## FEATURES

JESD204B (Subclass 1) coded serial digital outputs
In band SFDR = 83 dBFS at 340 MHz ( $\mathbf{7 5 0} \mathbf{~ M S P S}$ )
In band SNR = $\mathbf{6 6 . 7} \mathbf{~ d B F S}$ at 340 MHz ( $\mathbf{7 5 0} \mathbf{~ M S P S ) ~}$
1.4 W total power per channel at 750 MSPS (default settings)

Noise density $=-153 \mathrm{dBFS} / \mathrm{Hz}$ at 750 MSPS
1.25 V, 2.5 V, and 3.3 V dc supply operation

Flexible input range
AD6674-750 and AD6674-1000
1.46 V p-p to 1.94 V p-p (1.70 V p-p nominal)

AD6674-500
1.46 V p-p to 2.06 V p-p (2.06 V p-p nominal)

95 dB channel isolation/crosstalk
Amplitude detect bits for efficient automatic gain control
(AGC) implementation
Noise shaping requantizer (NSR) option for main receiver function
Variable dynamic range (VDR) option for digital predistortion (DPD) function
2 integrated wideband digital processors per channel
12-bit numerically controlled oscillator (NCO), up to
4 cascaded half-band filters
Differential clock inputs
Integer clock divide by 1, 2, 4, or 8
Energy saving power-down modes
Flexible JESD204B lane configurations
Small signal dither

## APPLICATIONS

Diversity multiband, multimode digital receivers
3G/4G, TD-SCDMA, W-CDMA, GSM, LTE, LTE-A
DOCSIS 3.0 CMTS upstream receive paths
HFC digital reverse path receivers

## GENERAL DESCRIPTION

The AD6674 is a 385 MHz bandwidth mixed-signal intermediate frequency (IF) receiver. It consists of two, 14-bit 1.0 GSPS/750 MSPS/500 MSPS analog-to-digital converters (ADC) and various digital signal processing blocks consisting of four wideband DDCs, an NSR, and VDR monitoring. It has an on-chip buffer and a sample-and-hold circuit designed for low power, small size, and ease of use. This product is designed to support communications applications capable of sampling wide bandwidth analog signals of up to 2 GHz . The AD6674 is optimized for wide input bandwidth, high sampling rate, excellent linearity, and low power in a small package.
The dual ADC cores feature a multistage, differential pipelined architecture with integrated output error correction logic. Each ADC features wide bandwidth inputs supporting a variety of user-selectable input ranges. An integrated voltage reference eases design considerations.

12/14-Revision A: Initial Version

The analog input and clock signals are differential inputs. The ADC data outputs are internally connected to four DDCs through a crossbar mux. Each DDC consists of up to five cascaded signal processing stages: a 12-bit frequency translator (NCO), and up to four half-band decimation filters.

Each ADC output is connected internally to an NSR block. The integrated NSR circuitry allows improved SNR performance in a smaller frequency band within the Nyquist bandwidth. The device supports two different output modes selectable via the SPI. With the NSR feature enabled, the outputs of the ADCs are processed such that the AD6674 supports enhanced SNR performance within a limited portion of the Nyquist bandwidth while maintaining a 9 -bit output resolution. NSR is enabled by default on the AD6674.

Each ADC output is also connected internally to a VDR block. This optional mode allows full dynamic range for defined input signals. Inputs that are within a defined mask (based on DPD applications) are passed unaltered. Inputs that violate this defined mask result in the reduction of the output resolution.
With VDR, the dynamic range of the observation receiver is determined by a defined input frequency mask. For signals falling within the mask, the outputs are presented at the maximum resolution allowed. For signals exceeding defined power levels within this frequency mask, the output resolution is truncated. This mask is based on DPD applications and supports tunable real IF sampling, and zero IF or complex IF receive architectures.

Operation of the AD6674 between the DDC, NSR, and VDR modes is selectable via SPI-programmable profiles.
In addition to the DDC blocks, the AD6674 has several functions that simplify the AGC function in a communications receiver. The programmable threshold detector allows monitoring of the incoming signal power using the fast detect control bits in Register 0x245 of the ADC. If the input signal level exceeds the programmable threshold, the fast detect
indicator goes high. Because this threshold indicator has low latency, the user can quickly turn down the system gain to avoid an overrange condition at the ADC input. Besides the fast detect outputs, the AD6674 also offers signal monitoring capability. The signal monitoring block provides additional information about the signal being digitized by the ADC.
Users can configure the Subclasss 1 JESD204B-based high speed serialized output in a variety of two-lane and four-lane configurations, depending on the DDC configuration and the acceptable lane rate of the receiving logic device. Multidevice synchronization is supported through the SYSREF $\pm$ and SYNCINB $\pm$ input pins.
The AD6674 has flexible power-down options that allow significant power savings when desired. All of these features can be programmed using a 1.8 V capable 3 -wire serial port interface (SPI).
The AD6674 is available in a Pb-free, 64-lead LFCSP, specified over the $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ industrial temperature range. This product is protected by a U.S. patent.

## PRODUCT HIGHLIGHTS

1. Wide full power bandwidth supports IF sampling of signals up to 2 GHz .
2. Buffered inputs with programmable input termination eases filter design and implementation.
3. Four integrated wideband decimation filters and numerically controlled oscillator (NCO) blocks supporting multiband receivers.
4. Flexible SPI controls various product features and functions to meet specific system requirements.
5. Programmable fast overrange detection and signal monitoring.
6. Programmable fast overrange detection.
7. $9 \mathrm{~mm} \times 9 \mathrm{~mm} 64$-lead LFCSP.

