

MC10H115

Quad Line Receiver

Description

The MC10H115 is a quad differential amplifier designed for use in sensing differential signals over long lines. This 10H part is a functional/ pinout duplication of the standard MECL 10K™ family part, with 100% improvement in counting frequency and no increase in power supply current.

The base bias supply (V_{BB}) is made available at Pin 9 to make the device useful as a Schmitt trigger, or in other applications where a stable reference voltage is necessary. Active current sources provide the MC10H115 with excellent common mode rejection. If any amplifier in a package is not used, one input of that amplifier must be connected to V_{BB} (Pin 9) to prevent upsetting the current source bias network.

The MC10H115 is designed to be used in sensing differential signals over long lines. The bias supply (V_{BB}) is made available to make the device useful as a Schmitt trigger, or in other applications where a stable reference voltage is necessary.

Active current sources provide these receivers with excellent common-mode noise rejection. If any amplifier in a package is not used, one input of that amplifier must be connected to V_{BB} to prevent unbalancing the current source bias network.

The MC10H115 does not have internal input pulldown resistors. This provides high impedance to the amplifier input and facilitates differential connections.

Table 1. MAXIMUM RATINGS

Symbol	Characteristic	Rating		Unit
V_{EE}	Power Supply ($V_{CC} = 0$)	-8.0 to 0		Vdc

Maximum ratings are those values beyond which device damage can occur. Maximum ratings applied to the device are individual stress limit values (not normal operating conditions) and are not valid simultaneously. If these limits are exceeded, device functional operation is not implied, damage may occur and reliability may be affected.
