the upper usable DRAM range or upper MMIO range. If Request Address[38:20])=TOUUD[38:20] and any bit in Request Address[38:32] is set, request is determined to target the upper MMIO range. **Power Well:** prst
19:1	0x0 RO	**Reserved (RESERVED_0):** Reserved should return 0s on read. **Power Well:** prst
0	0x0 RW	**TOUUD Register Lock (LOCK_RESERVED):** This bit will lock all writable settings in this register, including itself (client definition). **Power Well:** prst

44.2.13 Top of Upper Usable DRAM High (TOUUD_HI_0_0_0_PCI)—Offset ACh

Defines the top of the upper usable DRAM range and start of the upper MMIO address range. Formerly defined in BMBOUND_HI. This register contains the upper 32 bits of TOUUD.

Type: PCI Configuration Register (Size: 32 bits)

Offset: [B:0, D:0, F:0] + ACh

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:7	0x0 RO	**Reserved (RESERVED_0):** Reserved. **Power Well:** prst
6:0	0x0 RW	**Top of Upper Usable DRAM (TOUUD_HI):** TOUUD[38:20] is TOUUD_HI[6:0],TOUUD_LO[31:20]. Upper usable DRAM address range ends at the preceding byte. Upper MMIO Range starts at this address and extends up to the maximum system addressable memory range. Bits 38:20 are compared with bits 38:20 of the incoming request address to determine whether the request targets the upper usable DRAM range or upper MMIO range. If Request Address[38:20])=TOUUD[38:20] and any bit in Request Address[38:32] is set, request is determined to target the upper MMIO range. **Power Well:** prst

44.2.14 Base of Data Stolen Memory (BDSM_0_0_0_PCI)—Offset B0h

Defines the Base of the Data Stolen Memory. In addition, the GSM range is defined to end at the preceding byte. See BGSM register.

Type: PCI Configuration Register (Size: 32 bits)

Offset: [B:0, D:0, F:0] + B0h

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:20	0x0 RW	**Base of Data Stolen Memory (BDSM):** This register contains the base address of the Data Stolen Memory. The limit for the Data Stolen Memory is TOLUD-1. This range is not decoded by the system agent, but is a sub-region of BGSM decoded by the Integrated Graphics Device. Incoming Request Address[31:20] is compared against BDSM[31:20] and TOLUD[31:20] to determine if the address falls in the range. The comparison check is as follows: BDSM[31:20](=Address[31:20] and Address[31:20](TOLUD[31:20] and Address[38:32]==0. Request SAI is then checked against the allowed SAIs to determine if access is allowed. **Power Well:** prst
19:1	0x0 RO	**Reserved (RESERVED_0):** Reserved. **Power Well:** prst
0	0x0 RW	**BDSM Register Lock (LOCK):** This bit will lock all writable settings in this register, including itself. **Power Well:** prst

44.2.15 Base of Graphics Stolen Memory (BGSM_0_0_0_PCI)—Offset B4h

Defines the Base of the Graphics Stolen Memory. In addition, the SMM range is defined to end at the preceding byte. See TSEGMB register.

Type: PCI Configuration Register (Size: 32 bits)

Offset: [B:0, D:0, F:0] + B4h

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:20	0x0 RW	**Base of Graphics Stolen Memory (BGSM):** This register contains the base address of the Graphics Stolen Memory. The limit for the Graphics Stolen Memory is TOLUD-1. Incoming Request Address[31:20] is compared against BGSM[31:20] and TOLUD[31:20] to determine if the address falls in the range. **Power Well:** prst
19:1	0x0 RO	**Reserved (RESERVED_0):** Reserved. **Power Well:** prst
0	0x0 RW	**BGSM Register Lock (LOCK):** This bit will lock all writable settings in this register, including itself. **Power Well:** prst

44.2.16 Top Segment Memory Base (TSEGMB_0_0_0_PCI)—Offset B8h

TSEGMB defines the base of the SMM range, and the BGSM register defines the limit of the SMM range.

Note: In prior SoCs, the base register was defined in SMMRRL register and the limit was defined in the SMMRRH register.

Type: PCI Configuration Register (Size: 32 bits)

Offset: [B:0, D:0, F:0] + B8h

Default: 00100000h

Bit Range	Default & Access	Field Name (ID): Description
31:20	0x1 RW	**Base address of Top Segment DRAM Memory (TSEGMB):** BIOS determines the base of TSEG memory, which must be at or below Graphics Base of GTT Stolen Memory BGSM. SMM range starts at this base and ends at BGSM1. Incoming Request Address [31:20] will be compared with TSEGMB[31:20] and BGSM[31:20] to determine if the request targets the SMM range. **Power Well:** prst
19:1	0x0 RO	**Reserved (RESERVED_0):** Reserved. **Power Well:** prst
0	0x0 RW	**TSEGMB Register Lock (LOCK):** This bit will lock all writable settings in this register, including itself. **Power Well:** prst

44.2.17 Top of Lower Usable DRAM (TOLUD_0_0_0_PCI)—Offset BCh

This register defines the Top of Lower Usable DRAM range and start of the Lower MMIO Address range. Formerly defined in BMBOUND.

Type: PCI Configuration Register (Size: 32 bits)

Offset: [B:0, D:0, F:0] + BCh

Default: 00100000h

Bit Range	Default & Access	Field Name (ID): Description
31:20	0x1 RW	**Top of Lower Usable DRAM (TOLUD):** Defines the top of lower usable DRAM, which ends at the preceding byte. Lower MMIO Address range starts at this address and continues up to the 4GB Address 0xFFFF_FFFF. Bits 31:20 are compared with incoming request Address[31:20] to determine whether the request targets lower usable DRAM range or the lower MMIO range. If Request Address[31:20])=TOLUD[31:20] and Request Address[38:32]==0 then the Request Address falls in the Lower MMIO Address range. **Power Well:** prst
19:1	0x0 RO	**Reserved (RESERVED_0):** Reserved. **Power Well:** prst
0	0x0 RW	**TOLUD register lock (LOCK):** Reserved. **Power Well:** prst

44.2.18 Scratchpad (SKPD_0_0_0_PCI)—Offset DCh

This register holds 32 writable bits with no functionality behind them. It is for the convenience of BIOS and graphics drivers.

Type: PCI Configuration Register (Size: 32 bits)

Offset: [B:0, D:0, F:0] + DCh

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:0	0x0 RW	**Scratchpad (SKPD):** 1 DWORD of data storage.

44.2.19 Capability ID0 Capability Control (CAPID0_CAPCTRL0_0_0_0_PCI)—Offset E0h

Control bits in this register describe the attributes of CAPID0_A and CAPID0_B capability registers.

Type: PCI Configuration Register (Size: 32 bits)

Offset: [B:0, D:0, F:0] + E0h

Default: 010C0009h

Bit Range	Default & Access	Field Name (ID): Description
31:28	0x0 RO	**Reserved (RESERVED_0):** Reserved.
27:24	0x1 RO	**Capability ID Version (CAPID_VER):** This field has the value 0001b to identify the first revision of the CAPID register definition.
23:16	0xc RO	**Capability ID0 Structure Length (CAPIDLEN):** This field has the value 0Ch to indicate the structure length 12 bytes. This is the total size of this CAPCTRL and the CAPID0_A and CAPID0_B registers in the following bytes.
15:8	0x0 RO	**Next Capability Register Pointer (NEXT_CAP):** This field is hardwired to 00h, indicating the end of the capabilities linked list.
7:0	0x9 RO	**Capability ID (CAP_ID):** This field has the value 1001b to identify the CAP_ID assigned by the PCI SIG for vendor dependent capability pointers.

44.2.20 Capability ID0 A (CAPID0_A_0_0_0_PCI)—Offset E4h

Control of bits in this register is only required for customer visible SKU differentiation.

Type: PCI Configuration Register (Size: 32 bits)

Offset: [B:0, D:0, F:0] + E4h

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:24	0x0 RW	**Reserved:** Reserved
23	0x0 RW/Fuse	**VTd Disable (VTDD):** • 0: Enable VTd • 1: Disable VTd
22:16	0x0 RW/Fuse	**Reserved:** Reserved for future capabilities.
15	0x0 RO/V	**Dynamic Power Performance Management (DPPM) Disable:** • 0: DPPM associated memory spaces are accessible. • 1: DPPM associated memory and IO spaces are disabled. DEVEN_0_0_0_PCI field for DPPM cannot be set.
14:0	0x0 RW/Fuse	**Reserved:** Reserved

44.2.21 Capability ID0 B (CAPID0_B_0_0_0_PCI)—Offset E8h

Control of bits in this register is only required for customer visible SKU differentiation.

Type: PCI Configuration Register (Size: 32 bits)

Offset: [B:0, D:0, F:0] + E8h

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31	0x0 RO/V	**Reserved:** Reserved
30	0x0 RW/Fuse	**Reserved:** Reserved
29	0x0 RW/Fuse	**Reserved:** Reserved
28	0x0 RW/Fuse	**Reserved:** Reserved
27	0x0 RW/Fuse	**Reserved:** Reserved
26	0x0 RW/Fuse	**Reserved:** Reserved
25	0x0 RW/Fuse	**Reserved:** Reserved
24	0x0 RO/V	**Shared Virtual Memory Disable (SVMDIS):** • 0: Enable Shared Virtual Memory mode • 1: Disable Shared Virtual Memory mode
23:0	0x0 RW	**Spare bits[23:0] (SPARE23_0):** Reserved for future capabilities.

44.2.22 Manufacturer ID Register (MANUFACTURER_ID_0_0_0_PCI)—Offset F4h

This register describes the manufacturing characteristics of the device.

Type: PCI Configuration Register (Size: 32 bits)

Offset: [B:0, D:0, F:0] + F4h

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:28	0x0 RW/V	**Reserved (RESERVED_0):** Reserved.
27:24	0x0 RW/V	**DOT Portion of Process ID (DOT_PORTION_OF_PROCESS_ID):**
23:16	0x0 RW/V	**Process Portion or Process ID (PROCESS_PORTION_OF_PROCESS_ID):**
15:8	0x0 RW/V	**Manufacturing ID (MID):**
7:0	0x0 RW/V	**Manufacturing Stepping ID (MSID):**

44.3 Registers in Memory Space—MCHBAR

These registers are accessed in Host Memory Space starting at the relocatable memory address defined by the Base Address Register (BAR) MCHBAR. It is a 64-bit BAR and is located in Host Root Configuration Space at Bus 0, Device 0, Function 0, offset 48h and 4Ch.

See Section 44.2.7, "Memory Controller Hub Base Address Register (MCHBAR_LO_0_0_0_PCI)—Offset 48h" on page 1106 and Section 44.2.8, "Memory Controller Hub Base Address Register (MCHBAR_HI_0_0_0_PCI)—Offset 4Ch" on page 1106.

44.3.1 Default VTd Base Address Register (DEFVTDBAR_0_0_0_MCHBAR_C)—Offset 6C80h

This is the base address for the Default VT configuration space. There is no physical memory within this 4KB window that can be addressed. The 4KB reserved by this register does not alias to any PCI 2.3 compliant memory mapped space. On reset the DEFVTd configuration space is disabled and must be enabled by writing a 1'b1 to DEFVTBAREN. BIOS programs this register after which the register cannot be altered. BIOS must write DEFVTDBAR and then immediately follow it up with a read to DEFVTDBAR to ensure that all copies of DEFVTDBAR in the system are updated.

Type: Memory Mapped I/O Register (Size: 64 bits)

BAR and Offset: [MCHBAR] + 6C80h

Default: 0000000000000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
63:40	0x0 RO	**Reserved (RESERVED_1):** Reserved.
39	0x0 RO	**Reserved:** Reserved
38:12	0x0 RW	**Default VTd Base Address Register (DEFVTDBAR):** If DEFVTDBAR is enabled this field corresponds to bits 38:12 of the base address default IOMMU VTd configuration space. BIOS will program this register, resulting in a base address for a 4KB block of contiguous memory address space. This register ensures that a naturally aligned 4KB space is allocated within the first 512GB of addressable memory space. System Software uses this base address to program the default VTd IOMMU register set. If DEFVTDBAR is enabled and incoming Request Address[38:12] matches DEFVTDBAR[38:12], the request targets the Default VTd BAR.
11:2	0x0 RO	**Reserved (RESERVED_0):** Reserved.
1	0x0 RW	**DEFVTDBAR Register Lock (LOCK):** Locks the contents of the register, including itself.
0	0x0 RW/L	**Default VTd Base Address Range Enable (DEFVTDBAREN):** • 0: DEFVTDBAR is disabled and does not claim any memory • 1: DEFVTDBAR memory mapped accesses are claimed and decoded appropriately. This bit will remain 1'b0 if VTd capability is disabled.

44.3.2 Spare BIOS (A_CR_SPARE_BIOS_MCHBAR)—Offset 647Ch

Spare CR in MCHBAR.

Type: Memory Mapped I/O Register (Size: 32 bits)

Default: 00000000h

BAR and Offset: [MCHBAR] + 647Ch

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
31:0	0x0 RW	**SPARE RW Bits (SPARE_RW):** Spare RW 32 bits in BIOSWR policy group.

44.3.3 Uncorrectable Error Status Register (A_CR_UNCERRSTS_0_0_0_MCHBAR)—Offset 6588h

Errors that have been seen in A-Unit. The error is only logged if the respective bit in UNCERRMSK is 0.

Type: Memory Mapped I/O Register (Size: 32 bits)

BAR and Offset: [MCHBAR] + 6588h

Default: 00000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
31	0x0 RO	**Reserved** **Power Well:** prst
30	0x0 RO	**Reserved** **Power Well:** prst
29	0x0 RO	**Reserved** **Power Well:** prst
28	0x0 RO	**Reserved** **Power Well:** prst
27	0x0 RO	**Reserved** **Power Well:** prst
26	0x0 RO	**Reserved** **Power Well:** prst
25	0x0 RW/1C	**iommu data iotlb parity error (iommu_data_iotlb_par_err):** IOMMU IOTLB data parity error **Power Well:** prst
24	0x0 RW/1C	**iommu data cc parity error (iommu_data_cc_par_err):** IOMMU context cache data parity error **Power Well:** prst
23	0x0 RW/1C	**iommu data l4 parity error (iommu_data_l4_par_err):** IOMMU level 4 page walk data parity error **Power Well:** prst
22	0x0 RW/1C	**iommu data l3 parity error (iommu_data_l3_par_err):** IOMMU level 3 page walk data parity error **Power Well:** prst
21	0x0 RW/1C	**iommu data l2 parity error (iommu_data_l2_par_err):** IOMMU level 2 page walk data parity error **Power Well:** prst
20	0x0 RW/1C	**downstream cmd buffer parity error (downstream_cmd_buffer_par_err):** downstream cmd buffer parity error detected **Power Well:** prst

Bit Range	Default & Access	Field Name (ID): Description
19	0x0 RW/1C	**downstream data buffer parity error (downstream_data_buffer_par_err):** downstream data buffer parity error detected **Power Well:** prst
18	0x0 RW/1C	**upstream cmd buffer parity error (upstream_cmd_buffer_par_err):** upstream cmd buffer parity error detected **Power Well:** prst
17	0x0 RW/1C	**iosf upstream data parity error (iosf_upstream_data_par_err):** iosf upstream data parity error detected **Power Well:** prst
16	0x0 RW/1C	**iosf upstream cmd parity error (iosf_upstream_cmd_par_err):** iosf upstream cmd parity error detected **Power Well:** prst
15	0x0 RO	**Reserved** **Power Well:** prst
14	0x0 RO	**Reserved** **Power Well:** prst
13	0x0 RO	**Reserved** **Power Well:** prst
12	0x0 RO	**Reserved** **Power Well:** prst
11	0x0 RO	**Reserved** **Power Well:** prst
10	0x0 RW/1C	**msi rsvd set (msi_rsvd_set):** An MSI was received with reserved bits set **Power Well:** prst
9	0x0 RW/1C	**gpa overflow (gpa_overflow):** A transaction was received with a guest physical address that was too large **Power Well:** prst
8	0x0 RW/1C	**illegal msi (illegal_msi):** A malformed/illegal MSI was received in the upstream direction **Power Well:** prst
7	0x0 RW/1C	**at translated illegal device (at_translated_illegal_device):** A device that is not support to set the AT bit set it to an illegal value **Power Well:** prst
6	0x0 RO	**reserved (undefined5):** Reserved for future use. **Power Well:** prst
5	0x0 RW/1C	**bad sai cmpl (bad_sai_cmpl):** An incorrect/illegal sai was received with an upstream completion transaction. **Power Well:** prst

Bit Range	Default & Access	Field Name (ID): Description
4	0x0 RW/1C	**received lk cmpl (received_lk_cmpl):** Received a CmplLck completion from iosf. **Power Well:** prst
3	0x0 RW/1C	**bad sai nonposted (bad_sai_nonposted):** An incorrect/illegal sai was received with an upstream non-posted transaction. **Power Well:** prst
2	0x0 RW/1C	**illegal nonposted opcode (illegal_nonposted_opcode):** Illegal/Unsupported non-posted opcode received from iosf. **Power Well:** prst
1	0x0 RW/1C	**bad sai posted (bad_sai_posted):** An incorrect/illegal sai was received with an upstream posted transaction. **Power Well:** prst
0	0x0 RW/1C	**illegal posted opcode (illegal_posted_opcode):** Illegal/Unsupported posted opcode received from iosf. **Power Well:** prst

44.3.4 Uncorrectable Error Mask Register (A_CR_UNCERRMSK_0_0_0_MCHBAR)—Offset 658Ch

Masks whether a reported error is logged and signaled to the IEH.

1- do not log/signal.

0 - log/signal.

Type: Memory Mapped I/O Register (Size: 32 bits)

BAR and Offset: [MCHBAR] + 658Ch

Default: FFFFFFFFh

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
31	0x1 RO	**Reserved**
30	0x1 RO	**Reserved**
29	0x1 RO	**Reserved**
28	0x1 RO	**Reserved**
27	0x1 RO	**Reserved**
26	0x1 RO	**Reserved**
25	0x1 RW	**iommu data iotlb parity error (iommu_data_iotlb_par_err):** IOMMU IOTLB data parity error
24	0x1 RW	**iommu data cc parity error (iommu_data_cc_par_err):** IOMMU context cache data parity error
23	0x1 RW	**iommu data l4 parity error (iommu_data_l4_par_err):** IOMMU level 4 page walk data parity error
22	0x1 RW	**iommu data l3 parity error (iommu_data_l3_par_err):** IOMMU level 3 page walk data parity error
21	0x1 RW	**iommu data l2 parity error (iommu_data_l2_par_err):** IOMMU level 2 page walk data parity error
20	0x1 RW	**downstream cmd buffer parity error (downstream_cmd_buffer_par_err):** downstream cmd buffer parity error detected
19	0x1 RW	**downstream data buffer parity error (downstream_data_buffer_par_err):** downstream data buffer parity error detected
18	0x1 RW	**upstream cmd buffer parity error (upstream_cmd_buffer_par_err):** upstream cmd buffer parity error detected
17	0x1 RW	**iosf upstream data parity error (iosf_upstream_data_par_err):** iosf upstream data parity error detected
16	0x1 RW	**iosf upstream cmd parity error (iosf_upstream_cmd_par_err):** iosf upstream cmd parity error detected
15	0x1 RO	**Reserved**
14	0x1 RO	**Reserved**

Bit Range	Default & Access	Field Name (ID): Description
13	0x1 RO	**Reserved**
12	0x1 RO	**Reserved**
11	0x1 RO	**Reserved**
10	0x1 RW	**msi rsvd set (msi_rsvd_set):** An MSI was received with reserved bits set
9	0x1 RW	**gpa overflow (gpa_overflow):** A transaction was received with a guest physical address that was too large
8	0x1 RW	**illegal msi (illegal_msi):** A malformed/illegal MSI was received in the upstream direction
7	0x1 RW	**at translated illegal device (at_translated_illegal_device):** A device that is not support to set the AT bit set it to an illegal value
6	0x1 RO	**Reserved**
5	0x1 RW	**bad sai cmpl (bad_sai_cmpl):** An incorrect/illegal sai was received with an upstream completion transaction.
4	0x1 RW	**received lk cmpl (received_lk_cmpl):** Received a CmplLck completion from iosf.
3	0x1 RW	**bad sai nonposted (bad_sai_nonposted):** An incorrect/illegal sai was received with an upstream non-posted transaction.
2	0x1 RW	**illegal nonposted opcode (illegal_nonposted_opcode):** Illegal/Unsupported non-posted opcode received from iosf.
1	0x1 RW	**bad sai posted (bad_sai_posted):** An incorrect/illegal sai was received with an upstream posted transaction.
0	0x1 RW	**illegal posted opcode (illegal_posted_opcode):** Illegal/Unsupported posted opcode received from iosf.

44.3.5 Uncorrectable Error Severity Register (A_CR_UNCERRSEV_0_0_0_MCHBAR)—Offset 6590h

When set, escalate error as fatal to IEH, otherwise non-fatal.

Type: Memory Mapped I/O Register (Size: 32 bits)

BAR and Offset: [MCHBAR] + 6590h

Default: 00000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
31	0x0 RO	**Reserved**
30	0x0 RO	**Reserved**
29	0x0 RO	**Reserved**
28	0x0 RO	**Reserved**

25	0x0 RW	**iommu data iotlb parity error (iommu_data_iotlb_par_err):** IOMMU IOTLB data parity error
24	0x0 RW	**iommu data cc parity error (iommu_data_cc_par_err):** IOMMU context cache data parity error
23	0x0 RW	**iommu data l4 parity error (iommu_data_l4_par_err):** IOMMU level 4 page walk data parity error
22	0x0 RW	**iommu data l3 parity error (iommu_data_l3_par_err):** IOMMU level 3 page walk data parity error
21	0x0 RW	**iommu data l2 parity error (iommu_data_l2_par_err):** IOMMU level 2 page walk data parity error
20	0x0 RW	**downstream cmd buffer parity error (downstream_cmd_buffer_par_err):** downstream cmd buffer parity error detected
19	0x0 RW	**downstream data buffer parity error (downstream_data_buffer_par_err):** downstream data buffer parity error detected
18	0x0 RW	**upstream cmd buffer parity error (upstream_cmd_buffer_par_err):** upstream cmd buffer parity error detected
17	0x0 RW	**iosf upstream data parity error (iosf_upstream_data_par_err):** iosf upstream data parity error detected
16	0x0 RW	**iosf upstream cmd parity error (iosf_upstream_cmd_par_err):** iosf upstream cmd parity error detected
15	0x0 RO	**Reserved**
14	0x0 RO	**Reserved**
13	0x0 RO	**Reserved**
12	0x0 RO	**Reserved**

Bit Range	Default & Access	Field Name (ID): Description
11	0x0 RO	**Reserved**
10	0x0 RW	**msi rsvd set (msi_rsvd_set):** An MSI was received with reserved bits set.
9	0x0 RW	**gpa overflow (gpa_overflow):** A transaction was received with a guest physical address that was too large
8	0x0 RW	**illegal msi (illegal_msi):** A malformed/illegal MSI was received in the upstream direction
7	0x0 RW	**at translated illegal device (at_translated_illegal_device):** A device that is not support to set the AT bit set it to an illegal value
6	0x0 RO	**Reserved**
5	0x0 RW	**bad sai cmpl (bad_sai_cmpl):** An incorrect/illegal sai was received with an upstream completion transaction.
4	0x0 RW	**received lk cmpl (received_lk_cmpl):** Received a CmplLck completion from iosf.
3	0x0 RW	**bad sai nonposted (bad_sai_nonposted):** An incorrect/illegal sai was received with an upstream non-posted transaction.
2	0x0 RW	**illegal nonposted opcode (illegal_nonposted_opcode):** Illegal/Unsupported non-posted opcode received from iosf.
1	0x0 RW	**bad sai posted (bad_sai_posted):** An incorrect/illegal sai was received with an upstream posted transaction.
0	0x0 RW	**illegal posted opcode (illegal_posted_opcode):** Illegal/Unsupported posted opcode received from iosf.

44.3.6 First Uncorrectable Error Register (A_CR_UNCFERRSTS_0_0_0_MCHBAR)—Offset 6594h

First Error Status

Type: Memory Mapped I/O Register (Size: 32 bits)

BAR and Offset: [MCHBAR] + 6594h

Default: 00000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description

6	0x0 RO	**Reserved**
5	0x0 RW	**bad sai cmpl (bad_sai_cmpl):** An incorrect/illegal sai was received with an upstream completion transaction.
4	0x0 RW	**received lk cmpl (received_lk_cmpl):** Received a CmplLck completion from iosf.
3	0x0 RW	**bad sai nonposted (bad_sai_nonposted):** An incorrect/illegal sai was received with an upstream non-posted transaction.
2	0x0 RW	**illegal nonposted opcode (illegal_nonposted_opcode):** Illegal/Unsupported non-posted opcode received from iosf.
1	0x0 RW	**bad sai posted (bad_sai_posted):** An incorrect/illegal sai was received with an upstream posted transaction.
0	0x0 RW	**illegal posted opcode (illegal_posted_opcode):** Illegal/Unsupported posted opcode received from iosf.

44.3.9 Uncorrectable Error Count (A_CR_UNCERRCNT_0_0_0_MCHBAR)—Offset 65A0h

Counts the number of uncorrectable errors that have occurred.