## SPECIFICATIONS

## DC SPECIFICATIONS

AVDD1 $=1.25 \mathrm{~V}, \mathrm{AVDD} 2=2.5 \mathrm{~V}, \mathrm{AVDD} 3=3.3 \mathrm{~V}, \mathrm{AVDD} 1 \_\mathrm{SR}=1.25 \mathrm{~V}, \mathrm{DVDD}=1.25 \mathrm{~V}, \mathrm{DRVDD}=1.25 \mathrm{~V}, \mathrm{SPIVDD}=1.8 \mathrm{~V}$, specified maximum sampling rate, 1.0 V internal reference $\left(\mathrm{V}_{\text {REF }}\right), \mathrm{A}_{\text {IN }}=-1.0 \mathrm{dBFS}$, clock divider $=2$, default SPI settings, $\mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$, unless otherwise noted.

Table 1.

## AD6674

| Parameter | Temp | AD6674-1000 |  |  | AD6674-750 |  |  | AD6674-500 |  |  | Unit |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Min | Typ | Max | Min | Typ | Max | Min | Typ | Max |  |
| POWER CONSUMPTION |  |  |  |  |  |  |  |  |  |  |  |
| Total Power Dissipation ${ }^{2}$ | Full |  | 3.3 | 3.6 |  | 2.8 | 3.1 |  | 2.24 | 2.5 | W |
| Power-Down Dissipation | Full |  | 835 |  |  | 835 |  |  | 710 |  | mW |
| Standby ${ }^{6}$ | Full |  | 1.4 |  |  | 1.4 |  |  | 1.2 |  | W |

${ }^{1}$ Differential capacitance is measured between the VIN $+x$ and $\mathrm{VIN}-\mathrm{x}$ pins $(\mathrm{x}=\mathrm{A}, \mathrm{B})$.
${ }^{2}$ Measured with a low input frequency, full-scale sine wave.
${ }^{3}$ All lanes running. Power dissipation on DRVDD changes with lane rate and number of lanes used.
${ }^{4} \mathrm{~L}$ is the number of lanes per converter device (lanes per link).
${ }^{5} \mathrm{~N} /$ A means not applicable. At the maximum sample rate, it is not applicable to use $\mathrm{L}=2$ mode on the JESD204B output interface because this exceeds the maximum lane rate of 12.5 Gbps . $\mathrm{L}=2$ mode is supported when the equation $\left(\left(\mathrm{M} \times \mathrm{N}^{\prime} \times(10 / 8) \times\right.\right.$ fout $\left.) / \mathrm{L}\right)$ results in a lane rate that is $\leq 12.5 \mathrm{Gbps}$. fout is the output sample rate and is denoted by $\mathrm{f}_{\mathrm{s}} / D C M$, where $D C M=$ decimation ratio.
${ }^{6}$ Can be controlled by the SPI.

${ }^{1}$ The maximum sample rate is the clock rate after the divider.
${ }^{2}$ The minimum sample rate operates at 300 MSPS with $L=2$ or $L=1$.
${ }^{3}$ Baud rate $=1 /$ UI. A subset of this range can be supported.
${ }^{4}$ At full baud rate ( 12.5 Gbps ), each ADC outputs data on two differential pair lanes.
${ }^{5}$ Wake-up time is defined as the time required to return to normal operation from power-down mode or standby mode.

## TIMING SPECIFICATIONS

| Operating Temperature Range | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ |
| Junction Temperature Range | $-40^{\circ} \mathrm{C}$ to $+115^{\circ} \mathrm{C}$ |
| Storage Temperature Range | $-60^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| (Ambient) |  |

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

## THERMAL CHARACTERISTICS

Typical $\theta_{\mathrm{JA}}, \Psi_{\mathrm{JB}}$, and $\theta_{\mathrm{JC}}$ are specified vs. the number of printed circuit board (PCB) layers in different airflow velocities (in $\mathrm{m} / \mathrm{sec}$ ). Airflow increases heat dissipation, effectively reducing $\theta_{\text {IA }}$ and $\Psi_{\text {JB. }}$. In addition, metal in direct contact with the package leads and exposed pad from metal traces, through holes, ground, and power planes reduces the $\theta_{\text {IA }}$. Thermal performance for actual applications requires careful inspection of the conditions in an application. The use of appropriate thermal management techniques is recommended to ensure that the maximum junction temperature does not exceed the limits shown in Table 6.

## THEORY OF OPERATION

The AD6674 has two analog input channels and two JESD204B output lane pairs. The AD6674 is designed to sample wide bandwidth analog signals of up to 2 GHz . The AD6674 is optimized for wide input bandwidth, high sampling rate, excellent linearity, and low power in a small package.
The dual ADC cores feature a multistage, differential pipelined architecture with integrated output error correction logic. Each ADC features wide bandwidth inputs supporting a variety of user-selectable input ranges. An integrated voltage reference eases design considerations.
The AD6674 has several functions that simplify the AGC function in a communications receiver. The programmable threshold detector allows monitoring of the incoming signal power using the fast detect bits of the ADC output data stream, which are enabled and programmed via Register 0x245 through Register $0 \times 24 \mathrm{C}$. If the input signal level exceeds the programmable threshold, the fast detect indicator goes high. Because this threshold indicator has low latency, the user can quickly lower the system gain to avoid an overrange condition at the ADC input.
The Subclass 1 JESD204B-based high speed serialized output data rate can be configured in one-lane ( $\mathrm{L}=1$ ) and two-lane ( $\mathrm{L}=2$ ) configurations depending upon the sample rate and the decimation ratio. Multidevice synchronization is supported through the SYSREF $\pm$ and SYNCINB $\pm$ input pins.

