■ PIN CONFIGURATIONS

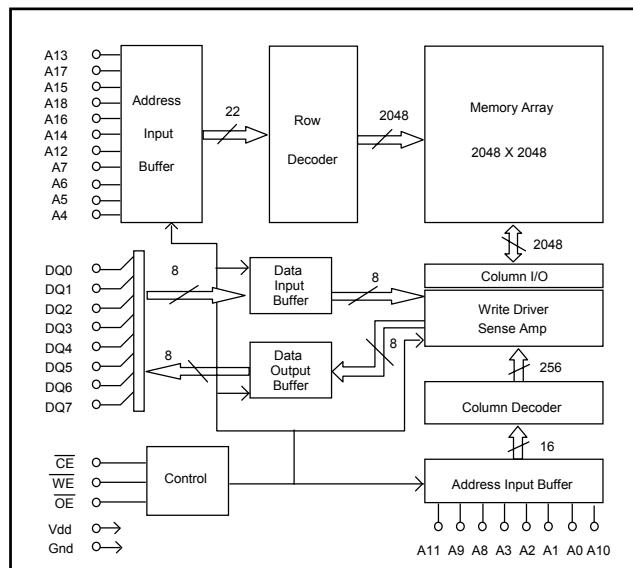

■ GENERAL DESCRIPTION

The BS62LV4005 is a high performance, low power CMOS Static Random Access Memory organized as 524,288 words by 8 bits and operates from a wide range of 4.5V to 5.5V supply voltage. Advanced CMOS technology and circuit techniques provide both high speed and low power features with maximum access time of 55/70ns in 5V operation.

Easy memory expansion is provided by active LOW chip enable (CE), active LOW output enable (OE) and three-state output drivers.

The BS62LV4005 has an automatic power down feature, reducing the power consumption significantly when chip is deselected. The BS62LV4005 is available in the JEDEC standard 32 pin SOP, TSOP, TSOP II and STSOP .

■ PIN DESCRIPTIONS

Name	Function
A0-A18 Address Input	These 19 address inputs select one of the 524,288 x 8-bit words in the RAM
CE Chip Enable Input	\overline{CE} is active LOW. Chip enable must be active when data read from or write to the device. If chip enable is not active, the device is deselected and is in a standby power mode. The DQ pins will be in the high impedance state when the device is deselected.
WE Write Enable Input	The write enable input is active LOW and controls read and write operations. With the chip selected, when \overline{WE} is HIGH and \overline{OE} is LOW, output data will be present on the DQ pins; when \overline{WE} is LOW, the data present on the DQ pins will be written into the selected memory location.
OE Output Enable Input	The output enable input is active LOW. If the output enable is active while the chip is selected and the write enable is inactive, data will be present on the DQ pins and they will be enabled. The DQ pins will be in the high impedance state when \overline{OE} is inactive.
DQ0-DQ7 Data Input/Output Ports	These 8 bi-directional ports are used to read data from or write data into the RAM.

■ SWITCHING WAVEFORMS (WRITE CYCLE)
WRITE CYCLE1 ⁽¹⁾

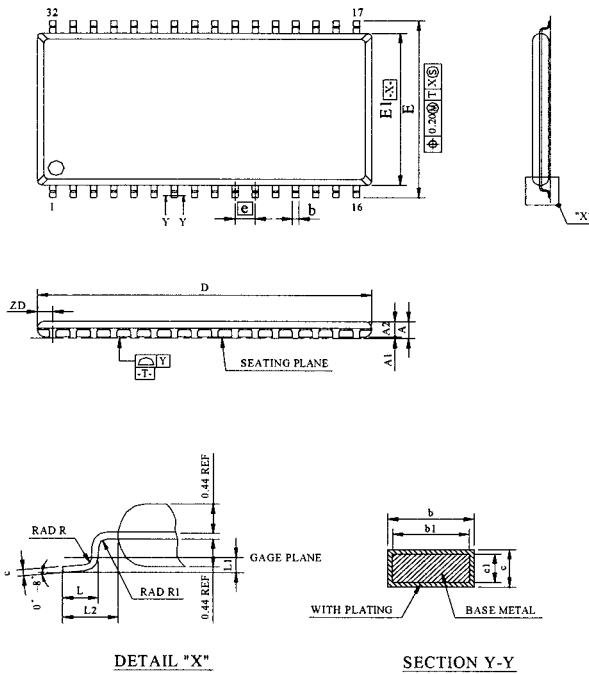

WRITE CYCLE2 (1,6)

NOTES:

1. WE must be high during address transitions.
2. The internal write time of the memory is defined by the overlap of CE and WE low. All signals must be active to initiate a write and any one signal can terminate a write by going inactive. The data input setup and hold timing should be referenced to the second transition edge of the signal that terminates the write.
3. T_{WR} is measured from the earlier of CE or WE going high at the end of write cycle.
4. During this period, DQ pins are in the output state so that the input signals of opposite phase to the outputs must not be applied.
5. If the CE low transition occurs simultaneously with the WE low transitions or after the WE transition, output remain in a high impedance state.
6. OE is continuously low ($OE = V_{IL}$).
7. D_{OUT} is the same phase of write data of this write cycle.
8. D_{OUT} is the read data of next address.
9. If CE is low during this period, DQ pins are in the output state. Then the data input signals of opposite phase to the outputs must not be applied to them.
10. Transition is measured $\pm 500\text{mV}$ from steady state with $C_L = 5\text{pF}$ as shown in Figure 1B. The parameter is guaranteed but not 100% tested.
11. T_{WC} is measured from the later of CE going low to the end of write.