Type: Memory Mapped I/O Register (Size: 32 bits)

BAR and Offset: [MCHBAR] + 65A0h

Default: 00000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
31:16	0x0 RO	**RSVD0:** Reserved
15	0x0 RW/1C	**Overflow (OVERFLOW):** Error count overflow. **Power Well:** prst
14:0	0x0 RW/1C	**Error Count (ERR_CNT):** Uncorrectable error count. **Power Well:** prst

44.3.10 Correctable Error Status Register (A_CR_CORERRSTS_0_0_0_MCHBAR)—Offset 65A4h

Errors that have been seen in A-Unit. This will always log errors irrespective of the CORERRMSK bit setting

Type: Memory Mapped I/O Register (Size: 32 bits)

BAR and Offset: [MCHBAR] + 65A4h

Default: 00000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
31	0x0 RO	**Reserved** **Power Well:** prst

44.3.15 Correctable Error Count (A_CR_CORERRCNT_0_0_0_MCHBAR)—Offset 65B8h

Counts the number of correctable errors that have occurred

Type: Memory Mapped I/O Register (Size: 32 bits)

BAR and Offset: [MCHBAR] + 65B8h

Default: 00000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
31:16	0x0 RO	**RSVD0:** Reserved
15	0x0 RW/1C	**Overflow (OVERFLOW):** Error count overflowed. **Power Well:** prst
14:0	0x0 RW/1C	**Error Count (ERR_CNT):** Correctable error count **Power Well:** prst

44.3.16 Slice and Channel Hash (A_CR_SLICE_CHANNEL_HASH_0_0_0_MCHBAR)—Offset 65C0h

A-Unit slice and channel hash function.

Type: Memory Mapped I/O Register (Size: 64 bits)

BAR and Offset: [MCHBAR] + 65C0h

Default: 0000000000000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
63	0x0 RW	**Lock (LOCK):** Intended usage is for BIOS to set the LOCK when it updates the CR.
62:52	0x0 RO	**RSVD0:** Reserved
51:38	0x0 RW	**Channel Hash Mask (CH_HASH_MASK):** When both PMI channels in a slice are enabled, this field specifies the Channel Hash Mask to be applied on Addr[19:6] postremap DRAM address of the request to compute which PMI channel a request must be routed to. Relevant only when HVM mode is disabled and only for requests that do not fall under the MOT region. B-Unit will override the programmed value to include the Channel Selector bit See SLICEHASH.INTERLEAVE_MODE field. Note that HVM mode and MOT regions have special hash requirements and hence they do not use the CH_HASH_MASK.
37:33	0x0 RO	**RSVD1:** Reserved
32	0x0 RW	**Channel 1 Disabled (CH_1_DISABLED):** Channel 1 in both slices are disabled no memory address mapped to ch 1. All requests sent to channel 0.
31	0x0 RW	**Spare (SPARE):** No identified usage yet.
30:20	0x0 RO	**RSVD2:** Reserved
19:6	0x0 RW	**Slice Hash Mask (SLICE_HASH_MASK):** When both slices are enabled this field specifies the Slice Hash Mask to be applied on Addr[19:6] physical address of the request to compute which slice a request must be routed to. Relevant only when HVM mode is disabled and only for physical addresses that do not fall under the Asymmetric Memory Region and the MOT region. B-Unit will override the programmed value to include the Slice Selector bit See INTERLEAVE_MODE field. Note that HVM mode non-address IDI requests asymmetric memory region and MOT regions have special hash requirements and hence they do not use the SLICE_HASH_MASK.
5	0x0 RO	**RSVD3:** Reserved
4	0x0 RW	**Reserved**

Bit Range	Default & Access	Field Name (ID): Description
3:2	0x0 RW	**Interleave Mode (INTERLEAVE_MODE):** Default interleave mode that specifies how the Slice Selector and Channel Selector bits are to be determined. Relevant only when HVM mode is disabled and only for system memory addresses that do not fall under the MOT region or the Asymmetric memory region in the System Address Map. Legal encodings are 0x0 0x1 and 0x2. An encoding of 0x3 is treated as if it was 0x2. When both slices and all four PMI channels are enabled: • 0h: Default Slice Selector is Addr[10] and Default Channel Selector is Addr[11] • 1h: Default Slice Selector is Addr[11] and Default Channel Selector is Addr[12] • 2h: Default Slice Selector is Addr[12] and Default Channel Selector is Addr[13] When both slices are enabled but only one channel in each slice enabled: • 0h: Default Slice Selector is Addr[10] • 1h: Default Slice Selector is Addr[11] • 2h: Default Slice Selector is Addr[12] When only SLICE0 is enabled and both channels on that slice are enabled: • 0h: Default Channel Selector is Addr[10] • 1h: Default Channel Selector is Addr[11] • 2h: Default Channel Selector is Addr[12] When SLICE0 and only one channel in that slice is enabled this field is not relevant. B-Unit overrides the setting of the SLICE_HASH_MASK to always include the Slice Selector bit. Similarly, B-Unit overrides the setting of the CH_HASH_MASK to always include the Channel Selector bit.
1	0x0 RW	**Reserved**
0	0x0 RW	**Slice 1 Disabled (SLICE_1_DISABLED):** Slice 1 is disabled; no memory address mapped to Slice 1. All request sent to Slice 0.

44.3.17 A_CR_ASYM_MEM_REGION0_0_0_0_MCHBAR—Offset 65D0h

Specification of asymmetric memory region 0 (in slice 0) for the configuration with 2 asymmetric memory regions.

Type: Memory Mapped I/O Register (Size: 32 bits)

BAR and Offset: [MCHBAR] + 65D0h

Default: 00000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
31	0x0 RW	**SLICE0_ASYM_ENABLE:** Setting this bit to 0 disables asymmetric memory region 0; setting it to 1 enables the region.
30:28	0x0 RO	**RSVD0:** Reserved
27:20	0x0 RW	**SLICE0_ASYM_LIMIT:** Specifies bits [38:31] of the highest address of asymmetric memory region 0 (in slice 0); all the lower bits of the region's highest address are equal to 1.
19:12	0x0 RO	**RSVD1:** Reserved
11:4	0x0 RW	**SLICE0_ASYM_BASE:** Specifies bits [38:31] of the base address of asymmetric memory region 0 (in slice 0); all the lower bits of the region's base address are equal to 0.
3:0	0x0 RO	**RSVD2:** Reserved

44.3.18 A_CR_ASYM_MEM_REGION1_0_0_0_MCHBAR—Offset 65D4h

Specification of asymmetric memory region 1 (in slice 1) for the configuration with 2 asymmetric memory regions.

Type: Memory Mapped I/O Register (Size: 32 bits)

BAR and Offset: [MCHBAR] + 65D4h

Default: 00000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
31	0x0 RW	**SLICE1_ASYM_ENABLE:** Setting this bit to 0 disables asymmetric memory region 1; setting it to 1 enables the region.
30:28	0x0 RO	**RSVD0:** Reserved
27:20	0x0 RW	**SLICE1_ASYM_LIMIT:** Specifies bits [38:31] of the highest address of asymmetric memory region 1 (in slice 1); all the lower bits of the region's highest address are equal to 1.
19:12	0x0 RO	**RSVD1:** Reserved
11:4	0x0 RW	**SLICE1_ASYM_BASE:** Specifies bits [38:31] of the base address of asymmetric memory region 1 (in slice 1); all the lower bits of the region's base address are equal to 0.
3:0	0x0 RO	**RSVD2:** Reserved

44.3.19 B-Unit Miscellaneous Configuration (B_CR_BMISC_0_0_0_MCHBAR)—Offset 6800h

Type: Memory Mapped I/O Register (Size: 32 bits)

Default: 00000007h

BAR and Offset: [MCHBAR] + 6800h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
31:4	0x0 RO	**Reserved (RESERVED_0):** Reserved.
3	0x0 RW	**Send Boot Vector to DRAM (SEND_BOOT_VECTOR_TO_DRAM):** When set, IA accesses to 0xFFFF_0000 to 0XFFFF_FFFF will be sent to memory, regardless of the Host IO Boundary setting in TOLUD.
2	0x1 RW	**ABSeginDRAM Legacy Video Area (ABSEGINDRAM):** When this bit is set, reads and writes targeting A or Bsegments are routed to DRAM. Asegment corresponds to the memory range 0xA_0000 to 0xA_FFFF. Bsegment corresponds to the memory ranges 0xB_0000 to 0xB_7FFF and 0xB_8000 to 0xB_FFFF.
1	0x1 RW	**Read FSeg from DRAM (READ_FSEG_FROM_DRAM):** Writes and reads targeting Fsegment are routed to DRAM. Fsegment corresponds to the memory range 0xF_0000 to 0xF_FFFF. This bit must be set '1'.
0	0x1 RW	**Read ESeg from DRAM (READ_ESEG_FROM_DRAM):** Writes and reads targeting Esegment are routed to DRAM. Esegment corresponds to the memory range 0xE_0000 to 0xE_FFFF. This bit must be set '1'.

44.3.20 Slice 0 Memory Access Count (B_CR_MEM_ACCESS_COUNT_SLICE0)—Offset 6868h

Type: Memory Mapped I/O Register (Size: 32 bits)

Default: 00000000h

BAR and Offset: [MCHBAR] + 6868h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
31:0	0x0 RO/V	**Memory Access Count (MEM_ACCESS_COUNT):** Counts the number of PMI transactions that the B-Unit has sent to any PMI channel. Counts both reads and writes. Counter is not saturating and will roll over to zero. It is up to the consumer of the counter to handle roll over cases.

44.3.21 Slice 1 Memory Access Count (B_CR_MEM_ACCESS_COUNT_SLICE1)—Offset 686Ch

Type: Memory Mapped I/O Register (Size: 32 bits)

Default: 00000000h

BAR and Offset: [MCHBAR] + 686Ch

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
31:0	0x0 RO/V	**Memory Access Count (MEM_ACCESS_COUNT):** Counts the number of PMI transactions that the B-Unit has sent to any PMI channel. Counts both reads and writes. Counter is not saturating and will roll over to zero. It is up to the consumer of the counter to handle roll over cases.

44.3.22 IMR0 Base (B_CR_BIMR0BASE_0_0_0_MCHBAR)—Offset 6870h

This register, along with IMR0MASK, IMR0RAC, and IMR0WAC, defines an isolated region of memory that can be masked to prohibit certain system agents from accessing memory. When an agent sends a request to the B-Unit, whether snooped or not, an IMR may optionally prevent that transaction from changing the state of memory or from getting correct data in response to the operation, if the agent's SAI field does not specify the correct Policy. The IMR's Policy is configured by the IMR0RAC and IMR0WAC registers.

Type: Memory Mapped I/O Register (Size: 32 bits)

BAR and Offset: [MCHBAR] + 6870h

Default: 00000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
31	0x0 RW	**IMR Enable (IMR_EN):** Enables access checking for the IMR region.
30	0x0 RW	**Asset Classification AC[0]: Trace Enable (TR_EN):** Enables snooping of transactions to the IMR region by tracing agents.
29	0x0 RO	**Reserved (RESERVED_1):** Reserved.
28:0	0x0 RW	**Base 0 IMR0 Base (IMR0_BASE):** Specifies bits 38:10 of the start address of IMR0 region. IMR region size must be a strict poweroftwo, at least 1KB, and naturally aligned to the size. These bits are compared with the result of the IMR0MASK[28:0] applied to bits 38:10 of the incoming address, to determine if an access falls within the IMR0 defined region.

44.3.23 IMR0 Mask (B_CR_BIMR0MASK_0_0_0_MCHBAR)—Offset 6874h

This register, along with IMR0BASE, IMR0RAC, and IMR0WAC, defines an isolated region of memory that can be masked to prohibit certain system agents from accessing memory. When an agent sends a request to the B-Unit, whether snooped or not, an IMR may optionally prevent that transaction from changing the state of memory or from getting correct data in response to the operation, if the agent's SAI field does not specify the correct Policy. The IMR's Policy is configured by the IMR0RAC and IMR0WAC registers.

Type: Memory Mapped I/O Register (Size: 32 bits)

BAR and Offset: [MCHBAR] + 6874h

Default: 00000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
31	0x0 RW	**Asset Classification AC[2]: GT Implicit WB Enable (GT_IWB_EN):** Enables implicit writebacks to protected region from GT caching agent. When set to 1, enables return to the requester of implicit writeback HITM data from GT. When set to 0, inhibits HITM data from GT from being returned to the requester. HITM data from IA cores may be returned to the requester depending on the setting of the IA_IWB_EN bit.
30	0x0 RW	**Asset Classification AC[1]: IA Implicit WB Enable (IA_IWB_EN):** Enables implicit writebacks to protected region from IA caching agent. When set to 1, enables implicit writeback HITM data from IA cores to be returned to the requester. When set to 0, inhibits HITM data from IA cores from being returned to the requester. HITM data from GT may be returned to the requester, depending on the setting of the GT_IWB_EN bit.
29	0x0 RO	**Reserved (RESERVED_0):** Reserved.
28:0	0x0 RW	**Mask 0 IMR0 Mask (IMR0_MASK):** These bits are ANDed with bits 38:10 of the incoming address to determine if the combined result matches the IMR0BASE[28:0] value. A match indicates that the incoming address falls within the IMR0 region.

44.3.24 IMR0 Control Policy (B_CR_BIMR0CP_0_0_0_MCHBAR)—Offset 6878h

This register controls the access policy to the Read Access Policy BIMR0RAC, Write Access Policy BIMR0WAC, and, self-referentially, to itself. The requesting agent's 6bit encoded SAI value is used as an index into this register's bits to determine both read access and write access.

Type: Memory Mapped I/O Register (Size: 64 bits)

BAR and Offset: [MCHBAR] + 6878h

Default: 00000C0061010202h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
63:0	0xc0061010202 RW	**IMR0 Control Policy (IMR0_CTRL_POL):** Bit vector used to determine which agents are allowed access to the BIMR0RAC, BIMR0WAC and BIMR0CP registers based on the value from each agent's 6bit SAI field.

44.3.25 IMR0 Read Access Policy (B_CR_BIMR0RAC_0_0_0_MCHBAR)—Offset 6880h

This register, along with IMR0BASE, IMR0MASK and IMR0WAC, defines an isolated region of memory that can be masked to prohibit certain agents from accessing memory. It is programmed with an SAI Policy that indicates which agents in the system are allowed to perform read operations to IMR0. The requesting agent's 6bit encoded SAI value is used as an index into this register's bits to determine read access.

Type: Memory Mapped I/O Register (Size: 64 bits)

BAR and Offset: [MCHBAR] + 6880h

Default: 0000000000000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
63	0x0 RW	**IMR0 Read Access Policy 63 (IMR0_READ_POL_63):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
62	0x0 RO	**IMR0 Read Access Policy 62 (IMR0_READ_POL_62):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
61	0x0 RO	**IMR0 Read Access Policy 61 (IMR0_READ_POL_61):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
60	0x0 RO	**IMR0 Read Access Policy 60 (IMR0_READ_POL_60):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
59	0x0 RO	**IMR0 Read Access Policy 59 (IMR0_READ_POL_59):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
58	0x0 RO	**IMR0 Read Access Policy 58 (IMR0_READ_POL_58):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
57	0x0 RO	**IMR0 Read Access Policy 57 (IMR0_READ_POL_57):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
56	0x0 RW	**IMR0 Read Access Policy 56 (IMR0_READ_POL_56):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
55	0x0 RW	**IMR0 Read Access Policy 55 (IMR0_READ_POL_55):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
54	0x0 RW	**IMR0 Read Access Policy 54 (IMR0_READ_POL_54):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
53	0x0 RO	**IMR0 Read Access Policy 53 (IMR0_READ_POL_53):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
52	0x0 RO	**IMR0 Read Access Policy 52 (IMR0_READ_POL_52):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
51	0x0 RO	**IMR0 Read Access Policy 51 (IMR0_READ_POL_51):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
50	0x0 RW	**IMR0 Read Access Policy 50 (IMR0_READ_POL_50):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
49	0x0 RW	**IMR0 Read Access Policy 49 (IMR0_READ_POL_49):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
48	0x0 RW	**IMR0 Read Access Policy 48 (IMR0_READ_POL_48):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
47	0x0 RO	**IMR0 Read Access Policy 47 (IMR0_READ_POL_47):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
46	0x0 RO	**IMR0 Read Access Policy 46 (IMR0_READ_POL_46):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.

Bit Range	Default & Access	Field Name (ID): Description
45	0x0 RO	**IMR0 Read Access Policy 45 (IMR0_READ_POL_45):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
44	0x0 RW	**IMR0 Read Access Policy 44 (IMR0_READ_POL_44):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
43	0x0 RW	**IMR0 Read Access Policy 43 (IMR0_READ_POL_43):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
42	0x0 RW	**IMR0 Read Access Policy 42 (IMR0_READ_POL_42):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
41	0x0 RW	**IMR0 Read Access Policy 41 (IMR0_READ_POL_41):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
40	0x0 RW	**IMR0 Read Access Policy 40 (IMR0_READ_POL_40):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
39	0x0 RO	**IMR0 Read Access Policy 39 (IMR0_READ_POL_39):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
38	0x0 RW	**IMR0 Read Access Policy 38 (IMR0_READ_POL_38):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
37	0x0 RO	**IMR0 Read Access Policy 37 (IMR0_READ_POL_37):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
36	0x0 RW	**IMR0 Read Access Policy 36 (IMR0_READ_POL_36):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
35	0x0 RO	**IMR0 Read Access Policy 35 (IMR0_READ_POL_35):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
34	0x0 RW	**IMR0 Read Access Policy 34 (IMR0_READ_POL_34):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
33	0x0 RW	**IMR0 Read Access Policy 33 (IMR0_READ_POL_33):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
32	0x0 RW	**IMR0 Read Access Policy 32 (IMR0_READ_POL_32):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
31	0x0 RO	**IMR0 Read Access Policy 31 (IMR0_READ_POL_31):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
30	0x0 RW	**IMR0 Read Access Policy 30 (IMR0_READ_POL_30):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
29	0x0 RW	**IMR0 Read Access Policy 29 (IMR0_READ_POL_29):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
28	0x0 RW	**IMR0 Read Access Policy 28 (IMR0_READ_POL_28):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
27	0x0 RW	**IMR0 Read Access Policy 27 (IMR0_READ_POL_27):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
26	0x0 RW	**IMR0 Read Access Policy 26 (IMR0_READ_POL_26):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
25	0x0 RW	**IMR0 Read Access Policy 25 (IMR0_READ_POL_25):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
24	0x0 RW	**IMR0 Read Access Policy 24 (IMR0_READ_POL_24):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
23	0x0 RO	**IMR0 Read Access Policy 23 (IMR0_READ_POL_23):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
22	0x0 RO	**IMR0 Read Access Policy 22 (IMR0_READ_POL_22):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.

Bit Range	Default & Access	Field Name (ID): Description
21	0x0 RW	**IMR0 Read Access Policy 21 (IMR0_READ_POL_21):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
20	0x0 RO	**IMR0 Read Access Policy 20 (IMR0_READ_POL_20):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
19	0x0 RO	**IMR0 Read Access Policy 19 (IMR0_READ_POL_19):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
18	0x0 RO	**IMR0 Read Access Policy 18 (IMR0_READ_POL_18):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
17	0x0 RW	**IMR0 Read Access Policy 17 (IMR0_READ_POL_17):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
16	0x0 RW	**IMR0 Read Access Policy 16 (IMR0_READ_POL_16):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
15	0x0 RO	**IMR0 Read Access Policy 15 (IMR0_READ_POL_15):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
14	0x0 RO	**IMR0 Read Access Policy 14 (IMR0_READ_POL_14):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
13	0x0 RW	**IMR0 Read Access Policy 13 (IMR0_READ_POL_13):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
12	0x0 RW	**IMR0 Read Access Policy 12 (IMR0_READ_POL_12):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
11	0x0 RO	**IMR0 Read Access Policy 11 (IMR0_READ_POL_11):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
10	0x0 RO	**IMR0 Read Access Policy 10 (IMR0_READ_POL_10):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
9	0x0 RO	**IMR0 Read Access Policy 9 (IMR0_READ_POL_9):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
8	0x0 RW	**IMR0 Read Access Policy 8 (IMR0_READ_POL_8):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
7	0x0 RO	**IMR0 Read Access Policy 7 (IMR0_READ_POL_7):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
6	0x0 RO	**IMR0 Read Access Policy 6 (IMR0_READ_POL_6):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
5	0x0 RW	**IMR0 Read Access Policy 5 (IMR0_READ_POL_5):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
4	0x0 RW	**IMR0 Read Access Policy 4 (IMR0_READ_POL_4):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
3	0x0 RW	**IMR0 Read Access Policy 3 (IMR0_READ_POL_3):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
2	0x0 RW	**IMR0 Read Access Policy 2 (IMR0_READ_POL_2):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
1	0x0 RW	**IMR0 Read Access Policy 1 (IMR0_READ_POL_1):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.
0	0x0 RW	**IMR0 Read Access Policy 0 (IMR0_READ_POL_0):** Bit vector used to determine which agents are allowed read access to the IMR0 region, based on each agent's 6bit encoded SAI value.

44.3.26 IMR0 Write Access Policy (B_CR_BIMR0WAC_0_0_0_MCHBAR)—Offset 6888h

This register, along with IMR0BASE, IMR0MASK and IMR0RAC, defines an isolated region of memory that can be masked to prohibit certain agents from accessing memory. It is programmed with an SAI Policy that indicates which agents in the system are allowed to perform read operations to IMR0. The requesting agent's 6bit encoded SAI value is used as an index into this register's bits to determine write access.

Type: Memory Mapped I/O Register (Size: 64 bits)

BAR and Offset: [MCHBAR] + 6888h

Default: 0000000000000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
63	0x0 RW	**IMR0 Write Access Policy 63 (IMR0_WRITE_POL_63):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
62	0x0 RO	**IMR0 Write Access Policy 62 (IMR0_WRITE_POL_62):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
61	0x0 RO	**IMR0 Write Access Policy 61 (IMR0_WRITE_POL_61):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
60	0x0 RO	**IMR0 Write Access Policy 60 (IMR0_WRITE_POL_60):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
59	0x0 RO	**IMR0 Write Access Policy 59 (IMR0_WRITE_POL_59):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
58	0x0 RO	**IMR0 Write Access Policy 58 (IMR0_WRITE_POL_58):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
57	0x0 RO	**IMR0 Write Access Policy 57 (IMR0_WRITE_POL_57):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
56	0x0 RW	**IMR0 Write Access Policy 56 (IMR0_WRITE_POL_56):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
55	0x0 RW	**IMR0 Write Access Policy 55 (IMR0_WRITE_POL_55):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
54	0x0 RW	**IMR0 Write Access Policy 54 (IMR0_WRITE_POL_54):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
53	0x0 RO	**IMR0 Write Access Policy 53 (IMR0_WRITE_POL_53):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
52	0x0 RO	**IMR0 Write Access Policy 52 (IMR0_WRITE_POL_52):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
51	0x0 RO	**IMR0 Write Access Policy 51 (IMR0_WRITE_POL_51):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
50	0x0 RW	**IMR0 Write Access Policy 50 (IMR0_WRITE_POL_50):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
49	0x0 RW	**IMR0 Write Access Policy 49 (IMR0_WRITE_POL_49):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
48	0x0 RW	**IMR0 Write Access Policy 48 (IMR0_WRITE_POL_48):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
47	0x0 RO	**IMR0 Write Access Policy 47 (IMR0_WRITE_POL_47):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
46	0x0 RO	**IMR0 Write Access Policy 46 (IMR0_WRITE_POL_46):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.

Bit Range	Default & Access	Field Name (ID): Description
45	0x0 RO	**IMR0 Write Access Policy 45 (IMR0_WRITE_POL_45):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
44	0x0 RW	**IMR0 Write Access Policy 44 (IMR0_WRITE_POL_44):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
43	0x0 RW	**IMR0 Write Access Policy 43 (IMR0_WRITE_POL_43):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
42	0x0 RW	**IMR0 Write Access Policy 42 (IMR0_WRITE_POL_42):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
41	0x0 RW	**IMR0 Write Access Policy 41 (IMR0_WRITE_POL_41):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
40	0x0 RW	**IMR0 Write Access Policy 40 (IMR0_WRITE_POL_40):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
39	0x0 RO	**IMR0 Write Access Policy 39 (IMR0_WRITE_POL_39):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
38	0x0 RW	**IMR0 Write Access Policy 38 (IMR0_WRITE_POL_38):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
37	0x0 RO	**IMR0 Write Access Policy 37 (IMR0_WRITE_POL_37):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
36	0x0 RW	**IMR0 Write Access Policy 36 (IMR0_WRITE_POL_36):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
35	0x0 RO	**IMR0 Write Access Policy 35 (IMR0_WRITE_POL_35):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
34	0x0 RW	**IMR0 Write Access Policy 34 (IMR0_WRITE_POL_34):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
33	0x0 RW	**IMR0 Write Access Policy 33 (IMR0_WRITE_POL_33):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
32	0x0 RW	**IMR0 Write Access Policy 32 (IMR0_WRITE_POL_32):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
31	0x0 RO	**IMR0 Write Access Policy 31 (IMR0_WRITE_POL_31):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
30	0x0 RW	**IMR0 Write Access Policy 30 (IMR0_WRITE_POL_30):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
29	0x0 RW	**IMR0 Write Access Policy 29 (IMR0_WRITE_POL_29):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
28	0x0 RW	**IMR0 Write Access Policy 28 (IMR0_WRITE_POL_28):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
27	0x0 RW	**IMR0 Write Access Policy 27 (IMR0_WRITE_POL_27):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
26	0x0 RW	**IMR0 Write Access Policy 26 (IMR0_WRITE_POL_26):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
25	0x0 RW	**IMR0 Write Access Policy 25 (IMR0_WRITE_POL_25):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
24	0x0 RW	**IMR0 Write Access Policy 24 (IMR0_WRITE_POL_24):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
23	0x0 RO	**IMR0 Write Access Policy 23 (IMR0_WRITE_POL_23):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
22	0x0 RO	**IMR0 Write Access Policy 22 (IMR0_WRITE_POL_22):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.