## ADC ARCHITECTURE

The architecture consists of an input buffered pipelined ADC. The input buffer is designed to provide a termination impedance to the analog input signal. This termination impedance can be changed using the SPI to meet the termination needs of the driver/amplifier. The default termination value is set to $400 \Omega$. The equivalent circuit diagram of the analog input termination is shown in Figure 60. The input buffer is optimized for high linearity, low noise, and low power.
The input buffer provides a linear high input impedance (for ease of drive) and reduces the kickback from the ADC. The quantized outputs from each stage are combined into a final 16 -bit result in the digital correction logic. The pipelined architecture permits the first stage to operate with a new input sample while the remaining stages operate with preceding samples. Sampling occurs on the rising edge of the clock.

## ANALOG INPUT CONSIDERATIONS

The analog input to the AD6674 is a differential buffer. The internal common-mode voltage of the buffer is 2.05 V . The clock signal alternately switches the input circuit between sample mode and hold mode. When the input circuit is switched into sample mode, the signal source must be capable of charging the sample capacitors and settling within one-half of a clock cycle. A small resistor, in series with each input, can help reduce the peak transient current inserted from the output stage of the
driving source. In addition, low $Q$ inductors or ferrite beads can be placed on each section of the input to reduce high differential capacitance at the analog inputs and, thus, achieve the maximum bandwidth of the ADC. Such use of low Q inductors or ferrite beads is required when driving the converter front end at high IF frequencies. Place either a differential capacitor or two single-ended capacitors on the inputs to provide a matching passive network. This ultimately creates a low-pass filter at the input, which limits unwanted broadband noise. For more information, refer to the AN-742 Application Note, the AN-827 Application Note, and the Analog Dialogue article "TransformerCoupled Front-End for Wideband A/D Converters" (Volume 39, April 2005) at www.analog.com. In general, the precise values depend on the application.
For best dynamic performance, match the source impedances driving VIN +x and VIN -x such that common-mode settling errors are symmetrical. These errors are reduced by the common-mode rejection of the ADC. An internal reference buffer creates a differential reference that defines the span of the ADC core.

Maximum SNR performance is achieved by setting the ADC to the largest span in a differential configuration. In the case of the AD6674, the available span is programmable through the SPI port from 1.46 V p-p to 2.06 V p-p differential, with 1.70 V p-p differential being the default for the AD6674-1000 and AD6674-750, whereas the default for the AD6674-500 is 2.06 V p-p.

## Differential Input Configurations

There are several ways to drive the AD6674, either actively or passively. However, optimum performance is achieved by driving the analog input differentially.
For applications where SNR and SFDR are key parameters, differential transformer coupling is the recommended input configuration (see Figure 71 and Table 9) because the noise performance of most amplifiers is not adequate to achieve the true performance of the AD6674.
For low to midrange frequencies, it is recommended to use a double balun or double transformer network (see Figure 71) for optimum performance from the AD6674. For higher frequencies in the second or third Nyquist zone, it is better to remove some of the front-end passive components to ensure wideband operation (see Figure 71 and Table 9).

NOTES

## Input Common Mode

The analog inputs of the AD6674 are internally biased to the common mode, as shown in Figure 72. The common-mode buffer has limited range in that the performance suffers greatly if the common-mode voltage drops by more than 100 mV . Therefore, in dc-coupled applications, set the common-mode voltage to $2.05 \mathrm{~V} \pm 100 \mathrm{mV}$ to ensure proper ADC operation.

## Analog Input Controls and SFDR Optimization

The AD6674 offers flexible controls for the analog inputs such as input termination, input capacitance, buffer current, and input full-scale adjustment. All of the available controls are shown in Figure 72.

Figure 72. Analog Input Controls
Use Register 0x018, Register 0x019, Register 0x01A, Register 0x11A, Register 0x934, and Register 0x935 to adjust the buffer behavior on each channel to optimize the SFDR over various input frequencies and bandwidths of interest.
Input Buffer Control Registers (Register 0x018, Register 0x019, Register 0x01A, Register 0x934, Register 0x935, Register 0x11A)
The input buffer has many registers that set the bias currents and other settings for operation at different frequencies. These bias currents and settings can be changed to suit the input frequency range of operation. Register 0x018 controls the buffer bias current to reduce the effects of charge kickback from the ADC core. This setting can be scaled from a low setting of $1.0 \times$ to
a high setting of $8.5 \times$. The default setting in Register $0 \times 018$ is $3.0 \times$ for the AD6674-750 and AD6674-1000, whereas the default for the AD6674-500 is $2.0 \times$. These settings are sufficient for operation in the first Nyquist zone. As the input buffer currents are set, the amount of current required by the AVDD3 supply changes. This relationship is shown in Figure 73. For a complete list of buffer current settings, see Table 45 for more details.

Figure 73. IAvDD3 vs. Buffer Current Setting in Register 0x018
Register 0x019, Register 0x01A, Register 0x11A, and Register 0x935 offer secondary bias controls for the input buffer for frequencies $>500 \mathrm{MHz}$. Register 0x934 can be used to reduce input capacitance to achieve wider signal bandwidth but doing so may result in slightly lower linearity and noise performance. These register settings do not affect the AVDD3 power as much as Register 0x018 does. For frequencies $<500 \mathrm{MHz}$, it is recommended to use the default settings for these registers. Table 10 shows the recommended values for the buffer current control registers for various speed grades.
Use Register 0x11A when sampling in higher Nyquist zones ( $>500 \mathrm{MHz}$ for the AD6674-1000). This setting enables the ADC sampling network to optimize the sampling and settling times internal to the ADC for high frequency operation. For frequencies greater than 500 MHz , it is recommended to operate the ADC core at a 1.46 V full-scale setting irrespective of the speed grade. This setting offers better SFDR without any significant decrease in SNR.
Figure 74, Figure 75, and Figure 76 show the SFDR vs. analog input frequency for various buffer settings ( $\mathrm{I}_{\text {buFf }}$ ) for the AD6674-1000.

