2 Overview

This datasheet describes PolarFire® FPGA device characteristics with industrial temperature range (–40 °C to 100 °C T_J) and extended commercial temperature range (0 °C to 100 °C T_J). The devices are provided with a standard speed grade (STD) and a –1 speed grade with higher performance. The FPGA core supply V_{DD} can operate at 1.0 V for lower-power or 1.05 V for higher performance. Similarly, the transceiver core supply V_{DDA} can also operate at 1.0 V or 1.05 V. Users select the core operating voltage while creating the Libero project.

Table 7 • Minimum and Maximum Rise and Fall times

Parameter	Symbol	Min	Max	Unit	Maximum frequency	Condition
Input rise time[1,4]	T_{RISE}	200 ps[2,3]	10% bit period	ps	100 KHz	Not to exceed 1 µs

			20% bit period	ps	50 MHz	Not to exceed 50 ns

1. Voltage ramp must be monotonic. For single-ended IO standards, input rise time is specified from 10%–90% of VDDIx and input fall time is specified from 90%–10% of VDDIx. For voltage referenced and differential IO configurations, ramp times must always comply with I/O standard requirements to ensure compliance.
2. Input slew rates must be controlled to never exceed PAD overshoot/undershoot requirements. Input pad overshoot and undershoot specifications are shown in section Maximum Allowed Overshoot and Undershoot (see page 10).
3. Rise and fall times in this table are for unterminated inputs. When inputs are terminated, minimum ramp time is not restricted. Recommended minimum ramp time is 25% of bit period, not to exceed a rate of 5 V/ns.
4. Ramp times must not exceed I/O standard requirements to ensure compliance.

6.2.2 Maximum Allowed Overshoot and Undershoot

The following table lists the maximum AC input voltage (V_{IN}) overshoot duration for HSIO.

During transitions, input signals may overshoot and undershoot the voltage listed as follows. Input currents must be limited to less than 100 mA per latch-up specifications.

The maximum overshoot duration is specified as a high-time percentage over the lifetime of the device. A DC signal is equivalent to 100% of the duty-cycle.

6.2.2.2 Hot Socketing

The following table lists the hot socketing DC characteristics over recommended operating conditions.

Table 13 • Hot Socketing DC Characteristics over Recommended Operating Conditions

Parameter	Symbol	Min	Typ	Max	Unit	Condition
Current per transceiver Rx input pin (P or N single-ended)[1, 2]	I_{XCVRRX_HS}			±4	mA	V_{DDA} = 0 V
Current per transceiver Tx output pin (P or N single-ended)[3]	I_{XCVRTX_HS}			±10	mA	V_{DDA} = 0 V
Current per transceiver reference clock input pin (P or N single-ended)[4]	$I_{XCVRREF\_HS}$			±1	mA	$V_{DD\_XCVR\_CLK}$ = 0 V
Current per GPIO pin (P or N single-ended)[5]	I_{GPIO_HS}			±1	mA	V_{DDIx} = 0 V
Current per HSIO pin (P or N single-ended)						Hot socketing is not supported in HSIO.

1. Assumes device is powered-down, all supplies are grounded, AC-coupled interface, and input pin pairs are driven by a CML driver at the maximum amplitude (1 V pk–pk) that is toggling at any rate with PRBS7 data.
2. Each P and N transceiver input has less than the specified maximum input current.
3. Each P and N transceiver output is connected to a 40 Ω resistor (50 Ω CML termination—20% tolerance) to the maximum allowed output voltage (V_{DDAmax} + 0.3 V = 1.4 V) through an AC-coupling capacitor with all PolarFire device supplies grounded. This shows the current for a worst-case DC coupled interface. As an AC-coupled interface, the output signal will settle at ground and no hot socket current will be seen.
4. $V_{DD\_XCVR\_CLK}$ is powered down and the device is driven to $-0.3\ V < V_{IN} < V_{DD\_XCVR\_CLK}$.
5. V_{DDIx} is powered down and the device is driven to $-0.3\ V < V_{IN} <$ GPIO V_{DDImax}.

Note: The following dedicated pins do not support hot socketing: TMS, TDI, TRSTB, and DEVRST_N.

Weak pull-up (as specified in GPIO) is always enabled.