Bit Range	Default & Access	Field Name (ID): Description
21	0x0 RW	**IMR0 Write Access Policy 21 (IMR0_WRITE_POL_21):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
20	0x0 RO	**IMR0 Write Access Policy 20 (IMR0_WRITE_POL_20):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
19	0x0 RO	**IMR0 Write Access Policy 19 (IMR0_WRITE_POL_19):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
18	0x0 RO	**IMR0 Write Access Policy 18 (IMR0_WRITE_POL_18):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
17	0x0 RW	**IMR0 Write Access Policy 17 (IMR0_WRITE_POL_17):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
16	0x0 RW	**IMR0 Write Access Policy 16 (IMR0_WRITE_POL_16):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
15	0x0 RO	**IMR0 Write Access Policy 15 (IMR0_WRITE_POL_15):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
14	0x0 RO	**IMR0 Write Access Policy 14 (IMR0_WRITE_POL_14):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
13	0x0 RW	**IMR0 Write Access Policy 13 (IMR0_WRITE_POL_13):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
12	0x0 RW	**IMR0 Write Access Policy 12 (IMR0_WRITE_POL_12):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
11	0x0 RO	**IMR0 Write Access Policy 11 (IMR0_WRITE_POL_11):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
10	0x0 RO	**IMR0 Write Access Policy 10 (IMR0_WRITE_POL_10):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
9	0x0 RO	**IMR0 Write Access Policy 9 (IMR0_WRITE_POL_9):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
8	0x0 RW	**IMR0 Write Access Policy 8 (IMR0_WRITE_POL_8):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
7	0x0 RO	**IMR0 Write Access Policy 7 (IMR0_WRITE_POL_7):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
6	0x0 RO	**IMR0 Write Access Policy 6 (IMR0_WRITE_POL_6):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
5	0x0 RW	**IMR0 Write Access Policy 5 (IMR0_WRITE_POL_5):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
4	0x0 RW	**IMR0 Write Access Policy 4 (IMR0_WRITE_POL_4):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
3	0x0 RW	**IMR0 Write Access Policy 3 (IMR0_WRITE_POL_3):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
2	0x0 RW	**IMR0 Write Access Policy 2 (IMR0_WRITE_POL_2):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
1	0x0 RW	**IMR0 Write Access Policy 1 (IMR0_WRITE_POL_1):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.
0	0x0 RW	**IMR0 Write Access Policy 0 (IMR0_WRITE_POL_0):** Bit vector used to determine which agents are allowed write access to the IMR0 region, based on each agent's 6bit encoded SAI value.

44.3.27 B_CR_BIMR1BASE_0_0_0_MCHBAR—Offset 6890h

This register, along with IMR1MASK, IMR1RAC and IMR1WAC, defines an isolated region of memory that can be masked to prohibit certain system agents from accessing memory. When an agent sends a request to the B-Unit, whether snooped or not, an IMR may optionally prevent that transaction from changing the state of memory or from getting correct data in response to the operation, if the agent's SAI field does not specify the correct Policy. The IMR's Policy is configured by the IMR1RAC and IMR1WAC registers.

Type: Memory Mapped I/O Register (Size: 32 bits)

BAR and Offset: [MCHBAR] + 6890h

Default: 00000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
31	0x0 RW	**IMR Enable (IMR_EN):** Enables access checking for the IMR region.
30	0x0 RW	**Trace Enable (TR_EN):** Asset Classification AC[0]: Enables snooping of transactions to the IMR region by tracing agents.
29	0x0 RO	**RESERVED_1:** Reserved
28:0	0x0 RW	**Base 1 IMR1 Base (IMR1_BASE):** Specifies bits 38:10 of the start address of IMR1 region. IMR region size must be a strict poweroftwo, at least 1KB, and naturally aligned to the size. These bits are compared with the result of the IMR1MASK[28:0] applied to bits 38:10 of the incoming address to determine if an access falls within the IMR1 defined region.

44.3.28 IMR1 Mask (B_CR_BIMR1MASK_0_0_0_MCHBAR)—Offset 6894h

This register, along with IMR1BASE, IMR1RAC and IMR1WAC, defines an isolated region of memory that can be masked to prohibit certain system agents from accessing memory. When an agent sends a request to the B-Unit, whether snooped or not, an IMR may optionally prevent that transaction from changing the state of memory or from getting correct data in response to the operation, if the agent's SAI field does not specify the correct Policy. The IMR's Policy is configured by the IMR1RAC and IMR1WAC registers.

Type: Memory Mapped I/O Register (Size: 32 bits)

BAR and Offset: [MCHBAR] + 6894h

Default: 00000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
31	0x0 RW	**GT Implicit Writeback Enable (GT_IWB_EN):** Asset Classification AC[2]: Enables implicit writebacks to protected region from GT caching agent. When set to 1, enables return to the requestor of implicit writeback HITM data from GT. When set to 0, inhibits HITM data from GT from being returned to the requestor. HITM data from IA cores may be returned to the requestor depending on the setting of the IA_IWB_EN bit.
30	0x0 RW	**Asset Classification AC[1]: Implicit Writeback Enable (IA_IWB_EN):** Enables implicit writebacks to protected region from IA caching agent. When set to 1, enables implicit writeback data HITM data from IA cores to be returned to the requestor. When set to 0, inhibits HITM data from IA cores from being returned to the requestor. HITM data from GT may be returned to the requestor depending on the setting of the GT_IWB_EN bit.
29	0x0 RO	**RESERVED_0:** Reserved
28:0	0x0 RW	**Mask 1 IMR1 Mask (IMR1_MASK):** These bits are ANDed with bits 38:10 of the incoming address to determine if the combined result matches the IMR1BASE[28:0] value. A match indicates that the incoming address falls within the IMR1 region.

44.3.29 IMR1 Control Policy (B_CR_BIMR1CP_0_0_0_MCHBAR)—Offset 6898h

This register controls the access policy to the Read Access Policy BIMR1RAC, the Write Access Policy BIMR1WAC, and, self-referentially, to itself. The requesting agent's 6bit encoded SAI value is used as an index into this register's bits to determine both read access and write access.

Type: Memory Mapped I/O Register (Size: 64 bits)

BAR and Offset: [MCHBAR] + 6898h

Default: 00000C0061010202h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
63:0	0xc0061010202 RW	**IMR1 Control Policy (IMR1_CTRL_POL):** Bit vector used to determine which agents are allowed access to the BIMR1RAC, BIMR1WAC and BIMR1CP registers, based on the value from each agent's 6bit SAI field.

44.3.30 IMR1 Read Access Policy (B_CR_BIMR1RAC_0_0_0_MCHBAR)—Offset 68A0h

This register, along with IMR1BASE, IMR1MASK and IMR1WAC, defines an isolated region of memory that can be masked to prohibit certain agents from accessing memory. It is programmed with an SAI Policy that indicates which agents in the system are allowed to perform read operations to IMR1. The requesting agent's 6bit encoded SAI value is used as an index into this register's bits to determine read access.

Type: Memory Mapped I/O Register (Size: 64 bits)

BAR and Offset: [MCHBAR] + 68A0h

34	0x0 RW	**IMR1 Write Access Policy 34 (IMR1_WRITE_POL_34):** Bit vector used to determine which agents are allowed write access to the IMR1 region, based on each agent's 6bit encoded SAI value.
33	0x0 RW	**IMR1 Write Access Policy 33 (IMR1_WRITE_POL_33):** Bit vector used to determine which agents are allowed write access to the IMR1 region, based on each agent's 6bit encoded SAI value.
32	0x0 RW	**IMR1 Write Access Policy 32 (IMR1_WRITE_POL_32):** Bit vector used to determine which agents are allowed write access to the IMR1 region, based on each agent's 6bit encoded SAI value.
31	0x0 RO	**IMR1 Write Access Policy 31 (IMR1_WRITE_POL_31):** Bit vector used to determine which agents are allowed write access to the IMR1 region, based on each agent's 6bit encoded SAI value.
30	0x0 RW	**IMR1 Write Access Policy 30 (IMR1_WRITE_POL_30):** Bit vector used to determine which agents are allowed write access to the IMR1 region, based on each agent's 6bit encoded SAI value.
29	0x0 RW	**IMR1 Write Access Policy 29 (IMR1_WRITE_POL_29):** Bit vector used to determine which agents are allowed write access to the IMR1 region, based on each agent's 6bit encoded SAI value.
28	0x0 RW	**IMR1 Write Access Policy 28 (IMR1_WRITE_POL_28):** Bit vector used to determine which agents are allowed write access to the IMR1 region, based on each agent's 6bit encoded SAI value.
27	0x0 RW	**IMR1 Write Access Policy 27 (IMR1_WRITE_POL_27):** Bit vector used to determine which agents are allowed write access to the IMR1 region, based on each agent's 6bit encoded SAI value.
26	0x0 RW	**IMR1 Write Access Policy 26 (IMR1_WRITE_POL_26):** Bit vector used to determine which agents are allowed write access to the IMR1 region, based on each agent's 6bit encoded SAI value.
25	0x0 RW	**IMR1 Write Access Policy 25 (IMR1_WRITE_POL_25):** Bit vector used to determine which agents are allowed write access to the IMR1 region, based on each agent's 6bit encoded SAI value.
24	0x0 RW	**IMR1 Write Access Policy 24 (IMR1_WRITE_POL_24):** Bit vector used to determine which agents are allowed write access to the IMR1 region, based on each agent's 6bit encoded SAI value.
23	0x0 RO	**IMR1 Write Access Policy 23 (IMR1_WRITE_POL_23):** Bit vector used to determine which agents are allowed write access to the IMR1 region, based on each agent's 6bit encoded SAI value.
22	0x0 RO	**IMR1 Write Access Policy 22 (IMR1_WRITE_POL_22):** Bit vector used to determine which agents are allowed write access to the IMR1 region, based on each agent's 6bit encoded SAI value.

Bit Range	Default & Access	Field Name (ID): Description
21	0x0 RW	**IMR1 Write Access Policy 21 (IMR1_WRITE_POL_21):** Bit vector used to determine which agents are allowed write access to the IMR1 region, based on each agent's 6bit encoded SAI value.
20	0x0 RO	**IMR1 Write Access Policy 20 (IMR1_WRITE_POL_20):** Bit vector used to determine which agents are allowed write access to the IMR1 region, based on each agent's 6bit encoded SAI value.
19	0x0 RO	**IMR1 Write Access Policy 19 (IMR1_WRITE_POL_19):** Bit vector used to determine which agents are allowed write access to the IMR1 region, based on each agent's 6bit encoded SAI value.
18	0x0 RO	**IMR1 Write Access Policy 18 (IMR1_WRITE_POL_18):** Bit vector used to determine which agents are allowed write access to the IMR1 region, based on each agent's 6bit encoded SAI value.
17	0x0 RW	**IMR1 Write Access Policy 17 (IMR1_WRITE_POL_17):** Bit vector used to determine which agents are allowed write access to the IMR1 region, based on each agent's 6bit encoded SAI value.
16	0x0 RW	**IMR1 Write Access Policy 16 (IMR1_WRITE_POL_16):** Bit vector used to determine which agents are allowed write access to the IMR1 region, based on each agent's 6bit encoded SAI value.
15	0x0 RO	**IMR1 Write Access Policy 15 (IMR1_WRITE_POL_15):** Bit vector used to determine which agents are allowed write access to the IMR1 region, based on each agent's 6bit encoded SAI value.
14	0x0 RO	**IMR1 Write Access Policy 14 (IMR1_WRITE_POL_14):** Bit vector used to determine which agents are allowed write access to the IMR1 region, based on each agent's 6bit encoded SAI value.
13	0x0 RW	**IMR1 Write Access Policy 13 (IMR1_WRITE_POL_13):** Bit vector used to determine which agents are allowed write access to the IMR1 region, based on each agent's 6bit encoded SAI value.
12	0x0 RW	**IMR1 Write Access Policy 12 (IMR1_WRITE_POL_12):** Bit vector used to determine which agents are allowed write access to the IMR1 region, based on each agent's 6bit encoded SAI value.
11	0x0 RO	**IMR1 Write Access Policy 11 (IMR1_WRITE_POL_11):** Bit vector used to determine which agents are allowed write access to the IMR1 region, based on each agent's 6bit encoded SAI value.
10	0x0 RO	**IMR1 Write Access Policy 10 (IMR1_WRITE_POL_10):** Bit vector used to determine which agents are allowed write access to the IMR1 region, based on each agent's 6bit encoded SAI value.
9	0x0 RO	**IMR1 Write Access Policy 9 (IMR1_WRITE_POL_9):** Bit vector used to determine which agents are allowed write access to the IMR1 region, based on each agent's 6bit encoded SAI value.
8	0x0 RW	**IMR1 Write Access Policy 8 (IMR1_WRITE_POL_8):** Bit vector used to determine which agents are allowed write access to the IMR1 region, based on each agent's 6bit encoded SAI value.
7	0x0 RO	**IMR1 Write Access Policy 7 (IMR1_WRITE_POL_7):** Bit vector used to determine which agents are allowed write access to the IMR1 region, based on each agent's 6bit encoded SAI value.
6	0x0 RO	**IMR1 Write Access Policy 6 (IMR1_WRITE_POL_6):** Bit vector used to determine which agents are allowed write access to the IMR1 region, based on each agent's 6bit encoded SAI value.
5	0x0 RW	**IMR1 Write Access Policy 5 (IMR1_WRITE_POL_5):** Bit vector used to determine which agents are allowed write access to the IMR1 region, based on each agent's 6bit encoded SAI value.
4	0x0 RW	**IMR1 Write Access Policy 4 (IMR1_WRITE_POL_4):** Bit vector used to determine which agents are allowed write access to the IMR1 region, based on each agent's 6bit encoded SAI value.
3	0x0 RW	**IMR1 Write Access Policy 3 (IMR1_WRITE_POL_3):** Bit vector used to determine which agents are allowed write access to the IMR1 region, based on each agent's 6bit encoded SAI value.
2	0x0 RW	**IMR1 Write Access Policy 2 (IMR1_WRITE_POL_2):** Bit vector used to determine which agents are allowed write access to the IMR1 region, based on each agent's 6bit encoded SAI value.
1	0x0 RW	**IMR1 Write Access Policy 1 (IMR1_WRITE_POL_1):** Bit vector used to determine which agents are allowed write access to the IMR1 region, based on each agent's 6bit encoded SAI value.
0	0x0 RW	**IMR1 Write Access Policy 0 (IMR1_WRITE_POL_0):** Bit vector used to determine which agents are allowed write access to the IMR1 region, based on each agent's 6bit encoded SAI value.

44.3.32 Base 0 IMR2 Base (B_CR_BIMR2BASE_0_0_0_MCHBAR)—Offset 68B0h

This register, along with IMR2MASK, IMR2RAC and IMR2WAC, defines an isolated region of memory that can be masked to prohibit certain system agents from accessing memory. When an agent sends a request to the B-Unit, whether snooped or not, an IMR may optionally prevent that transaction from changing the state of memory or from getting correct data in response to the operation, if the agent's SAI field does not specify the correct Policy. The IMR's Policy is configured by the IMR2RAC and IMR2WAC registers.

Type: Memory Mapped I/O Register (Size: 32 bits)

BAR and Offset: [MCHBAR] + 68B0h

Default: 00000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
31	0x0 RW	**IMR Enable (IMR_EN):** Enables access checking for the IMR region.
30	0x0 RW	**Asset Classification AC[0]: Trace Enable (TR_EN):** Enables snooping of transactions to the IMR region by tracing agents.
29	0x0 RO	**RESERVED_1:** Reserved
28:0	0x0 RW	**Base 0 IMR2 Base (IMR2_BASE):** Specifies bits 38:10 of the start address of IMR2 region. IMR region size must be a strict poweroftwo, at least 1KB and naturally aligned to the size. These bits are compared with the result of the IMR2MASK[28:0] applied to bits 38:10 of the incoming address to determine if an access falls within the IMR2 defined region.

44.3.33 IMR2 Mask (B_CR_BIMR2MASK_0_0_0_MCHBAR)—Offset 68B4h

This register, along with IMR2BASE, IMR2RAC, and IMR2WAC, defines an isolated region of memory that can be masked to prohibit certain system agents from accessing memory. When an agent sends a request to the B-Unit, whether snooped or not, an IMR may optionally prevent that transaction from changing the state of memory or from getting correct data in response to the operation if the agent's SAI field does not specify the correct Policy. The IMR's Policy is configured by the IMR2RAC and IMR2WAC registers.

Type: Memory Mapped I/O Register (Size: 32 bits)

BAR and Offset: [MCHBAR] + 68B4h

Default: 00000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
31	0x0 RW	**Asset Classification AC[2]: GT Implicit Writeback Enable (GT_IWB_EN):** Enables implicit writebacks to protected region from GT caching agent. When set to 1, enables implicit writeback HITM data from GT to be returned to the requestor. When set to 0, inhibits HITM data from GT from being returned to the requestor. HITM data from IA cores may be returned to the requestpr depending on the setting of the IA_IWB_EN bit.
30	0x0 RW	**Asset Classification AC[1]: IA Implicit Writeback Enable (IA_IWB_EN):** Enables implicit writebacks to protected region from IA caching agent. When set to 1, enables implicit writeback HITM data from IA cores to be returned to the requestor. When set to 0, inhibits HITM data from IA cores from being returned to the requestor. HITM data from GT may be returned to the requestor depending on the setting of the GT_IWB_EN bit.
29	0x0 RO	**RESERVED_0:** Reserved
28:0	0x0 RW	**Mask 0 IMR2 Mask (IMR2_MASK):** These bits are ANDed with bits 38:10 of the incoming address to determine if the combined result matches the IMR2BASE[28:0] value. A match indicates that the incoming address falls within the IMR2 region.

44.3.34 IMR2 Control Policy (B_CR_BIMR2CP_0_0_0_MCHBAR)—Offset 68B8h

This register controls the access policy to the Read Access Policy BIMR2RAC, Write Access Policy BIMR2WAC, and, self-referentially, to itself. The requesting agent's 6bit encoded SAI value is used as an index into this register's bits to determine both read access and write access.

Type: Memory Mapped I/O Register (Size: 64 bits)

BAR and Offset: [MCHBAR] + 68B8h

Default: 00000C0061010202h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
63:0	0xc0061010202 RW	**IMR2 Control Policy (IMR2_CTRL_POL):** Bit vector used to determine which agents are allowed access to the BIMR2RAC, BIMR2WAC and BIMR2CP registers, based on the value from each agent's 6bit SAI field.

44.3.35 IMR2 Read Access Policy (B_CR_BIMR2RAC_0_0_0_MCHBAR)—Offset 68C0h

This register, along with IMR2BASE, IMR2MASK and IMR2WAC, defines an isolated region of memory that can be masked to prohibit certain agents from accessing memory. It is programmed with an SAI Policy that indicates which agents in the system are allowed to perform read operations to IMR2. The requesting agent's 6bit encoded SAI value is used as an index into this register's bits to determine read access.

Type: Memory Mapped I/O Register (Size: 64 bits)

BAR and Offset: [MCHBAR] + 68C0h

Default: 0000000000000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
63	0x0 RW	**IMR2 Read Access Policy 63 (IMR2_READ_POL_63):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
62	0x0 RO	**IMR2 Read Access Policy 62 (IMR2_READ_POL_62):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
61	0x0 RO	**IMR2 Read Access Policy 61 (IMR2_READ_POL_61):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
60	0x0 RO	**IMR2 Read Access Policy 60 (IMR2_READ_POL_60):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
59	0x0 RO	**IMR2 Read Access Policy 59 (IMR2_READ_POL_59):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
58	0x0 RO	**IMR2 Read Access Policy 58 (IMR2_READ_POL_58):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
57	0x0 RO	**IMR2 Read Access Policy 57 (IMR2_READ_POL_57):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
56	0x0 RW	**IMR2 Read Access Policy 56 (IMR2_READ_POL_56):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
55	0x0 RW	**IMR2 Read Access Policy 55 (IMR2_READ_POL_55):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
54	0x0 RW	**IMR2 Read Access Policy 54 (IMR2_READ_POL_54):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
53	0x0 RO	**IMR2 Read Access Policy 53 (IMR2_READ_POL_53):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
52	0x0 RO	**IMR2 Read Access Policy 52 (IMR2_READ_POL_52):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
51	0x0 RO	**IMR2 Read Access Policy 51 (IMR2_READ_POL_51):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
50	0x0 RW	**IMR2 Read Access Policy 50 (IMR2_READ_POL_50):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
49	0x0 RW	**IMR2 Read Access Policy 49 (IMR2_READ_POL_49):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
48	0x0 RW	**IMR2 Read Access Policy 48 (IMR2_READ_POL_48):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
47	0x0 RO	**IMR2 Read Access Policy 47 (IMR2_READ_POL_47):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
46	0x0 RO	**IMR2 Read Access Policy 46 (IMR2_READ_POL_46):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.

Bit Range	Default & Access	Field Name (ID): Description
45	0x0 RO	**IMR2 Read Access Policy 45 (IMR2_READ_POL_45):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
44	0x0 RW	**IMR2 Read Access Policy 44 (IMR2_READ_POL_44):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
43	0x0 RW	**IMR2 Read Access Policy 43 (IMR2_READ_POL_43):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
42	0x0 RW	**IMR2 Read Access Policy 42 (IMR2_READ_POL_42):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
41	0x0 RW	**IMR2 Read Access Policy 41 (IMR2_READ_POL_41):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
40	0x0 RW	**IMR2 Read Access Policy 40 (IMR2_READ_POL_40):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
39	0x0 RO	**IMR2 Read Access Policy 39 (IMR2_READ_POL_39):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
38	0x0 RW	**IMR2 Read Access Policy 38 (IMR2_READ_POL_38):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
37	0x0 RO	**IMR2 Read Access Policy 37 (IMR2_READ_POL_37):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
36	0x0 RW	**IMR2 Read Access Policy 36 (IMR2_READ_POL_36):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
35	0x0 RO	**IMR2 Read Access Policy 35 (IMR2_READ_POL_35):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
34	0x0 RW	**IMR2 Read Access Policy 34 (IMR2_READ_POL_34):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
33	0x0 RW	**IMR2 Read Access Policy 33 (IMR2_READ_POL_33):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
32	0x0 RW	**IMR2 Read Access Policy 32 (IMR2_READ_POL_32):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
31	0x0 RO	**IMR2 Read Access Policy 31 (IMR2_READ_POL_31):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
30	0x0 RW	**IMR2 Read Access Policy 30 (IMR2_READ_POL_30):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
29	0x0 RW	**IMR2 Read Access Policy 29 (IMR2_READ_POL_29):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
28	0x0 RW	**IMR2 Read Access Policy 28 (IMR2_READ_POL_28):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
27	0x0 RW	**IMR2 Read Access Policy 27 (IMR2_READ_POL_27):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
26	0x0 RW	**IMR2 Read Access Policy 26 (IMR2_READ_POL_26):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
25	0x0 RW	**IMR2 Read Access Policy 25 (IMR2_READ_POL_25):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
24	0x0 RW	**IMR2 Read Access Policy 24 (IMR2_READ_POL_24):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
23	0x0 RO	**IMR2 Read Access Policy 23 (IMR2_READ_POL_23):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
22	0x0 RO	**IMR2 Read Access Policy 22 (IMR2_READ_POL_22):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.

Bit Range	Default & Access	Field Name (ID): Description
21	0x0 RW	**IMR2 Read Access Policy 21 (IMR2_READ_POL_21):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
20	0x0 RO	**IMR2 Read Access Policy 20 (IMR2_READ_POL_20):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
19	0x0 RO	**IMR2 Read Access Policy 19 (IMR2_READ_POL_19):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
18	0x0 RO	**IMR2 Read Access Policy 18 (IMR2_READ_POL_18):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
17	0x0 RW	**IMR2 Read Access Policy 17 (IMR2_READ_POL_17):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
16	0x0 RW	**IMR2 Read Access Policy 16 (IMR2_READ_POL_16):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
15	0x0 RO	**IMR2 Read Access Policy 15 (IMR2_READ_POL_15):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
14	0x0 RO	**IMR2 Read Access Policy 14 (IMR2_READ_POL_14):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
13	0x0 RW	**IMR2 Read Access Policy 13 (IMR2_READ_POL_13):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
12	0x0 RW	**IMR2 Read Access Policy 12 (IMR2_READ_POL_12):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
11	0x0 RO	**IMR2 Read Access Policy 11 (IMR2_READ_POL_11):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
10	0x0 RO	**IMR2 Read Access Policy 10 (IMR2_READ_POL_10):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
9	0x0 RO	**IMR2 Read Access Policy 9 (IMR2_READ_POL_9):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
8	0x0 RW	**IMR2 Read Access Policy 8 (IMR2_READ_POL_8):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
7	0x0 RO	**IMR2 Read Access Policy 7 (IMR2_READ_POL_7):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
6	0x0 RO	**IMR2 Read Access Policy 6 (IMR2_READ_POL_6):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
5	0x0 RW	**IMR2 Read Access Policy 5 (IMR2_READ_POL_5):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
4	0x0 RW	**IMR2 Read Access Policy 4 (IMR2_READ_POL_4):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
3	0x0 RW	**IMR2 Read Access Policy 3 (IMR2_READ_POL_3):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
2	0x0 RW	**IMR2 Read Access Policy 2 (IMR2_READ_POL_2):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
1	0x0 RW	**IMR2 Read Access Policy 1 (IMR2_READ_POL_1):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.
0	0x0 RW	**IMR2 Read Access Policy 0 (IMR2_READ_POL_0):** Bit vector used to determine which agents are allowed read access to the IMR2 region, based on each agent's 6bit encoded SAI value.

44.3.36 IMR2 Write Access Policy (B_CR_BIMR2WAC_0_0_0_MCHBAR)—Offset 68C8h

This register, along with IMR2BASE, IMR2MASK and IMR2RAC, defines an isolated region of memory that can be masked to prohibit certain agents from accessing memory. It is programmed with an SAI Policy that indicates which agents in the system are allowed to perform read operations to IMR2. The requesting agent's 6bit encoded SAI value is used as an index into this register's bits to determine write access.

