

## FEATURES

- Fully ISO 7816-3 and EMV Compliant (Including Auxiliary I/O Pins)
- Buck-Boost Charge Pump Generates 3V or 5V
- 2.7V to 6.0V Input Voltage Range (LTC1755)
- Very Low Operating Current: 60 $\mu$ A
- >10kV ESD on All Smart Card Pins
- Dynamic Pull-Ups Deliver Fast Signal Rise Times
- Soft-Start Limits Inrush Current at Turn On
- 3V  $\leftrightarrow$  5V Signal Level Translators
- Shutdown Current: < 1 $\mu$ A
- Short-Circuit and Overtemperature Protected
- Alarm Output Indicates Fault Condition
- Multiple Devices May Be Paralleled for Multicard Applications (LTC1755)
- Available in 16- and 24-Pin SSOP Packages

## APPLICATIONS

- Handheld Payment Terminals
- Pay Telephones
- ATMs
- Key Chain Readers
- Smart Card Readers

## DESCRIPTION

The LTC<sup>®</sup>1755/LTC1756 universal Smart Card interfaces are fully compliant with ISO 7816-3 and EMV specifications. The parts provide the smallest and simplest interface circuits between a host microcontroller and general purpose Smart Cards.

An internal charge pump DC/DC converter delivers regulated 3V or 5V to the Smart Card, while on-chip level shifters allow connection to a low voltage controller. All Smart Card contacts are rated for 10kV ESD, eliminating the need for external ESD protection devices.

Input voltage may range from 2.7V to 6.0V, allowing direct connection to a battery. Internal soft-start mitigates start-up problems that may result when the input power is provided by another regulator. Multiple devices may be paralleled and connected to a single controller for multicard applications.

Battery life is maximized by 60 $\mu$ A operating current and 1 $\mu$ A shutdown current. The narrow SSOP packages minimize PCB area for compact portable systems.

LT, LTC and LT are registered trademarks of Linear Technology Corporation.

## TYPICAL APPLICATION

**Note 1:** Absolute Maximum Ratings are those values beyond which the life of a device may be impaired.

**Note 2:** The LTC1755/LTC1756 are guaranteed to meet performance specifications from  $0^\circ\text{C}$  to  $70^\circ\text{C}$ . Specifications over the  $-40^\circ\text{C}$  to  $85^\circ\text{C}$  operating temperature range are assured by design, characterization and correlation with statistical process controls.

**Note 3:** The DATA, AUX1IN, AUX2IN, AUX1, AUX2 and I/O pull-down drivers must sink up to  $250\mu\text{A}$  sourced by the internal current sources.

**Note 4:** On the LTC1756,  $DV_{CC}$  is internally connected to the  $V_{IN}$  pin. Specifications that call out  $DV_{CC}$  should be referred to  $V_{IN}$  instead.

## TYPICAL PERFORMANCE CHARACTERISTICS

17556 G10

17556 G11

## PIN FUNCTIONS LTC1755/LTC1756

**PRES (Pin 1):** (Input) Connects to the Smart Card acceptor's PRESENT indicator switch to detect if a card is inserted. This pin has a pull-up current source so that a grounded switch can be detected with no external components. The pull-up current source is nonlinear, delivering higher current when the PRES pin is above 1V but very little current below 1V. This helps resist false card indications due to leakage current. The activation state of the PRES pin can be set by the NC/NO pin so that both normally open (NO) and normally closed (NC) switches are easily recognized (see NC/NO pin description).

$DV_{CC}$  sets the logic reference level for the PRES pin.

**PWR (Pin 2):** (Input) A low on the PWR pin places the LTC1755/LTC1756 in the ACTIVE state enabling the charge pump. The READY pin indicates when the card supply voltage ( $V_{CC}$ ) has reached its final value and communication with the Smart Card is possible. The reset and clock channels are enabled after READY goes low. The three I/O channels are also enabled only after READY goes low, however they may be disabled separately via the CS pin (CS is not available on the LTC1756).

The falling edge of PWR latches the state of the 5V/3V pin. After PWR is low, changes on the 5V/3V pin are ignored.

**CS (Pin 3, LTC1755 Only):** (Input) The CS pin enables the three bidirectional I/O channels of the LTC1755. When the I/O channels are disabled the Smart Card pins (I/O, AUX1, AUX2) are forced to logic one and the controller pins (DATA, AUX2IN, AUX1IN) are high impedance. CS can be brought low along with PWR when the device is first enabled, however communication with the Smart Card is inhibited until  $V_{CC}$  reaches its final value as indicated by a low on the READY pin. CS does not affect the charge pump, CLK or RST channels. On the LTC1756, CS is internally connected to the PWR pin.

$DV_{CC}$  sets the logic reference level for the CS pin.

**NC/NO (Pin 4, LTC1755 Only):** (Input) This pin controls the activation level of the PRES pin. When it is high ( $DV_{CC}$ ) the PRES pin is active high. When it is low (GND) the PRES pin is active low. In either case the presence of a Smart Card is indicated by a low on the CARD output. When a ground side normally open (NO) switch is used the NC/NO pin should be grounded. When a ground side normally closed (NC) switch is used the NC/NO pin should be connected to  $DV_{CC}$ . The LTC1756 is permanently configured to accept a normally open switch.