6.3 Input and Output

The following section describes DC I/O levels, differential and complementary differential DC I/O levels, HSIO and GPIO on-die termination specifications, and LVDS specifications.

1. V_{OH} is the single-ended high-output voltage.
2. The total DC sink/source current of all I/Os within a lane is limited as follows:
   a. HSIO lane: 120 mA per 12 I/O buffers.
   b. GPIO lane: 160 mA per 12 I/O buffers.
3. V_{OH_MAX} is based on external pull-up termination (pseudo-open drain).
4. I_{OL}/I_{OH} units for impedance standards are in amps (not mA).

1. Measurements are made at typical, minimum, and maximum V_{REF} values. Reported delays reflect worst-case of these measurements. V_{REF} values listed are typical. Input waveform switches between V_{IL} and V_{IH}. All rise and fall rates must be 1 V/ns for non-mixed mode input buffers as one-third the minimum period for mixed-mode input buffers.
2. Differential receiver standards all use 250 mV V_{ID} for timing. V_{CM} is different between different standards.
3. Input voltage level from which measurement starts.
4. The value given is the differential input voltage.
5. This is an input voltage reference that bears no relation to the V_{REF}/V_{MEAS} parameters found in IBIS models or shown in the figure Output Delay Measurement—Single-Ended Test Setup (see page 29).
6. Emulated bidirectional interface.

The following table describes clocking specifications from –40 °C to 100 °C.

Table 39 • High-Speed I/O Clock Characteristics (–40 °C to 100 °C)

High-speed I/O clock F_{MAX}	F_{MAXB}	1000	1250	1000	1250	MHz	HSIO and GPIO
High-speed I/O clock skew[1]	F_{SKEWB}	30	20	30	20	ps	HSIO without bridging
	F_{SKEWB}	See table HSIO Clock Skew with Bridging (see page 39)				ps	HSIO with bridging
	F_{SKEWB}	45	35	45	35	ps	GPIO without bridging
	F_{SKEWB}	75	60	75	60	ps	GPIO with bridging
High-speed I/O clock duty cycle distortion[2]	T_{DCB}	90	90	90	90	ps	HSIO without bridging
	T_{DCB}	115	115	115	115	ps	HSIO with bridging
	T_{DCB}	90	90	90	90	ps	GPIO without bridging
	T_{DCB}	115	115	115	115	ps	GPIO with bridging

1. F_{SKEWB} is the worst-case clock-tree skew observable between sequential I/O elements. Clock-tree skew is significantly smaller at I/O registers close to each other because they are fed by the same or adjacent clock-tree branches. Use the Microsemi Timing Analyzer tool to evaluate clock skew specific to the design.

2. Parameters listed in this table correspond to the worst-case duty cycle distortion observable at the I/O flip flops. IBIS should be used to calculate any additional duty cycle distortion that might be caused by asymmetrical rise/fall times for any I/O standard.

The following table describes high-speed I/O clock skew (F_{SKEWB}) with bridging from –40 °C to 100 °C.

Note: F_{SKEWB} is the worst-case clock-tree skew observable between sequential I/O elements. Clock-tree skew is significantly smaller at I/O registers close to each other and fed by the same or adjacent clock-tree branches. Use the Microsemi Timing Analyzer tool to evaluate clock skew specific to the design.

1. NNW source designates bridging that originates from the North West Corner or PIOs inside I/O bank 0 (the most western I/O bank at the north edge).
2. NNE source designates bridging that originates from the North East Corner or PIOs inside I/O bank 1 (the most eastern I/O bank at the north edge).

6. Unlock occurs if two cycles slip within LOCKCOUNT/4 PFD cycles.

PLL is configured with internal feedback enabled and in integer mode. FPGA fabric is active during testing (75% utilization).

Note: In order to meet all datasheet specifications, the PLL must be programmed such that the PLL Loop Bandwidth < (0.0017 * VCO Frequency) – 0.4863 MHz. The Libero PLL configuration tool will enforce this rule when creating PLL configurations.

7.4.3 Transceiver Reference Clock I/O Standards

The following differential I/O standards are supported as transceiver reference clocks.

- LVDS25/33
- HCLS25 (for PCIe)
- RSDS25/33
- MINILVDS25/33
- SUBLVDS25/33
- PPDS25/33
- SLVS25/33
- BUSLVDS25
- MLVDS25
- LVPECL33
- MIPI25

For DC input levels, see table Differential DC Input and Output Levels.

