## **General Description**

The MAX19777 is a 12-bit, compact, high-speed, lowpower, successive approximation analog-to-digital converter (ADC). This high-performance ADC includes a high dynamic range sample-and-hold, as well as a highspeed serial interface.

The MAX19777 features dual, single-ended analog inputs connected to the ADC core using a 2:1 MUX.

This ADC operates from a 2.2V to 3.3V supply and consumes only 6.2mW at 3Msps. The device includes a full power-down mode and fast wake up for optimal power management and a high-speed 3-wire serial interface. The 3-wire serial interface directly connects to SPI, QSPI™, and MICROWIRE® devices without external logic.

Excellent dynamic performance, low voltage, low power, ease-of-use, and small package size make this converter ideal for portable, battery-powered data-acquisition applications, as well as for other applications that demand low power consumption and minimal space.

This ADC is available in an 8-pin wafer-level package (WLP). This device operates over the -40°C to +125°C temperature range.

## **Benefits and Features**

- 3Msps Conversion Rate, No Pipeline Delay
- 12-Bit Resolution
- 2-Channel, Single-Ended Analog Inputs
- Low-Noise 72.5dB SNR
- 2.2V to 3.3V Supply Voltage
- Low Power
	- 6.2mW at 3Msps
	- Very Low Power Consumption at 2.5μA/ksps
- 2μA Power-Down Current
- SPI/QSPI/MICROWIRE-Compatible Serial Interface
- 8-Pin, 0.857mm x 1.431mm WLP Package
- Wide -40°C to +125°C Operation

### **Applications**

- Data Acquisition
- Portable Data Logging
- **Medical Instrumentation**
- Battery-Operated Systems
- Communication Systems
- Automotive Systems

## **Detailed Description**

The MAX19777 is a fast, 12-bit, low-power, single-supply ADC. The device operates from a 2.2V to 3.3V supply and consume only 8.4mW ( $V<sub>DD</sub> = 3V$ )/6.2mW ( $V<sub>DD</sub> = 2.2V$ ) at 3Msps. The 3Msps device is capable of sampling at full rate when driven by a 48MHz clock.

The conversion result appears at DOUT, MSB first, with a leading zero followed by the 12-bit result. A 12-bit result is followed by two trailing zeros. See [Figure 1](#page-4-0) and [Figure 5](#page-9-0).

The input signal range for AIN1/AIN2 is defined as 0V to  $V<sub>DD</sub>$  with respect to GND.

This ADC includes a power-down feature allowing minimized power consumption at 2.5µA/ksps for lower throughput rates. The wake up and power-down feature is controlled by using the SPI interface as described in the *[Operating Modes](#page-10-0)* section.

## **Serial Interface**

The device features a 3-wire serial interface that directly connects to SPI, QSPI, and MICROWIRE device without external logic. [Figure 1](#page-4-0) and [Figure 5](#page-9-0) show the interface signals for a single conversion frame to achieve maximum throughput.

The falling-edge of  $\overline{CS}$  defines the sampling instant. Once CS transitions low, the external clock signal (SCLK) controls the conversion.

The SAR core successively extracts binary-weighted bits in every clock cycle. The MSB appears on the data bus during the 2nd clock cycle with a delay outlined in the timing specifications. All extracted data bits appear successively on the data bus with the LSB appearing during the 13th clock cycle for 12-bit operation. The serial data stream of conversion bits is preceded by a leading "zero" and succeeded by trailing "zeros." The data output (DOUT) goes into high-impedance state during the 16th clock cycle.

To sustain the maximum sample rate, the device has to be resampled immediately after the 16th clock cycle. For lower sample rates, the  $\overline{\text{CS}}$  falling edge can be delayed leaving DOUT in a high-impedance condition. Pull CS high after the 10th SCLK falling edge (see the *[Operating Modes](#page-10-0)* section).

<span id="page-9-0"></span>

*Figure 5. 12-Bit Timing Diagrams*

### <span id="page-10-3"></span>**Analog Input**

The devices produce a digital output that corresponds to the analog input voltage within the specified operating range of 0 to  $V_{\text{DD}}$  for the dual-channel device.

[Figure 6](#page-10-1) shows an equivalent circuit for the analog input AIN1/AIN2. Internal protection diodes D1/D2 confine the analog input voltage within the power rails ( $V_{DD}$ , GND). The analog input voltage can swing from GND - 0.3V to  $V<sub>DD</sub> + 0.3V$  without damaging the device.

