

MP2333H

4.2 - 18V Input, 3A, 1.2MHz Synchronous Buck Converter with Power Good and Soft Start in SOT583 (1.6x2mm) Package

DESCRIPTION

The MP2333H is a fully integrated, high-frequency, synchronous, rectified, step-down, switch-mode converter with internal power MOSFETs. The MP2333H offers a very compact solution that achieves 3A of continuous output current with excellent load and line regulation over a wide input range. The MP2333H uses synchronous mode operation for higher efficiency over the output current load range.

Constant-on-time (COT) control operation provides very fast transient response, easy loop design, and very tight output regulation.

Full protection features include short-circuit protection (SCP), over-current protection (OCP), under-voltage protection (UVP), and thermal shutdown.

The MP2333H requires a minimal number of readily available, standard, external components and is available in a space-saving SOT583 package

FEATURES

- Wide 4.2V to 18V Operating Input Range
- 75mΩ/40mΩ Low $R_{DS(ON)}$ Internal Power MOSFETs
- 200μA Low I_Q
- High-Efficiency Synchronous Mode Operation
- Fast Load Transient Response
- 1.2MHz Switching Frequency
- T_{ON} Extension
- Forced PWM Operation
- Programmable Soft-Start Time
- Power Good (PG) Indication
- Over-Current Protection (OCP) and Hiccup
- Pre-Bias Start-Up
- Thermal Shutdown
- Available in a SOT583 (1.6mmx2.0mm) Package

APPLICATIONS

- Game Consoles
- Digital Set-Top Boxes
- Flat-Panel Television and Monitors
- General Consumer Purposes

All MPS parts are lead-free, halogen-free, and adhere to the RoHS directive. For MPS green status, please visit the MPS website under Quality Assurance. "MPS", the MPS logo, and "Simple, Easy Solutions" are trademarks of Monolithic Power Systems, Inc. or its subsidiaries.

TYPICAL APPLICATION

Efficiency

$V_{OUT} = 3.3V$, $L = 1.5\mu H$, $DCR = 4.3m\Omega$

PACKAGE REFERENCE

PIN FUNCTIONS

Package Pin #	Name	Description
1	PG	Power good output. The output of PG is an open drain. Decouple PG with a 1nF capacitor.
2	IN	Supply voltage. The MP2333H operates from a 4.2V to 18V input rail. A capacitor (C1) is required to decouple the input rail. Connect IN using a wide PCB trace.
3	SW	Switch output. Connect SW using a wide PCB trace.
4	GND	System ground. GND is the reference ground of the regulated output voltage and requires extra care during the PCB layout. Connect GND with copper traces and vias.
5	BST	Bootstrap. Connect a 1μF BST capacitor and a resistor between SW and BST to form a floating supply across the high-side switch driver.
6	EN	Enable. Drive EN high to enable the MP2333H. For automatic start-up, connect EN to V _{IN} through a 604kΩ pull-up resistor.
7	SS	Soft start. Connect an external capacitor to SS to program the soft-start time for the switch-mode regulator.
8	FB	Feedback. Connect FB to the tap of an external resistor divider from the output to GND to set the output voltage.

ABSOLUTE MAXIMUM RATINGS ⁽¹⁾

V _{IN}	-0.3V to 20V
V _{SW}	-0.3V (-6.5V for <10ns, -0.6V for <2μs) to 20V (21V for <10ns)
V _{BST}	V _{SW} + 5V
V _{EN}	-0.3V to 5V ⁽²⁾
All other pins	-0.3V to 4V
Continuous power dissipation (T _A = +25°C) ⁽³⁾⁽⁵⁾	2.2W
Junction temperature	150°C
Lead temperature.....	260°C
Storage temperature	-65°C to 150°C

Recommended Operating Conditions ⁽⁴⁾

Supply voltage (V _{IN})	4.2V to 18V
Output voltage (V _{OUT}).....	0.8V to 0.9 * V _{IN} or 13V max
Operating junction temp. (T _J).....	-40°C to +125°C

Thermal Resistance

SOT583 (1.6mmx2.0mm)	θ _{JA}	θ _{JC}
EV2333H-TL-00A ⁽⁵⁾	55	21 ... °C/W
JESD51-7 ⁽⁶⁾	130	60 ... °C/W