The recommended settings shown in Table 10 were used to collect the data while changing only the contents of Register 0x018.

Figure 74. Buffer Current Sweeps, AD6674-1000 (SFDR vs. Input Frequency and I BUFF ); $10 \mathrm{MHz}<f_{I N}<500 \mathrm{MHz}$; Front-End Network Shown in Figure 71

Figure 75. Buffer Current Sweeps, AD6674-1000 (SFDR vs. Input Frequency and I BuFf); $500 \mathrm{MHz}<f_{\text {IN }}<1500 \mathrm{MHz}$; Front-End Network Shown in Figure 71

In certain high frequency applications, the SFDR can be improved by reducing the full-scale setting, as shown in Table 10 . At high frequencies, the performance of the ADC core is limited by jitter. The SFDR can be improved by reducing the full-scale level.

Figure 77. SNR/SFDR vs. Input Level and Input Frequencies, AD6674-1000
Figure 78, Figure 79, and Figure 80 show the SFDR vs. analog input frequency for various buffer settings for the AD6674-500. The recommended settings shown in Table 10 were used to take the data while changing the contents of register $0 x 018$ only.

[^3]
## Absolute Maximum Input Swing

The absolute maximum input swing allowed at the inputs of the AD6674 is 4.3 V p-p differential. Signals operating near or at this level can cause permanent damage to the ADC.

## VOLTAGE REFERENCE

A stable and accurate 1.0 V voltage reference is built into the AD6674. This internal 1.0 V reference sets the full-scale input range of the ADC. The full-scale input range can be adjusted via Register $0 \times 025$. For more information on adjusting the input swing, see Table 45 . Figure 84 shows the block diagram of the internal 1.0 V reference controls.

Figure 84. Internal Reference Configuration and Controls
Register 0x024 enables the user to either use this internal 1.0 V reference or to provide an external 1.0 V reference. When using an external voltage reference, provide a 1.0 V reference. The full-scale adjustment is made using the SPI, irrespective of the
reference voltage. For more information on adjusting the fullscale level of the AD6674, refer to the Memory Map Register Table section.

The use of an external reference may be necessary, in some applications, to enhance the gain accuracy of the ADC or improve thermal drift characteristics. Figure 85 shows the typical drift characteristics of the internal 1.0 V reference.

Figure 85. Typical V_1PO Drift
The external reference must be a stable 1.0 V reference. The ADR130 is a good option for providing the 1.0 V reference. Figure 86 shows how the ADR130 can be used to provide the external 1.0 V reference to the AD6674. The grayed out areas show unused blocks within the AD6674 while the ADR130 provides the external reference.

Figure 86. External Reference Using the ADR130

## CLOCK INPUT CONSIDERATIONS

For optimum performance, drive the AD6674 sample clock inputs (CLK+ and CLK-) with a differential signal. This signal is typically ac-coupled to the CLK+ and CLK- pins via a transformer or clock drivers. These pins are biased internally and require no additional biasing.

Figure 87 shows one preferred method for clocking the AD6674. The low jitter clock source is converted from a singleended signal to a differential signal using an RF transformer.

Figure 87. Transformer Coupled Differential Clock
Another option is to ac couple a differential CML or LVDS signal to the sample clock input pins as shown in Figure 88 and Figure 89.

Figure 88. Differential CML Sample Clock

$150 \Omega$ RESISTORS ARE OPTIONAL.
Figure 89. Differential LVDS Sample Clock

## Clock Duty Cycle Considerations

Typical high speed ADCs use both clock edges to generate a variety of internal timing signals. As a result, these ADCs may be sensitive to clock duty cycle. Commonly, a $5 \%$ tolerance is required on the clock duty cycle to maintain dynamic performance characteristics. In applications where the clock duty cycle cannot be guaranteed to be $50 \%$, a higher multiple frequency clock can be supplied to the AD6674. For example, the AD6674-1000 can be clocked at 2 GHz with the internal clock divider set to 2 . This ensures a $50 \%$ duty cycle, high slew rate internal clock for the ADC. See the Memory Map section for more details on using this feature.

## Input Clock Divider

The AD6674 contains an input clock divider with the ability to divide the Nyquist input clock by $1,2,4$, or 8 . The divide ratios can be selected using Register 0x10B. This is shown in Figure 90. The maximum frequency at the output of the divider is 1.0 GHz .
The maximum frequency at the $\mathrm{CLK} \pm$ inputs is 4 GHz . This is the limit of the divider. In applications where the clock input is a multiple of the sample clock, take care to program the appropriate divider ratio into the clock divider before applying the clock signal. This ensures that the current transients during device startup are controlled.

Figure 90. Clock Divider Circuit
The AD6674 clock divider can be synchronized using the external SYSREF $\pm$ input. A valid SYSREF $\pm$ causes the clock divider to reset to a programmable state. This feature is enabled by setting Bit 7 of Register 0x10D. This synchronization feature allows multiple devices to have their clock dividers aligned to guarantee simultaneous input sampling.

## Input Clock Divider ½ Period Delay Adjustment

The input clock divider inside the AD6674 provides phase delay in increments of $1 / 2$ the input clock cycle. Program Register 0x10C to enable this delay independently for each channel. Changing the register does not affect the stability of the JESD204B link.

