Calculating Maximum Frequency

Based on the rise and fall time data given in Table 1 through 5, the maximum frequency the oscillator can operate with a guaranteed full swing of the output voltage over temperature is calculated as follows:

$$Max. Frequency = \frac{1}{5 \times T_{r/f}}$$

Example:

Calculate F_{max} of a 1MHz ~ 110MHz device with the following condition:

- V_{dd} = 1.8V (Table 1)
- Capacitive Load = 30pF
- Desired T_{r/f} Time: = 3ns (rise/fall time option code “E”)

The F_{max} is 66.66666MHz.

| Pin | Name | Functionality |
|-----|---------------------|---|
| 1 | OE/ \overline{ST} | Output Enable H or Open ⁽⁴⁾ : specified frequency output L: output is high impedance. Only output driver is disabled |
| | | Standby H or Open ⁽⁴⁾ : specified frequency output L: output is low (weak pull down). Device goes to sleep mode. Supply current reduces to I_{std} . |
| | | No Connect Any voltage between 0 and V_{dd} or Open ⁽⁴⁾ : specified frequency output. Pin 1 has no function. |

Notes: 4. In OE or \overline{ST} mode, a pull-up resistor of 10k Ω or less between OE/ \overline{ST} pin and V_{dd} is recommended if pin 1 is not externally driven. If pin 1 needs to be left floating, use the NC option.
5. A capacitor value of 0.1 μ F or higher between V_{dd} and GND is required.