NOTES:

- Exceeding these ratings may damage the device.
- For details on EN's ABS max rating, refer to the Enable Control section on page 12.
- The maximum allowable power dissipation is a function of the maximum junction temperature T_J(MAX), the junction-to-ambient thermal resistance θ_{JA}, and the ambient temperature T_A. The maximum allowable continuous power dissipation on EV2333H Board at any ambient temperature is calculated by P_D(MAX) = (T_J(MAX)-T_A)/θ_{JA}. Exceeding the maximum allowable power dissipation produces an excessive die temperature, causing the regulator to go into thermal shutdown. Internal thermal shutdown circuitry protects the device from permanent damage.
- The device is not guaranteed to function outside of its operating conditions.
- Measured on EV2333H-TL-00A, 2-layer PCB, 64mmx48mm.
- The value of θ_{JA} given in this table is only valid for comparison with other packages and cannot be used for design purposes. These values were calculated in accordance with JESD51-7, and simulated on a specified JEDEC board. They do not represent the performance obtained in an actual application.

ELECTRICAL CHARACTERISTICS

$V_{IN} = 12V$, $T_J = -40^{\circ}C$ to $+125^{\circ}C$ ⁽⁷⁾, typical value is tested at $T_J = +25^{\circ}C$, unless otherwise noted.

Parameter	Symbol	Condition	Min	Typ	Max	Units

BLOCK DIAGRAM

Figure 1: Functional Block Diagram

OPERATION

The MP2333H is a fully integrated, synchronous, rectified, step-down, switch-mode converter. Constant-on-time (COT) control is employed to provide fast transient response and easy loop stabilization.

At the beginning of each cycle, the high-side MOSFET (HS-FET) is turned on when the FB voltage (V_{FB}) drops below the reference voltage (V_{REF}). The HS-FET is turned on for a fixed interval determined by the one-shot on-timer. The on-timer is determined by both the output voltage and input voltage to make the switching frequency fairly constant over the input voltage range. After the on period elapses, the HS-FET is turned off until the next period begins. By repeating this operation, the converter regulates the output voltage.

The MP2333H operates in forced continuous conduction mode (CCM). The low-side MOSFET (LS-FET) is turned on when the HS-FET is in its off state to minimize conduction loss. There is a dead short between the input and GND if both the HS-FET and LS-FET are turned on at the same time. This is called shoot-through. To prevent shoot-through, a dead time is generated internally between the HS-FET off and LS-FET on period, or the LS-FET off and HS-FET on period.

Enable Control (EN)

EN is a digital control pin that turns the regulator on and off. Drive EN high to turn on the regulator, drive EN low to turn off the regulator. EN is clamped internally using a 2.8V series Zener diode (see Figure 2). Connecting the EN input through a pull-up resistor to V_{IN} limits the EN input current below 40 μ A to prevent damage to the Zener diode. For example, when connecting a 604k Ω pull-up resistor to 12V V_{IN} , $I_{Zener} = (12V - 2.8V) / (604k\Omega + 35k\Omega) = 14\mu A$.

Figure 2: Zener Diode between EN and GND

Under-Voltage Lockout (UVLO)

Under-voltage lockout (UVLO) protects the chip from operating at an insufficient supply voltage. The MP2333H UVLO comparator monitors the output voltage of the internal regulator (V_{CC}). The UVLO rising threshold is about 4V, while its falling threshold is 3.6V.

Soft Start (SS)

The MP2333H employs a soft start (SS) mechanism to ensure smooth output ramping during power-up. When the MP2333H starts up, an internal current source (typically 7.3 μ A) charges up the SS capacitor to generate a soft-start voltage (V_{SS}). When $V_{SS}/2$ is below V_{REF} , $V_{SS}/2$ overrides V_{REF} . The error amplifier (EA) uses $V_{SS}/2$ as the reference. The output voltage ramps up smoothly. Once $V_{SS}/2$ rises above the V_{REF} , the EA uses V_{REF} as the reference. At this point, the soft start finishes, and the MP2333H enters steady-state operation.