## Clock Fine Delay Adjustment

Adjust the AD6674 sampling edge instant by writing to Register 0x117 and Register 0x118. Setting Bit 0 of Register 0x117 enables the feature, and Register $0 \times 118$, Bits[7:0], set the value of the delay. This value can be programmed individually for each channel. The clock delay can be adjusted from -151.7 ps to +150 ps in $\sim 1.7 \mathrm{ps}$ increments. The clock delay adjustment takes effect immediately when it is enabled via SPI writes. Enabling the clock fine delay adjustment in Register 0x117 causes a datapath reset. However, the contents of Register 0x118 can be changed without affecting the stability of the JESD204B link.

## Clock Jitter Considerations

High speed, high resolution ADCs are sensitive to the quality of the clock input. The degradation in SNR at a given input frequency
$\left(f_{A}\right)$ due only to aperture jitter $\left(\mathrm{t}_{\mathrm{t}}\right)$ is calculated by

$$
S N R=20 \times \log 10\left(2 \times \pi \times f_{A} \times t_{J}\right)
$$

In this equation, the rms aperture jitter represents the root mean square of all jitter sources, including the clock input, analog input signal, and ADC aperture jitter specifications. IF undersampling applications are particularly sensitive to jitter (see Figure 91).

Figure 91. Ideal SNR vs. Analog Input Frequency and Jitter
Treat the clock input as an analog signal in cases where aperture jitter may affect the dynamic range of the AD6674. Separate power supplies for clock drivers from the ADC output driver supplies to avoid modulating the clock signal with digital noise. If the clock is generated from another type of source (by gating, dividing, or other methods), retime it using the original clock at the last step. See the AN-501 Application Note and the AN-756 Application Note for more in-depth information about jitter performance as it relates to ADCs.
Figure 92 shows the estimated SNR of the AD6674-1000 across input frequency for different clock induced jitter values. The SNR can be estimated by using the following equation:
$S N R(\mathrm{dBFS})=10 \log \left[10\left(\frac{-S N R_{\text {ADC }}}{10}\right)+10\left(\frac{-S N R_{\text {IITTER }}}{10}\right)\right]$

Figure 92. Estimated SNR Degradation for the AD6674-1000 vs. Input Frequency and Jitter

## POWER-DOWN/STANDBY MODE

The AD6674 has a PDWN/STBY pin that can be used to configure the device in power-down or standby mode. The default operation is the PDWN function. The PDWN/STBY pin is a logic high pin. When in power-down mode, the JESD204B link is disrupted. The power-down option can also be set via Register 0x03F and Register 0x040.

In standby mode, the JESD204B link is not disrupted and transmits zeros for all converter samples. This can be changed using Register 0x571[7] to select /K/ characters.

## TEMPERATURE DIODE

The AD6674 contains a diode-based temperature sensor for measuring the temperature of the die. This diode outputs a voltage and serve as a coarse temperature sensor to monitor the internal die temperature.
The temperature diode voltage can be output to the FD_A pin using the SPI. Use Register 0x028[0] to enable or disable the diode. Register 0x028 is a local register. Channel A must be selected in the device index register (Register 0x008) to enable the temperature diode readout. Configure the FD_A pin to output the diode voltage by programming Register 0x040[2:0]. See Table 45 for more information.
The voltage response of the temperature diode (with SPIVDD = 1.8 V ) is shown in Figure 93.

Figure 93. Temperature Diode Voltage vs. Temperature

## ADC OVERRANGE AND FAST DETECT

In receiver applications, it is desirable to have a mechanism to reliably determine when the converter is about to be clipped. The standard overrange bit in the JESD204B outputs provides information on the state of the analog input that is of limited usefulness. Therefore, it is helpful to have a programmable threshold below full scale that allows time to reduce the gain before the clip actually occurs. In addition, because input signals can have significant slew rates, the latency of this function is of major concern. Highly pipelined converters can have significant latency. The AD6674 contains fast detect circuitry for individual channels to monitor the threshold and assert the FD_A and FD_B pins.

## ADC OVERRANGE (OR)

The ADC overrange indicator is asserted when an overrange is detected on the input of the ADC. The overrange indicator can be embedded within the JESD204B link as a control bit (when CSB $>0$ ). The latency of this overrange indicator matches the sample latency.

The AD6674 constantly monitors the analog input level and records any overrange condition in any of the eight virtual converters. For more information on the virtual converters, refer to Figure 99. The overrange status of each virtual converter is registered as a sticky bit (that is, it is set until cleared) in Register 0x563. Clear the contents of Register 0x563 using Register $0 \times 562$ by toggling the bits corresponding to the virtual converter to set and reset the position.

## FAST THRESHOLD DETECTION (FD_A AND FD_B)

The fast detect (FD) bit (enabled in the control bits via Register 0x559 and Register 0x55A) is immediately set whenever the absolute value of the input signal exceeds the programmable upper threshold level. The FD bit is only cleared when the absolute value of the input signal drops below the lower threshold level for greater than the programmable dwell
time. This provides hysteresis and prevents the FD bit from excessively toggling.
The operation of the upper threshold and lower threshold registers, along with the dwell time registers, is shown in Figure 94.
The FD_x indicator is asserted if the input magnitude exceeds the value programmed in the fast detect upper threshold registers, located in Register 0x247 and Register 0x248. The selected threshold register is compared with the signal magnitude at the output of the ADC. The fast upper threshold detection has a latency of 28. The approximate upper threshold magnitude is defined by