Type: Memory Mapped I/O Register (Size: 64 bits)

BAR and Offset: [MCHBAR] + 68C8h

Default: 0000000000000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
63	0x0 RW	**IMR2 Write Access Policy 63 (IMR2_WRITE_POL_63):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
62	0x0 RO	**IMR2 Write Access Policy 62 (IMR2_WRITE_POL_62):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
61	0x0 RO	**IMR2 Write Access Policy 61 (IMR2_WRITE_POL_61):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
60	0x0 RO	**IMR2 Write Access Policy 60 (IMR2_WRITE_POL_60):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
59	0x0 RO	**IMR2 Write Access Policy 59 (IMR2_WRITE_POL_59):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
58	0x0 RO	**IMR2 Write Access Policy 58 (IMR2_WRITE_POL_58):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
57	0x0 RO	**IMR2 Write Access Policy 57 (IMR2_WRITE_POL_57):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
56	0x0 RW	**IMR2 Write Access Policy 56 (IMR2_WRITE_POL_56):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
55	0x0 RW	**IMR2 Write Access Policy 55 (IMR2_WRITE_POL_55):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
54	0x0 RW	**IMR2 Write Access Policy 54 (IMR2_WRITE_POL_54):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
53	0x0 RO	**IMR2 Write Access Policy 53 (IMR2_WRITE_POL_53):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
52	0x0 RO	**IMR2 Write Access Policy 52 (IMR2_WRITE_POL_52):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
51	0x0 RO	**IMR2 Write Access Policy 51 (IMR2_WRITE_POL_51):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
50	0x0 RW	**IMR2 Write Access Policy 50 (IMR2_WRITE_POL_50):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
49	0x0 RW	**IMR2 Write Access Policy 49 (IMR2_WRITE_POL_49):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
48	0x0 RW	**IMR2 Write Access Policy 48 (IMR2_WRITE_POL_48):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
47	0x0 RO	**IMR2 Write Access Policy 47 (IMR2_WRITE_POL_47):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
46	0x0 RO	**IMR2 Write Access Policy 46 (IMR2_WRITE_POL_46):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.

Bit Range	Default & Access	Field Name (ID): Description
45	0x0 RO	**IMR2 Write Access Policy 45 (IMR2_WRITE_POL_45):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
44	0x0 RW	**IMR2 Write Access Policy 44 (IMR2_WRITE_POL_44):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
43	0x0 RW	**IMR2 Write Access Policy 43 (IMR2_WRITE_POL_43):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
42	0x0 RW	**IMR2 Write Access Policy 42 (IMR2_WRITE_POL_42):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
41	0x0 RW	**IMR2 Write Access Policy 41 (IMR2_WRITE_POL_41):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
40	0x0 RW	**IMR2 Write Access Policy 40 (IMR2_WRITE_POL_40):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
39	0x0 RO	**IMR2 Write Access Policy 39 (IMR2_WRITE_POL_39):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
38	0x0 RW	**IMR2 Write Access Policy 38 (IMR2_WRITE_POL_38):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
37	0x0 RO	**IMR2 Write Access Policy 37 (IMR2_WRITE_POL_37):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
36	0x0 RW	**IMR2 Write Access Policy 36 (IMR2_WRITE_POL_36):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
35	0x0 RO	**IMR2 Write Access Policy 35 (IMR2_WRITE_POL_35):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
34	0x0 RW	**IMR2 Write Access Policy 34 (IMR2_WRITE_POL_34):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
33	0x0 RW	**IMR2 Write Access Policy 33 (IMR2_WRITE_POL_33):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
32	0x0 RW	**IMR2 Write Access Policy 32 (IMR2_WRITE_POL_32):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
31	0x0 RO	**IMR2 Write Access Policy 31 (IMR2_WRITE_POL_31):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
30	0x0 RW	**IMR2 Write Access Policy 30 (IMR2_WRITE_POL_30):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
29	0x0 RW	**IMR2 Write Access Policy 29 (IMR2_WRITE_POL_29):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
28	0x0 RW	**IMR2 Write Access Policy 28 (IMR2_WRITE_POL_28):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
27	0x0 RW	**IMR2 Write Access Policy 27 (IMR2_WRITE_POL_27):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
26	0x0 RW	**IMR2 Write Access Policy 26 (IMR2_WRITE_POL_26):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
25	0x0 RW	**IMR2 Write Access Policy 25 (IMR2_WRITE_POL_25):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
24	0x0 RW	**IMR2 Write Access Policy 24 (IMR2_WRITE_POL_24):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
23	0x0 RO	**IMR2 Write Access Policy 23 (IMR2_WRITE_POL_23):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
22	0x0 RO	**IMR2 Write Access Policy 22 (IMR2_WRITE_POL_22):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.

Bit Range	Default & Access	Field Name (ID): Description
21	0x0 RW	**IMR2 Write Access Policy 21 (IMR2_WRITE_POL_21):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
20	0x0 RO	**IMR2 Write Access Policy 20 (IMR2_WRITE_POL_20):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
19	0x0 RO	**IMR2 Write Access Policy 19 (IMR2_WRITE_POL_19):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
18	0x0 RO	**IMR2 Write Access Policy 18 (IMR2_WRITE_POL_18):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
17	0x0 RW	**IMR2 Write Access Policy 17 (IMR2_WRITE_POL_17):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
16	0x0 RW	**IMR2 Write Access Policy 16 (IMR2_WRITE_POL_16):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
15	0x0 RO	**IMR2 Write Access Policy 15 (IMR2_WRITE_POL_15):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
14	0x0 RO	**IMR2 Write Access Policy 14 (IMR2_WRITE_POL_14):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
13	0x0 RW	**IMR2 Write Access Policy 13 (IMR2_WRITE_POL_13):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
12	0x0 RW	**IMR2 Write Access Policy 12 (IMR2_WRITE_POL_12):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
11	0x0 RO	**IMR2 Write Access Policy 11 (IMR2_WRITE_POL_11):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
10	0x0 RO	**IMR2 Write Access Policy 10 (IMR2_WRITE_POL_10):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
9	0x0 RO	**IMR2 Write Access Policy 9 (IMR2_WRITE_POL_9):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
8	0x0 RW	**IMR2 Write Access Policy 8 (IMR2_WRITE_POL_8):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
7	0x0 RO	**IMR2 Write Access Policy 7 (IMR2_WRITE_POL_7):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
6	0x0 RO	**IMR2 Write Access Policy 6 (IMR2_WRITE_POL_6):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
5	0x0 RW	**IMR2 Write Access Policy 5 (IMR2_WRITE_POL_5):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
4	0x0 RW	**IMR2 Write Access Policy 4 (IMR2_WRITE_POL_4):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
3	0x0 RW	**IMR2 Write Access Policy 3 (IMR2_WRITE_POL_3):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
2	0x0 RW	**IMR2 Write Access Policy 2 (IMR2_WRITE_POL_2):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
1	0x0 RW	**IMR2 Write Access Policy 1 (IMR2_WRITE_POL_1):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.
0	0x0 RW	**IMR2 Write Access Policy 0 (IMR2_WRITE_POL_0):** Bit vector used to determine which agents are allowed write access to the IMR2 region, based on each agent's 6bit encoded SAI value.

44.3.37 IMR3 Base (B_CR_BIMR3BASE_0_0_0_MCHBAR)—Offset 68D0h

This register, along with IMR3MASK, IMR3RAC and IMR3WAC, defines an isolated region of memory that can be masked to prohibit certain system agents from accessing memory. When an agent sends a request to the B-Unit, whether snooped or not, an IMR may optionally prevent that transaction from changing the state of memory or from getting correct data in response to the operation, if the agent's SAI field does not specify the correct Policy. The IMR's Policy is configured by the IMR3RAC and IMR3WAC registers.

Type: Memory Mapped I/O Register (Size: 32 bits)

BAR and Offset: [MCHBAR] + 68D0h

Default: 00000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
31	0x0 RW	**IMR Enable (IMR_EN):** Enables access checking for the IMR region.
30	0x0 RW	**Asset Classification AC[0]: Trace Enable (TR_EN):** Enables snooping of transactions to the IMR region by tracing agents.
29	0x0 RO	**RESERVED_1:** Reserved
28:0	0x0 RW	**Base 0 IMR3 Base (IMR3_BASE):** Specifies bits 38:10 of the start address of IMR3 region. IMR region size must be a strict poweroftwo, at least 1KB, and naturally aligned to the size. These bits are compared with the result of the IMR3MASK[28:0] applied to bits 38:10 of the incoming address to determine if an access falls within the IMR3 defined region.

44.3.38 IMR3 Mask (B_CR_BIMR3MASK_0_0_0_MCHBAR)—Offset 68D4h

This register, along with IMR3BASE, IMR3RAC and IMR3WAC, defines an isolated region of memory that can be masked to prohibit certain system agents from accessing memory. When an agent sends a request to the B-Unit, whether snooped or not, an IMR may optionally prevent that transaction from changing the state of memory or from getting correct data in response to the operation if the agent's SAI field does not specify the correct Policy. The IMR's Policy is configured by the IMR3RAC and IMR3WAC registers.

Type: Memory Mapped I/O Register (Size: 32 bits)

BAR and Offset: [MCHBAR] + 68D4h

Default: 00000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
31	0x0 RW	**Asset Classification AC[2]: GT Implicit Writeback Enable (GT_IWB_EN):** Enables implicit writebacks to protected region from GT caching agent. When set to 1, enables implicit writeback HITM data from GT to be returned to the requestor. When set to 0, inhibits HITM data from GT from being returned to the requestor. HITM data from IA cores may be returned to the requestor depending on the setting of the IA_IWB_EN bit.
30	0x0 RW	**Asset Classification AC[1]: IA Implicit Writeback Enable (IA_IWB_EN):** Enables implicit writebacks to protected region from IA caching agent. When set to 1, enables implicit writeback HITM data from IA cores to be returned to the requestor. When set to 0, inhibits HITM data from IA cores from being returned to the requestor. HITM data from GT may be returned to the requestor depending on the setting of the GT_IWB_EN bit.
29	0x0 RO	**RESERVED_0:** Reserved
28:0	0x0 RW	**Mask 0 IMR3 Mask (IMR3_MASK):** These bits are ANDed with bits 38:10 of the incoming address to determine if the combined result matches the IMR3BASE[28:0] value. A match indicates that the incoming address falls within the IMR3 region.

44.3.39 IMR3 Control Policy (B_CR_BIMR3CP_0_0_0_MCHBAR)—Offset 68D8h

This register controls the access policy to the Read Access Policy BIMR3RAC, the Write Access Policy BIMR3WAC, and, self-referentially, to itself. The requesting agent's 6bit encoded SAI value is used as an index into this register's bits to determine both read access and write access.

Type: Memory Mapped I/O Register (Size: 64 bits)

BAR and Offset: [MCHBAR] + 68D8h

Default: 00000C0061010202h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
63:0	0xc0061010202 RW	**IMR3 Control Policy (IMR3_CTRL_POL):** Bit vector used to determine which agents are allowed access to the BIMR3RAC, BIMR3WAC and BIMR3CP registers, based on the value from each agent's 6bit SAI field.

44.3.40 IMR3 Read Access Policy (B_CR_BIMR3RAC_0_0_0_MCHBAR)—Offset 68E0h

This register, along with IMR3BASE, IMR3MASK and IMR3WAC, defines an isolated region of memory that can be masked to prohibit certain agents from accessing memory. It is programmed with an SAI Policy that indicates which agents in the system are allowed to perform read operations to IMR3. The requesting agent's 6bit encoded SAI value is used as an index into this register's bits to determine read access.

Type: Memory Mapped I/O Register (Size: 64 bits)

BAR and Offset: [MCHBAR] + 68E0h

Default: 0000000000000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
63	0x0 RW	**IMR3 Read Access Policy 63 (IMR3_READ_POL_63):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
62	0x0 RO	**IMR3 Read Access Policy 62 (IMR3_READ_POL_62):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
61	0x0 RO	**IMR3 Read Access Policy 61 (IMR3_READ_POL_61):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
60	0x0 RO	**IMR3 Read Access Policy 60 (IMR3_READ_POL_60):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
59	0x0 RO	**IMR3 Read Access Policy 59 (IMR3_READ_POL_59):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
58	0x0 RO	**IMR3 Read Access Policy 58 (IMR3_READ_POL_58):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
57	0x0 RO	**IMR3 Read Access Policy 57 (IMR3_READ_POL_57):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
56	0x0 RW	**IMR3 Read Access Policy 56 (IMR3_READ_POL_56):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
55	0x0 RW	**IMR3 Read Access Policy 55 (IMR3_READ_POL_55):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
54	0x0 RW	**IMR3 Read Access Policy 54 (IMR3_READ_POL_54):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
53	0x0 RO	**IMR3 Read Access Policy 53 (IMR3_READ_POL_53):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
52	0x0 RO	**IMR3 Read Access Policy 52 (IMR3_READ_POL_52):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
51	0x0 RO	**IMR3 Read Access Policy 51 (IMR3_READ_POL_51):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
50	0x0 RW	**IMR3 Read Access Policy 50 (IMR3_READ_POL_50):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
49	0x0 RW	**IMR3 Read Access Policy 49 (IMR3_READ_POL_49):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
48	0x0 RW	**IMR3 Read Access Policy 48 (IMR3_READ_POL_48):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
47	0x0 RO	**IMR3 Read Access Policy 47 (IMR3_READ_POL_47):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
46	0x0 RO	**IMR3 Read Access Policy 46 (IMR3_READ_POL_46):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.

Bit Range	Default & Access	Field Name (ID): Description
45	0x0 RO	**IMR3 Read Access Policy 45 (IMR3_READ_POL_45):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
44	0x0 RW	**IMR3 Read Access Policy 44 (IMR3_READ_POL_44):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
43	0x0 RW	**IMR3 Read Access Policy 43 (IMR3_READ_POL_43):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
42	0x0 RW	**IMR3 Read Access Policy 42 (IMR3_READ_POL_42):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
41	0x0 RW	**IMR3 Read Access Policy 41 (IMR3_READ_POL_41):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
40	0x0 RW	**IMR3 Read Access Policy 40 (IMR3_READ_POL_40):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
39	0x0 RO	**IMR3 Read Access Policy 39 (IMR3_READ_POL_39):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
38	0x0 RW	**IMR3 Read Access Policy 38 (IMR3_READ_POL_38):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
37	0x0 RO	**IMR3 Read Access Policy 37 (IMR3_READ_POL_37):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
36	0x0 RW	**IMR3 Read Access Policy 36 (IMR3_READ_POL_36):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
35	0x0 RO	**IMR3 Read Access Policy 35 (IMR3_READ_POL_35):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
34	0x0 RW	**IMR3 Read Access Policy 34 (IMR3_READ_POL_34):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
33	0x0 RW	**IMR3 Read Access Policy 33 (IMR3_READ_POL_33):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
32	0x0 RW	**IMR3 Read Access Policy 32 (IMR3_READ_POL_32):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
31	0x0 RO	**IMR3 Read Access Policy 31 (IMR3_READ_POL_31):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
30	0x0 RW	**IMR3 Read Access Policy 30 (IMR3_READ_POL_30):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
29	0x0 RW	**IMR3 Read Access Policy 29 (IMR3_READ_POL_29):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
28	0x0 RW	**IMR3 Read Access Policy 28 (IMR3_READ_POL_28):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
27	0x0 RW	**IMR3 Read Access Policy 27 (IMR3_READ_POL_27):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
26	0x0 RW	**IMR3 Read Access Policy 26 (IMR3_READ_POL_26):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
25	0x0 RW	**IMR3 Read Access Policy 25 (IMR3_READ_POL_25):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
24	0x0 RW	**IMR3 Read Access Policy 24 (IMR3_READ_POL_24):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
23	0x0 RO	**IMR3 Read Access Policy 23 (IMR3_READ_POL_23):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
22	0x0 RO	**IMR3 Read Access Policy 22 (IMR3_READ_POL_22):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.

Bit Range	Default & Access	Field Name (ID): Description
21	0x0 RW	**IMR3 Read Access Policy 21 (IMR3_READ_POL_21):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
20	0x0 RO	**IMR3 Read Access Policy 20 (IMR3_READ_POL_20):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
19	0x0 RO	**IMR3 Read Access Policy 19 (IMR3_READ_POL_19):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
18	0x0 RO	**IMR3 Read Access Policy 18 (IMR3_READ_POL_18):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
17	0x0 RW	**IMR3 Read Access Policy 17 (IMR3_READ_POL_17):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
16	0x0 RW	**IMR3 Read Access Policy 16 (IMR3_READ_POL_16):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
15	0x0 RO	**IMR3 Read Access Policy 15 (IMR3_READ_POL_15):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
14	0x0 RO	**IMR3 Read Access Policy 14 (IMR3_READ_POL_14):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
13	0x0 RW	**IMR3 Read Access Policy 13 (IMR3_READ_POL_13):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
12	0x0 RW	**IMR3 Read Access Policy 12 (IMR3_READ_POL_12):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
11	0x0 RO	**IMR3 Read Access Policy 11 (IMR3_READ_POL_11):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
10	0x0 RO	**IMR3 Read Access Policy 10 (IMR3_READ_POL_10):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
9	0x0 RO	**IMR3 Read Access Policy 9 (IMR3_READ_POL_9):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
8	0x0 RW	**IMR3 Read Access Policy 8 (IMR3_READ_POL_8):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
7	0x0 RO	**IMR3 Read Access Policy 7 (IMR3_READ_POL_7):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
6	0x0 RO	**IMR3 Read Access Policy 6 (IMR3_READ_POL_6):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
5	0x0 RW	**IMR3 Read Access Policy 5 (IMR3_READ_POL_5):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
4	0x0 RW	**IMR3 Read Access Policy 4 (IMR3_READ_POL_4):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
3	0x0 RW	**IMR3 Read Access Policy 3 (IMR3_READ_POL_3):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
2	0x0 RW	**IMR3 Read Access Policy 2 (IMR3_READ_POL_2):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
1	0x0 RW	**IMR3 Read Access Policy 1 (IMR3_READ_POL_1):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.
0	0x0 RW	**IMR3 Read Access Policy 0 (IMR3_READ_POL_0):** Bit vector used to determine which agents are allowed read access to the IMR3 region, based on each agent's 6bit encoded SAI value.

44.3.41 IMR3 Write Access Policy (B_CR_BIMR3WAC_0_0_0_MCHBAR)—Offset 68E8h

This register, along with IMR3BASE, IMR3MASK and IMR3RAC, defines an isolated region of memory that can be masked to prohibit certain agents from accessing memory. It is programmed with an SAI Policy that indicates which agents in the system are allowed to perform read operations to IMR3. The requesting agent's 6bit encoded SAI value is used as an index into this register's bits to determine write access.

Type: Memory Mapped I/O Register (Size: 64 bits)

BAR and Offset: [MCHBAR] + 68E8h

Default: 0000000000000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
63	0x0 RW	**IMR3 Write Access Policy 63 (IMR3_WRITE_POL_63):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
62	0x0 RO	**IMR3 Write Access Policy 62 (IMR3_WRITE_POL_62):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
61	0x0 RO	**IMR3 Write Access Policy 61 (IMR3_WRITE_POL_61):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
60	0x0 RO	**IMR3 Write Access Policy 60 (IMR3_WRITE_POL_60):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
59	0x0 RO	**IMR3 Write Access Policy 59 (IMR3_WRITE_POL_59):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
58	0x0 RO	**IMR3 Write Access Policy 58 (IMR3_WRITE_POL_58):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
57	0x0 RO	**IMR3 Write Access Policy 57 (IMR3_WRITE_POL_57):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
56	0x0 RW	**IMR3 Write Access Policy 56 (IMR3_WRITE_POL_56):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
55	0x0 RW	**IMR3 Write Access Policy 55 (IMR3_WRITE_POL_55):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
54	0x0 RW	**IMR3 Write Access Policy 54 (IMR3_WRITE_POL_54):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
53	0x0 RO	**IMR3 Write Access Policy 53 (IMR3_WRITE_POL_53):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
52	0x0 RO	**IMR3 Write Access Policy 52 (IMR3_WRITE_POL_52):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
51	0x0 RO	**IMR3 Write Access Policy 51 (IMR3_WRITE_POL_51):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
50	0x0 RW	**IMR3 Write Access Policy 50 (IMR3_WRITE_POL_50):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
49	0x0 RW	**IMR3 Write Access Policy 49 (IMR3_WRITE_POL_49):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
48	0x0 RW	**IMR3 Write Access Policy 48 (IMR3_WRITE_POL_48):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
47	0x0 RO	**IMR3 Write Access Policy 47 (IMR3_WRITE_POL_47):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
46	0x0 RO	**IMR3 Write Access Policy 46 (IMR3_WRITE_POL_46):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.

Bit Range	Default & Access	Field Name (ID): Description
45	0x0 RO	**IMR3 Write Access Policy 45 (IMR3_WRITE_POL_45):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
44	0x0 RW	**IMR3 Write Access Policy 44 (IMR3_WRITE_POL_44):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
43	0x0 RW	**IMR3 Write Access Policy 43 (IMR3_WRITE_POL_43):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
42	0x0 RW	**IMR3 Write Access Policy 42 (IMR3_WRITE_POL_42):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
41	0x0 RW	**IMR3 Write Access Policy 41 (IMR3_WRITE_POL_41):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
40	0x0 RW	**IMR3 Write Access Policy 40 (IMR3_WRITE_POL_40):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
39	0x0 RO	**IMR3 Write Access Policy 39 (IMR3_WRITE_POL_39):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
38	0x0 RW	**IMR3 Write Access Policy 38 (IMR3_WRITE_POL_38):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
37	0x0 RO	**IMR3 Write Access Policy 37 (IMR3_WRITE_POL_37):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
36	0x0 RW	**IMR3 Write Access Policy 36 (IMR3_WRITE_POL_36):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
35	0x0 RO	**IMR3 Write Access Policy 35 (IMR3_WRITE_POL_35):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
34	0x0 RW	**IMR3 Write Access Policy 34 (IMR3_WRITE_POL_34):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
33	0x0 RW	**IMR3 Write Access Policy 33 (IMR3_WRITE_POL_33):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
32	0x0 RW	**IMR3 Write Access Policy 32 (IMR3_WRITE_POL_32):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
31	0x0 RO	**IMR3 Write Access Policy 31 (IMR3_WRITE_POL_31):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
30	0x0 RW	**IMR3 Write Access Policy 30 (IMR3_WRITE_POL_30):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
29	0x0 RW	**IMR3 Write Access Policy 29 (IMR3_WRITE_POL_29):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
28	0x0 RW	**IMR3 Write Access Policy 28 (IMR3_WRITE_POL_28):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
27	0x0 RW	**IMR3 Write Access Policy 27 (IMR3_WRITE_POL_27):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
26	0x0 RW	**IMR3 Write Access Policy 26 (IMR3_WRITE_POL_26):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
25	0x0 RW	**IMR3 Write Access Policy 25 (IMR3_WRITE_POL_25):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
24	0x0 RW	**IMR3 Write Access Policy 24 (IMR3_WRITE_POL_24):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
23	0x0 RO	**IMR3 Write Access Policy 23 (IMR3_WRITE_POL_23):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
22	0x0 RO	**IMR3 Write Access Policy 22 (IMR3_WRITE_POL_22):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.

Bit Range	Default & Access	Field Name (ID): Description
21	0x0 RW	**IMR3 Write Access Policy 21 (IMR3_WRITE_POL_21):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
20	0x0 RO	**IMR3 Write Access Policy 20 (IMR3_WRITE_POL_20):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
19	0x0 RO	**IMR3 Write Access Policy 19 (IMR3_WRITE_POL_19):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
18	0x0 RO	**IMR3 Write Access Policy 18 (IMR3_WRITE_POL_18):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
17	0x0 RW	**IMR3 Write Access Policy 17 (IMR3_WRITE_POL_17):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
16	0x0 RW	**IMR3 Write Access Policy 16 (IMR3_WRITE_POL_16):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
15	0x0 RO	**IMR3 Write Access Policy 15 (IMR3_WRITE_POL_15):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
14	0x0 RO	**IMR3 Write Access Policy 14 (IMR3_WRITE_POL_14):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
13	0x0 RW	**IMR3 Write Access Policy 13 (IMR3_WRITE_POL_13):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
12	0x0 RW	**IMR3 Write Access Policy 12 (IMR3_WRITE_POL_12):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
11	0x0 RO	**IMR3 Write Access Policy 11 (IMR3_WRITE_POL_11):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
10	0x0 RO	**IMR3 Write Access Policy 10 (IMR3_WRITE_POL_10):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
9	0x0 RO	**IMR3 Write Access Policy 9 (IMR3_WRITE_POL_9):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
8	0x0 RW	**IMR3 Write Access Policy 8 (IMR3_WRITE_POL_8):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
7	0x0 RO	**IMR3 Write Access Policy 7 (IMR3_WRITE_POL_7):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
6	0x0 RO	**IMR3 Write Access Policy 6 (IMR3_WRITE_POL_6):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
5	0x0 RW	**IMR3 Write Access Policy 5 (IMR3_WRITE_POL_5):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
4	0x0 RW	**IMR3 Write Access Policy 4 (IMR3_WRITE_POL_4):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
3	0x0 RW	**IMR3 Write Access Policy 3 (IMR3_WRITE_POL_3):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
2	0x0 RW	**IMR3 Write Access Policy 2 (IMR3_WRITE_POL_2):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
1	0x0 RW	**IMR3 Write Access Policy 1 (IMR3_WRITE_POL_1):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.
0	0x0 RW	**IMR3 Write Access Policy 0 (IMR3_WRITE_POL_0):** Bit vector used to determine which agents are allowed write access to the IMR3 region, based on each agent's 6bit encoded SAI value.