The SS capacitor value can be determined with Equation (1):

$$C_{ss}(\text{nF}) = \frac{T_{ss}(\text{ms}) \times I_{ss}(\text{uA})}{2V_{REF}} \quad (1)$$

Over-Current Protection (OCP) and Short-Circuit Protection (SCP)

The MP2333H has a valley-limit control. The inductor current is monitored during the LS-FET on state. When the sensed inductor current reaches the valley current limit, the LS limit comparator turns over, and the MP2333H enters over-current protection (OCP) mode, the HS-FET waits until the valley current limit is removed before turning on again. Meanwhile, the output voltage drops until V_{FB} is below the under-voltage (UV) threshold. Once UV is triggered, the MP2333H enters hiccup mode to restart the part periodically.

In OCP, the device attempts to recover from the over-current (OC) fault with hiccup mode. In hiccup mode, the chip disables the output power stage, discharges the soft start, and attempts to soft start again automatically. If the OC condition still remains after the soft start ends, the device repeats this operation cycle until the OC condition is removed and the output rises back to the regulation level. OCP is a non-latch protection.

Power Good (PG)

Power good (PG) indicates whether the output voltage is in the normal range or not compared to the internal reference voltage. PG is an open-drain structure and requires an external pull-up supply. During power-up, the power good output is pulled low. This indicates to the system to remain off and keep the load on the output to a minimum. This helps reduce inrush current during start-up.

When the output voltage is higher than 92% and lower than 120% of the internal reference voltage and the soft start is finished, the power good signal is pulled high. When the output voltage is lower than 87% after the soft start finishes, the PG signal remains low. When the output voltage is higher than 120% of the internal reference, PG is switched low. The PG signal rises high again after the output voltage drops below 107% of the internal reference voltage.

The PG output is pulled low when EN is low, V_{IN} is low, or OCP or over-temperature protection (OTP) is triggered.

Pre-Bias Start-Up

The MP2333H is designed for monotonic start-up into pre-biased loads. If the output is pre-biased to a certain voltage during start-up, the BST voltage is refreshed and charged, and the voltage on the soft start is charged as well. If the BST voltage exceeds its rising threshold voltage, and $V_{SS}/2$ exceeds the sensed output voltage at FB, the part begins working normally.

T_{ON} Extension Operation

To improve dropout, the MP2333H is designed to extend the on time when the minimum off time is reached. The HS-FET on time extends, and the frequency drops. The typical minimum frequency is 280kHz. When the frequency drops to 280kHz, the frequency cannot reduce further, and the duty cycle reaches the max duty cycle (Dmax). If the input voltage continues to drop, the MP2333H works at the max duty cycle, and the output voltage drops. The typical Dmax is 95%.

Thermal Shutdown

Thermal shutdown prevents the chip from operating at exceedingly high temperatures. When the silicon die temperature exceeds 150°C, the entire chip shuts down. When the temperature falls below its lower threshold (typically 130°C), the chip is enabled again.

Floating Driver and Bootstrap Charging

An external bootstrap capacitor powers the floating power MOSFET driver. This floating driver has its own UVLO protection with a rising threshold of 2.2V and a hysteresis of 150mV. V_{IN} regulates the bootstrap capacitor voltage internally through D1, M1, R4, C3, L1, and C2 (see Figure 3). If $V_{IN} - V_{SW}$ exceeds 3.3V, U2 regulates M1 to maintain a 3.3V BST voltage across C3.

Figure 3: Internal Bootstrap Charger

Start-Up and Shutdown

If both V_{IN} and EN exceed their respective thresholds, the chip starts up. The reference block starts first, generating a stable reference voltage and current, and then the internal regulator is enabled. The regulator provides a stable supply for the remaining circuits.

Three events can shut down the chip: EN low, V_{IN} low, and thermal shutdown. The shutdown procedure starts by blocking the signaling path initially to avoid any fault triggering. The internal supply rail is then pulled down.

APPLICATION INFORMATION

Setting the Output Voltage

An external resistor divider is used to set the output voltage. First, choose a value for R2. R2 should be chosen reasonably, since a small R2 leads to considerable quiescent current loss, but a large R2 makes FB noise-sensitive. Typically, an R2 value between 5 - 30μA provides a good balance between system stability and no-load loss. Then determine R1 with Equation (2):

$$R1 = \frac{V_{OUT} - V_{REF}}{V_{REF}} \times R2 \quad (2)$$

The feedback circuit is shown in Figure 4.

