

## Low Power/Fast MODE alternative 200mA LDO REGULATOR

NO.EA-279-160324

### OUTLINE

The RP202x Series consist of CMOS-based voltage regulator ICs with high output voltage accuracy, low dropout voltage and low supply current. These ICs perform with the chip enable function and realize a standby mode with ultra low supply current. To prevent the destruction by over current, the current limit circuit is included. The RP202 Series have 3-mode. One is standby mode with CE pin. The other two are the fast response mode (Fast Mode) and the low power mode, and switch over automatically according to the load current of the LDO. Supply current of IC itself at light load is automatically reduced. The output voltage is maintained between Fast Mode and ECO Mode.

The RP202x consists of a voltage reference unit, an error amplifier, a resistor net for voltage setting, and a current limit circuit.

Since the packages for these ICs are SOT-23-5, SC-88A, and DFN(PLP)1010-4, high density mounting of the ICs on boards is possible.

## TYPICAL APPLICATION

(External Components)

C1, C2 : Ceramic Capacitor 0.47 $\mu$ F MURATA: GRM155B31A474KE14

## TECHNICAL NOTES

When using these ICs, consider the following points:

### Phase Compensation

In these ICs, phase compensation is made for securing stable operation even if the load current is varied. For this purpose, use a capacitor C2 with 0.47 $\mu$ F or more and good ESR (Equivalent Series Resistance).

(Note: If additional ceramic capacitors are connected with parallel to the output pin with an output capacitor for phase compensation, the operation might be unstable. Because of this, test these ICs with as same external components as ones to be used on the PCB.)

### PCB Layout

The impedances of  $V_{DD}$  line and GND line has to be low as possible. The high impedances may result in the unstable operation or a noise pickup. The output capacitor with 0.47 $\mu$ F or more should be placed between  $V_{DD}$  and GND. The line from  $V_{DD}$  to the output capacitor, and the line from the output capacitor to GND must be wired as short as possible.

The output capacitor is placed between  $V_{OUT}$  and GND as phase compensation. The line from  $V_{OUT}$  to the output capacitor, and the line from the capacitor to GND must be wired as short as possible. Please refer to the "Basic Test Circuit" below.
