General Description

The APR3021/2/3 are designed to monitor voltage supplies in μ P and digital systems. The quiescent current is extremely low, typically 1.5 μ A, making it ideal for portable battery operated equipment. The APR3021/2/3 operate by monitoring the system power supply voltage. When the input voltage drops below a fixed threshold, the device asserts a reset signal for a fixed time period after V_{CC} rises above the fixed threshold. The APR3021/2/3 series is available with three output stage versions : APR3021 push-pull active low output, APR3022 push-pull active high output and APR3023 open drain active low output. They are also designed to reject fast line transient glitches on V_{CC} . The APR3021/2/3 are come in a miniature SOT-23, SOT-23-5, SOT-89 packages.

Application Information

V_{CC} Transient Rejection

The APR3021/2/3 have the function to reject the transient glitches from the power line. The Maximum Transient Duration vs. Reset Threshold Overdrive shows at Typical Characteristics. The transient voltage with the duration under the curve will not generate a reset signal, e.g. a transient of 100mV below the reset threshold voltage have the duration more than 35us, it will generate a reset signal. Connect a 0.1uF bypass capacitor to the V_{CC} pin can improve the transient immunity.

Figure 1. Ensuring RESET Valid to V_{CC} = 0 V

Reset Output

The APR3021/2/3 have 3 output stage versions: APR3001 is an active low push-pull output, when the V_{CC} drops below the reset threshold, the RESET output generates a low signal. APR3022 is an active high push-pull output, when the V_{CC} drops below the reset threshold, the RESET output generates a high signal (see Timing Chart). APR3023 is an active low open drain output, the RESET output must be connected a pull-up resistor to a supply voltage that is lower than 6V, it suits to use in multiple voltage systems (see Figure 2). The APR3021 RESET output is valid until the V_{CC}=1.2V, below 1.2V the IC is shutdown, and the output becomes a floating state. If it is a trouble, a resistor should be connected from reset output to ground to keep the reset output low (see Figure 1). For The APR3022, a pull-up resistor to V_{CC} is required to keep the valid reset output for V_{CC} below 1.2V.