Figure 4: Feedback Network

Table 1 and Table 2 list the recommended parameters for common output voltages.

Table 1: Parameter Selection for Common Output Voltages, $V_{IN} = 12V$ ⁽⁹⁾

V_{OUT} (V)	R1 (kΩ)	R2 (kΩ)	RT (kΩ)	L (μH)
1.0	33	133	30	1
1.2	40.2	82	30	1
1.5	40.2	45.3	30	1.2
1.8	40.2	32.4	20	1.2
2.5	40.2	19.1	20	1.5
3.3	40.2	13	20	1.5
5	40.2	7.68	10	2.2

NOTE:

- 9) Different output inductor values and output capacitor values may affect the selection of R1, R2, and RT. For additional component parameters, refer to the Typical Application Circuits on page 17 to page 19.

Table 2: Parameter Selection for Common Output Voltages, $V_{IN} = 5V$

V_{OUT} (V)	R1 (kΩ)	R2 (kΩ)	RT (kΩ)	L (μH)
1.0	33	133	30	0.47
1.2	40.2	82	30	0.68
1.5	40.2	45.3	30	0.68
1.8	40.2	32.4	20	0.68
2.5	40.2	19.1	20	0.68
3.3	40.2	13	40.2	0.47
5 ⁽¹⁰⁾	40.2	7.68	10	0.68

NOTE:

- 10) For $V_{OUT} = 5V$, V_{IN} should be no lower than 6.5V.

Selecting the Inductor

An inductor is necessary for supplying constant current to the output load while being driven by the switched input voltage. A larger-value inductor results in less ripple current and a lower output ripple voltage but also has a larger physical footprint, higher series resistance, and lower saturation current. A good rule for determining the inductance value is to design the peak-to-peak ripple current in the inductor to be in the range of 30 - 60% of the maximum output current. The peak inductor current should be below the maximum switch current limit. The inductance value can be calculated with Equation (3):

$$L = \frac{V_{OUT}}{F_{SW} \times \Delta I_L} \times \left(1 - \frac{V_{OUT}}{V_{IN}}\right) \quad (3)$$

Where ΔI_L is the peak-to-peak inductor ripple current.

The inductor should not saturate under the maximum inductor peak current, where the peak inductor current can be calculated with Equation (4):

$$I_{LP} = I_{OUT} + \frac{V_{OUT}}{2F_{SW} \times L} \times \left(1 - \frac{V_{OUT}}{V_{IN}}\right) \quad (4)$$

Selecting the Input Capacitor

The input current to the step-down converter is discontinuous and therefore requires a capacitor to supply AC current to the step-down converter while maintaining the DC input voltage. For the best performance, use ceramic capacitors placed as close to IN as possible. Capacitors with X5R and X7R ceramic dielectrics are recommended because they are fairly stable with temperature fluctuations.

The capacitors must also have a ripple current rating greater than the maximum input ripple current of the converter. The input ripple current can be estimated with Equation (5):

$$I_{CIN} = I_{OUT} \times \sqrt{\frac{V_{OUT}}{V_{IN}} \times \left(1 - \frac{V_{OUT}}{V_{IN}}\right)} \quad (5)$$

The worst-case condition occurs at $V_{IN} = 2V_{OUT}$, shown in Equation (6):

$$I_{CIN} = \frac{I_{OUT}}{2} \quad (6)$$

For simplification, choose an input capacitor with an RMS current rating greater than half of the maximum load current.

The input capacitance value determines the input voltage ripple of the converter. If there is an input voltage ripple requirement in the system, choose an input capacitor that meets the specification.