## Upper Threshold Magnitude (dBFS) $=20 \log$ (Threshold Magnitude/ $2^{13}$ )

The FD_x indicators are not cleared until the signal drops below the lower threshold for the programmed dwell time. The lower threshold is programmed in the fast detect lower threshold registers, located in Register 0x249 and Register 0x24A. The fast detect lower threshold register is a 13-bit register that is compared with the signal magnitude at the output of the ADC. This comparison is subject to the ADC pipeline latency but is accurate in terms of converter resolution. The lower threshold magnitude is defined by

## Lower Threshold Magnitude (dBFS) $=20 \log$ (Threshold Magnitude/ $2{ }^{13}$ )

For example, to set an upper threshold of -6 dBFS , write 0x0FFF to Register 0x247 and Register 0x248; and to set a lower threshold of -10 dBFS , write 0x0A1D to Register 0x249 and Register 0x24A.

The dwell time can be programmed from 1 to 65,535 sample clock cycles by placing the desired value in the fast detect dwell time registers, located in Register 0x24B and Register 0x24C. See the Memory Map section (Register 0x245 to Register 0x24C in Table 45) for more details.

## SIGNAL MONITOR

The signal monitor block provides additional information about the signal being digitized by the ADC. The signal monitor computes the peak magnitude of the digitized signal. This information can be used to drive an AGC loop to optimize the range of the ADC in the presence of real-world signals.
The results of the signal monitor block can be obtained either by reading back the internal values from the SPI port or by embedding the signal monitoring information into the JESD204B interface as special control bits. A global, 24-bit programmable period controls the duration of the measurement. Figure 95 shows the simplified block diagram of the signal monitor block.

Figure 95. Signal Monitor Block
The peak detector captures the largest signal within the observation period. This period observes only the magnitude of the signal. The resolution of the peak detector is a 13-bit value, and the observation period is 24 bits and represents converter output samples. The peak magnitude is derived by using the following equation:

$$
\text { Peak Magnitude }(\mathrm{dBFS})=20 \log \left(\text { Peak Detector Value } / 2^{13}\right)
$$

The magnitude of the input port signal is monitored over a programmable time period that is determined by the signal monitor period registers (SMPRs). Only even values of the SMPR are supported. The peak detector function is enabled by setting Bit 1 of Register 0x270 in the signal monitor control register. The 24 -bit SMPR must be programmed before activating this mode.

After enabling this mode, the value in the SMPR is loaded into a monitor period timer that decrements at the decimated clock rate. The magnitude of the input signal is compared with the value in the internal magnitude storage register (not accessible to the user), and the greater of the two is updated as the current peak level. The initial value of the magnitude storage register is set to the current ADC input signal magnitude. This comparison continues until the monitor period timer reaches a count of 1 .
When the monitor period timer reaches a count of 1 , the 13-bit peak level value is transferred to the signal monitor holding register, which can be read through the memory map or output through the serial port (SPORT) over the JESD204B interface. The monitor period timer is reloaded with the value in the SMPR, and the countdown is restarted. In addition, the magnitude of the first input sample is updated in the internal magnitude storage register, and the comparison and update procedure, as explained previously, continues.

## SPORT OVER JESD204B

The signal monitor data can also be serialized and sent over the JESD204B interface as control bits. These control bits must be deserialized from the samples to reconstruct the statistical data. This signal control monitor function is enabled by setting Bits[1:0] of Register 0x279 and Bit 1 of Register 0x27A.
Figure 96 shows two different example configurations for the signal monitor control bit locations inside the JESD204B samples. There are a maximum of three control bits that can be inserted into the JESD204B samples; however, only one control bit is required for the signal monitor. Control bits are inserted from MSB to LSB. If only one control bit is to be inserted (CS = 1), only the most significant control bit is used (see Configuration 1 and Configuration 2 in Figure 96). To select the SPORT over JESD204B option, program Register 0x559, Register 0x55A, and Register 0x58F. See the Memory Map Register Table section for more information on setting these bits.
Figure 97 shows the 25 -bit frame data that encapsulates the peak detector value. The frame data is transmitted MSB first with five 5-bit subframes. Each subframe contains a start bit that can be used by a receiver to validate the deserialized data. Figure 98 shows the SPORT over the JESD204B signal monitor frame data with a monitor period timer set to 80 samples.

## DIGITAL DOWNCONVERTER (DDC)

The AD6674 includes four digital downconverters (DDCs) that provide filtering and reduce the output data rate. This digital processing section includes an NCO, a half-band decimating filter, an FIR filter, a gain stage, and a complex to real conversion stage. Each of these processing blocks has control lines that allow it to be independently enabled and disabled to provide the desired processing function. The digital downconverter can be configured to output either real data or complex output data.
The DDCs output a 16-bit stream. To enable this operation, the converter number of bits, N , is set to a default value of 16 , even though the analog core only outputs 14 bits. In full bandwidth operation, the ADC outputs are the 14 -bit word followed by two zeros, unless the tail bits are enabled.

## DDC I/Q INPUT SELECTION

The AD6674 has two ADC channels and four DDC channels. Each DDC channel has two input ports that can be paired to support both real and complex inputs through the I/Q crossbar mux. For real signals, both DDC input ports must select the same ADC channel (that is, DDC Input Port I = ADC Channel A and DDC Input Port $\mathrm{Q}=\mathrm{ADC}$ Channel A). For complex signals, each DDC input port must select different ADC channels (that is, DDC Input Port I = ADC Channel A and DDC Input Port $\mathrm{Q}=\mathrm{ADC}$ Channel B ).
The inputs to each DDC are controlled by the DDC input selection registers (Register 0x311, Register 0x331, Register 0x351, and Register 0x371). See Table 45 for information on how to configure the DDCs.