The electric load presented to the external stage driving the analog input varies depending on which mode the ADC is in: track mode vs. conversion mode. In track mode, the internal sampling capacitor  $C_S$  (16pF) has to be charged through the resistor R ( $R = 50\Omega$ ) to the input voltage. For faithful sampling of the input, the capacitor voltage on  $C_{\rm S}$  has to settle to the required accuracy during the track time.

The source impedance of the external driving stage in conjunction with the sampling switch resistance affects the settling performance. The THD vs. Input Resistance graph in the *[Typical Operating Characteristics](#page-5-0)* shows THD sensitivity as a function of the signal source impedance. Keep the source impedance at a minimum for high dynamic performance applications. Use a high-performance op

<span id="page-10-1"></span>

*Figure 6. Analog Input Circuit*

amp, such as the MAX4430, to drive the analog input, thereby decoupling the signal source and the ADC.

While the ADC is in conversion mode, the sampling switch is open presenting a pin capacitance,  $C_P$  ( $C_P$  = 5pF), to the driving stage. See the *[Applications Information](#page-13-0)* section for information on choosing an appropriate buffer for the ADC.

### **ADC Transfer Function**

The output format is straight binary. The code transitions midway between successive integer LSB values such as 0.5 LSB, 1.5 LSB, etc. The LSB size for dual-channel devices is  $V<sub>DD</sub>/2<sup>n</sup>$ , where n is the resolution. The ideal transfer characteristic is shown in [Figure 10.](#page-11-0)

### <span id="page-10-0"></span>**Operating Modes**

The ICs offer two modes of operation: normal mode and power-down mode. The logic state of the CS signal during a conversion activates these modes. The power-down mode can be used to optimize power dissipation with respect to sample rate.

### **Normal Mode**

In normal mode, the devices are powered up at all times, thereby achieving their maximum throughput rates. [Figure](#page-10-2)  [7](#page-10-2) shows the timing diagram of these devices in normal mode. The falling edge of  $\overline{CS}$  samples the analog input signal, starts a conversion, and frames the serial data transfer.

To remain in normal mode, keep CS low until the falling edge of the 10th SCLK cycle. Pulling  $\overline{CS}$  high after the 10th SCLK falling edge keeps the part in normal mode. However, pulling  $\overline{CS}$  high before the 10th SCLK falling edge terminates the conversion, DOUT goes into highimpedance mode, and the device enters power-down mode. See [Figure 8](#page-11-1).

<span id="page-10-2"></span>

*Figure 7. Normal Mode*

<span id="page-11-1"></span>

<span id="page-11-2"></span>

*Figure 9. Exiting Power-Down Mode*

<span id="page-11-0"></span>

*Figure 10. ADC Transfer Function*

### **Power-Down Mode**

In power-down mode, all bias circuitry is shut down drawing typically only 1.3µA of leakage current. To save power, put the device in power-down mode between conversions. Using the power-down mode between conversions is ideal for saving power when sampling the analog input infrequently.

### **Entering Power-Down Mode**

To enter power-down mode, drive  $\overline{CS}$  high between the 2nd and 10th falling edges of SCLK (see [Figure 8](#page-11-1)). By pulling  $\overline{CS}$  high, the current conversion terminates and DOUT enters high impedance.

### **Exiting Power-Down Mode**

To exit power-down mode, implement one dummy conversion by driving  $\overline{CS}$  low for at least 10 clock cycles (see [Figure 9](#page-11-2)). The data on DOUT is invalid during this dummy conversion. The first conversion following the dummy cycle contains a valid conversion result.

The power-up time equals the duration of the dummy cycle, and is dependent on the clock frequency. The powerup time for 3Msps operation (48MHz SCLK) is 333ns.

### **Supply Current vs. Sampling Rate**

For applications requiring lower throughput rates, the user can reduce the clock frequency  $(f_{SCLK})$  to lower the sample rate. [Figure 11](#page-12-0) shows the typical supply current  $(I_{VDD})$  as a function of sample rate  $(f_S)$  for the 3Msps devices. The part operates in normal mode and is never powered down.

The user can also power down the ADC between conversions by using the power-down mode. [Figure 12](#page-12-1) shows for the 3Msps device that as the sample rate is reduced, the device remains in the power-down state longer and the average supply current  $(I_{VDD})$  drops accordingly.