## PIN FUNCTIONS LTC1755/LTC1756

**Note:** If a normally closed switch is used, a small current (several microamperes) will flow through the switch whenever a Smart Card is not present. For ultralow power consumption in shutdown, a normally open switch is optimum.

$DV_{CC}$  sets the logic reference level for the NC/ $\overline{NO}$  pin.

**GND (Pins 5/3):** Ground Reference for the IC. This pin should be connected to a low impedance ground plane. Bypass capacitors for  $V_{IN}$  and  $V_{CC}$  should be in close proximity to the GND pin.

**$V_{IN}$  (Pins 6/4):** Supply Voltage for the Charge Pump. May be between 2.7V and 6V. A 10 $\mu$ F low ESR ceramic bypass capacitor is required on this pin for optimum performance.

**$V_{CC}$  (Pins 7/5):** Regulated Smart Card Supply Voltage. This pin should be connected to the Smart Card  $V_{CC}$  contact. The 5V/3V pin determines the  $V_{CC}$  output voltage.

The  $V_{CC}$  pin is protected against short circuits by comparing the actual output voltage with an internal reference voltage. If  $V_{CC}$  is below its correct level (for as little as 5 $\mu$ s) the LTC1755/LTC1756 switch to the Alarm state (see the State Diagram). The  $V_{CC}$  pin requires a 10 $\mu$ F charge storage capacitor to ground. For optimum performance a low ESR ceramic capacitor should be used.

During the Idle and Alarm states the  $V_{CC}$  pin is rapidly discharged to ground to comply with the deactivation requirements of the EMV and ISO-7816 specifications.

**AUX1 (Pin 8, LTC1755 Only):** (Input/Output) Smart Card Side Auxiliary I/O Pin. This pin is used for auxiliary bidirectional data transfer between the microcontroller and the Smart Card. It has the same characteristics as the I/O pin.

**AUX2 (Pin 9, LTC1755 Only):** (Input/Output) Smart Card Side Auxiliary I/O Pin. This pin is used for auxiliary bidirectional data transfer between the microcontroller and the Smart Card. It has the same characteristics as the I/O pin.

**I/O (Pins 10/6):** (Input/Output) Smart Card Side Data I/O Pin. This pin is used for bidirectional data transfer between the microcontroller and the Smart Card. It should be connected to the Smart Card I/O contact. The Smart Card I/O pin must be able to sink up to 250 $\mu$ A when driving the I/O

pin low due to the pull-up current source. The I/O pin becomes a low impedance to ground during the Idle state. It does not become active until  $\overline{READY}$  goes low indicating that  $V_{CC}$  is stable.

Once  $\overline{READY}$  is low the I/O pin is protected against short circuits to  $V_{CC}$  by current limiting to 5mA maximum.

The DATA-I/O channel is bidirectional for half-duplex transmissions. Its idle state is H-H. Once an L is detected on one side of the channel the direction of transmission is established. Specifically, the side which received an L first is now the input, and the opposite side is the output. Transmission from the output side back to the input side is inhibited, thereby preventing a latch condition. Once the input side releases its L, both sides return to H, and the channel is now ready for a new L to be transmitted in either direction. If an L is forced externally on the output side, and it persists until after the L on the input side is released, this illegal input will not be transmitted to the input side because the transmission direction will not have changed. The direction of transmission can only be established from the idle (H-H) state and is determined by the first receipt of an L on either side.

**RST (Pins 11/7):** (Output) Level-Shifted Reset Output Pin. This pin should be connected to the Smart Card RST contact. The RST pin becomes a low impedance to ground during the Idle state (see the State Diagram). The reset channel does not become active until the  $\overline{READY}$  signal goes low indicating that  $V_{CC}$  is stable.

Short-circuit protection is provided on the RST pin by comparing RST with  $R_{IN}$ . If these signals differ for several microseconds then the LTC1755/LTC1756 switch to the Alarm state. This fault checking is only performed after the  $V_{CC}$  pin has reached its final value (as indicated by the  $\overline{READY}$  pin).

**CLK (Pins 12/8):** (Output) Level-Shifted Clock Output Pin. This pin should be connected to the Smart Card CLK contact. The CLK pin becomes a low impedance to ground during the Idle state (see the State Diagram). The clock channel does not become active until the  $\overline{READY}$  signal goes low indicating that  $V_{CC}$  is stable.

Short-circuit protection is provided on the CLK pin by comparing CLK with  $C_{IN}$ . If these signals differ for several

## PIN FUNCTIONS LTC1755/LTC1756

microseconds then the LTC1755/LTC1756 switch to the Alarm state. This fault checking is only performed after the  $V_{CC}$  pin has reached its final value (as indicated by the  $\overline{\text{READY}}$  pin).

The clock channel is optimized for signal integrity in order to meet the stringent duty cycle requirements of the EMV specification. Therefore, to reduce power in low power applications, clock stop mode is recommended when data is not being exchanged.

**CIN (Pins 13/9):** (Input) Clock Input Pin from the Microcontroller. During the Active state this signal appears on the CLK pin after being level-shifted and buffered.

$DV_{CC}$  sets the logic reference level for the  $C_{IN}$  pin.