## DDC I/Q OUTPUT SELECTION

Each DDC channel has two output ports that can be paired to support both real and complex outputs. For real output signals, only the DDC Output Port I is used (the DDC Output Port Q is invalid). For complex I/Q output signals, both DDC Output Port I and DDC Output Port Q are used.

The I/Q outputs to each DDC channel are controlled by the DDC complex to real enable bit, Bit 3, in the DDC control registers (Register 0x310, Register 0x330, Register 0x350, and Register 0x370).
The Chip Q ignore bit in the chip mode register (Register 0x200[5]) controls the chip output muxing of all the DDC channels. When all DDC channels use real outputs, set this bit high to
ignore all DDC Q output ports. When any of the DDC channels are set to use complex I/Q outputs, the user must clear this bit to use both DDC Output Port I and DDC Output Port Q. For more information, see Figure 107.

## DDC GENERAL DESCRIPTION

The four DDC blocks are used to extract a portion of the full digital spectrum captured by the $\mathrm{ADC}(\mathrm{s})$. They are intended for IF sampling or oversampled baseband radios requiring wide bandwidth input signals.
Each DDC block contains the following signal processing stages:

- Frequency translation stage (optional)
- Filtering stage
- Gain stage (optional)
- Complex to real conversion stage (optional)

## Frequency Translation Stage (Optional)

This stage consists of a 12-bit complex NCO and quadrature mixers that can be used for frequency translation of both real and complex input signals. This stage shifts a portion of the available digital spectrum down to baseband.

## Filtering Stage

After shifting down to baseband, this stage decimates the frequency spectrum using a chain of up to four half-band lowpass filters for rate conversion. The decimation process lowers the output data rate, which in turn reduces the output interface rate.

## Gain Stage (Optional)

Due to losses associated with mixing a real input signal down to baseband, this stage compensates by adding an additional 0 dB or 6 dB of gain.

## Complex to Real Conversion Stage (Optional)

When real outputs are necessary, this stage converts the complex outputs back to real by performing an $\mathrm{f}_{\mathrm{s}} / 4$ mixing operation plus a filter to remove the complex component of the signal.
Figure 99 shows the detailed block diagram of the DDCs implemented in the AD6674.

Figure 99. DDC Detailed Block Diagram

Figure 100 shows an example usage of one of the four DDC blocks with a real input signal and four half-band filters (HB4 + HB3 + HB2 + HB1). It shows both complex (decimate by 16) and real (decimate by 8 ) output options.
When DDCs have different decimation ratios, the chip decimation ratio (Register 0x201) must be set to the lowest decimation ratio of all the DDC blocks. In this scenario, samples of higher decimation ratio DDCs are repeated to match the chip decimation ratio sample rate. Whenever the NCO frequency is set or changed, the DDC soft reset must be issued.

If the DDC soft reset is not issued, the output may potentially show amplitude variations.
Table 11, Table 12, Table 13, Table 14, and Table 15 show the DDC samples when the chip decimation ratio is set to $1,2,4,8$, or 16 , respectively. When DDCs have different decimation ratios, the chip decimation ratio must be set to the lowest decimation ratio of all the DDC channels. In this scenario, samples of higher decimation ratio DDCs are repeated to match the chip decimation ratio sample rate.

## FREQUENCY TRANSLATION <br> GENERAL DESCRIPTION

Frequency translation is accomplished by using a 12-bit complex NCO with a digital quadrature mixer. This stage translates either a real or complex input signal from an IF to a baseband complex digital output (carrier frequency $=0 \mathrm{~Hz}$ ).
The frequency translation stage of each DDC can be controlled individually and supports four different IF modes using Bits[5:4] of the DDC control registers (Register 0x310, Register 0x330, Register 0x350, and Register 0x370). These IF modes are

- Variable IF mode
- 0 Hz IF or zero IF (ZIF) mode
- $\mathrm{f}_{\mathrm{s}} / 4 \mathrm{~Hz}$ IF mode
- Test mode

## Variable IF Mode

NCO and mixers are enabled. NCO output frequency can be used to digitally tune the IF frequency.

## 0 Hz IF (ZIF) Mode

The mixers are bypassed, and the NCO is disabled.

## $f_{s} / \mathbf{4 ~ H z ~ I F ~ M o d e ~}$

The mixers and the NCO are enabled in special downmixing by $\mathrm{f}_{\mathrm{s}} / 4$ mode to save power.

## Test Mode

Input samples are forced to 0.999 to positive full scale. The NCO is enabled. This test mode allows the NCOs to directly drive the decimation filters.

Figure 101 and Figure 102 show examples of the frequency translation stage for both real and complex inputs.

Figure 101. DDC NCO Frequency Tuning Word Selection—Real Inputs

Figure 102. DDC NCO Frequency Tuning Word Selection—Complex Inputs

## DDC NCO + MIXER LOSS AND SFDR

When mixing a real input signal down to baseband, 6 dB of loss is introduced in the signal due to filtering of the negative image. An additional 0.05 dB of loss is introduced by the NCO. The total loss of a real input signal mixed down to baseband is 6.05 dB . For this reason, it is recommended that the user compensate for this loss by enabling the 6 dB of gain in the gain stage of the DDC to recenter the dynamic range of the signal within the full scale of the output bits.

When mixing a complex input signal down to baseband, the maximum value each $I / Q$ sample can reach is $1.414 \times$ full scale after it passes through the complex mixer. To avoid overrange of the I/Q samples and to keep the data bit-widths aligned with real mixing, 3.06 dB of loss is introduced in the mixer for complex signals. An additional 0.05 dB of loss is introduced by the NCO. The total loss of a complex input signal mixed down to baseband is -3.11 dB .