Note: The transceiver reference clock differential receiver supports V_{ICM} common mode.

Note: The amount of jitter from the input receiver increases at common modes of less 0.2 V or greater than VDDSREF–0.4 V. Therefore, for improved SerDes operation, it is recommended that the V_{CM} of the signal into the SerDes reference clock input be at a minimum of 0.2 V and below VDDSREF–0.4 V.

The following single-ended I/O standards are supported as transceiver reference clocks.

- LVTTL
- LVCMOS33
- LVCMOS25
- LVCMOS18
- SSTL25I/II
- SSTL18I/II
- HSUL18I/II

For DC input levels, see table DC Input and Output Levels.

Note: Generally, Hysteresis = Off is recommended. In extremely high noise systems with degraded reference clock input, Hysteresis = On may improve results.

7.4.4 Transmitter Performance

The following tables describe performance of the transmitter.

Table 52 • Transceiver Reference Clock Input Termination

1. Increased DC common mode settings above 50% reduce allowed V_{OD} output swing capabilities.
2. Adjustable through transmit emphasis.
3. With estimated package differences.
4. Single PLL applies to all four lanes in the same quad location with the same T xPLL. Multiple PLL applies to N lanes using multiple TxPLLs from different quad locations.
5. Improved jitter characteristics for a specific industry standard are possible in many cases due to improved reference clock or higher V_{CO} rate used.
6. Tx jitter is specified with all transmitters on the device enabled, a 10–12-bit error rate (BER) and Tx data pattern of PRBS7.
7. From the PMA mode, the TX_ELEC_IDLE port to the XVCR TXP/N pins.
8. FTxRefClk = 75 MHz with typical settings.
9. For data rates greater than 10.3125 Gbps, VDDA must be set to 1.05 V mode. See supply tolerance in the section Recommended Operating Conditions (see page 7).
10. Transmit alignment in this case will automatically align upon the TX PLL obtaining lock. For details on transmit alignment, see UG0677: PolarFire FPGA Transceiver User Guide.
11. In order to obtain the required alignment for these configurations, an FPGA fabric TX alignment circuit must be implemented. For details on transmit alignment, see UG0677: PolarFire FPGA Transceiver User Guide.
12. Re fclk skew is the amount of skew between the reference clocks of the two PLL.
13. Jitter decomposition can be found in the protocol characterization reports.

1. Valid at 3.2 Gbps and below.
2. Data vs Rx reference clock frequency.
3. Achieves compliance with PCIe electrical idle detection.
4. Achieves compliance with SATA OOB specification.
5. Rx jitter values based on bit error ratio (BER) of 10–12, AC-coupled input with 400 mV V_{ID}, all stages of Rx CTLE enabled, DFE disabled, 80 MHz sinusoidal jitter injected to Rx data.
6. Rx jitter values based on bit error ratio (BER) of 10–12, AC-coupled input with 400 mV V_{ID}, all stages of Rx CTLE enabled, DFE enabled, 80 MHz sinusoidal jitter injected to Rx data.
7. For PCIe: Low Threshold Setting= 0, High Threshold Setting= 2.
8. For SATA: Low Threshold Setting= 2, High Threshold Setting= 3.
9. Loss of signal is valid for data rates of 1 Gbps to 5 Gbps for PRBS7 (8B/10B) or PRBS31 (64b/6xb) data formats. It is also valid for detection of SATA out-of-band signals at data rates up to 6 Gbps. If the default settings for the low threshold (0x0) and high threshold (0x2) using the low range option for the peak detector are used, then the Rx $V_{Amplitude}$ pk-pk (outside of data eye) at the receiver input package pins must be a minimum of 300 mV for short reach (6.5 dB insertion loss at 5 GHz) applications, 350 mV for medium reach (17.0 dB insertion loss at 5 GHz) applications, and 450 mV for long reach (25.0 dB insertion loss at 5 GHz) applications—generally the settings are less limiting than what is required for good BER operation of the SerDes. Note that if the option to force CDR Lock2Ref upon Rx Idle is set (default at data rates of 5 Gbps and below), this minimum $V_{Amplitude}$ pk-pk must be enforced for proper CDR operation.
10. Detect values measured at 1.5 Gbps with PRBS7 data pattern.
11. For data rates greater than 10.3125 Gbps, VDDA must be set to 1.05 V mode. See supply tolerance in the section Recommended Operating Conditions (see page 7).
12. $T_{HGSTATE}$ is based on the condition where the CDR was in lock (to reference or data) for at least 5.2 µs before moving to the high-gain state. At this point, if the receive data is outside the ppm tolerance of the CDR, the CDR will unlock after the time specified by the parameter.
13. The following definitions apply:
    a. T_{CDRREF} is the transceiver CDR reference clock period in nanoseconds.
    b. $W_{XCVRFABRX}$ is the parallel interface width of the transceiver receive fabric interface.
    c. CDR_{FBDIV} is the feedback divider of the transceiver.
    d. $CDR_{CDRREFDIV}$ is the reference divider of the transceiver CDR.