**RIN (Pins 14/10):** (Input) Reset Input Pin from the Microcontroller. During the Active state this signal appears on the RST pin after being level-shifted and buffered.

$DV_{CC}$  sets the logic reference level for the  $R_{IN}$  pin.

**DATA (Pins 15/11):** (Input/Output) Microcontroller Side Data I/O Pin. This pin is used for bidirectional data transfer between the microcontroller and the Smart Card. The microcontroller data pin must be open drain and must be able to sink up to 250 $\mu$ A when driving the DATA pin low due to the pull-up current source. The DATA pin becomes high impedance during the Idle state or when  $\overline{\text{CS}}$  is high (see the State Diagram). It does not become active until the  $\overline{\text{READY}}$  signal goes low indicating that  $V_{CC}$  is stable.

**AUX2IN (Pin 16, LTC1755 Only):** (Input/Output) Microcontroller Side Auxiliary I/O pin. This pin is used for bidirectional auxiliary data transfer between the microcontroller and the Smart Card. It has the same characteristics as the DATA pin.

**AUX1IN (Pin 17, LTC1755 Only):** (Input/Output) Microcontroller Side Auxiliary I/O Pin. This pin is used for bidirectional auxiliary data transfer between the microcontroller and the Smart Card. It has the same characteristics as the DATA pin.

**C<sup>+</sup>, C<sup>-</sup> (Pins 18/12, 19/13):** Charge Pump Flying Capacitor Terminals. Optimum values for the flying capacitor range from 0.68 $\mu$ F to 1 $\mu$ F. Best performance is achieved with a low ESR X7R ceramic capacitor.

**DV<sub>CC</sub> (Pin 20, LTC1755 Only):** Supply Voltage for the Microcontroller Side Digital Input and Input/Output Pins (Typically 3V). If the charge pump input pin ( $V_{IN}$ ) is powered from the same source as the microcontroller, then  $DV_{CC}$  should be connected directly to  $V_{IN}$ . In this case only one (10 $\mu$ F) input bypass capacitor is needed for the LTC1755. If the  $DV_{CC}$  pin is powered separately then it should be bypassed separately with a 0.1 $\mu$ F capacitor. The  $DV_{CC}$  pin may be between 2V and 5.5V.

The  $DV_{CC}$  pin is monitored for adequate voltage. If  $DV_{CC}$  drops below approximately 1.5V the LTC1755 automatically enters the Idle state. On the LTC1756,  $DV_{CC}$  is connected internally to  $V_{IN}$ .

**READY (Pins 21/14):** (Output) Readiness Indicator of the Smart Card Supply Voltage ( $V_{CC}$ ). When the LTC1755/LTC1756 are placed in the Active state the soft-start feature slowly ramps the  $V_{CC}$  voltage. A low on the  $\overline{\text{READY}}$  pin indicates that  $V_{CC}$  has reached its final value.

The  $\overline{\text{READY}}$  pin also indicates if the LTC1756 is in Alarm mode. The LTC1756 detects faults such as  $V_{CC}$  underrange for at least 5 $\mu$ s, overtemperature shutdown, CLK or RST invalid output levels and card removal during Active state. CLK or RST invalid and overtemperature faults are detected only after  $V_{CC}$  has reached its final value.  $V_{CC}$  underrange and card removal during Active faults are detected at any time during the Active period (i.e., once  $\overline{\text{PWR}} = 0V$ ).

If the LTC1756 has been activated normally and  $V_{CC}$ , the card voltage, has reached its final value then  $\overline{\text{READY}}$  will go low indicating normal operation. If, following this, a fault occurs and the LTC1756 enters the Alarm state, the  $\overline{\text{READY}}$  pin will return high.

In the event that a fault precedes the activation of  $V_{CC}$ , such as a direct short circuit from  $V_{CC}$  to GND, the LTC1756 will attempt to operate until the fault is detected and then automatically shut down and enter the Alarm state. In this case the  $\overline{\text{READY}}$  pin will never go low after the command to start the smart card is given (i.e.,  $\overline{\text{PWR}} = 0V$ ).

If the LTC1755/LTC1756 enter the Alarm state they can only be cleared by returning the  $\overline{\text{PWR}}$  pin high.

## PIN FUNCTIONS LTC1755/LTC1756

The  $\overline{\text{READY}}$  pin is configured as an open-drain pull-down with a weak pull-up current source. This permits wired-OR connections of multiple LTC1755/LTC1756s to a single microcontroller.

**$\overline{\text{ALARM}}$  (Pin 22, LTC1755 Only):** (Output) A low on this pin indicates that a fault has occurred and that the LTC1755 is in the Alarm state (see the State Diagram). Possible faults include  $V_{\text{CC}}$  underrange for at least 5 $\mu\text{s}$ , overtemperature shutdown, CLK or RST invalid output levels, and card removal during the Active state.

CLK or RST invalid and overtemperature faults are detected only after  $V_{\text{CC}}$  has reached its final value (as indicated by the  $\overline{\text{READY}}$  pin).  $V_{\text{CC}}$  underrange and card removal during Active faults are detected at any time during the Active period (i.e., once  $\overline{\text{PWR}} = 0\text{V}$ ).