<span id="page-12-0"></span>

*Figure 11. Supply Current vs. Sample Rate (Normal Operating Mode, 3Msps Devices)*

<span id="page-12-1"></span>

*Figure 12. Supply Current vs. Sample Rate (Device Powered Down Between Conversions, 3Msps Devices)*

### **Dual-Channel Operation**

The MAX19777 features dual-input channels. This device uses a channel-select (CHSEL) input to select between analog input AIN1 (CHSEL = 0) or AIN2 (CHSEL = 1). As shown in [Figure 13](#page-13-1), the CHSEL signal is required to change between the 2nd and 12th clock cycle within a regular conversion to guarantee proper switching between channels.

### **14-Cycle Conversion Mode**

The ICs can operate with 14 cycles per conversion. [Figure 14](#page-13-2) shows the corresponding timing diagram. Observe that DOUT does not go into high-impedance mode. Also, observe that  $t_{ACQ}$  needs to be sufficiently long to guarantee proper settling of the analog input voltage. See the *[Electrical Characteristics](#page-1-0)* table for t<sub>ACQ</sub> requirements and the *[Analog Input](#page-10-3)* section for a description of the analog inputs.

## <span id="page-13-0"></span>**Applications Information**

### **Layout, Grounding, and Bypassing**

For best performance, use PCBs with a solid ground plane. Ensure that digital and analog signal lines are separated from each other. Do not run analog and digital (especially clock) lines parallel to one another or digital lines underneath the ADC package. Noise in the  $V_{DD}$ power supply affects the ADC's performance. Bypass  $V<sub>DD</sub>$  to ground with 0.1µF and 10µF bypass capacitors. Minimize capacitor lead and trace lengths for best supplynoise rejection.

### **Choosing an Input Amplifier**

It is important to match the settling time of the input amplifier to the acquisition time of the ADC. The conversion results are accurate when the ADC samples the input signal for an interval longer than the input signal's worst-case settling time. By definition, settling time is the interval between the application of an input voltage step and the

<span id="page-13-1"></span>

*Figure 13. Channel Select Timing Diagram*

<span id="page-13-2"></span>

*Figure 14. 14-Clock Cycle Operation*

point at which the output signal reaches and stays within a given error band centered on the resulting steady-state amplifier output level. The ADC input sampling capacitor charges during the sampling cycle, referred to as the acquisition period. During this acquisition period, the settling time is affected by the input resistance and the input sampling capacitance. This error can be estimated by looking at the settling of an RC time constant using the input capacitance and the source impedance over the acquisition time period.

[Figure 15](#page-14-0) shows a typical application circuit. The MAX4430, offering a settling time of 37ns at 16 bits, is an excellent choice for this application. See the THD vs. Input Resistance graph in the *Typical Operating Characteristics*.

<span id="page-14-0"></span>

*Figure 15. Typical Application Circuit*

## **Definitions**

For the MAX19777,  $V_{RFF}$  is internally tied to  $V_{DD}$ .

### **Integral Nonlinearity**

Integral nonlinearity (INL) is the deviation of the values on an actual transfer function from a straight line. For this device, the straight line is a line drawn between the end points of the transfer function after offset and gain errors are nulled.

### **Differential Nonlinearity**

Differential nonlinearity (DNL) is the difference between an actual step width and the ideal value of 1 LSB. A DNL error specification of ±1 LSB or less guarantees no missing codes and a monotonic transfer function.

### **Offset Error**

The deviation of the first code transition (00 . . . 000) to  $(00 \ldots 001)$  from the ideal, that is, AGND + 0.5 LSB.

### **Gain Error**

The deviation of the last code transition (111 . . . 110) to (111 . . . 111) from the ideal after adjusting for the offset error, that is,  $V_{REF}$  - 1.5 LSB.

### **Aperture Jitter**

Aperture jitter  $(t_{A,J})$  is the sample-to-sample variation in the time between the samples.

## **Aperture Delay**

Aperture delay  $(t_{AD})$  is the time between the falling edge of sampling clock and the instant when an actual sample is taken.