44.3.42 IMR4 Base (B_CR_BIMR4BASE_0_0_0_MCHBAR)—Offset 68F0h

This register, along with IMR4MASK, IMR4RAC and IMR4WAC, defines an isolated region of memory that can be masked to prohibit certain system agents from accessing memory. When an agent sends a request to the B-Unit, whether snooped or not, an IMR may optionally prevent that transaction from changing the state of memory or from getting correct data in response to the operation if the agent's SAI field does not specify the correct Policy. The IMR's Policy is configured by the IMR4RAC and IMR4WAC registers.

Type: Memory Mapped I/O Register (Size: 32 bits)

BAR and Offset: [MCHBAR] + 68F0h

Default: 00000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
31	0x0 RW	**IMR Enable (IMR_EN):** Enables access checking for the IMR region.
30	0x0 RW	**Asset Classification AC[0]: Trace Enable (TR_EN):** Enables snooping of transactions to the IMR region by tracing agents.
29	0x0 RO	**RESERVED_1:** Reserved
28:0	0x0 RW	**Base 0 IMR4 Base (IMR4_BASE):** Specifies bits 38:10 of the start address of IMR4 region. IMR region size must be a strict poweroftwo, at least 1KB, and naturally aligned to the size. These bits are compared with the result of the IMR4MASK[28:0] applied to bits 38:10 of the incoming address to determine if an access falls within the IMR4 defined region.

44.3.43 IMR4 Mask (B_CR_BIMR4MASK_0_0_0_MCHBAR)—Offset 68F4h

This register, along with IMR4BASE, IMR4RAC and IMR4WAC, defines an isolated region of memory that can be masked to prohibit certain system agents from accessing memory. When an agent sends a request to the B-Unit, whether snooped or not, an IMR may optionally prevent that transaction from changing the state of memory or from getting correct data in response to the operation, if the agent's SAI field does not specify the correct Policy. The IMR's Policy is configured by the IMR4RAC and IMR4WAC registers.

Type: Memory Mapped I/O Register (Size: 32 bits)

BAR and Offset: [MCHBAR] + 68F4h

Default: 00000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
31	0x0 RW	**Asset Classification AC[2]: GT Implicit Writeback Enable (GT_IWB_EN):** Enables implicit writebacks to protected region from GT caching agent. When set to 1, enables implicit writeback HITM data from GT to be returned to the requestor. When set to 0, inhibits HITM data from GT from being returned to the requestor. HITM data from IA cores may be returned to the requestor, depending on the setting of the IA_IWB_EN bit.
30	0x0 RW	**Asset Classification AC[1]: IA Implicit Writeback Enable (IA_IWB_EN):** Enables implicit writebacks to protected region from IA caching agent. When set to 1, enables implicit writeback data HITM data from IA cores to be returned to the requestor. When set to 0, inhibits HITM data from IA cores from being returned to the requestor. HITM data from GT may be returned to the requestor, depending on the setting of the GT_IWB_EN bit.
29	0x0 RO	**RESERVED_0:** Reserved
28:0	0x0 RW	**Mask 0 IMR4 Mask (IMR4_MASK):** These bits are ANDed with bits 38:10 of the incoming address to determine if the combined result matches the IMR4BASE[28:0] value. A match indicates that the incoming address falls within the IMR4 region.

44.3.44 B-Unit IMR4 Control Policy (B_CR_BIMR4CP_0_0_0_MCHBAR)—Offset 68F8h

This register controls the access policy to the Read Access Policy BIMR4RAC, the Write Access Policy BIMR4WAC, and, self-referentially, to itself. The requesting agent's 6bit encoded SAI value is used as an index into this register's bits to determine both read access and write access.

Type: Memory Mapped I/O Register (Size: 64 bits)

BAR and Offset: [MCHBAR] + 68F8h

Default: 00000C0061010202h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
63:0	0xc0061010202 RW	**B-Unit IMR4 Control Policy (IMR4_CTRL_POL):** Bit vector used to determine which agents are allowed access to the BIMR4RAC, BIMR4WAC and BIMR4CP registers, based on the value from each agent's 6bit SAI field.

44.3.45 IMR4 Read Access Policy (B_CR_BIMR4RAC_0_0_0_MCHBAR)—Offset 6900h

This register, along with IMR4BASE, IMR4MASK and IMR4WAC, defines an isolated region of memory that can be masked to prohibit certain agents from accessing memory. It is programmed with an SAI Policy that indicates which agents in the system are allowed to perform read operations to IMR4. The requesting agent's 6bit encoded SAI value is used as an index into this register's bits to determine read access.

Type: Memory Mapped I/O Register (Size: 64 bits)

BAR and Offset: [MCHBAR] + 6900h

Default: 0000000000000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
63	0x0 RW	**IMR4 Read Access Policy 63 (IMR4_READ_POL_63):** Bit vector used to determine which agents are allowed read access to the IMR4 region, based on each agent's 6bit encoded SAI value.
62	0x0 RO	**IMR4 Read Access Policy 62 (IMR4_READ_POL_62):** Bit vector used to determine which agents are allowed read access to the IMR4 region, based on each agent's 6bit encoded SAI value.
61	0x0 RO	**IMR4 Read Access Policy 61 (IMR4_READ_POL_61):** Bit vector used to determine which agents are allowed read access to the IMR4 region, based on each agent's 6bit encoded SAI value.

22	0x0 RO	**IMR4 Read Access Policy 22 (IMR4_READ_POL_22):** Bit vector used to determine which agents are allowed read access to the IMR4 region, based on each agent's 6bit encoded SAI value.

Bit Range	Default & Access	Field Name (ID): Description
21	0x0 RW	**IMR4 Read Access Policy 21 (IMR4_READ_POL_21):** Bit vector used to determine which agents are allowed read access to the IMR4 region, based on each agent's 6bit encoded SAI value.
20	0x0 RO	**IMR4 Read Access Policy 20 (IMR4_READ_POL_20):** Bit vector used to determine which agents are allowed read access to the IMR4 region, based on each agent's 6bit encoded SAI value.
19	0x0 RO	**IMR4 Read Access Policy 19 (IMR4_READ_POL_19):** Bit vector used to determine which agents are allowed read access to the IMR4 region, based on each agent's 6bit encoded SAI value.
18	0x0 RO	**IMR4 Read Access Policy 18 (IMR4_READ_POL_18):** Bit vector used to determine which agents are allowed read access to the IMR4 region, based on each agent's 6bit encoded SAI value.
17	0x0 RW	**IMR4 Read Access Policy 17 (IMR4_READ_POL_17):** Bit vector used to determine which agents are allowed read access to the IMR4 region, based on each agent's 6bit encoded SAI value.
16	0x0 RW	**IMR4 Read Access Policy 16 (IMR4_READ_POL_16):** Bit vector used to determine which agents are allowed read access to the IMR4 region, based on each agent's 6bit encoded SAI value.
15	0x0 RO	**IMR4 Read Access Policy 15 (IMR4_READ_POL_15):** Bit vector used to determine which agents are allowed read access to the IMR4 region, based on each agent's 6bit encoded SAI value.
14	0x0 RO	**IMR4 Read Access Policy 14 (IMR4_READ_POL_14):** Bit vector used to determine which agents are allowed read access to the IMR4 region, based on each agent's 6bit encoded SAI value.
13	0x0 RW	**IMR4 Read Access Policy 13 (IMR4_READ_POL_13):** Bit vector used to determine which agents are allowed read access to the IMR4 region, based on each agent's 6bit encoded SAI value.
12	0x0 RW	**IMR4 Read Access Policy 12 (IMR4_READ_POL_12):** Bit vector used to determine which agents are allowed read access to the IMR4 region, based on each agent's 6bit encoded SAI value.
11	0x0 RO	**IMR4 Read Access Policy 11 (IMR4_READ_POL_11):** Bit vector used to determine which agents are allowed read access to the IMR4 region, based on each agent's 6bit encoded SAI value.
10	0x0 RO	**IMR4 Read Access Policy 10 (IMR4_READ_POL_10):** Bit vector used to determine which agents are allowed read access to the IMR4 region, based on each agent's 6bit encoded SAI value.
9	0x0 RO	**IMR4 Read Access Policy 9 (IMR4_READ_POL_9):** Bit vector used to determine which agents are allowed read access to the IMR4 region, based on each agent's 6bit encoded SAI value.
8	0x0 RW	**IMR4 Read Access Policy 8 (IMR4_READ_POL_8):** Bit vector used to determine which agents are allowed read access to the IMR4 region, based on each agent's 6bit encoded SAI value.
7	0x0 RO	**IMR4 Read Access Policy 7 (IMR4_READ_POL_7):** Bit vector used to determine which agents are allowed read access to the IMR4 region, based on each agent's 6bit encoded SAI value.
6	0x0 RO	**IMR4 Read Access Policy 6 (IMR4_READ_POL_6):** Bit vector used to determine which agents are allowed read access to the IMR4 region, based on each agent's 6bit encoded SAI value.
5	0x0 RW	**IMR4 Read Access Policy 5 (IMR4_READ_POL_5):** Bit vector used to determine which agents are allowed read access to the IMR4 region, based on each agent's 6bit encoded SAI value.
4	0x0 RW	**IMR4 Read Access Policy 4 (IMR4_READ_POL_4):** Bit vector used to determine which agents are allowed read access to the IMR4 region, based on each agent's 6bit encoded SAI value.
3	0x0 RW	**IMR4 Read Access Policy 3 (IMR4_READ_POL_3):** Bit vector used to determine which agents are allowed read access to the IMR4 region, based on each agent's 6bit encoded SAI value.
2	0x0 RW	**IMR4 Read Access Policy 2 (IMR4_READ_POL_2):** Bit vector used to determine which agents are allowed read access to the IMR4 region, based on each agent's 6bit encoded SAI value.
1	0x0 RW	**IMR4 Read Access Policy 1 (IMR4_READ_POL_1):** Bit vector used to determine which agents are allowed read access to the IMR4 region, based on each agent's 6bit encoded SAI value.
0	0x0 RW	**IMR4 Read Access Policy 0 (IMR4_READ_POL_0):** Bit vector used to determine which agents are allowed read access to the IMR4 region, based on each agent's 6bit encoded SAI value.

44.3.46 IMR4 Write Access Policy (B_CR_BIMR4WAC_0_0_0_MCHBAR)—Offset 6908h

This register, along with IMR4BASE, IMR4MASK and IMR4RAC, defines an isolated region of memory that can be masked to prohibit certain agents from accessing memory. It is programmed with a SAI Policy that indicates which agents in the system are allowed to perform read operations to IMR4. The requesting agent's 6bit encoded SAI value is used as an index into this register's bits to determine write access.

Type: Memory Mapped I/O Register (Size: 64 bits)

BAR and Offset: [MCHBAR] + 6908h

Default: 0000000000000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

4	0x0 RW	**IMR4_WRITE_POL_4:** B-Unit IMR4 Write Access Policy: Bit vector used to determine which agents are allowed write access to the IMR4 region, based on each agent's 6bit encoded SAI value.
3	0x0 RW	**IMR4_WRITE_POL_3:** B-Unit IMR4 Write Access Policy: Bit vector used to determine which agents are allowed write access to the IMR4 region, based on each agent's 6bit encoded SAI value.
2	0x0 RW	**IMR4_WRITE_POL_2:** B-Unit IMR4 Write Access Policy: Bit vector used to determine which agents are allowed write access to the IMR4 region, based on each agent's 6bit encoded SAI value.
1	0x0 RW	**IMR4_WRITE_POL_1:** B-Unit IMR4 Write Access Policy: Bit vector used to determine which agents are allowed write access to the IMR4 region, based on each agent's 6bit encoded SAI value.
0	0x0 RW	**IMR4_WRITE_POL_0:** B-Unit IMR4 Write Access Policy: Bit vector used to determine which agents are allowed write access to the IMR4 region, based on each agent's 6bit encoded SAI value.

44.3.47 IMR5 Base (B_CR_BIMR5BASE_0_0_0_MCHBAR)—Offset 6910h

This register, along with IMR5MASK, IMR5RAC and IMR5WAC, defines an isolated region of memory that can be masked to prohibit certain system agents from accessing memory. When an agent sends a request to the B-Unit, whether snooped or not, an IMR may optionally prevent that transaction from changing the state of memory or from getting correct data in response to the operation if the agent's SAI field does not specify the correct Policy. The IMR's Policy is configured by the IMR5RAC and IMR5WAC registers.

Type: Memory Mapped I/O Register (Size: 32 bits)

BAR and Offset: [MCHBAR] + 6910h

Default: 00000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
31	0x0 RW	**IMR Enable (IMR_EN):** Enables access checking for the IMR region.
30	0x0 RW	**Asset Classification AC[0]: Trace Enable (TR_EN):** Enables snooping of transactions to the IMR region by tracing agents.
29	0x0 RO	**RESERVED_1:** Reserved
28:0	0x0 RW	**Base 0 IMR5 Base (IMR5_BASE):** Specifies bits 38:10 of the start address of IMR5 region. IMR region size must be a strict poweroftwo, at least 1KB, and naturally aligned to the size. These bits are compared with the result of the IMR5MASK[28:0] applied to bits 38:10 of the incoming address to determine if an access falls within the IMR5 defined region.

44.3.48 IMR5 Mask (B_CR_BIMR5MASK_0_0_0_MCHBAR)—Offset 6914h

This register, along with IMR5BASE, IMR5RAC and IMR5WAC, defines an isolated region of memory that can be masked to prohibit certain system agents from accessing memory. When an agent sends a request to the B-Unit, whether snooped or not, an IMR may optionally prevent that transaction from changing the state of memory or from getting correct data in response to the operation, if the agent's SAI field does not specify the correct Policy. The IMR's Policy is configured by the IMR5RAC and IMR5WAC registers.

Type: Memory Mapped I/O Register (Size: 32 bits)

BAR and Offset: [MCHBAR] + 6914h

Default: 00000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
31	0x0 RW	**Asset Classification AC[2]: GT Implicit Writeback Enable (GT_IWB_EN):** Enables implicit writebacks to protected region from GT caching agent. When set to 1, enables implicit writeback HITM data from GT to be returned to the requestor. When set to 0, inhibits HITM data from GT from being returned to the requestor. HITM data from IA cores may be returned to the requestor, depending on the setting of the IA_IWB_EN bit.
30	0x0 RW	**Asset Classification AC[1]: IA Implicit Writeback Enable (IA_IWB_EN):** Enables implicit writebacks to protected region from IA caching agent. When set to 1, enables implicit writeback HITM data from IA cores to be returned to the requestor. When set to 0, inhibits HITM data from IA cores from being returned to the requestor. HITM data from GT may be returned to the requestor, depending on the setting of the GT_IWB_EN bit.
29	0x0 RO	**RESERVED_0:** Reserved
28:0	0x0 RW	**Mask 0 IMR5 Mask (IMR5_MASK):** These bits are ANDed with bits 38:10 of the incoming address to determine if the combined result matches the IMR5BASE[28:0] value. A match indicates that the incoming address falls within the IMR5 region.

44.3.49 IMR5 Control Policy (B_CR_BIMR5CP_0_0_0_MCHBAR)—Offset 6918h

This register controls the access policy to the Read Access Policy BIMR5RAC, the Write Access Policy BIMR5WAC, and, self-referentially, to itself. The requesting agent's 6bit encoded SAI value is used as an index into this register's bits to determine both read access and write access.

Type: Memory Mapped I/O Register (Size: 64 bits)

BAR and Offset: [MCHBAR] + 6918h

Default: 00000C0061010202h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
63:0	0xc0061010202 RW	**IMR5 Control Policy (IMR5_CTRL_POL):** Bit vector used to determine which agents are allowed access to the BIMR5RAC, BIMR5WAC and BIMR5CP registers, based on the value from each agent's 6bit SAI field.

44.3.50 IMR5 Read Access Policy (B_CR_BIMR5RAC_0_0_0_MCHBAR)—Offset 6920h

This register, along with IMR5BASE, IMR5MASK and IMR5WAC, defines an isolated region of memory that can be masked to prohibit certain agents from accessing memory. It is programmed with an SAI Policy that indicates which agents in the system are allowed to perform read operations to IMR5. The requesting agent's 6bit encoded SAI value is used as an index into this register's bits to determine read access.

Type: Memory Mapped I/O Register (Size: 64 bits)

BAR and Offset: [MCHBAR] + 6920h

Default: 0000000000000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
63	0x0 RW	**IMR5 Read Access Policy 63 (IMR5_READ_POL_63):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
62	0x0 RO	**IMR5 Read Access Policy 62 (IMR5_READ_POL_62):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
61	0x0 RO	**IMR5 Read Access Policy 61 (IMR5_READ_POL_61):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
60	0x0 RO	**IMR5 Read Access Policy 60 (IMR5_READ_POL_60):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
59	0x0 RO	**IMR5 Read Access Policy 59 (IMR5_READ_POL_59):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
58	0x0 RO	**IMR5 Read Access Policy 58 (IMR5_READ_POL_58):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
57	0x0 RO	**IMR5 Read Access Policy 57 (IMR5_READ_POL_57):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
56	0x0 RW	**IMR5 Read Access Policy 56 (IMR5_READ_POL_56):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
55	0x0 RW	**IMR5 Read Access Policy 55 (IMR5_READ_POL_55):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
54	0x0 RW	**IMR5 Read Access Policy 54 (IMR5_READ_POL_54):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
53	0x0 RO	**IMR5 Read Access Policy 53 (IMR5_READ_POL_53):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
52	0x0 RO	**IMR5 Read Access Policy 52 (IMR5_READ_POL_52):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
51	0x0 RO	**IMR5 Read Access Policy 51 (IMR5_READ_POL_51):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
50	0x0 RW	**IMR5 Read Access Policy 50 (IMR5_READ_POL_50):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
49	0x0 RW	**IMR5 Read Access Policy 49 (IMR5_READ_POL_49):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
48	0x0 RW	**IMR5 Read Access Policy 48 (IMR5_READ_POL_48):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
47	0x0 RO	**IMR5 Read Access Policy 47 (IMR5_READ_POL_47):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
46	0x0 RO	**IMR5 Read Access Policy 46 (IMR5_READ_POL_46):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.

Bit Range	Default & Access	Field Name (ID): Description
45	0x0 RO	**IMR5 Read Access Policy 45 (IMR5_READ_POL_45):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
44	0x0 RW	**IMR5 Read Access Policy 44 (IMR5_READ_POL_44):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
43	0x0 RW	**IMR5 Read Access Policy 43 (IMR5_READ_POL_43):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
42	0x0 RW	**IMR5 Read Access Policy 42 (IMR5_READ_POL_42):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
41	0x0 RW	**IMR5 Read Access Policy 41 (IMR5_READ_POL_41):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
40	0x0 RW	**IMR5 Read Access Policy 40 (IMR5_READ_POL_40):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
39	0x0 RO	**IMR5 Read Access Policy 39 (IMR5_READ_POL_39):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
38	0x0 RW	**IMR5 Read Access Policy 38 (IMR5_READ_POL_38):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
37	0x0 RO	**IMR5 Read Access Policy 37 (IMR5_READ_POL_37):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
36	0x0 RW	**IMR5 Read Access Policy 36 (IMR5_READ_POL_36):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
35	0x0 RO	**IMR5 Read Access Policy 35 (IMR5_READ_POL_35):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
34	0x0 RW	**IMR5 Read Access Policy 34 (IMR5_READ_POL_34):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
33	0x0 RW	**IMR5 Read Access Policy 33 (IMR5_READ_POL_33):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
32	0x0 RW	**IMR5 Read Access Policy 32 (IMR5_READ_POL_32):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
31	0x0 RO	**IMR5 Read Access Policy 31 (IMR5_READ_POL_31):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
30	0x0 RW	**IMR5 Read Access Policy 30 (IMR5_READ_POL_30):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
29	0x0 RW	**IMR5 Read Access Policy 29 (IMR5_READ_POL_29):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
28	0x0 RW	**IMR5 Read Access Policy 28 (IMR5_READ_POL_28):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
27	0x0 RW	**IMR5 Read Access Policy 27 (IMR5_READ_POL_27):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
26	0x0 RW	**IMR5 Read Access Policy 26 (IMR5_READ_POL_26):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
25	0x0 RW	**IMR5 Read Access Policy 25 (IMR5_READ_POL_25):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
24	0x0 RW	**IMR5 Read Access Policy 24 (IMR5_READ_POL_24):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
23	0x0 RO	**IMR5 Read Access Policy 23 (IMR5_READ_POL_23):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
22	0x0 RO	**IMR5 Read Access Policy 22 (IMR5_READ_POL_22):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.

Bit Range	Default & Access	Field Name (ID): Description
21	0x0 RW	**IMR5 Read Access Policy 21 (IMR5_READ_POL_21):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
20	0x0 RO	**IMR5 Read Access Policy 20 (IMR5_READ_POL_20):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
19	0x0 RO	**IMR5 Read Access Policy 19 (IMR5_READ_POL_19):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
18	0x0 RO	**IMR5 Read Access Policy 18 (IMR5_READ_POL_18):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
17	0x0 RW	**IMR5 Read Access Policy 17 (IMR5_READ_POL_17):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
16	0x0 RW	**IMR5 Read Access Policy 16 (IMR5_READ_POL_16):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
15	0x0 RO	**IMR5 Read Access Policy 15 (IMR5_READ_POL_15):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
14	0x0 RO	**IMR5 Read Access Policy 14 (IMR5_READ_POL_14):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
13	0x0 RW	**IMR5 Read Access Policy 13 (IMR5_READ_POL_13):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
12	0x0 RW	**IMR5 Read Access Policy 12 (IMR5_READ_POL_12):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
11	0x0 RO	**IMR5 Read Access Policy 11 (IMR5_READ_POL_11):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
10	0x0 RO	**IMR5 Read Access Policy 10 (IMR5_READ_POL_10):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
9	0x0 RO	**IMR5 Read Access Policy 9 (IMR5_READ_POL_9):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
8	0x0 RW	**IMR5 Read Access Policy 8 (IMR5_READ_POL_8):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
7	0x0 RO	**IMR5 Read Access Policy 7 (IMR5_READ_POL_7):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
6	0x0 RO	**IMR5 Read Access Policy 6 (IMR5_READ_POL_6):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
5	0x0 RW	**IMR5 Read Access Policy 5 (IMR5_READ_POL_5):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
4	0x0 RW	**IMR5 Read Access Policy 4 (IMR5_READ_POL_4):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
3	0x0 RW	**IMR5 Read Access Policy 3 (IMR5_READ_POL_3):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
2	0x0 RW	**IMR5 Read Access Policy 2 (IMR5_READ_POL_2):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
1	0x0 RW	**IMR5 Read Access Policy 1 (IMR5_READ_POL_1):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.
0	0x0 RW	**IMR5 Read Access Policy 0 (IMR5_READ_POL_0):** Bit vector used to determine which agents are allowed read access to the IMR5 region, based on each agent's 6bit encoded SAI value.

44.3.51 IMR5 Write Access Policy (B_CR_BIMR5WAC_0_0_0_MCHBAR)—Offset 6928h

This register, along with IMR5BASE, IMR5MASK and IMR5RAC, defines an isolated region of memory that can be masked to prohibit certain agents from accessing memory. It is programmed with an SAI Policy that indicates which agents in the system are allowed to perform read operations to IMR5. The requesting agent's 6bit encoded SAI value is used as an index into this register's bits to determine write access.

Type: Memory Mapped I/O Register (Size: 64 bits)

BAR and Offset: [MCHBAR] + 6928h

Default: 0000000000000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
63	0x0 RW	**IMR5 Write Access Policy 63 (IMR5_WRITE_POL_63):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
62	0x0 RO	**IMR5 Write Access Policy 62 (IMR5_WRITE_POL_62):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
61	0x0 RO	**IMR5 Write Access Policy 61 (IMR5_WRITE_POL_61):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
60	0x0 RO	**IMR5 Write Access Policy 60 (IMR5_WRITE_POL_60):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
59	0x0 RO	**IMR5 Write Access Policy 59 (IMR5_WRITE_POL_59):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
58	0x0 RO	**IMR5 Write Access Policy 58 (IMR5_WRITE_POL_58):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
57	0x0 RO	**IMR5 Write Access Policy 57 (IMR5_WRITE_POL_57):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
56	0x0 RW	**IMR5 Write Access Policy 56 (IMR5_WRITE_POL_56):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
55	0x0 RW	**IMR5 Write Access Policy 55 (IMR5_WRITE_POL_55):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
54	0x0 RW	**IMR5 Write Access Policy 54 (IMR5_WRITE_POL_54):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
53	0x0 RO	**IMR5 Write Access Policy 53 (IMR5_WRITE_POL_53):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
52	0x0 RO	**IMR5 Write Access Policy 52 (IMR5_WRITE_POL_52):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
51	0x0 RO	**IMR5 Write Access Policy 51 (IMR5_WRITE_POL_51):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
50	0x0 RW	**IMR5 Write Access Policy 50 (IMR5_WRITE_POL_50):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
49	0x0 RW	**IMR5 Write Access Policy 49 (IMR5_WRITE_POL_49):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
48	0x0 RW	**IMR5 Write Access Policy 48 (IMR5_WRITE_POL_48):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
47	0x0 RO	**IMR5 Write Access Policy 47 (IMR5_WRITE_POL_47):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
46	0x0 RO	**IMR5 Write Access Policy 46 (IMR5_WRITE_POL_46):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.