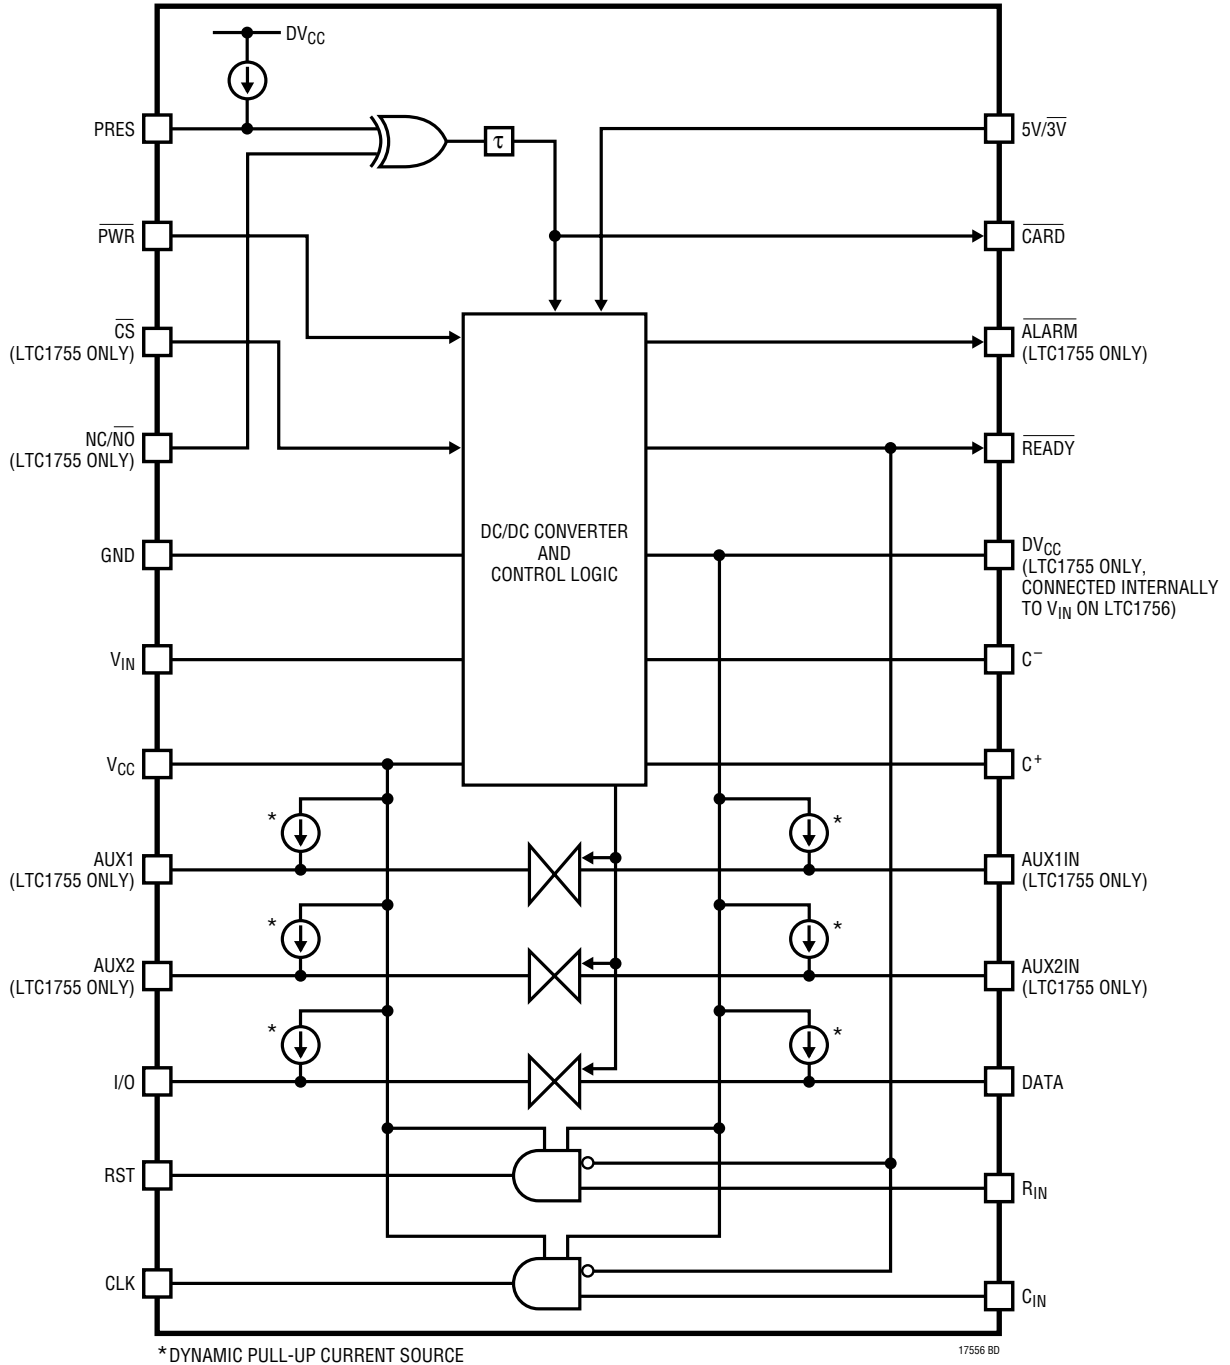

The  $\overline{\text{ALARM}}$  pin is configured as an open-drain pull-down with a weak pull-up current source. This permits wired-OR connections of multiple LTC1755s to a single microcontroller.