7.6.4 Digest Cycles

Digests verify the integrity of the programmed non-volatile data. Digests are a cryptographic hash of various data areas. Any digest that reports back an error raises the digest tamper flag.

Table 86 • Maximum Number of Digest Cycles

		Retention Since Programmed (N = Number Digests During that Time)[1]								
Digest T_J	Storage and Operating T_J	N ≤300	N = 500	N = 1000	N = 1500	N = 2000	N = 4000	N = 6000	Unit	Retention
–40 to 100	–40 to 100	20 × LF	17 × LF	12 × LF	10 × LF	8 × LF	4 × LF	2 × LF	°C	Years
–40 to 100	0 to 100	20 × LF	17 × LF	12 × LF	10 × LF	8 × LF	4 × LF	2 × LF	°C	Years

–40 to 55	–40 to 55	20 × LF	20 × LF	20 × LF	20 × LF	20 × LF	20 × LF	20 × LF	°C	Years

1. LF = Lifetime factor as defined by the number of programming cycles the device has seen under the conditions listed in the following table.

Table 87 • FPGA Programming Cycles Lifetime Factor

Programming T_J	Programming Cycles	LF
–40 °C to 100 °C	500	1
–40 °C to 85 °C	1000	0.8
–40 °C to 55 °C	2000	0.6

Notes:

- The maximum number of device digest cycles is 100K.
- Digests are operational only over the –40 °C to 100 °C temperature range.
- After a program cycle, an additional N digests cycles are allowed with the resultant retention characteristics for the total operating and storage temperature shown.
- Retention is specified for total device storage and operating temperature.
- All temperatures are junction temperatures (T_J).
- Example 1—500 digests cycles are performed between programming cycles. N = 500. The operating conditions are –40 °C to 85 °C T_J. 501 programming cycles have occurred. The retention under these operating conditions is 20 × LF = 20 × .8 = 16 years.
- Example 2—one programming cycle has occurred, N = 1500 digest cycles have occurred. Temperature range is –40 °C to 100 °C. The resultant retention is 10 × LF or 10 years over the industrial temperature range.

2. SmartFusion2 with MSS running at 100 MHz, MSS_SPI_0 port r unning at 6.67 MHz. Bitstream stored in DDR. DirectC version 4.1.

Notes:

- Standalone verify is limited to 2,000 total device hours over the industrial –40 °C to 100 °C temperature.
- Use the digest system service, for verify device time more than 2,000 hours.
- Standalone verify checks the programming margin on both the P and N gates of the push-pull cell.
- Digest checks only the P side of the push-pull gate. However, the push-pull gates work in tandem. Digest check is recommended if users believe they will exceed the 2,000-hour verify time specification.

7.8.4 Tamper Detectors

The following section describes tamper detectors.

Table 103 • ADC Conversion Rate

Parameter	Description	Min	Typ[1]	Max	Unit
T_{CONV1}	Time from enable changing from zero to non-zero value to first conversion completes. Minimum value applies when POWEROFF = 0.	350		470	µs
T_{CONVN}	Time between subsequent channel conversions.		480		µs
T_{SETUP}	Data channel and output to valid asserted. Data is held until next conversion completes, that is >480 µs.	0			ns
T_{VALID}[2]	Width of the valid pulse.	1.5		2.5	µs
T_{RATE}	Time from start of first set of conversions to the start of the next set. Can be considered as the conversion rate. Is set by the conversion rate parameter.		Rate × 32		µs

1. Min, typ, and max refer to variation due to functional configuration and the raw TVS value. The actual internal correction time will vary based on the raw TVS value.
2. The pulse width varies depending on the time taken to complete the internal calibration multiplication, this can be up to 375 ns.