Bit Range	Default & Access	Field Name (ID): Description
45	0x0 RO	**IMR5 Write Access Policy 45 (IMR5_WRITE_POL_45):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
44	0x0 RW	**IMR5 Write Access Policy 44 (IMR5_WRITE_POL_44):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
43	0x0 RW	**IMR5 Write Access Policy 43 (IMR5_WRITE_POL_43):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
42	0x0 RW	**IMR5 Write Access Policy 42 (IMR5_WRITE_POL_42):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
41	0x0 RW	**IMR5 Write Access Policy 41 (IMR5_WRITE_POL_41):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
40	0x0 RW	**IMR5 Write Access Policy 40 (IMR5_WRITE_POL_40):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
39	0x0 RO	**IMR5 Write Access Policy 39 (IMR5_WRITE_POL_39):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
38	0x0 RW	**IMR5 Write Access Policy 38 (IMR5_WRITE_POL_38):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
37	0x0 RO	**IMR5 Write Access Policy 37 (IMR5_WRITE_POL_37):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
36	0x0 RW	**IMR5 Write Access Policy 36 (IMR5_WRITE_POL_36):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
35	0x0 RO	**IMR5 Write Access Policy 35 (IMR5_WRITE_POL_35):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
34	0x0 RW	**IMR5 Write Access Policy 34 (IMR5_WRITE_POL_34):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
33	0x0 RW	**IMR5 Write Access Policy 33 (IMR5_WRITE_POL_33):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
32	0x0 RW	**IMR5 Write Access Policy 32 (IMR5_WRITE_POL_32):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
31	0x0 RO	**IMR5 Write Access Policy 31 (IMR5_WRITE_POL_31):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
30	0x0 RW	**IMR5 Write Access Policy 30 (IMR5_WRITE_POL_30):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
29	0x0 RW	**IMR5 Write Access Policy 29 (IMR5_WRITE_POL_29):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
28	0x0 RW	**IMR5 Write Access Policy 28 (IMR5_WRITE_POL_28):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
27	0x0 RW	**IMR5 Write Access Policy 27 (IMR5_WRITE_POL_27):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
26	0x0 RW	**IMR5 Write Access Policy 26 (IMR5_WRITE_POL_26):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
25	0x0 RW	**IMR5 Write Access Policy 25 (IMR5_WRITE_POL_25):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
24	0x0 RW	**IMR5 Write Access Policy 24 (IMR5_WRITE_POL_24):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
23	0x0 RO	**IMR5 Write Access Policy 23 (IMR5_WRITE_POL_23):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
22	0x0 RO	**IMR5 Write Access Policy 22 (IMR5_WRITE_POL_22):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.

Bit Range	Default & Access	Field Name (ID): Description
21	0x0 RW	**IMR5 Write Access Policy 21 (IMR5_WRITE_POL_21):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
20	0x0 RO	**IMR5 Write Access Policy 20 (IMR5_WRITE_POL_20):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
19	0x0 RO	**IMR5 Write Access Policy 19 (IMR5_WRITE_POL_19):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
18	0x0 RO	**IMR5 Write Access Policy 18 (IMR5_WRITE_POL_18):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
17	0x0 RW	**IMR5 Write Access Policy 17 (IMR5_WRITE_POL_17):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
16	0x0 RW	**IMR5 Write Access Policy 16 (IMR5_WRITE_POL_16):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
15	0x0 RO	**IMR5 Write Access Policy 15 (IMR5_WRITE_POL_15):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
14	0x0 RO	**IMR5 Write Access Policy 14 (IMR5_WRITE_POL_14):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
13	0x0 RW	**IMR5 Write Access Policy 13 (IMR5_WRITE_POL_13):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
12	0x0 RW	**IMR5 Write Access Policy 12 (IMR5_WRITE_POL_12):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
11	0x0 RO	**IMR5 Write Access Policy 11 (IMR5_WRITE_POL_11):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
10	0x0 RO	**IMR5 Write Access Policy 10 (IMR5_WRITE_POL_10):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
9	0x0 RO	**IMR5 Write Access Policy 9 (IMR5_WRITE_POL_9):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
8	0x0 RW	**IMR5 Write Access Policy 8 (IMR5_WRITE_POL_8):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
7	0x0 RO	**IMR5 Write Access Policy 7 (IMR5_WRITE_POL_7):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
6	0x0 RO	**IMR5 Write Access Policy 6 (IMR5_WRITE_POL_6):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
5	0x0 RW	**IMR5 Write Access Policy 5 (IMR5_WRITE_POL_5):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
4	0x0 RW	**IMR5 Write Access Policy 4 (IMR5_WRITE_POL_4):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
3	0x0 RW	**IMR5 Write Access Policy 3 (IMR5_WRITE_POL_3):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
2	0x0 RW	**IMR5 Write Access Policy 2 (IMR5_WRITE_POL_2):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
1	0x0 RW	**IMR5 Write Access Policy 1 (IMR5_WRITE_POL_1):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.
0	0x0 RW	**IMR5 Write Access Policy 0 (IMR5_WRITE_POL_0):** Bit vector used to determine which agents are allowed write access to the IMR5 region, based on each agent's 6bit encoded SAI value.

44.3.52 IMR6 Base (B_CR_BIMR6BASE_0_0_0_MCHBAR)—Offset 6930h

This register, along with IMR6MASK, IMR6RAC and IMR6WAC, defines an isolated region of memory that can be masked to prohibit certain system agents from accessing memory. When an agent sends a request to the B-Unit, whether snooped or not, an IMR may optionally prevent that transaction from changing the state of memory or from getting correct data in response to the operation if the agent's SAI field does not specify the correct Policy. The IMR's Policy is configured by the IMR6RAC and IMR6WAC registers.

Type: Memory Mapped I/O Register (Size: 32 bits)

BAR and Offset: [MCHBAR] + 6930h

Default: 00000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
31	0x0 RW	**IMR Enable (IMR_EN):** Enables access checking for the IMR region.
30	0x0 RW	**Asset Classification AC[0]: Trace Enable (TR_EN):** Enables snooping of transactions to the IMR region by tracing agents.
29	0x0 RO	**RESERVED_1:** Reserved
28:0	0x0 RW	**Base 0 IMR6 Base (IMR6_BASE):** Specifies bits 38:10 of the start address of IMR6 region. IMR region size must be a strict poweroftwo, at least 1KB, and naturally aligned to the size. These bits are compared with the result of the IMR6MASK[28:0] applied to bits 38:10 of the incoming address to determine if an access falls within the IMR6 defined region.

44.3.53 IMR6 Mask (B_CR_BIMR6MASK_0_0_0_MCHBAR)—Offset 6934h

This register, along with IMR6BASE, IMR6RAC and IMR6WAC, defines an isolated region of memory that can be masked to prohibit certain system agents from accessing memory. When an agent sends a request to the B-Unit, whether snooped or not, an IMR may optionally prevent that transaction from changing the state of memory or from getting correct data in response to the operation, if the agent's SAI field does not specify the correct Policy. The IMR's Policy is configured by the IMR6RAC and IMR6WAC registers.

Type: Memory Mapped I/O Register (Size: 32 bits)

BAR and Offset: [MCHBAR] + 6934h

Default: 00000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
31	0x0 RW	**Asset Classification AC[2]: GT Implicit WB Enable (GT_IWB_EN):** Enables implicit writebacks to protected region from GT caching agent. When set to 1, enables implicit writeback HITM data from GT to be returned to the requestor. When set to 0, inhibits HITM data from GT from being returned to the requestor. HITM data from IA cores may be returned to the requestor, depending on the setting of the IA_IWB_EN bit.
30	0x0 RW	**Asset Classification AC[1]: IA Implicit WB Enable (IA_IWB_EN):** Enables implicit writebacks to protected region from IA caching agent. When set to 1, enables implicit writeback HITM data from IA cores to be returned to the requestor. When set to 0, inhibits HITM data from IA cores from being returned to the requestor. HITM data from GT may be returned to the requestor, depending on the setting of the GT_IWB_EN bit.
29	0x0 RO	**RESERVED_0:** Reserved
28:0	0x0 RW	**Mask 0 IMR6 Mask (IMR6_MASK):** These bits are ANDed with bits 38:10 of the incoming address to determine if the combined result matches the IMR6BASE[28:0] value. A match indicates that the incoming address falls within the IMR6 region.

44.3.54 IMR6 Control Policy (B_CR_BIMR6CP_0_0_0_MCHBAR)—Offset 6938h

This register controls the access policy to the Read Access Policy BIMR6RAC, the Write Access Policy BIMR6WAC, and, self-referentially, to itself. The requesting agent's 6bit encoded SAI value is used as an index into this register's bits to determine both read access and write access.

Type: Memory Mapped I/O Register (Size: 64 bits)

BAR and Offset: [MCHBAR] + 6938h

Default: 00000C0061010202h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
63:0	0xc0061010202 RW	**IMR6 Control Policy (IMR6_CTRL_POL):** Bit vector used to determine which agents are allowed access to the BIMR6RAC, BIMR6WAC, BIMR6CP registers, based on the value from each agent's 6bit SAI field.

44.3.55 IMR6 Read Access Policy (B_CR_BIMR6RAC_0_0_0_MCHBAR)—Offset 6940h

This register, along with IMR6BASE, IMR6MASK and IMR6WAC, defines an isolated region of memory that can be masked to prohibit certain agents from accessing memory. It is programmed with an SAI Policy that indicates which agents in the system are allowed to perform read operations to IMR6. The requesting agent's 6bit encoded SAI value is used as an index into this register's bits to determine read access.

Type: Memory Mapped I/O Register (Size: 64 bits)

BAR and Offset: [MCHBAR] + 6940h

Default: 0000000000000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
63	0x0 RW	**IMR6 Read Access Policy 63 (IMR6_READ_POL_63):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
62	0x0 RO	**IMR6 Read Access Policy 62 (IMR6_READ_POL_62):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
61	0x0 RO	**IMR6 Read Access Policy 61 (IMR6_READ_POL_61):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
60	0x0 RO	**IMR6 Read Access Policy 60 (IMR6_READ_POL_60):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
59	0x0 RO	**IMR6 Read Access Policy 59 (IMR6_READ_POL_59):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
58	0x0 RO	**IMR6 Read Access Policy 58 (IMR6_READ_POL_58):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
57	0x0 RO	**IMR6 Read Access Policy 57 (IMR6_READ_POL_57):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
56	0x0 RW	**IMR6 Read Access Policy 56 (IMR6_READ_POL_56):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
55	0x0 RW	**IMR6 Read Access Policy 55 (IMR6_READ_POL_55):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
54	0x0 RW	**IMR6 Read Access Policy 54 (IMR6_READ_POL_54):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
53	0x0 RO	**IMR6 Read Access Policy 53 (IMR6_READ_POL_53):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
52	0x0 RO	**IMR6 Read Access Policy 52 (IMR6_READ_POL_52):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
51	0x0 RO	**IMR6 Read Access Policy 51 (IMR6_READ_POL_51):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
50	0x0 RW	**IMR6 Read Access Policy 50 (IMR6_READ_POL_50):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
49	0x0 RW	**IMR6 Read Access Policy 49 (IMR6_READ_POL_49):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
48	0x0 RW	**IMR6 Read Access Policy 48 (IMR6_READ_POL_48):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
47	0x0 RO	**IMR6 Read Access Policy 47 (IMR6_READ_POL_47):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
46	0x0 RO	**IMR6 Read Access Policy 46 (IMR6_READ_POL_46):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.

Bit Range	Default & Access	Field Name (ID): Description
45	0x0 RO	**IMR6 Read Access Policy 45 (IMR6_READ_POL_45):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
44	0x0 RW	**IMR6 Read Access Policy 44 (IMR6_READ_POL_44):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
43	0x0 RW	**IMR6 Read Access Policy 43 (IMR6_READ_POL_43):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
42	0x0 RW	**IMR6 Read Access Policy 42 (IMR6_READ_POL_42):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
41	0x0 RW	**IMR6 Read Access Policy 41 (IMR6_READ_POL_41):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
40	0x0 RW	**IMR6 Read Access Policy 40 (IMR6_READ_POL_40):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
39	0x0 RO	**IMR6 Read Access Policy 39 (IMR6_READ_POL_39):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
38	0x0 RW	**IMR6 Read Access Policy 38 (IMR6_READ_POL_38):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
37	0x0 RO	**IMR6 Read Access Policy 37 (IMR6_READ_POL_37):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
36	0x0 RW	**IMR6 Read Access Policy 36 (IMR6_READ_POL_36):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
35	0x0 RO	**IMR6 Read Access Policy 35 (IMR6_READ_POL_35):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
34	0x0 RW	**IMR6 Read Access Policy 34 (IMR6_READ_POL_34):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
33	0x0 RW	**IMR6 Read Access Policy 33 (IMR6_READ_POL_33):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
32	0x0 RW	**IMR6 Read Access Policy 32 (IMR6_READ_POL_32):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
31	0x0 RO	**IMR6 Read Access Policy 31 (IMR6_READ_POL_31):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
30	0x0 RW	**IMR6 Read Access Policy 30 (IMR6_READ_POL_30):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
29	0x0 RW	**IMR6 Read Access Policy 29 (IMR6_READ_POL_29):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
28	0x0 RW	**IMR6 Read Access Policy 28 (IMR6_READ_POL_28):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
27	0x0 RW	**IMR6 Read Access Policy 27 (IMR6_READ_POL_27):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
26	0x0 RW	**IMR6 Read Access Policy 26 (IMR6_READ_POL_26):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
25	0x0 RW	**IMR6 Read Access Policy 25 (IMR6_READ_POL_25):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
24	0x0 RW	**IMR6 Read Access Policy 24 (IMR6_READ_POL_24):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
23	0x0 RO	**IMR6 Read Access Policy 23 (IMR6_READ_POL_23):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
22	0x0 RO	**IMR6 Read Access Policy 22 (IMR6_READ_POL_22):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.

Bit Range	Default & Access	Field Name (ID): Description
21	0x0 RW	**IMR6 Read Access Policy 21 (IMR6_READ_POL_21):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
20	0x0 RO	**IMR6 Read Access Policy 20 (IMR6_READ_POL_20):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
19	0x0 RO	**IMR6 Read Access Policy 19 (IMR6_READ_POL_19):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
18	0x0 RO	**IMR6 Read Access Policy 18 (IMR6_READ_POL_18):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
17	0x0 RW	**IMR6 Read Access Policy 17 (IMR6_READ_POL_17):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
16	0x0 RW	**IMR6 Read Access Policy 16 (IMR6_READ_POL_16):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
15	0x0 RO	**IMR6 Read Access Policy 15 (IMR6_READ_POL_15):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
14	0x0 RO	**IMR6 Read Access Policy 14 (IMR6_READ_POL_14):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
13	0x0 RW	**IMR6 Read Access Policy 13 (IMR6_READ_POL_13):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
12	0x0 RW	**IMR6 Read Access Policy 12 (IMR6_READ_POL_12):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
11	0x0 RO	**IMR6 Read Access Policy 11 (IMR6_READ_POL_11):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
10	0x0 RO	**IMR6 Read Access Policy 10 (IMR6_READ_POL_10):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
9	0x0 RO	**IMR6 Read Access Policy 9 (IMR6_READ_POL_9):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
8	0x0 RW	**IMR6 Read Access Policy 8 (IMR6_READ_POL_8):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
7	0x0 RO	**IMR6 Read Access Policy 7 (IMR6_READ_POL_7):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
6	0x0 RO	**IMR6 Read Access Policy 6 (IMR6_READ_POL_6):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
5	0x0 RW	**IMR6 Read Access Policy 5 (IMR6_READ_POL_5):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
4	0x0 RW	**IMR6 Read Access Policy 4 (IMR6_READ_POL_4):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
3	0x0 RW	**IMR6 Read Access Policy 3 (IMR6_READ_POL_3):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
2	0x0 RW	**IMR6 Read Access Policy 2 (IMR6_READ_POL_2):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
1	0x0 RW	**IMR6 Read Access Policy 1 (IMR6_READ_POL_1):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.
0	0x0 RW	**IMR6 Read Access Policy 0 (IMR6_READ_POL_0):** Bit vector used to determine which agents are allowed read access to the IMR6 region, based on each agent's 6bit encoded SAI value.

44.3.56 IMR6 Write Access Policy (B_CR_BIMR6WAC_0_0_0_MCHBAR)—Offset 6948h

This register, along with IMR6BASE, IMR6MASK and IMR6RAC, defines an isolated region of memory that can be masked to prohibit certain agents from accessing memory. It is programmed with a SAI Policy that indicates which agents in the system are allowed to perform read operations to IMR6. The requesting agent's 6bit encoded SAI value is used as an index into this register's bits to determine write access.

Type: Memory Mapped I/O Register (Size: 64 bits)

BAR and Offset: [MCHBAR] + 6948h

Default: 0000000000000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
63	0x0 RW	**IMR6 Write Access Policy 63 (IMR6_WRITE_POL_63):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
62	0x0 RO	**IMR6 Write Access Policy 62 (IMR6_WRITE_POL_62):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
61	0x0 RO	**IMR6 Write Access Policy 61 (IMR6_WRITE_POL_61):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
60	0x0 RO	**IMR6 Write Access Policy 60 (IMR6_WRITE_POL_60):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
59	0x0 RO	**IMR6 Write Access Policy 59 (IMR6_WRITE_POL_59):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
58	0x0 RO	**IMR6 Write Access Policy 58 (IMR6_WRITE_POL_58):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
57	0x0 RO	**IMR6 Write Access Policy 57 (IMR6_WRITE_POL_57):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
56	0x0 RW	**IMR6 Write Access Policy 56 (IMR6_WRITE_POL_56):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
55	0x0 RW	**IMR6 Write Access Policy 55 (IMR6_WRITE_POL_55):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
54	0x0 RW	**IMR6 Write Access Policy 54 (IMR6_WRITE_POL_54):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
53	0x0 RO	**IMR6 Write Access Policy 53 (IMR6_WRITE_POL_53):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
52	0x0 RO	**IMR6 Write Access Policy 52 (IMR6_WRITE_POL_52):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
51	0x0 RO	**IMR6 Write Access Policy 51 (IMR6_WRITE_POL_51):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
50	0x0 RW	**IMR6 Write Access Policy 50 (IMR6_WRITE_POL_50):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
49	0x0 RW	**IMR6 Write Access Policy 49 (IMR6_WRITE_POL_49):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
48	0x0 RW	**IMR6 Write Access Policy 48 (IMR6_WRITE_POL_48):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
47	0x0 RO	**IMR6 Write Access Policy 47 (IMR6_WRITE_POL_47):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
46	0x0 RO	**IMR6 Write Access Policy 46 (IMR6_WRITE_POL_46):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.

Bit Range	Default & Access	Field Name (ID): Description
45	0x0 RO	**IMR6 Write Access Policy 45 (IMR6_WRITE_POL_45):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
44	0x0 RW	**IMR6 Write Access Policy 44 (IMR6_WRITE_POL_44):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
43	0x0 RW	**IMR6 Write Access Policy 43 (IMR6_WRITE_POL_43):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
42	0x0 RW	**IMR6 Write Access Policy 42 (IMR6_WRITE_POL_42):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
41	0x0 RW	**IMR6 Write Access Policy 41 (IMR6_WRITE_POL_41):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
40	0x0 RW	**IMR6 Write Access Policy 40 (IMR6_WRITE_POL_40):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
39	0x0 RO	**IMR6 Write Access Policy 39 (IMR6_WRITE_POL_39):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
38	0x0 RW	**IMR6 Write Access Policy 38 (IMR6_WRITE_POL_38):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
37	0x0 RO	**IMR6 Write Access Policy 37 (IMR6_WRITE_POL_37):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
36	0x0 RW	**IMR6 Write Access Policy 36 (IMR6_WRITE_POL_36):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
35	0x0 RO	**IMR6 Write Access Policy 35 (IMR6_WRITE_POL_35):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
34	0x0 RW	**IMR6 Write Access Policy 34 (IMR6_WRITE_POL_34):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
33	0x0 RW	**IMR6 Write Access Policy 33 (IMR6_WRITE_POL_33):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
32	0x0 RW	**IMR6 Write Access Policy 32 (IMR6_WRITE_POL_32):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
31	0x0 RO	**IMR6 Write Access Policy 31 (IMR6_WRITE_POL_31):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
30	0x0 RW	**IMR6 Write Access Policy 30 (IMR6_WRITE_POL_30):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
29	0x0 RW	**IMR6 Write Access Policy 29 (IMR6_WRITE_POL_29):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
28	0x0 RW	**IMR6 Write Access Policy 28 (IMR6_WRITE_POL_28):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
27	0x0 RW	**IMR6 Write Access Policy 27 (IMR6_WRITE_POL_27):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
26	0x0 RW	**IMR6 Write Access Policy 26 (IMR6_WRITE_POL_26):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
25	0x0 RW	**IMR6 Write Access Policy 25 (IMR6_WRITE_POL_25):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
24	0x0 RW	**IMR6 Write Access Policy 24 (IMR6_WRITE_POL_24):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
23	0x0 RO	**IMR6 Write Access Policy 23 (IMR6_WRITE_POL_23):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
22	0x0 RO	**IMR6 Write Access Policy 22 (IMR6_WRITE_POL_22):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.

Bit Range	Default & Access	Field Name (ID): Description
21	0x0 RW	**IMR6 Write Access Policy 21 (IMR6_WRITE_POL_21):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
20	0x0 RO	**IMR6 Write Access Policy 20 (IMR6_WRITE_POL_20):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
19	0x0 RO	**IMR6 Write Access Policy 19 (IMR6_WRITE_POL_19):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
18	0x0 RO	**IMR6 Write Access Policy 18 (IMR6_WRITE_POL_18):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
17	0x0 RW	**IMR6 Write Access Policy 17 (IMR6_WRITE_POL_17):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
16	0x0 RW	**IMR6 Write Access Policy 16 (IMR6_WRITE_POL_16):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
15	0x0 RO	**IMR6 Write Access Policy 15 (IMR6_WRITE_POL_15):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
14	0x0 RO	**IMR6 Write Access Policy 14 (IMR6_WRITE_POL_14):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
13	0x0 RW	**IMR6 Write Access Policy 13 (IMR6_WRITE_POL_13):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
12	0x0 RW	**IMR6 Write Access Policy 12 (IMR6_WRITE_POL_12):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
11	0x0 RO	**IMR6 Write Access Policy 11 (IMR6_WRITE_POL_11):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
10	0x0 RO	**IMR6 Write Access Policy 10 (IMR6_WRITE_POL_10):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
9	0x0 RO	**IMR6 Write Access Policy 9 (IMR6_WRITE_POL_9):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
8	0x0 RW	**IMR6 Write Access Policy 8 (IMR6_WRITE_POL_8):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
7	0x0 RO	**IMR6 Write Access Policy 7 (IMR6_WRITE_POL_7):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
6	0x0 RO	**IMR6 Write Access Policy 6 (IMR6_WRITE_POL_6):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
5	0x0 RW	**IMR6 Write Access Policy 5 (IMR6_WRITE_POL_5):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
4	0x0 RW	**IMR6 Write Access Policy 4 (IMR6_WRITE_POL_4):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
3	0x0 RW	**IMR6 Write Access Policy 3 (IMR6_WRITE_POL_3):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
2	0x0 RW	**IMR6 Write Access Policy 2 (IMR6_WRITE_POL_2):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
1	0x0 RW	**IMR6 Write Access Policy 1 (IMR6_WRITE_POL_1):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.
0	0x0 RW	**IMR6 Write Access Policy 0 (IMR6_WRITE_POL_0):** Bit vector used to determine which agents are allowed write access to the IMR6 region, based on each agent's 6bit encoded SAI value.

44.3.57 IMR7 Base (B_CR_BIMR7BASE_0_0_0_MCHBAR)—Offset 6950h

This register, along with IMR7MASK, IMR7RAC and IMR7WAC, defines an isolated region of memory that can be masked to prohibit certain system agents from accessing memory. When an agent sends a request to the B-Unit, whether snooped or not, an IMR may optionally prevent that transaction from changing the state of memory or from getting correct data in response to the operation, if the agent's SAI field does not specify the correct Policy. The IMR's Policy is configured by the IMR7RAC and IMR7WAC registers.

Type: Memory Mapped I/O Register (Size: 32 bits)

BAR and Offset: [MCHBAR] + 6950h

Default: 00000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
31	0x0 RW	**IMR Enable (IMR_EN):** Enables access checking for the IMR region.
30	0x0 RW	**Asset Classification AC[0]: Trace Enable (TR_EN):** Enables snooping of transactions to the IMR region by tracing agents.
29	0x0 RO	**RESERVED_1:** Reserved
28:0	0x0 RW	**Base 0 IMR7 Base (IMR7_BASE):** Specifies bits 38:10 of the start address of IMR7 region. IMR region size must be a strict poweroftwo, at least 1KB, and naturally aligned to the size. These bits are compared with the result of the IMR7MASK[28:0] applied to bits 38:10 of the incoming address to determine if an access falls within the IMR7 defined region.

44.3.58 IMR7 Mask (B_CR_BIMR7MASK_0_0_0_MCHBAR)—Offset 6954h

This register, along with IMR7BASE, IMR7RAC and IMR7WAC, defines an isolated region of memory that can be masked to prohibit certain system agents from accessing memory. When an agent sends a request to the B-Unit, whether snooped or not, an IMR may optionally prevent that transaction from changing the state of memory or from getting correct data in response to the operation, if the agent's SAI field does not specify the correct Policy. The IMR's Policy is configured by the IMR7RAC and IMR7WAC registers.

Type: Memory Mapped I/O Register (Size: 32 bits)

BAR and Offset: [MCHBAR] + 6954h

Default: 00000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
31	0x0 RW	**Asset Classification AC[2]: GT Implicit WB Enable (GT_IWB_EN):** Enables implicit writebacks to protected region from GT caching agent. When set to 1, enables implicit writeback HITM data from GT to be returned to the requestor. When set to 0, inhibits HITM data from GT from being returned to the requestor. HITM data from IA cores may be returned to the requestor, depending on the setting of the IA_IWB_EN bit.
30	0x0 RW	**Asset Classification AC[1]: IA Implicit WB Enable (IA_IWB_EN):** Enables implicit writebacks to protected region from IA caching agent. When set to 1, enables implicit writeback HITM data from IA cores to be returned to the requestor. When set to 0, inhibits HITM data from IA cores from being returned to the requestor. HITM data from GT may be returned to the requestor, depending on the setting of the GT_IWB_EN bit.
29	0x0 RO	**RESERVED_0:** Reserved
28:0	0x0 RW	**Mask 0 IMR7 Mask (IMR7_MASK):** These bits are ANDed with bits 38:10 of the incoming address to determine if the combined result matches the IMR7BASE[28:0] value. A match indicates that the incoming address falls within the IMR7 region.