**$\overline{\text{CARD}}$  (Pin 23/15):** (Output) Level-Shifted and Debounced PRES Signal from the Smart Card Acceptor Switch. When a valid card indication appears, this pin communicates the presence of the Smart Card to the microcontroller. The  $\overline{\text{CARD}}$  pin has an open-drain active pull-down with a weak pull-up current source for logic-OR connections. The debounce circuit ensures that a card has been present for a continuous period of at least 40ms before asserting  $\overline{\text{CARD}}$  low. The  $\overline{\text{CARD}}$  pin returns high within 50 $\mu\text{s}$  of card removal. The PRES pin, in conjunction with the NC/ $\overline{\text{NO}}$  pin, determines if a card is present.

**$5\text{V}/\overline{3\text{V}}$  (Pin 24/16):** (Input) Controls the output voltage ( $V_{\text{CC}}$ ) of the DC/DC converter during the Active state. A valid high sets  $V_{\text{CC}}$  to 5V. A valid low sets  $V_{\text{CC}}$  to 3V. The  $5\text{V}/\overline{3\text{V}}$  pin is latched on the falling edge of the  $\overline{\text{PWR}}$  pin. When  $\overline{\text{PWR}}$  is low, changes on the  $5\text{V}/\overline{3\text{V}}$  pin are ignored. To change the voltage on  $V_{\text{CC}}$  the LTC1755/LTC1756 must first be returned to the Idle state by bringing the  $\overline{\text{PWR}}$  pin high.

$\text{DV}_{\text{CC}}$  sets the logic reference level for the  $5\text{V}/\overline{3\text{V}}$  pin.

**BLOCK DIAGRAM**

## APPLICATIONS INFORMATION

### 10kV ESD Protection

All Smart Card pins (CLK, RST, I/O, AUX1, AUX2,  $V_{CC}$  and GND) can withstand over 10kV of human body model ESD in situ. In order to ensure proper ESD protection, careful board layout is required. The GND pin should be tied directly to a ground plane. The  $V_{CC}$  capacitor should be located very close to the  $V_{CC}$  pin and tied immediately to the ground plane.

### Capacitor Selection

The style and value of capacitors used with the LTC1755/LTC1756 determine several parameters such as output ripple voltage, charge pump strength, Smart Card switch debounce time and  $V_{CC}$  discharge rate.

Due to the switching nature of a capacitive charge pump, low equivalent series resistance (ESR) capacitors are recommended for the capacitors at  $V_{IN}$  and  $V_{CC}$ . Whenever the flying capacitor is switched to the  $V_{CC}$  charge storage capacitor, considerable current flows. The product of this high current and the ESR of the output capacitor can generate substantial voltage spikes on the  $V_{CC}$  output. These spikes may cause problems with the Smart Card or may interfere with the regulation loop of the LTC1755/LTC1756. Therefore, ceramic or tantalum capacitors are recommended rather than higher ESR aluminum capacitors. Between ceramic and tantalum, ceramic capacitors generally have the lowest ESR. Some manufacturers have developed low ESR tantalum capacitors but they can be expensive and may still have higher ESR than ceramic types. Thus, while they cannot be avoided, ESR spikes will typically be lowest when using ceramic capacitors.

For ceramic capacitors there are several different materials available to choose from. The choice of ceramic material is generally based on factors such as available capacitance, case size, voltage rating, electrical performance and cost. For example, capacitors made of Y5V material have high packing density, which provides high capacitance for a given case size. However, Y5V capacitors tend to lose considerable capacitance over the  $-40^{\circ}\text{C}$  to  $85^{\circ}\text{C}$  temperature range. X7R ceramic capacitors are more stable over temperature but don't provide the high packing density. Therefore, large capacitance values are generally not available in X7R ceramic.

The value and style of the flying capacitor are important not only for the charge pump but also because they provide the large debounce time for the Smart Card detection channel. A  $0.68\mu\text{F}$  X7R capacitor is a good choice for the flying capacitor because it provides fairly constant capacitance over temperature and its value is not prohibitively large.

The charge storage capacitor on the  $V_{CC}$  pin determines the ripple voltage magnitude and the discharge time of the Smart Card voltage. To minimize ripple, generally, a large value is needed. However, to meet the  $V_{CC}$  discharge rate specification, the value should not exceed  $20\mu\text{F}$ . A  $10\mu\text{F}$  capacitor can be used but the ripple magnitude will be higher leading to worse apparent DC load regulation. Typically a  $15\mu\text{F}$  to  $18\mu\text{F}$  Y5V ceramic capacitor is the best choice for the  $V_{CC}$  charge storage capacitor. For best performance, this capacitor should be connected as close as possible to the  $V_{CC}$  and GND pins. Note that most of the electrostatic discharge (ESD) current on the Smart Card pins is absorbed by this capacitor.