Note: Once the TVS block is active, the enable signal is sampled 25 ns before the falling edge of valid. The next enabled channel in the sequence 0-1-2-3 is started; that is, if channel 0 has just completed and only channels 0 and 3 are enabled, the next channel will be 3. When all the enabled channels in the sequence 0-1-2-3 are completed, the TVS waits for the conversion rate timer to expire. The enable signal may be changed at any time if it changes to 4'b0000 while valid is asserted (and 25 ns before valid is de-asserted), then no further conversions will be started.

1. The timing does not impact the user design, but it is useful for security analysis.
2. System service requests from the fabric will interrupt the system controller delaying the generation of the flag.
3. Timing of these depends highly on supply ramp rate.

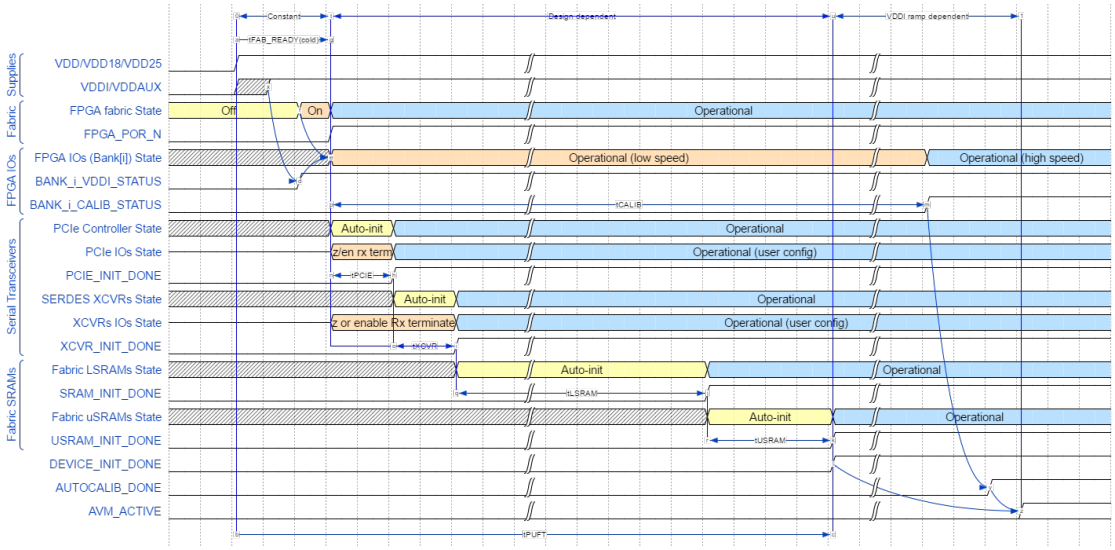
7.9 Power-Up to Functional Timing

Microsemi non-volatile FPGA technology offers the fastest boot-time of any mid-range FPGA in the market. The following tables describes both cold-boot (from power-on) and warm-boot (assertion of DEVRST_N pin or assertion of reset from the tamper macro) timing. The power-up diagrams assume all power supplies to the device are stable.

7.9.1 Power-On (Cold) Reset Initialization Sequence

The following cold reset timing diagram shows the initialization sequencing of the device.

Figure 8 • Cold Reset Timing



Notes:

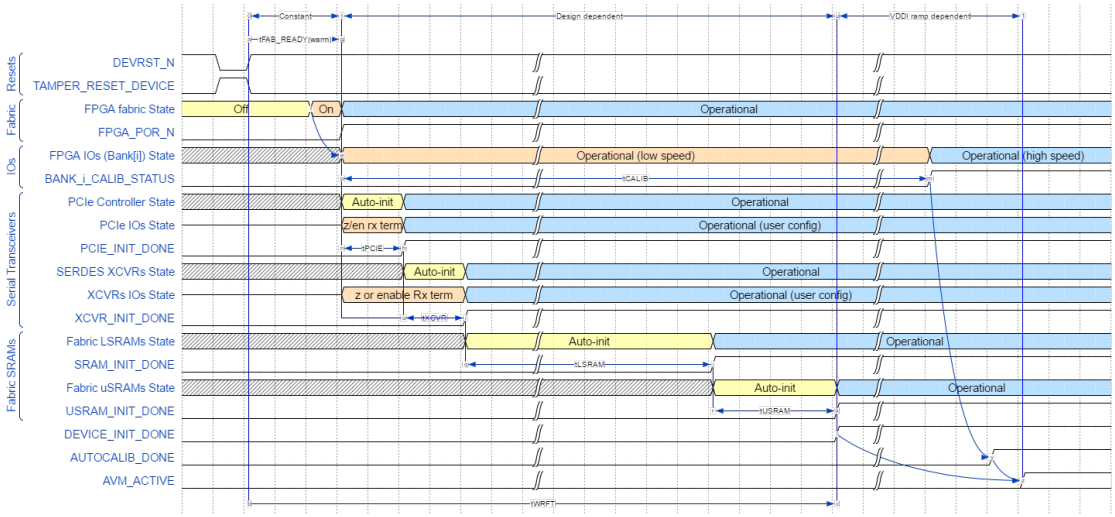
- The previous diagram shows the case where VDDI/VDDAUX of I/O banks are powered either before or sufficiently soon after VDD/VDD18/VDD25 that the I/O bank enable time is measured from the assertion time of VDD/VDD18/VDD25 (that is, the PUFT specification). If VDDI/VDDAUX of I/O banks are powered sufficiently after VDD/VDD18/VDD25, then the I/O bank enable time is measured from the assertion of VDDI/VDDAUX and is not specified by the PUFT specification. In this case, I/O operation is indicated by the assertion of BANK_i_VDDI_STATUS, rather than being measured relative to FABRIC_POR_N negation.
- AUTOCALIB_DONE assertion indicates the completion of calibration for any I/O banks specified by the user for auto-calibration. AUTOCALIB_DONE asserts independently of DEVICE_INIT_DONE. It may assert before or after DEVICE_INIT_DONE and is determined by the following:
  - How long after VDD/VDD18/VDD25 that VDDI/VDDAUX are powered on. Note that if any of the user-specified I/O banks are not powered on within the auto-calibration timeout window, then AUTOCALIB_DONE doesn't assert until after this timeout.
  - The specified ramp times of VDDI of each I/O bank designated for auto-calibration.
  - How much auto-initialization is to be performed for the PCIe, SERDES transceivers, and fabric LSRAMs.
- If any of the I/O banks specified for auto-calibration do not have their VDDI/VDDAUX powered on within the auto-calibration timeout window, then it will be approximately auto-calibrated whenever VDDI/VDDAUX is subsequently powered on. To obtain an accurate calibration however, on such IO banks, it is necessary to initiate a re-calibration (using CALIB_START from fabric).

- AVM_ACTIVE only asserts if avionics mode is being used. It is asserted when the later of DEVICE_INIT_DONE or AUTOCALIB_DONE assert.

7.9.2 Warm Reset Initialization Sequence

The following warm reset timing diagram shows the initialization sequencing of the device when either DEVRST_N or TAMPER_RESET_DEVICE signals are asserted.

Figure 9 • Warm Reset Timing



7.9.3 Power-On Reset Voltages

The following sections describe the power-on reset voltages.

7.9.3.1 Main Supplies

The start of power-up to functional time (T_{PUFT}) is defined as the point at which the latest of the main supplies (VDD, VDD18, VDD25) reach the reference voltage levels specified in the following table. This starts the process of releasing the reset of the device and powering on the FPGA fabric and IOs.

Table 110 • POR Ref Voltages

Supply	Power-On Reset Start Point (V)	Note
VDD	0.95	Applies to both 1.0 V and 1.05 V operation.
VDD18	1.71	
VDD25	2.25	

7.9.3.2 I/O-Related Supplies

For the I/Os to become functional (for low speed, sub-400 MHz operation), the (per-bank) I/O supplies (VDDI, VDDAUX) must reach the trip point voltage levels specified in the following table and the main supplies above must also be powered on.