44.3.59 IMR7 Control Policy (B_CR_BIMR7CP_0_0_0_MCHBAR)—Offset 6958h

This register controls the access policy to the Read Access Policy BIMR7RAC, the Write Access Policy BIMR7WAC, and, self-referentially, to itself. The requesting agent's 6bit encoded SAI value is used as an index into this register's bits to determine both read access and write access.

Type: Memory Mapped I/O Register (Size: 64 bits)

BAR and Offset: [MCHBAR] + 6958h

Default: 00000C0061010202h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
63:0	0xc0061010202 RW	**IMR7 Control Policy (IMR7_CTRL_POL):** Bit vector used to determine which agents are allowed access to the BIMR7RAC, BIMR7WAC and BIMR7CP registers, based on the value from each agent's 6bit SAI field.

44.3.60 IMR7 Read Access Policy (B_CR_BIMR7RAC_0_0_0_MCHBAR)—Offset 6960h

This register, along with IMR7BASE, IMR7MASK and IMR7WAC, defines an isolated region of memory that can be masked to prohibit certain agents from accessing memory. It is programmed with an SAI Policy that indicates which agents in the system are allowed to perform read operations to IMR7. The requesting agent's 6bit encoded SAI value is used as an index into this register's bits to determine read access.

Type: Memory Mapped I/O Register (Size: 64 bits)

BAR and Offset: [MCHBAR] + 6960h

Default: 0000000000000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
63	0x0 RW	**IMR7 Read Access Policy 63 (IMR7_READ_POL_63):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
62	0x0 RO	**IMR7 Read Access Policy 62 (IMR7_READ_POL_62):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
61	0x0 RO	**IMR7 Read Access Policy 61 (IMR7_READ_POL_61):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
60	0x0 RO	**IMR7 Read Access Policy 60 (IMR7_READ_POL_60):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
59	0x0 RO	**IMR7 Read Access Policy 59 (IMR7_READ_POL_59):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
58	0x0 RO	**IMR7 Read Access Policy 58 (IMR7_READ_POL_58):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
57	0x0 RO	**IMR7 Read Access Policy 57 (IMR7_READ_POL_57):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
56	0x0 RW	**IMR7 Read Access Policy 56 (IMR7_READ_POL_56):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
55	0x0 RW	**IMR7 Read Access Policy 55 (IMR7_READ_POL_55):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
54	0x0 RW	**IMR7 Read Access Policy 54 (IMR7_READ_POL_54):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
53	0x0 RO	**IMR7 Read Access Policy 53 (IMR7_READ_POL_53):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
52	0x0 RO	**IMR7 Read Access Policy 52 (IMR7_READ_POL_52):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
51	0x0 RO	**IMR7 Read Access Policy 51 (IMR7_READ_POL_51):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
50	0x0 RW	**IMR7 Read Access Policy 50 (IMR7_READ_POL_50):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
49	0x0 RW	**IMR7 Read Access Policy 49 (IMR7_READ_POL_49):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
48	0x0 RW	**IMR7 Read Access Policy 48 (IMR7_READ_POL_48):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
47	0x0 RO	**IMR7 Read Access Policy 47 (IMR7_READ_POL_47):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
46	0x0 RO	**IMR7 Read Access Policy 46 (IMR7_READ_POL_46):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.

Bit Range	Default & Access	Field Name (ID): Description
45	0x0 RO	**IMR7 Read Access Policy 45 (IMR7_READ_POL_45):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
44	0x0 RW	**IMR7 Read Access Policy 44 (IMR7_READ_POL_44):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
43	0x0 RW	**IMR7 Read Access Policy 43 (IMR7_READ_POL_43):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
42	0x0 RW	**IMR7 Read Access Policy 42 (IMR7_READ_POL_42):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
41	0x0 RW	**IMR7 Read Access Policy 41 (IMR7_READ_POL_41):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
40	0x0 RW	**IMR7 Read Access Policy 40 (IMR7_READ_POL_40):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
39	0x0 RO	**IMR7 Read Access Policy 39 (IMR7_READ_POL_39):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
38	0x0 RW	**IMR7 Read Access Policy 38 (IMR7_READ_POL_38):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
37	0x0 RO	**IMR7 Read Access Policy 37 (IMR7_READ_POL_37):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
36	0x0 RW	**IMR7 Read Access Policy 36 (IMR7_READ_POL_36):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
35	0x0 RO	**IMR7 Read Access Policy 35 (IMR7_READ_POL_35):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
34	0x0 RW	**IMR7 Read Access Policy 34 (IMR7_READ_POL_34):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
33	0x0 RW	**IMR7 Read Access Policy 33 (IMR7_READ_POL_33):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
32	0x0 RW	**IMR7 Read Access Policy 32 (IMR7_READ_POL_32):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
31	0x0 RO	**IMR7 Read Access Policy 31 (IMR7_READ_POL_31):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
30	0x0 RW	**IMR7 Read Access Policy 30 (IMR7_READ_POL_30):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
29	0x0 RW	**IMR7 Read Access Policy 29 (IMR7_READ_POL_29):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
28	0x0 RW	**IMR7 Read Access Policy 28 (IMR7_READ_POL_28):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
27	0x0 RW	**IMR7 Read Access Policy 27 (IMR7_READ_POL_27):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
26	0x0 RW	**IMR7 Read Access Policy 26 (IMR7_READ_POL_26):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
25	0x0 RW	**IMR7 Read Access Policy 25 (IMR7_READ_POL_25):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
24	0x0 RW	**IMR7 Read Access Policy 24 (IMR7_READ_POL_24):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
23	0x0 RO	**IMR7 Read Access Policy 23 (IMR7_READ_POL_23):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
22	0x0 RO	**IMR7 Read Access Policy 22 (IMR7_READ_POL_22):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.

Bit Range	Default & Access	Field Name (ID): Description
21	0x0 RW	**IMR7 Read Access Policy 21 (IMR7_READ_POL_21):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
20	0x0 RO	**IMR7 Read Access Policy 20 (IMR7_READ_POL_20):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
19	0x0 RO	**IMR7 Read Access Policy 19 (IMR7_READ_POL_19):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
18	0x0 RO	**IMR7 Read Access Policy 18 (IMR7_READ_POL_18):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
17	0x0 RW	**IMR7 Read Access Policy 17 (IMR7_READ_POL_17):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
16	0x0 RW	**IMR7 Read Access Policy 16 (IMR7_READ_POL_16):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
15	0x0 RO	**IMR7 Read Access Policy 15 (IMR7_READ_POL_15):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
14	0x0 RO	**IMR7 Read Access Policy 14 (IMR7_READ_POL_14):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
13	0x0 RW	**IMR7 Read Access Policy 13 (IMR7_READ_POL_13):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
12	0x0 RW	**IMR7 Read Access Policy 12 (IMR7_READ_POL_12):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
11	0x0 RO	**IMR7 Read Access Policy 11 (IMR7_READ_POL_11):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
10	0x0 RO	**IMR7 Read Access Policy 10 (IMR7_READ_POL_10):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
9	0x0 RO	**IMR7 Read Access Policy 9 (IMR7_READ_POL_9):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
8	0x0 RW	**IMR7 Read Access Policy 8 (IMR7_READ_POL_8):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
7	0x0 RO	**IMR7 Read Access Policy 7 (IMR7_READ_POL_7):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
6	0x0 RO	**IMR7 Read Access Policy 6 (IMR7_READ_POL_6):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
5	0x0 RW	**IMR7 Read Access Policy 5 (IMR7_READ_POL_5):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
4	0x0 RW	**IMR7 Read Access Policy 4 (IMR7_READ_POL_4):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
3	0x0 RW	**IMR7 Read Access Policy 3 (IMR7_READ_POL_3):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
2	0x0 RW	**IMR7 Read Access Policy 2 (IMR7_READ_POL_2):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
1	0x0 RW	**IMR7 Read Access Policy 1 (IMR7_READ_POL_1):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.
0	0x0 RW	**IMR7 Read Access Policy 0 (IMR7_READ_POL_0):** Bit vector used to determine which agents are allowed read access to the IMR7 region, based on each agent's 6bit encoded SAI value.

44.3.61 IMR7 Write Access Policy (B_CR_BIMR7WAC_0_0_0_MCHBAR)—Offset 6968h

This register, along with IMR7BASE, IMR7MASK and IMR7RAC, defines an isolated region of memory that can be masked to prohibit certain agents from accessing memory. It is programmed with an SAI Policy that indicates which agents in the system are allowed to perform read operations to IMR7. The requesting agent's 6bit encoded SAI value is used as an index into this register's bits to determine write access.

Type: Memory Mapped I/O Register (Size: 64 bits)

BAR and Offset: [MCHBAR] + 6968h

Default: 0000000000000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
63	0x0 RW	**IMR7 Write Access Policy 63 (IMR7_WRITE_POL_63):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
62	0x0 RO	**IMR7 Write Access Policy 62 (IMR7_WRITE_POL_62):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
61	0x0 RO	**IMR7 Write Access Policy 61 (IMR7_WRITE_POL_61):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
60	0x0 RO	**IMR7 Write Access Policy 60 (IMR7_WRITE_POL_60):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
59	0x0 RO	**IMR7 Write Access Policy 59 (IMR7_WRITE_POL_59):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
58	0x0 RO	**IMR7 Write Access Policy 58 (IMR7_WRITE_POL_58):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
57	0x0 RO	**IMR7 Write Access Policy 57 (IMR7_WRITE_POL_57):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
56	0x0 RW	**IMR7 Write Access Policy 56 (IMR7_WRITE_POL_56):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
55	0x0 RW	**IMR7 Write Access Policy 55 (IMR7_WRITE_POL_55):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
54	0x0 RW	**IMR7 Write Access Policy 54 (IMR7_WRITE_POL_54):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
53	0x0 RO	**IMR7 Write Access Policy 53 (IMR7_WRITE_POL_53):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
52	0x0 RO	**IMR7 Write Access Policy 52 (IMR7_WRITE_POL_52):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
51	0x0 RO	**IMR7 Write Access Policy 51 (IMR7_WRITE_POL_51):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
50	0x0 RW	**IMR7 Write Access Policy 50 (IMR7_WRITE_POL_50):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
49	0x0 RW	**IMR7 Write Access Policy 49 (IMR7_WRITE_POL_49):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
48	0x0 RW	**IMR7 Write Access Policy 48 (IMR7_WRITE_POL_48):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
47	0x0 RO	**IMR7 Write Access Policy 47 (IMR7_WRITE_POL_47):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
46	0x0 RO	**IMR7 Write Access Policy 46 (IMR7_WRITE_POL_46):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.

Bit Range	Default & Access	Field Name (ID): Description
45	0x0 RO	**IMR7 Write Access Policy 45 (IMR7_WRITE_POL_45):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
44	0x0 RW	**IMR7 Write Access Policy 44 (IMR7_WRITE_POL_44):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
43	0x0 RW	**IMR7 Write Access Policy 43 (IMR7_WRITE_POL_43):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
42	0x0 RW	**IMR7 Write Access Policy 42 (IMR7_WRITE_POL_42):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
41	0x0 RW	**IMR7 Write Access Policy 41 (IMR7_WRITE_POL_41):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
40	0x0 RW	**IMR7 Write Access Policy 40 (IMR7_WRITE_POL_40):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
39	0x0 RO	**IMR7 Write Access Policy 39 (IMR7_WRITE_POL_39):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
38	0x0 RW	**IMR7 Write Access Policy 38 (IMR7_WRITE_POL_38):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
37	0x0 RO	**IMR7 Write Access Policy 37 (IMR7_WRITE_POL_37):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
36	0x0 RW	**IMR7 Write Access Policy 36 (IMR7_WRITE_POL_36):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
35	0x0 RO	**IMR7 Write Access Policy 35 (IMR7_WRITE_POL_35):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
34	0x0 RW	**IMR7 Write Access Policy 34 (IMR7_WRITE_POL_34):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
33	0x0 RW	**IMR7 Write Access Policy 33 (IMR7_WRITE_POL_33):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
32	0x0 RW	**IMR7 Write Access Policy 32 (IMR7_WRITE_POL_32):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
31	0x0 RO	**IMR7 Write Access Policy 31 (IMR7_WRITE_POL_31):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
30	0x0 RW	**IMR7 Write Access Policy 30 (IMR7_WRITE_POL_30):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
29	0x0 RW	**IMR7 Write Access Policy 29 (IMR7_WRITE_POL_29):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
28	0x0 RW	**IMR7 Write Access Policy 28 (IMR7_WRITE_POL_28):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
27	0x0 RW	**IMR7 Write Access Policy 27 (IMR7_WRITE_POL_27):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
26	0x0 RW	**IMR7 Write Access Policy 26 (IMR7_WRITE_POL_26):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
25	0x0 RW	**IMR7 Write Access Policy 25 (IMR7_WRITE_POL_25):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
24	0x0 RW	**IMR7 Write Access Policy 24 (IMR7_WRITE_POL_24):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
23	0x0 RO	**IMR7 Write Access Policy 23 (IMR7_WRITE_POL_23):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
22	0x0 RO	**IMR7 Write Access Policy 22 (IMR7_WRITE_POL_22):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.

Bit Range	Default & Access	Field Name (ID): Description
21	0x0 RW	**IMR7 Write Access Policy 21 (IMR7_WRITE_POL_21):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
20	0x0 RO	**IMR7 Write Access Policy 20 (IMR7_WRITE_POL_20):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
19	0x0 RO	**IMR7 Write Access Policy 19 (IMR7_WRITE_POL_19):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
18	0x0 RO	**IMR7 Write Access Policy 18 (IMR7_WRITE_POL_18):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
17	0x0 RW	**IMR7 Write Access Policy 17 (IMR7_WRITE_POL_17):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
16	0x0 RW	**IMR7 Write Access Policy 16 (IMR7_WRITE_POL_16):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
15	0x0 RO	**IMR7 Write Access Policy 15 (IMR7_WRITE_POL_15):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
14	0x0 RO	**IMR7 Write Access Policy 14 (IMR7_WRITE_POL_14):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
13	0x0 RW	**IMR7 Write Access Policy 13 (IMR7_WRITE_POL_13):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
12	0x0 RW	**IMR7 Write Access Policy 12 (IMR7_WRITE_POL_12):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
11	0x0 RO	**IMR7 Write Access Policy 11 (IMR7_WRITE_POL_11):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
10	0x0 RO	**IMR7 Write Access Policy 10 (IMR7_WRITE_POL_10):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
9	0x0 RO	**IMR7 Write Access Policy 9 (IMR7_WRITE_POL_9):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
8	0x0 RW	**IMR7 Write Access Policy 8 (IMR7_WRITE_POL_8):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
7	0x0 RO	**IMR7 Write Access Policy 7 (IMR7_WRITE_POL_7):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
6	0x0 RO	**IMR7 Write Access Policy 6 (IMR7_WRITE_POL_6):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
5	0x0 RW	**IMR7 Write Access Policy 5 (IMR7_WRITE_POL_5):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
4	0x0 RW	**IMR7 Write Access Policy 4 (IMR7_WRITE_POL_4):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
3	0x0 RW	**IMR7 Write Access Policy 3 (IMR7_WRITE_POL_3):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
2	0x0 RW	**IMR7 Write Access Policy 2 (IMR7_WRITE_POL_2):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
1	0x0 RW	**IMR7 Write Access Policy 1 (IMR7_WRITE_POL_1):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.
0	0x0 RW	**IMR7 Write Access Policy 0 (IMR7_WRITE_POL_0):** Bit vector used to determine which agents are allowed write access to the IMR7 region, based on each agent's 6bit encoded SAI value.

44.3.62 IMR8 Base (B_CR_BIMR8BASE_0_0_0_MCHBAR)—Offset 6970h

This register, along with IMR8MASK, IMR8RAC and IMR8WAC, defines an isolated region of memory that can be masked to prohibit certain system agents from accessing memory. When an agent sends a request to the B-Unit, whether snooped or not, an IMR may optionally prevent that transaction from changing the state of memory or from getting correct data in response to the operation, if the agent's SAI field does not specify the correct Policy. The IMR's Policy is configured by the IMR8RAC and IMR8WAC registers.

Type: Memory Mapped I/O Register (Size: 32 bits)

BAR and Offset: [MCHBAR] + 6970h

Default: 00000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
31	0x0 RW	**IMR Enable (IMR_EN):** Enables access checking for the IMR region.
30	0x0 RW	**Asset Classification AC[0]: Trace Enable (TR_EN):** Enables snooping of transactions to the IMR region by tracing agents.
29	0x0 RO	**RESERVED_1:** Reserved
28:0	0x0 RW	**Base 0 IMR8 Base (IMR8_BASE):** Specifies bits 38:10 of the start address of IMR8 region. IMR region size must be a strict poweroftwo at least 1KB and naturally aligned to the size. These bits are compared with the result of the IMR8MASK[28:0] applied to bits 38:10 of the incoming address to determine if an access falls within the IMR8 defined region.

44.3.63 IMR8 Mask (B_CR_BIMR8MASK_0_0_0_MCHBAR)—Offset 6974h

This register, along with IMR8BASE, IMR8RAC and IMR8WAC, defines an isolated region of memory that can be masked to prohibit certain system agents from accessing memory. When an agent sends a request to the B-Unit, whether snooped or not, an IMR may optionally prevent that transaction from changing the state of memory or from getting correct data in response to the operation, if the agent's SAI field does not specify the correct Policy. The IMR's Policy is configured by the IMR8RAC and IMR8WAC registers.

Type: Memory Mapped I/O Register (Size: 32 bits)

BAR and Offset: [MCHBAR] + 6974h

Default: 00000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
31	0x0 RW	**Asset Classification AC[2]: GT Implicit Writeback Enable (GT_IWB_EN):** Enables implicit writebacks to protected region from GT caching agent. When set to 1, enables implicit writeback HITM data from GT to be returned to the requestor. When set to 0, inhibits HITM data from GT from being returned to the requestor. HITM data from IA cores may be returned to the requestor depending on the setting of the IA_IWB_EN bit.
30	0x0 RW	**Asset Classification AC[1]: IA Implicit Writeback Enable (IA_IWB_EN):** Enables implicit writebacks to protected region from IA caching agent. When set to 1, enables implicit writeback data HITM data from IA cores to be returned to the requestor. When set to 0, inhibits HITM data from IA cores from being returned to the requestor. HITM data from GT may be returned to the requestor depending on the setting of the GT_IWB_EN bit.
29	0x0 RO	**RESERVED_0:** Reserved
28:0	0x0 RW	**Mask 0 IMR8 Mask (IMR8_MASK):** These bits are ANDed with bits 38:10 of the incoming address to determine if the combined result matches the IMR8BASE[28:0] value. A match indicates that the incoming address falls within the IMR8 region.

44.3.64 IMR8 Control Policy (B_CR_BIMR8CP_0_0_0_MCHBAR)—Offset 6978h

This register controls the access policy to the Read Access Policy BIMR8RAC, the Write Access Policy BIMR8WAC, and, self-referentially to itself. The requesting agent's 6bit encoded SAI value is used as an index into this register's bits to determine both read access and write access.

Type: Memory Mapped I/O Register (Size: 64 bits)

BAR and Offset: [MCHBAR] + 6978h

Default: 00000C0061010202h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
63:0	0xc0061010202 RW	**IMR8 Control Policy (IMR8_CTRL_POL):** Bit vector used to determine which agents are allowed access to the BIMR8RAC, BIMR8WAC and BIMR8CP registers, based on the value from each agent's 6bit SAI field.

44.3.65 IMR8 Read Access Policy (B_CR_BIMR8RAC_0_0_0_MCHBAR)—Offset 6980h

This register, along with IMR8BASE, IMR8MASK and IMR8WAC, defines an isolated region of memory that can be masked to prohibit certain agents from accessing memory. It is programmed with an SAI Policy that indicates which agents in the system are allowed to perform read operations to IMR8. The requesting agent's 6bit encoded SAI value is used as an index into this register's bits to determine read access.

Type: Memory Mapped I/O Register (Size: 64 bits)

30	0x0 RW	**IMR8 Read Access Policy 30 (IMR8_READ_POL_30):** Bit vector used to determine which agents are allowed read access to the IMR8 region, based on each agent's 6bit encoded SAI value.
29	0x0 RW	**IMR8 Read Access Policy 29 (IMR8_READ_POL_29):** Bit vector used to determine which agents are allowed read access to the IMR8 region, based on each agent's 6bit encoded SAI value.
28	0x0 RW	**IMR8 Read Access Policy 28 (IMR8_READ_POL_28):** Bit vector used to determine which agents are allowed read access to the IMR8 region, based on each agent's 6bit encoded SAI value.
27	0x0 RW	**IMR8 Read Access Policy 27 (IMR8_READ_POL_27):** Bit vector used to determine which agents are allowed read access to the IMR8 region, based on each agent's 6bit encoded SAI value.
26	0x0 RW	**IMR8 Read Access Policy 26 (IMR8_READ_POL_26):** Bit vector used to determine which agents are allowed read access to the IMR8 region, based on each agent's 6bit encoded SAI value.
25	0x0 RW	**IMR8 Read Access Policy 25 (IMR8_READ_POL_25):** Bit vector used to determine which agents are allowed read access to the IMR8 region, based on each agent's 6bit encoded SAI value.
24	0x0 RW	**IMR8 Read Access Policy 24 (IMR8_READ_POL_24):** Bit vector used to determine which agents are allowed read access to the IMR8 region, based on each agent's 6bit encoded SAI value.
23	0x0 RO	**IMR8 Read Access Policy 23 (IMR8_READ_POL_23):** Bit vector used to determine which agents are allowed read access to the IMR8 region, based on each agent's 6bit encoded SAI value.
22	0x0 RO	**IMR8 Read Access Policy 22 (IMR8_READ_POL_22):** Bit vector used to determine which agents are allowed read access to the IMR8 region, based on each agent's 6bit encoded SAI value.

Bit Range	Default & Access	Field Name (ID): Description
21	0x0 RW	**IMR8 Read Access Policy 21 (IMR8_READ_POL_21):** Bit vector used to determine which agents are allowed read access to the IMR8 region, based on each agent's 6bit encoded SAI value.
20	0x0 RO	**IMR8 Read Access Policy 20 (IMR8_READ_POL_20):** Bit vector used to determine which agents are allowed read access to the IMR8 region, based on each agent's 6bit encoded SAI value.
19	0x0 RO	**IMR8 Read Access Policy 19 (IMR8_READ_POL_19):** Bit vector used to determine which agents are allowed read access to the IMR8 region, based on each agent's 6bit encoded SAI value.
18	0x0 RO	**IMR8 Read Access Policy 18 (IMR8_READ_POL_18):** Bit vector used to determine which agents are allowed read access to the IMR8 region, based on each agent's 6bit encoded SAI value.
17	0x0 RW	**IMR8 Read Access Policy 17 (IMR8_READ_POL_17):** Bit vector used to determine which agents are allowed read access to the IMR8 region, based on each agent's 6bit encoded SAI value.
16	0x0 RW	**IMR8 Read Access Policy 16 (IMR8_READ_POL_16):** Bit vector used to determine which agents are allowed read access to the IMR8 region, based on each agent's 6bit encoded SAI value.
15	0x0 RO	**IMR8 Read Access Policy 15 (IMR8_READ_POL_15):** Bit vector used to determine which agents are allowed read access to the IMR8 region, based on each agent's 6bit encoded SAI value.
14	0x0 RO	**IMR8 Read Access Policy 14 (IMR8_READ_POL_14):** Bit vector used to determine which agents are allowed read access to the IMR8 region, based on each agent's 6bit encoded SAI value.
13	0x0 RW	**IMR8 Read Access Policy 13 (IMR8_READ_POL_13):** Bit vector used to determine which agents are allowed read access to the IMR8 region, based on each agent's 6bit encoded SAI value.
12	0x0 RW	**IMR8 Read Access Policy 12 (IMR8_READ_POL_12):** Bit vector used to determine which agents are allowed read access to the IMR8 region, based on each agent's 6bit encoded SAI value.
11	0x0 RO	**IMR8 Read Access Policy 11 (IMR8_READ_POL_11):** Bit vector used to determine which agents are allowed read access to the IMR8 region, based on each agent's 6bit encoded SAI value.
10	0x0 RO	**IMR8 Read Access Policy 10 (IMR8_READ_POL_10):** Bit vector used to determine which agents are allowed read access to the IMR8 region, based on each agent's 6bit encoded SAI value.
9	0x0 RO	**IMR8 Read Access Policy 9 (IMR8_READ_POL_9):** Bit vector used to determine which agents are allowed read access to the IMR8 region, based on each agent's 6bit encoded SAI value.
8	0x0 RW	**IMR8 Read Access Policy 8 (IMR8_READ_POL_8):** Bit vector used to determine which agents are allowed read access to the IMR8 region, based on each agent's 6bit encoded SAI value.
7	0x0 RO	**IMR8 Read Access Policy 7 (IMR8_READ_POL_7):** Bit vector used to determine which agents are allowed read access to the IMR8 region, based on each agent's 6bit encoded SAI value.
6	0x0 RO	**IMR8 Read Access Policy 6 (IMR8_READ_POL_6):** Bit vector used to determine which agents are allowed read access to the IMR8 region, based on each agent's 6bit encoded SAI value.
5	0x0 RW	**IMR8 Read Access Policy 5 (IMR8_READ_POL_5):** Bit vector used to determine which agents are allowed read access to the IMR8 region, based on each agent's 6bit encoded SAI value.
4	0x0 RW	**IMR8 Read Access Policy 4 (IMR8_READ_POL_4):** Bit vector used to determine which agents are allowed read access to the IMR8 region, based on each agent's 6bit encoded SAI value.
3	0x0 RW	**IMR8 Read Access Policy 3 (IMR8_READ_POL_3):** Bit vector used to determine which agents are allowed read access to the IMR8 region, based on each agent's 6bit encoded SAI value.
2	0x0 RW	**IMR8 Read Access Policy 2 (IMR8_READ_POL_2):** Bit vector used to determine which agents are allowed read access to the IMR8 region, based on each agent's 6bit encoded SAI value.
1	0x0 RW	**IMR8 Read Access Policy 1 (IMR8_READ_POL_1):** Bit vector used to determine which agents are allowed read access to the IMR8 region, based on each agent's 6bit encoded SAI value.
0	0x0 RW	**IMR8 Read Access Policy 0 (IMR8_READ_POL_0):** Bit vector used to determine which agents are allowed read access to the IMR8 region, based on each agent's 6bit encoded SAI value.