The bypass capacitor at  $V_{IN}$  is also important. Large dips on the input supply due to ESR may cause problems with the internal circuitry of the LTC1755/LTC1756. A good choice for the input bypass capacitor is a  $10\mu\text{F}$  Y5V style ceramic

### Dynamic Pull-Up Current Sources

The current sources on the bidirectional pins (DATA, AUX2IN, AUX1IN, I/O, AUX2 and AUX1) are dynamically activated to achieve a fast rise time with a relatively small static current (Figure 1). Once a bidirectional pin is relinquished, a small start-up current begins to charge the node. An edge rate detector determines if the pin is

Figure 1. Dynamic Pull-Up Current Sources

## APPLICATIONS INFORMATION

released by comparing its slew rate with an internal reference value. If a valid transition is detected, a large pull-up current enhances the edge rate on the node. The higher slew rate corroborates the decision to charge the node thereby effecting a dynamic form of hysteresis. Once the node has reached the power supply voltage the internal comparator requires several hundred nanoseconds to reset. Pulling down on the pin before the reset delay expires will result in a momentary contention and a higher current flow. Therefore, the comparator delay sets the upper limit on the maximum data rate of the bidirectional channels to about 500kHz.

The dynamic pull-up current sources are designed to trigger with as much as 50pF of capacitive load on the bidirectional pins. At approximately 90pF (or greater), the edge rate on the node will be insufficient to trigger the edge rate detector and the node will only ramp up at a rate given by the  $I_{START}$  current source and the load capacitance. In these instances the edge rate of the bidirectional pin may not meet the requirements of existing smart card standards. Therefore, it is recommended that the sum of both explicit and parasitic capacitances on the bidirectional pins be kept below 50pF.

If excessive capacitance (either explicit or parasitic) is present on the bidirectional pins, the starting pull-up current must also be increased. This can be accomplished with a pull-up resistor to the respective supply. For the smart card side (I/O, AUX1 and AUX2), the pull-up resistor should be connected to  $V_{CC}$ . For the microcontroller side (DATA, AUX1IN and AUX2IN), the pull-up resistor should be connected to  $DV_{CC}$  on the LTC1755 ( $V_{IN}$  on the LTC1756). To maintain an edge rate of approximately

5V/ $\mu$ s, the following expression for  $R_{PULL-UP}$  should be applied:

$$R_{PULL-UP} = \frac{V_{SUPPLY} - 1V}{(C_{PAR} - 50pF)(5 \cdot 10^6)}$$

where  $C_{PAR}$  is the extra capacitance on the bidirectional pin and  $V_{SUPPLY}$  is the minimum local supply for the bidirectional pin. For example, on the smart card side, 3V should be assumed for  $V_{SUPPLY}$ .

Note that the addition of a pull-up resistor will give a higher output voltage when the bidirectional pin pulls down. Care should be taken so that the  $V_{IL}$  or  $V_{OL}$  specifications are not compromised with this technique.

### Bidirectional Channels

As described in Pin Functions (Pins 10/6), the bidirectional channels allow transmission in only one direction at a time. Figure 2 shows a simplified block diagram of one of the three bidirectional channels. The three channels operate in an identical fashion.

Figure 3 shows an example of normal transmit and receive operations as well as the two possible collision scenarios. If a channel is activated from one direction and an L is imposed in the other direction before both sides return H a collision results. The result of the collision is that the receiving side (*Slave Side*) will remain low until it is released, but the transmitting side (first side to go low or *Master Side*), will be allowed to return high if released. The colliding L externally imposed on the slave side will not be transmitted back through the channel.

Figure 2. Bidirectional Channel Simplified Block Diagram

## APPLICATIONS INFORMATION

### I<sup>2</sup>C™ Compatibility

Some smart cards still require I<sup>2</sup>C compatibility. In the I<sup>2</sup>C format it is permissible to impose an L before the signal line has returned H. This is used, for example, as an acknowledge signal. Such a scenario will cause a collision as shown in Figure 3.

Figure 4 shows an analog level translation technique that can be used along with the LTC1755 to support I<sup>2</sup>C smart cards. In this technique it is important to connect the gate of the external MOSFET to the lower of the two supplies (i.e., the lower of V<sub>CC</sub> or DV<sub>CC</sub>). If DV<sub>CC</sub> is operating from a fixed 5V supply, the gate of MN1 should be connected to V<sub>CC</sub>. If DV<sub>CC</sub> is operating from a regulated 3.3V supply, the gate of MN1 should be connected to DV<sub>CC</sub>. In the latter case, the gate may need to be connected to a digital signal ranging from 0V to DV<sub>CC</sub> so that it can be disabled when the LTC1755 is in shutdown. Otherwise, the the LTC1755 will try to assert an L on the microcontroller side of the channel when it is in shutdown.

### Supporting Synchronous and Asynchronous Cards

In synchronous/asynchronous applications it is necessary to switch the CLK pin of the card socket from a free running asynchronous clock to a controlled synchronous clock. To avoid glitches and pulses shorter than the minimum allowed pulse width, the circuit shown in Figure 5 should be used as a clock selection circuit. Note that for this circuit to be effective the SYNC input should be held constant while switching the ASYNC\SYNC control signal.