The input voltage ripple can be estimated with Equation (7):

$$\Delta V_{IN} = \frac{I_{OUT}}{F_{SW} \times C_{IN}} \times \frac{V_{OUT}}{V_{IN}} \times \left(1 - \frac{V_{OUT}}{V_{IN}}\right) \quad (7)$$

The worst-case scenario occurs at $V_{IN} = 2V_{OUT}$, shown in Equation (8):

$$\Delta V_{IN} = \frac{1}{4} \times \frac{I_{OUT}}{F_{SW} \times C_{IN}} \quad (8)$$

Selecting the Output Capacitor

An output capacitor is required to maintain the DC output voltage. Ceramic or POSCAP capacitors are recommended. The output voltage ripple can be estimated with Equation (9):

$$\Delta V_{OUT} = \frac{V_{OUT}}{F_{SW} \times L} \times \left(1 - \frac{V_{OUT}}{V_{IN}}\right) \times \left(R_{ESR} + \frac{1}{8 \times F_{SW} \times C_{OUT}}\right) \quad (9)$$

In the case of ceramic capacitors, the impedance at the switching frequency is dominated by the capacitance. The output voltage ripple is caused mainly by the capacitance.

For simplification, the output voltage ripple can be estimated with Equation (10):

$$\Delta V_{OUT} = \frac{V_{OUT}}{8 \times F_{SW}^2 \times L \times C_{OUT}} \times \left(1 - \frac{V_{OUT}}{V_{IN}}\right) \quad (10)$$

The output voltage ripple caused by the ESR is very small. In the case of POSCAP capacitors, the ESR dominates the impedance at the switching frequency. For simplification, the output ripple can be approximated with Equation (11):

$$\Delta V_{OUT} = \frac{V_{OUT}}{F_{SW} \times L} \times \left(1 - \frac{V_{OUT}}{V_{IN}}\right) \times R_{ESR} \quad (11)$$

Choose a larger output capacitor for a better load transient response, but be sure to consider the maximum output capacitor limitation in the design application. If the output capacitor value is too high, the output voltage cannot reach the design value during the soft-start time and will fail to regulate. The maximum output capacitor value (C_{O_MAX}) can be limited approximately with Equation (12):

$$C_{O_MAX} = (I_{LIM_AVG} - I_{OUT}) \times T_{SS} / V_{OUT} \quad (12)$$

Where I_{LIM_AVG} is the average start-up current during the soft-start period, and T_{SS} is the soft-start time.

PCB Layout Guidelines

Efficient PCB layout of the switching power supplies is critical for stable operation. A poor layout design can result in poor line or load regulation and stability issues. For best results, refer to Figure 5 and follow the guidelines below.

1. Place the high-current paths (GND, VIN, and SW) as close to the device as possible with short, direct, and wide traces.
2. Place the input capacitor as close to IN and GND as possible (recommended within 1mm).
3. Place the external feedback resistors next to FB.
4. Keep the switching node (SW) short and away from the feedback network.

Компания «ЭлектроПласт» предлагает заключение долгосрочных отношений при поставках импортных электронных компонентов на взаимовыгодных условиях!

Наши преимущества:

- Оперативные поставки широкого спектра электронных компонентов отечественного и импортного производства напрямую от производителей и с крупнейших мировых складов;
- Поставка более 17-ти миллионов наименований электронных компонентов;
- Поставка сложных, дефицитных, либо снятых с производства позиций;
- Оперативные сроки поставки под заказ (от 5 рабочих дней);
- Экспресс доставка в любую точку России;
- Техническая поддержка проекта, помощь в подборе аналогов, поставка прототипов;
- Система менеджмента качества сертифицирована по Международному стандарту ISO 9001;
- Лицензия ФСБ на осуществление работ с использованием сведений, составляющих государственную тайну;
- Поставка специализированных компонентов (Xilinx, Altera, Analog Devices, Intersil, Interpoint, Microsemi, Aeroflex, Peregrine, Syfer, Eurofarad, Texas Instrument, Miteq, Cobham, E2V, MA-COM, Hittite, Mini-Circuits, General Dynamics и др.);

Помимо этого, одним из направлений компании «ЭлектроПласт» является направление «Источники питания». Мы предлагаем Вам помощь Конструкторского отдела:

- Подбор оптимального решения, техническое обоснование при выборе компонента;
- Подбор аналогов;
- Консультации по применению компонента;
- Поставка образцов и прототипов;
- Техническая поддержка проекта;
- Защита от снятия компонента с производства.