### **Signal-to-Noise Ratio (SNR)**

SNR is a dynamic figure of merit that indicates the converter's noise performance. For a waveform perfectly reconstructed from digital samples, the theoretical maximum SNR is the ratio of the full-scale analog input (RMS value) to the RMS quantization error (residual error). The ideal, theoretical minimum analog-to-digital noise is caused by quantization error only and results directly from the ADC's resolution (N bits):

SNR (dB) 
$$
(MAX) = (6.02 \times N + 1.76) (dB)
$$

In reality, there are other noise sources such as thermal noise, reference noise, and clock jitter that also degrade SNR. SNR is computed by taking the ratio of the RMS signal to the RMS noise. RMS noise includes all spectral components to the Nyquist frequency excluding the fundamental, the first five harmonics, and the DC offset.

### **Signal-to-Noise Ratio and Distortion (SINAD)**

SINAD is a dynamic figure of merit that indicates the converter's noise and distortion performance. SINAD is computed by taking the ratio of the RMS signal to the RMS noise plus distortion. RMS noise plus distortion includes all spectral components to the Nyquist frequency excluding the fundamental and the DC offset:

$$
SINAD(dB) = 20 \times log \left[ \frac{SIGNAL_{RMS}}{(NOISE + DISTORTION)_{RMS}} \right]
$$

## **Total Harmonic Distortion**

Total harmonic distortion (THD) is the ratio of the RMS sum of the first five harmonics of the input signal to the fundamental itself. This is expressed as:

$$
\text{THD} = 20 \times \text{log} \left( \frac{\sqrt{v_2^2 + v_3^2 + v_4^2 + v_5^2}}{v_1} \right)
$$

where  $V_1$  is the fundamental amplitude and  $V_2-V_5$  are the amplitudes of the 2nd- through 5th-order harmonics.

## **Spurious-Free Dynamic Range (SFDR)**

SFDR is a dynamic figure of merit that indicates the lowest usable input signal amplitude. SFDR is the ratio of the RMS amplitude of the fundamental (maximum signal component) to the RMS value of the next largest spurious component, excluding DC offset. SFDR is specified in decibels with respect to the carrier (dBc).

### **Full-Power Bandwidth**

Full-power bandwidth is the frequency at which the input signal amplitude attenuates by 3dB for a full-scale input.

### **Full-Linear Bandwidth**

Full-linear bandwidth is the frequency at which the signalto-noise ratio and distortion (SINAD) is equal to a specified value.

## **Intermodulation Distortion**

Any device with nonlinearities creates distortion products when two sine waves at two different frequencies ( $f_1$  and  $f<sub>2</sub>$ ) are applied into the device. Intermodulation distortion (IMD) is the total power of the IM2 to IM5 intermodulation products to the Nyquist frequency relative to the total input power of the two input tones,  $f_1$  and  $f_2$ . The individual input tone levels are at -6dBFS.

## **Package Information**

For the latest package outline information and land patterns (footprints), go to **[www.maximintegrated.com/packages](http://www.maximintegrated.com/packages)**. Note that a "+", "#", or "-" in the package code indicates RoHS status only. Package drawings may show a different suffix character, but the drawing pertains to the package regardless of RoHS status.

Компания «ЭлектроПласт» предлагает заключение долгосрочных отношений при поставках импортных электронных компонентов на взаимовыгодных условиях!

Наши преимущества:

- Оперативные поставки широкого спектра электронных компонентов отечественного и импортного производства напрямую от производителей и с крупнейших мировых складов;
- Поставка более 17-ти миллионов наименований электронных компонентов;
- Поставка сложных, дефицитных, либо снятых с производства позиций;
- Оперативные сроки поставки под заказ (от 5 рабочих дней);
- Экспресс доставка в любую точку России;
- Техническая поддержка проекта, помощь в подборе аналогов, поставка прототипов;
- Система менеджмента качества сертифицирована по Международному стандарту ISO 9001;
- Лицензия ФСБ на осуществление работ с использованием сведений, составляющих государственную тайну;
- Поставка специализированных компонентов (Xilinx, Altera, Analog Devices, Intersil, Interpoint, Microsemi, Aeroflex, Peregrine, Syfer, Eurofarad, Texas Instrument, Miteq, Cobham, E2V, MA-COM, Hittite, Mini-Circuits,General Dynamics и др.);

Помимо этого, одним из направлений компании «ЭлектроПласт» является направление «Источники питания». Мы предлагаем Вам помощь Конструкторского отдела:

- Подбор оптимального решения, техническое обоснование при выборе компонента;
- Подбор аналогов;
- Консультации по применению компонента;
- Поставка образцов и прототипов;
- Техническая поддержка проекта;
- Защита от снятия компонента с производства.