### Low Power Operation

The LTC1755/LTC1756 are inherently low power devices. When there is no Smart Card present the supply current is

less than 10μA. If DV<sub>CC</sub> is 0V the current drops below 1μA. When a Smart Card is present the LTC1755/LTC1756 operate with a quiescent current of only 60μA, thus the majority of power is consumed by charge pump losses and the card itself. If the card can be made to consume less power during idle times a significant power savings will be achieved. Whenever possible Clock Stop Mode should be used (or alternatively a very low “idling” clock speed). Furthermore, in the Active state, the bidirectional pins should all be relinquished whenever possible since there is some static current flow when a bidirectional pin is pulled down.

## APPLICATIONS INFORMATION

### Overtemperature Fault Protection

An overtemperature circuit disables the chip and activates the **ALARM** pin if the IC's junction temperature exceeds 150°C.

### Self-Start Mode

By connecting the  $\overline{\text{CARD}}$  pin to the  $\overline{\text{PWR}}$  pin, the LTC1755/LTC1756 can be made to start up automatically when a Smart Card is detected (Figure 6). In this mode, the **READY** pin becomes an interrupt signal indicating to the microcontroller that a Smart Card is present and that  $V_{\text{CC}}$ , the charge pump voltage, is at its final value. The Smart Card remains powered as long as it is detected by the **PRES** pin. When the Smart Card is removed the LTC1755/LTC1756 will automatically be deactivated by the fault detection circuitry.

### Deactivation Sequence

For maximum flexibility the Smart Card can be deactivated either manually or automatically. In manual mode the deactivation is controlled by explicitly manipulating the LTC1755/LTC1756 input and control pins (**DATA**, **AUX1IN**, **AUX2IN**, **RIN** and **CIN** followed by  $\overline{\text{PWR}}$  and  $\overline{\text{CS}}$ ). In automatic mode the  $\overline{\text{PWR}}$  pin is used to perform the built-in

Figure 6. Self-Start Mode

Figure 7. Deactivation Sequence

deactivation sequence. Once  $\overline{\text{PWR}}$  is brought high the built-in deactivation sequence occurs as shown in Figure 7.

In the event of a fault, the LTC1755/LTC1756 automatically implement the built-in deactivation sequence.

### PC Board Layout

For best performance, the  $V_{\text{IN}}$  and  $V_{\text{CC}}$  capacitors should be placed as close to the LTC1755/LTC1756 as possible. This will help reduce ringing due to inductance on the  $V_{\text{IN}}$  and  $V_{\text{CC}}$  pins that could cause problems with the LTC1755/LTC1756 control circuitry or Smart Card. Figure 8 illustrates a possible layout technique using only a single layer of the PC board.

### State Definitions

#### IDLE/DEACTIVATION

$V_{\text{CC}}$ , **RST**, **CLK**, I/O **AUX2**, **AUX1** = L

$\overline{\text{READY}}$ ,  $\overline{\text{ALARM}}$ , **DATA**, **AUX2IN**, **AUX1IN** = Z

$\overline{\text{CARD}}$  =  $\overline{\text{PRES}} \oplus \text{NC/NO}$

Once the LTC1755/LTC1756 enter the Idle/Deactivation state the deactivation sequence begins. The deactivation sequence will continue until  $V_{\text{CC}}$  is discharged to approximately 1V. An activation command ( $\overline{\text{PWR}} = 0\text{V}$ ) will only be acknowledged once this occurs.

#### ALARM/DEACTIVATION

Same as Idle/Deactivation except:

$\overline{\text{ALARM}}$  = L

Figure 8. Optimum Bypass Capacitor Placement

## APPLICATIONS INFORMATION

The only possible next state is Idle/Deactivation which is achieved by disabling the LTC1755/LTC1756 via the  $\overline{\text{PWR}}$  pin (i.e.,  $\overline{\text{PWR}} = \text{DV}_{\text{CC}}$ ).

The alarm indication can be cleared by rapidly cycling the  $\overline{\text{PWR}}$  pin. However, a new activation cycle will not begin until  $\text{V}_{\text{CC}}$  is or has dropped below approximately 1V.

### ACTIVE

$\text{V}_{\text{CC}} = 3\text{V}$  or  $5\text{V}$  (as determined by the  $5\text{V}/3\text{V}$  pin)

$\text{RST} = \text{R}_{\text{IN}}$ ,  $\text{CLK} = \text{C}_{\text{IN}}$

I/O, AUX2, AUX1, DATA, AUX2IN, AUX1IN = Ready for data (after  $\overline{\text{READY}}$  becomes low)

$\overline{\text{CARD}} = \text{PRES} \oplus \text{NC}/\overline{\text{NO}}$

$\overline{\text{ALARM}} = \text{H}$

### FAULT TIMEOUT

Same as Active except:

The duration of a fault is being measured. If the fault duration exceeds  $5\mu\text{s}$  then the Alarm/Deactivation state follows. If the fault duration is less than  $5\mu\text{s}$ , then the device is returned to the Active state.

## PACKAGE DESCRIPTION

Dimensions in inches (millimeters) unless otherwise noted.