44.3.66 IMR8 Write Access Policy (B_CR_BIMR8WAC_0_0_0_MCHBAR)—Offset 6988h

This register, along with IMR8BASE, IMR8MASK and IMR8RAC, defines an isolated region of memory that can be masked to prohibit certain agents from accessing memory. It is programmed with an SAI Policy that indicates which agents in the system are allowed to perform read operations to IMR8. The requesting agent's 6bit encoded SAI value is used as an index into this register's bits to determine write access.

Type: Memory Mapped I/O Register (Size: 64 bits)

BAR and Offset: [MCHBAR] + 6988h

Default: 0000000000000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

40	0x0 RW	**IMR8 Write Access Policy 40 (IMR8_WRITE_POL_40):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
39	0x0 RO	**IMR8 Write Access Policy 39 (IMR8_WRITE_POL_39):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
38	0x0 RW	**IMR8 Write Access Policy 38 (IMR8_WRITE_POL_38):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
37	0x0 RO	**IMR8 Write Access Policy 37 (IMR8_WRITE_POL_37):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
36	0x0 RW	**IMR8 Write Access Policy 36 (IMR8_WRITE_POL_36):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
35	0x0 RO	**IMR8 Write Access Policy 35 (IMR8_WRITE_POL_35):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
34	0x0 RW	**IMR8 Write Access Policy 34 (IMR8_WRITE_POL_34):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
33	0x0 RW	**IMR8 Write Access Policy 33 (IMR8_WRITE_POL_33):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
32	0x0 RW	**IMR8 Write Access Policy 32 (IMR8_WRITE_POL_32):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
31	0x0 RO	**IMR8 Write Access Policy 31 (IMR8_WRITE_POL_31):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
30	0x0 RW	**IMR8 Write Access Policy 30 (IMR8_WRITE_POL_30):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
29	0x0 RW	**IMR8 Write Access Policy 29 (IMR8_WRITE_POL_29):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
28	0x0 RW	**IMR8 Write Access Policy 28 (IMR8_WRITE_POL_28):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
27	0x0 RW	**IMR8 Write Access Policy 27 (IMR8_WRITE_POL_27):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
26	0x0 RW	**IMR8 Write Access Policy 26 (IMR8_WRITE_POL_26):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
25	0x0 RW	**IMR8 Write Access Policy 25 (IMR8_WRITE_POL_25):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
24	0x0 RW	**IMR8 Write Access Policy 24 (IMR8_WRITE_POL_24):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
23	0x0 RO	**IMR8 Write Access Policy 23 (IMR8_WRITE_POL_23):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
22	0x0 RO	**IMR8 Write Access Policy 22 (IMR8_WRITE_POL_22):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.

Bit Range	Default & Access	Field Name (ID): Description
21	0x0 RW	**IMR8 Write Access Policy 21 (IMR8_WRITE_POL_21):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
20	0x0 RO	**IMR8 Write Access Policy 20 (IMR8_WRITE_POL_20):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
19	0x0 RO	**IMR8 Write Access Policy 19 (IMR8_WRITE_POL_19):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
18	0x0 RO	**IMR8 Write Access Policy 18 (IMR8_WRITE_POL_18):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
17	0x0 RW	**IMR8 Write Access Policy 17 (IMR8_WRITE_POL_17):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
16	0x0 RW	**IMR8 Write Access Policy 16 (IMR8_WRITE_POL_16):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
15	0x0 RO	**IMR8 Write Access Policy 15 (IMR8_WRITE_POL_15):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
14	0x0 RO	**IMR8 Write Access Policy 14 (IMR8_WRITE_POL_14):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
13	0x0 RW	**IMR8 Write Access Policy 13 (IMR8_WRITE_POL_13):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
12	0x0 RW	**IMR8 Write Access Policy 12 (IMR8_WRITE_POL_12):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
11	0x0 RO	**IMR8 Write Access Policy 11 (IMR8_WRITE_POL_11):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
10	0x0 RO	**IMR8 Write Access Policy 10 (IMR8_WRITE_POL_10):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
9	0x0 RO	**IMR8 Write Access Policy 9 (IMR8_WRITE_POL_9):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
8	0x0 RW	**IMR8 Write Access Policy 8 (IMR8_WRITE_POL_8):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
7	0x0 RO	**IMR8 Write Access Policy 7 (IMR8_WRITE_POL_7):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
6	0x0 RO	**IMR8 Write Access Policy 6 (IMR8_WRITE_POL_6):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
5	0x0 RW	**IMR8 Write Access Policy 5 (IMR8_WRITE_POL_5):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
4	0x0 RW	**IMR8 Write Access Policy 4 (IMR8_WRITE_POL_4):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
3	0x0 RW	**IMR8 Write Access Policy 3 (IMR8_WRITE_POL_3):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
2	0x0 RW	**IMR8 Write Access Policy 2 (IMR8_WRITE_POL_2):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
1	0x0 RW	**IMR8 Write Access Policy 1 (IMR8_WRITE_POL_1):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.
0	0x0 RW	**IMR8 Write Access Policy 0 (IMR8_WRITE_POL_0):** Bit vector used to determine which agents are allowed write access to the IMR8 region, based on each agent's 6bit encoded SAI value.

44.3.67 IMR9 Base (B_CR_BIMR9BASE_0_0_0_MCHBAR)—Offset 6990h

This register, along with IMR9MASK, IMR9RAC and IMR9WAC, defines an isolated region of memory that can be masked to prohibit certain system agents from accessing memory. When an agent sends a request to the B-Unit, whether snooped or not, an IMR may optionally prevent that transaction from changing the state of memory or from getting correct data in response to the operation if the agent's SAI field does not specify the correct Policy. The IMR's Policy is configured by the IMR9RAC and IMR9WAC registers.

Type: Memory Mapped I/O Register (Size: 32 bits)

BAR and Offset: [MCHBAR] + 6990h

Default: 00000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
31	0x0 RW	**IMR Enable (IMR_EN):** Enables access checking for the IMR region.
30	0x0 RW	**Asset Classification AC[0]: Trace Enable (TR_EN):** Enables snooping of transactions to the IMR region by tracing agents.
29	0x0 RO	**RESERVED_1:** Reserved
28:0	0x0 RW	**Base 1 IMR9 Base (IMR9_BASE):** Specifies bits 38:10 of the start address of IMR9 region. IMR region size must be a strict poweroftwo, at least 1KB, and naturally aligned to the size. These bits are compared with the result of the IMR9MASK[28:0] applied to bits 38:10 of the incoming address to determine if an access falls within the IMR9 defined region.

44.3.68 IMR9 Mask (B_CR_BIMR9MASK_0_0_0_MCHBAR)—Offset 6994h

This register, along with IMR9BASE, IMR9RAC and IMR9WAC, defines an isolated region of memory that can be masked to prohibit certain system agents from accessing memory. When an agent sends a request to the B-Unit, whether snooped or not, an IMR may optionally prevent that transaction from changing the state of memory or from getting correct data in response to the operation, if the agent's SAI field does not specify the correct Policy. The IMR's Policy is configured by the IMR9RAC and IMR9WAC registers.

Type: Memory Mapped I/O Register (Size: 32 bits)

BAR and Offset: [MCHBAR] + 6994h

Default: 00000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
31	0x0 RW	**Asset Classification AC[2]: GT Implicit Writeback Enable (GT_IWB_EN):** Enables implicit writebacks to protected region from GT caching agent. When set to 1, enables implicit writeback data HITM data from GT to be returned to the requestor. When set to 0, inhibits HITM data from GT from being returned to the requestor. HITM data from IA cores may be returned to the requestor depending on the setting of the IA_IWB_EN bit.
30	0x0 RW	**Asset Classification AC[1]: IA Implicit Writeback Enable (IA_IWB_EN):** Enables implicit writebacks to protected region from IA caching agent. When set to 1, enables implicit writeback HITM data from IA cores to be returned to the requestor. When set to 0, inhibits HITM data from IA cores from being returned to the requestor. HITM data from GT may be returned to the requestor, depending on the setting of the GT_IWB_EN bit.
29	0x0 RO	**RESERVED_0:** Reserved
28:0	0x0 RW	**Mask 1 IMR9 Mask (IMR9_MASK):** These bits are ANDed with bits 38:10 of the incoming address to determine if the combined result matches the IMR9BASE[28:0] value. A match indicates that the incoming address falls within the IMR9 region.

44.3.69 IMR9 Control Policy (B_CR_BIMR9CP_0_0_0_MCHBAR)—Offset 6998h

This register controls the access policy to the Read Access Policy BIMR9RAC, the Write Access Policy BIMR9WAC, and, self-referentially, to itself. The requesting agent's 6bit encoded SAI value is used as an index into this register's bits to determine both read access and write access.

Type: Memory Mapped I/O Register (Size: 64 bits)

BAR and Offset: [MCHBAR] + 6998h

Default: 00000C0061010202h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
63:0	0xc0061010202 RW	**IMR9 Control Policy (IMR9_CTRL_POL):** Bit vector used to determine which agents are allowed access to the BIMR9RAC, BIMR9WAC, BIMR9CP registers based on the value from each agent's 6bit SAI field.

44.3.70 IMR9 Read Access Policy (B_CR_BIMR9RAC_0_0_0_MCHBAR)—Offset 69A0h

This register, along with IMR9BASE, IMR9MASK and IMR9WAC, defines an isolated region of memory that can be masked to prohibit certain agents from accessing memory. It is programmed with an SAI Policy that indicates which agents in the system are allowed to perform read operations to IMR9. The requesting agent's 6bit encoded SAI value is used as an index into this register's bits to determine read access.

Type: Memory Mapped I/O Register (Size: 64 bits)

BAR and Offset: [MCHBAR] + 69A0h

Default: 0000000000000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
63	0x0 RW	**IMR9 Read Access Policy 63 (IMR9_READ_POL_63):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
62	0x0 RO	**IMR9 Read Access Policy 62 (IMR9_READ_POL_62):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
61	0x0 RO	**IMR9 Read Access Policy 61 (IMR9_READ_POL_61):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
60	0x0 RO	**IMR9 Read Access Policy 60 (IMR9_READ_POL_60):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
59	0x0 RO	**IMR9 Read Access Policy 59 (IMR9_READ_POL_59):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
58	0x0 RO	**IMR9 Read Access Policy 58 (IMR9_READ_POL_58):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
57	0x0 RO	**IMR9 Read Access Policy 57 (IMR9_READ_POL_57):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
56	0x0 RW	**IMR9 Read Access Policy 56 (IMR9_READ_POL_56):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
55	0x0 RW	**IMR9 Read Access Policy 55 (IMR9_READ_POL_55):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
54	0x0 RW	**IMR9 Read Access Policy 54 (IMR9_READ_POL_54):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
53	0x0 RO	**IMR9 Read Access Policy 53 (IMR9_READ_POL_53):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
52	0x0 RO	**IMR9 Read Access Policy 52 (IMR9_READ_POL_52):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
51	0x0 RO	**IMR9 Read Access Policy 51 (IMR9_READ_POL_51):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
50	0x0 RW	**IMR9 Read Access Policy 50 (IMR9_READ_POL_50):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
49	0x0 RW	**IMR9 Read Access Policy 49 (IMR9_READ_POL_49):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
48	0x0 RW	**IMR9 Read Access Policy 48 (IMR9_READ_POL_48):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
47	0x0 RO	**IMR9 Read Access Policy 47 (IMR9_READ_POL_47):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
46	0x0 RO	**IMR9 Read Access Policy 46 (IMR9_READ_POL_46):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.

Bit Range	Default & Access	Field Name (ID): Description
45	0x0 RO	**IMR9 Read Access Policy 45 (IMR9_READ_POL_45):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
44	0x0 RW	**IMR9 Read Access Policy 44 (IMR9_READ_POL_44):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
43	0x0 RW	**IMR9 Read Access Policy 43 (IMR9_READ_POL_43):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
42	0x0 RW	**IMR9 Read Access Policy 42 (IMR9_READ_POL_42):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
41	0x0 RW	**IMR9 Read Access Policy 41 (IMR9_READ_POL_41):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
40	0x0 RW	**IMR9 Read Access Policy 40 (IMR9_READ_POL_40):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
39	0x0 RO	**IMR9 Read Access Policy 39 (IMR9_READ_POL_39):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
38	0x0 RW	**IMR9 Read Access Policy 38 (IMR9_READ_POL_38):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
37	0x0 RO	**IMR9 Read Access Policy 37 (IMR9_READ_POL_37):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
36	0x0 RW	**IMR9 Read Access Policy 36 (IMR9_READ_POL_36):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
35	0x0 RO	**IMR9 Read Access Policy 35 (IMR9_READ_POL_35):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
34	0x0 RW	**IMR9 Read Access Policy 34 (IMR9_READ_POL_34):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
33	0x0 RW	**IMR9 Read Access Policy 33 (IMR9_READ_POL_33):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
32	0x0 RW	**IMR9 Read Access Policy 32 (IMR9_READ_POL_32):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
31	0x0 RO	**IMR9 Read Access Policy 31 (IMR9_READ_POL_31):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
30	0x0 RW	**IMR9 Read Access Policy 30 (IMR9_READ_POL_30):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
29	0x0 RW	**IMR9 Read Access Policy 29 (IMR9_READ_POL_29):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
28	0x0 RW	**IMR9 Read Access Policy 28 (IMR9_READ_POL_28):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
27	0x0 RW	**IMR9 Read Access Policy 27 (IMR9_READ_POL_27):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
26	0x0 RW	**IMR9 Read Access Policy 26 (IMR9_READ_POL_26):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
25	0x0 RW	**IMR9 Read Access Policy 25 (IMR9_READ_POL_25):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
24	0x0 RW	**IMR9 Read Access Policy 24 (IMR9_READ_POL_24):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
23	0x0 RO	**IMR9 Read Access Policy 23 (IMR9_READ_POL_23):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
22	0x0 RO	**IMR9 Read Access Policy 22 (IMR9_READ_POL_22):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.

Bit Range	Default & Access	Field Name (ID): Description
21	0x0 RW	**IMR9 Read Access Policy 21 (IMR9_READ_POL_21):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
20	0x0 RO	**IMR9 Read Access Policy 20 (IMR9_READ_POL_20):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
19	0x0 RO	**IMR9 Read Access Policy 19 (IMR9_READ_POL_19):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
18	0x0 RO	**IMR9 Read Access Policy 18 (IMR9_READ_POL_18):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
17	0x0 RW	**IMR9 Read Access Policy 17 (IMR9_READ_POL_17):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
16	0x0 RW	**IMR9 Read Access Policy 16 (IMR9_READ_POL_16):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
15	0x0 RO	**IMR9 Read Access Policy 15 (IMR9_READ_POL_15):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
14	0x0 RO	**IMR9 Read Access Policy 14 (IMR9_READ_POL_14):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
13	0x0 RW	**IMR9 Read Access Policy 13 (IMR9_READ_POL_13):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
12	0x0 RW	**IMR9 Read Access Policy 12 (IMR9_READ_POL_12):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
11	0x0 RO	**IMR9 Read Access Policy 11 (IMR9_READ_POL_11):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
10	0x0 RO	**IMR9 Read Access Policy 10 (IMR9_READ_POL_10):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
9	0x0 RO	**IMR9 Read Access Policy 9 (IMR9_READ_POL_9):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
8	0x0 RW	**IMR9 Read Access Policy 8 (IMR9_READ_POL_8):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
7	0x0 RO	**IMR9 Read Access Policy 7 (IMR9_READ_POL_7):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
6	0x0 RO	**IMR9 Read Access Policy 6 (IMR9_READ_POL_6):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
5	0x0 RW	**IMR9 Read Access Policy 5 (IMR9_READ_POL_5):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
4	0x0 RW	**IMR9 Read Access Policy 4 (IMR9_READ_POL_4):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
3	0x0 RW	**IMR9 Read Access Policy 3 (IMR9_READ_POL_3):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
2	0x0 RW	**IMR9 Read Access Policy 2 (IMR9_READ_POL_2):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
1	0x0 RW	**IMR9 Read Access Policy 1 (IMR9_READ_POL_1):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.
0	0x0 RW	**IMR9 Read Access Policy 0 (IMR9_READ_POL_0):** Bit vector used to determine which agents are allowed read access to the IMR9 region, based on each agent's 6bit encoded SAI value.

44.3.71 IMR9 Write Access Policy (B_CR_BIMR9WAC_0_0_0_MCHBAR)—Offset 69A8h

This register, along with IMR9BASE, IMR9MASK and IMR9RAC, defines an isolated region of memory that can be masked to prohibit certain agents from accessing memory. It is programmed with an SAI Policy that indicates which agents in the system are allowed to perform read operations to IMR9. The requesting agent's 6bit encoded SAI value is used as an index into this register's bits to determine write access.

Type: Memory Mapped I/O Register (Size: 64 bits)

BAR and Offset: [MCHBAR] + 69A8h

Default: 0000000000000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
63	0x0 RW	**IMR9 Write Access Policy 63 (IMR9_WRITE_POL_63):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
62	0x0 RO	**IMR9 Write Access Policy 62 (IMR9_WRITE_POL_62):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
61	0x0 RO	**IMR9 Write Access Policy 61 (IMR9_WRITE_POL_61):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
60	0x0 RO	**IMR9 Write Access Policy 60 (IMR9_WRITE_POL_60):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
59	0x0 RO	**IMR9 Write Access Policy 59 (IMR9_WRITE_POL_59):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
58	0x0 RO	**IMR9 Write Access Policy 58 (IMR9_WRITE_POL_58):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
57	0x0 RO	**IMR9 Write Access Policy 57 (IMR9_WRITE_POL_57):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
56	0x0 RW	**IMR9 Write Access Policy 56 (IMR9_WRITE_POL_56):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
55	0x0 RW	**IMR9 Write Access Policy 55 (IMR9_WRITE_POL_55):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
54	0x0 RW	**IMR9 Write Access Policy 54 (IMR9_WRITE_POL_54):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
53	0x0 RO	**IMR9 Write Access Policy 53 (IMR9_WRITE_POL_53):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
52	0x0 RO	**IMR9 Write Access Policy 52 (IMR9_WRITE_POL_52):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
51	0x0 RO	**IMR9 Write Access Policy 51 (IMR9_WRITE_POL_51):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
50	0x0 RW	**IMR9 Write Access Policy 50 (IMR9_WRITE_POL_50):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
49	0x0 RW	**IMR9 Write Access Policy 49 (IMR9_WRITE_POL_49):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
48	0x0 RW	**IMR9 Write Access Policy 48 (IMR9_WRITE_POL_48):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
47	0x0 RO	**IMR9 Write Access Policy 47 (IMR9_WRITE_POL_47):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
46	0x0 RO	**IMR9 Write Access Policy 46 (IMR9_WRITE_POL_46):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.

Bit Range	Default & Access	Field Name (ID): Description
45	0x0 RO	**IMR9 Write Access Policy 45 (IMR9_WRITE_POL_45):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
44	0x0 RW	**IMR9 Write Access Policy 44 (IMR9_WRITE_POL_44):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
43	0x0 RW	**IMR9 Write Access Policy 43 (IMR9_WRITE_POL_43):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
42	0x0 RW	**IMR9 Write Access Policy 42 (IMR9_WRITE_POL_42):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
41	0x0 RW	**IMR9 Write Access Policy 41 (IMR9_WRITE_POL_41):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
40	0x0 RW	**IMR9 Write Access Policy 40 (IMR9_WRITE_POL_40):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
39	0x0 RO	**IMR9 Write Access Policy 39 (IMR9_WRITE_POL_39):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
38	0x0 RW	**IMR9 Write Access Policy 38 (IMR9_WRITE_POL_38):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
37	0x0 RO	**IMR9 Write Access Policy 37 (IMR9_WRITE_POL_37):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
36	0x0 RW	**IMR9 Write Access Policy 36 (IMR9_WRITE_POL_36):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
35	0x0 RO	**IMR9 Write Access Policy 35 (IMR9_WRITE_POL_35):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
34	0x0 RW	**IMR9 Write Access Policy 34 (IMR9_WRITE_POL_34):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
33	0x0 RW	**IMR9 Write Access Policy 33 (IMR9_WRITE_POL_33):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
32	0x0 RW	**IMR9 Write Access Policy 32 (IMR9_WRITE_POL_32):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
31	0x0 RO	**IMR9 Write Access Policy 31 (IMR9_WRITE_POL_31):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
30	0x0 RW	**IMR9 Write Access Policy 30 (IMR9_WRITE_POL_30):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
29	0x0 RW	**IMR9 Write Access Policy 29 (IMR9_WRITE_POL_29):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
28	0x0 RW	**IMR9 Write Access Policy 28 (IMR9_WRITE_POL_28):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
27	0x0 RW	**IMR9 Write Access Policy 27 (IMR9_WRITE_POL_27):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
26	0x0 RW	**IMR9 Write Access Policy 26 (IMR9_WRITE_POL_26):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
25	0x0 RW	**IMR9 Write Access Policy 25 (IMR9_WRITE_POL_25):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
24	0x0 RW	**IMR9 Write Access Policy 24 (IMR9_WRITE_POL_24):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
23	0x0 RO	**IMR9 Write Access Policy 23 (IMR9_WRITE_POL_23):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
22	0x0 RO	**IMR9 Write Access Policy 22 (IMR9_WRITE_POL_22):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.

Bit Range	Default & Access	Field Name (ID): Description
21	0x0 RW	**IMR9 Write Access Policy 21 (IMR9_WRITE_POL_21):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
20	0x0 RO	**IMR9 Write Access Policy 20 (IMR9_WRITE_POL_20):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
19	0x0 RO	**IMR9 Write Access Policy 19 (IMR9_WRITE_POL_19):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
18	0x0 RO	**IMR9 Write Access Policy 18 (IMR9_WRITE_POL_18):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
17	0x0 RW	**IMR9 Write Access Policy 17 (IMR9_WRITE_POL_17):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
16	0x0 RW	**IMR9 Write Access Policy 16 (IMR9_WRITE_POL_16):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
15	0x0 RO	**IMR9 Write Access Policy 15 (IMR9_WRITE_POL_15):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
14	0x0 RO	**IMR9 Write Access Policy 14 (IMR9_WRITE_POL_14):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
13	0x0 RW	**IMR9 Write Access Policy 13 (IMR9_WRITE_POL_13):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
12	0x0 RW	**IMR9 Write Access Policy 12 (IMR9_WRITE_POL_12):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
11	0x0 RO	**IMR9 Write Access Policy 11 (IMR9_WRITE_POL_11):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
10	0x0 RO	**IMR9 Write Access Policy 10 (IMR9_WRITE_POL_10):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
9	0x0 RO	**IMR9 Write Access Policy 9 (IMR9_WRITE_POL_9):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
8	0x0 RW	**IMR9 Write Access Policy 8 (IMR9_WRITE_POL_8):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
7	0x0 RO	**IMR9 Write Access Policy 7 (IMR9_WRITE_POL_7):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
6	0x0 RO	**IMR9 Write Access Policy 6 (IMR9_WRITE_POL_6):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
5	0x0 RW	**IMR9 Write Access Policy 5 (IMR9_WRITE_POL_5):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
4	0x0 RW	**IMR9 Write Access Policy 4 (IMR9_WRITE_POL_4):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
3	0x0 RW	**IMR9 Write Access Policy 3 (IMR9_WRITE_POL_3):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
2	0x0 RW	**IMR9 Write Access Policy 2 (IMR9_WRITE_POL_2):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
1	0x0 RW	**IMR9 Write Access Policy 1 (IMR9_WRITE_POL_1):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.
0	0x0 RW	**IMR9 Write Access Policy 0 (IMR9_WRITE_POL_0):** Bit vector used to determine which agents are allowed write access to the IMR9 region, based on each agent's 6bit encoded SAI value.

44.3.72 IMR10 Base (B_CR_BIMR10BASE_0_0_0_MCHBAR)—Offset 69B0h

This register, along with IMR10MASK, IMR10RAC and IMR10WAC, defines an isolated region of memory that can be masked to prohibit certain system agents from accessing memory. When an agent sends a request to the B-Unit, whether snooped or not, an IMR may optionally prevent that transaction from changing the state of memory or from getting correct data in response to the operation if the agent's SAI field does not specify the correct Policy. The IMR's Policy is configured by the IMR10RAC and IMR10WAC registers.

Type: Memory Mapped I/O Register (Size: 32 bits)

BAR and Offset: [MCHBAR] + 69B0h

Default: 00000000h

MCHBAR Type: PCI Configuration Register (Size: 64 bits)
MCHBAR Reference: [B:0, D:0, F:0] + 48h

Bit Range	Default & Access	Field Name (ID): Description
31	0x0 RW	**IMR Enable (IMR_EN):** Enables access checking for the IMR region.
30	0x0 RW	**Asset Classification AC[0]: Trace Enable (TR_EN):** Enables snooping of transactions to the IMR region by tracing agents.
29	0x0 RO	**RESERVED_1:** Reserved