Table 111 • I/O-Related Supplies

Supply	I/O Power-Up Start Point (V)
VDDI	0.85
VDDAUX	1.6

There are no sequencing requirements for the power supplies. However, VDDI3 and must be valid at same time as the main supplies. The other I/O supplies (VDDI, VDDAUX) have no effect on power-up of FPGA fabric (that is, the fabric still powers up even if the I/O supplies of some I/O banks remain powered off).

7.9.4 User Design Dependence of Power-Up Times

Some phases of the device initialization are user design dependent, as the device automatically initializes certain resources to user-specified configurations if those resources are used in the design. It is necessary to compute the overall power-up to functional time by referencing the following tables and adding the relevant phases, according to the design configuration. The following equation refers to timing parameters specified in the above timing diagrams. Please note T_{PCIE} , T_{XCVR}, T_{LSRAM}, and T_{USRAM} can be found in the PolarFire FPGA device power-up and resets user guide UG0725.

$$T_{PUFT} = T_{FAB\_READY(cold)} + \max((T_{PCIE} + T_{XCVR} + T_{LSRAM} + T_{USRAM}), T_{CALIB})$$

$$T_{WRFT} = T_{FAB\_READY(warm)} + \max((T_{PCIE} + T_{XCVR} + T_{LSRAM} + T_{USRAM}), T_{CALIB})$$

Note: T_{PCIE}, T_{XCVR}, T_{LSRAM}, T_{USRAM}, and T_{CALIB} are common to both cold and warm reset scenarios.

Auto-initialization of FPGA (if required) occurs in parallel with I/O calibration. The device may be considered fully functional only when the later of these two activities has finished, which may be either one, depending on the configuration, as may be calculated from the following tables. Note that I/O calibration may extend beyond T_{PUFT} (as I/O calibration process is independent of main device power-on and is instead dependent on I/O bank supply relative power-on time and ramp times). The previous timing diagram for power-on initialization shows the earliest that I/Os could be enabled, if the I/O power supplies are powered on before or at the same time as the main supplies.

7.9.5 Cold Reset to Fabric and I/Os (Low Speed) Functional

The following table specifies the minimum, typical, and maximum times from the power supplies reaching the above trip point levels until the FPGA fabric is operational and the FPGA IOs are functional for low-speed (sub-400 MHz) operation.

Table 112 • Cold Boot

7.9.6 Warm Reset to Fabric and I/Os (Low Speed) Functional

The following table specifies the minimum, typical, and maximum times from the negation of the warm reset event until the FPGA fabric is operational and the FPGA IOs are functional for low-speed (sub-400 MHz) operation.

Table 113 • Warm Boot

Time when output pins start driving – $T_{OUT\_ACTIVE(warm)}$	0.70	1.68	2.67	ms

7.9.7 Miscellaneous Initialization Parameters

In the following table, T_{FAB_READY} refers to either $T_{FAB\_READY(cold)}$ or $T_{FAB\_READY(warm)}$ as specified in the previous tables, depending on whether the initialization is occurring as a result of a cold or warm reset, respectively.

Table 114 • Cold and Warm Boot

Parameter	Symbol	Min	Typ	Max	Unit	Condition

1. Programming depends on the PUF to power up. Refer to T_{PUF_OVHD} at section Secure NVM Performance (see page 74).

7.9.8 I/O Calibration

The following tables specify the initial I/O calibration time for the fastest and slowest supported VDDI ramp times of 0.2 ms to 50 ms, respectively. This only applies to I/O banks specified by the user to be auto-calibrated.

Table 115 • I/O Initial Calibration Time (TCALIB)

0.2 ms	0.98	2.63	Applies to HSIO and GPIO banks
50 ms	41.62	62.19	Applies to HSIO and GPIO banks

Notes:

- The user may specify any VDDI ramp time in the range specified above. The nominal initial calibration time is given by the specified VDDI ramp time plus 2 ms.
- In order for IO calibration to start, VDDI and VDDAUX of the I/O bank must be higher than the trip point levels specified in I/O-Related Supplies (see page 83).

HSIO bank	0.11	0.20	0.30	HSIO configured for 1.8 V operation

Note: In order to obtain fast re-calibration, the user must assert the relevant clock request signal from the FPGA fabric to the I/O bank controller.