### GN Package 16-Lead Plastic SSOP (Narrow 0.150) (LTC DWG # 05-08-1641)

\* DIMENSION DOES NOT INCLUDE MOLD FLASH. MOLD FLASH SHALL NOT EXCEED 0.006" (0.152mm) PER SIDE  
 \*\* DIMENSION DOES NOT INCLUDE INTERLEAD FLASH. INTERLEAD FLASH SHALL NOT EXCEED 0.010" (0.254mm) PER SIDE

### GN Package 24-Lead Plastic SSOP (Narrow 0.150) (LTC DWG # 05-08-1641)

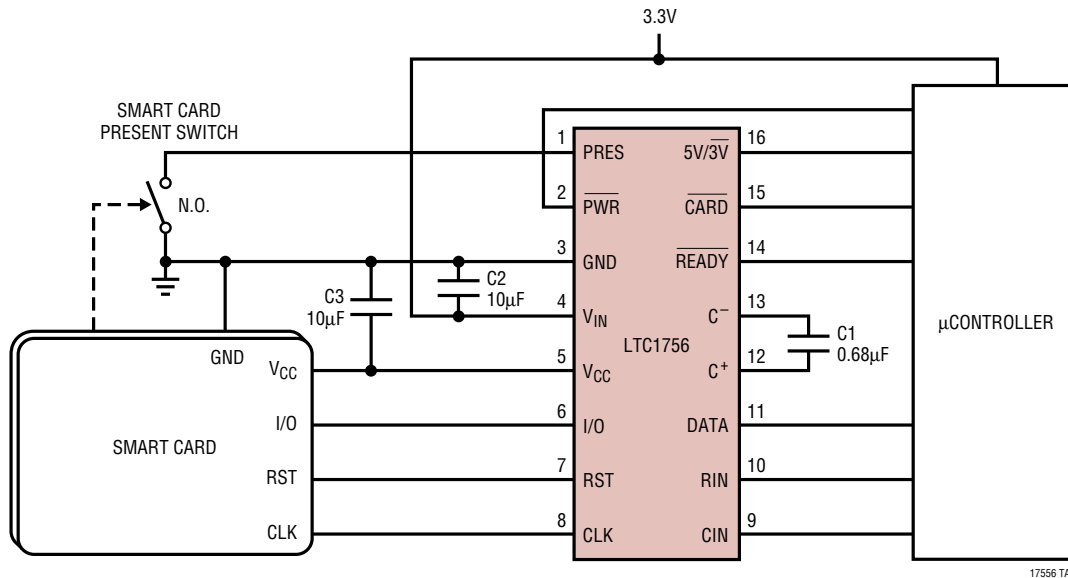

\* DIMENSION DOES NOT INCLUDE MOLD FLASH. MOLD FLASH SHALL NOT EXCEED 0.006" (0.152mm) PER SIDE  
 \*\* DIMENSION DOES NOT INCLUDE INTERLEAD FLASH. INTERLEAD FLASH SHALL NOT EXCEED 0.010" (0.254mm) PER SIDE

## TYPICAL APPLICATION

### Asynchronous Smart Card Interface

17556 TA02

## RELATED PARTS

PART NUMBER	DESCRIPTION	COMMENTS
LTC1514/LTC1515	Micropower Step-Up/Step-Down Inductorless DC/DC Converters	Regulated Output Up to 50mA, $V_{IN}$ from 2V to 10V, SO-8 Package
LTC1516	Micropower Regulated 5V Charge Pump	5V/50mA Output from 2V to 5V Input, SO-8 Package
LTC1555/LTC1556	SIM Power Supply and Level Translator	Step-Up/Step-Down Charge Pump + Generates 3V or 5V
LTC1754-5	5V Charge Pump with Shutdown in SOT-23	$V_{IN}$ from 2.7V to 5.5V, 50mA Output with $V_{IN} \geq 3V$
LTC1986	3V/5V SIM Power Supply in SOT-23	$V_{IN}$ from 2.6V to 4.4V, 3V/5V Output at 10mA

Компания «ЭлектроПласт» предлагает заключение долгосрочных отношений при поставках импортных электронных компонентов на взаимовыгодных условиях!

Наши преимущества:

- Оперативные поставки широкого спектра электронных компонентов отечественного и импортного производства напрямую от производителей и с крупнейших мировых складов;
- Поставка более 17-ти миллионов наименований электронных компонентов;
- Поставка сложных, дефицитных, либо снятых с производства позиций;
- Оперативные сроки поставки под заказ (от 5 рабочих дней);
- Экспресс доставка в любую точку России;
- Техническая поддержка проекта, помощь в подборе аналогов, поставка прототипов;
- Система менеджмента качества сертифицирована по Международному стандарту ISO 9001;
- Лицензия ФСБ на осуществление работ с использованием сведений, составляющих государственную тайну;
- Поставка специализированных компонентов (Xilinx, Altera, Analog Devices, Intersil, Interpoint, Microsemi, Aeroflex, Peregrine, Syfer, Eurofarad, Texas Instrument, Miteq, Cobham, E2V, MA-COM, Hittite, Mini-Circuits, General Dynamics и др.);

Помимо этого, одним из направлений компании «ЭлектроПласт» является направление «Источники питания». Мы предлагаем Вам помощь Конструкторского отдела:

- Подбор оптимального решения, техническое обоснование при выборе компонента;
- Подбор аналогов;
- Консультации по применению компонента;
- Поставка образцов и прототипов;
- Техническая поддержка проекта;
- Защита от снятия компонента с производства.