The worst case spurious signal from the NCO is greater than 102 dBc SFDR for all output frequencies.

## NUMERICALLY CONTROLLED OSCILLATOR

The AD6674 has a 12-bit NCO for each DDC that enables the frequency translation process. The NCO allows the input spectrum to be tuned to dc, where it can be effectively filtered by the subsequent filter blocks to prevent aliasing. The NCO can be set up by providing a frequency tuning word (FTW) and a phase offset word (POW).

## Setting Up the NCO FTW and POW

The NCO frequency value is given by the 12-bit twos complement number entered in the NCO FTW. Frequencies between $-\mathrm{f}_{\mathrm{s}} / 2$ and $+\mathrm{f}_{\mathrm{s}} / 2\left(\mathrm{f}_{\mathrm{s}} / 2\right.$ excluded) are represented using the following frequency words:

- $0 x 800$ represents a frequency of $-\mathrm{f}_{\mathrm{s}} / 2$.
- $0 x 000$ represents dc (frequency is 0 Hz ).
- $0 x 7 \mathrm{FF}$ represents a frequency of $+\mathrm{f}_{\mathrm{s}} / 2-\mathrm{f}_{\mathrm{s}} / 2^{12}$.

The NCO frequency tuning word can be calculated using the following equation:

$$
N C O_{-} F T W=\operatorname{round}\left(2^{12} \frac{\bmod \left(f_{C}, f_{S}\right)}{f_{S}}\right)
$$

where:
NCO_FTW is a 12-bit twos complement number representing the NCO FTW.
$f_{\mathrm{C}}$ is the desired carrier frequency in Hz .
$f_{s}$ is the AD6674 sampling frequency (clock rate) in Hz.
$\bmod ()$ is a remainder function. For example, $\bmod (110,100)=$ 10 and for negative numbers, $\bmod (-32,10)=-2$.
round ( ) is a rounding function. For example, round (3.6) $=4$ and for negative numbers, $\operatorname{round}(-3.4)=-3$.
Note that this equation applies to the aliasing of signals in the digital domain (that is, aliasing introduced when digitizing analog signals).

For example, if the ADC sampling frequency ( $\mathrm{f}_{\mathrm{s}}$ ) is 1250 MSPS and the carrier frequency $\left(\mathrm{f}_{\mathrm{c}}\right)$ is 416.667 MHz , then

$$
N C O \_F T W=\operatorname{round}\left(2^{12} \frac{\bmod (416.667,1250)}{1250}\right)=1365 \mathrm{MHz}
$$

This, in turn, converts to $0 x 555$ in the 12-bit twos complement representation for NCO_FTW. The actual carrier frequency is calculated based on the following equation:

$$
f_{C_{-} A C T U A L}=\frac{N C O_{-} F T W \times f_{S}}{2^{12}}=416.56 \mathrm{MHz}
$$

A 12-bit POW is available for each NCO to create a known phase relationship between multiple AD6674 chips or individual DDC channels inside one AD6674 chip.
The following procedure must be followed to update the FTW and/or POW registers to ensure proper operation of the NCO:

1. Write to the FTW registers for all the DDCs.
2. Write to the POW registers for all the DDCs.
3. Synchronize the NCOs either through the DDC NCO soft reset bit (Register 0x300[4]) accessible through the SPI or through the assertion of the SYSREF $\pm$ pin.

It is important to note that the NCOs must be synchronized either through the SPI or through the SYSREF $\pm$ pin after all writes to the FTW or POW registers have completed. This is necessary to ensure the proper operation of the NCO.

## NCO Synchronization

Each NCO contains a separate phase accumulator word (PAW) that determines the instantaneous phase of the NCO. The initial reset value of each PAW is determined by the POW. The phase increment value of each PAW is determined by the FTW See the Setting Up the NCO FTW and POW section for more information.

Use the following two methods to synchronize multiple PAWs within the chip.

- Using the SPI. Use the DDC NCO soft reset bit in the DDC synchronization control register (Register 0x300[4]) to reset all the PAWs in the chip. This is accomplished by setting the DDC NCO soft reset bit high and then setting this bit low. Note that this method can only be used to synchronize DDC channels within the same AD6674 chip.
- Using the SYSREF $\pm$ pin. When the SYSREF $\pm$ pin is enabled in the SYSREF $\pm$ control registers (Register 0x120 and Register 0x121) and the DDC synchronization is enabled in the DDC synchronization control register (Register 0x300[1:0]), any subsequent SYSREF $\pm$ event resets all the PAWs in the chip. Note that this method can be used to synchronize DDC channels within the same AD6674 chip or DDC channels within separate AD6674 chips.

## Mixer

The NCO is accompanied by a mixer. Its operation is similar to an analog quadrature mixer. It performs the downconversion of input signals (real or complex) by using the NCO frequency as a local oscillator. For real input signals, this mixer performs a real mixer operation (with two multipliers). For complex input signals, the mixer performs a complex mixer operation (with four multipliers and two adders). The mixer adjusts its operation based on the input signal (real or complex) provided to each individual channel. The selection of real or complex inputs can be controlled individually for each DDC block using Bit 7 of the DDC control registers (Register 0x310, Register 0x330, Register 0x350, and Register 0x370).

## FIR FILTERS

## GENERAL DESCRIPTION

There are four sets of decimate by 2, low-pass, half-band, finite impulse response (FIR) filters (labeled HB1 FIR, HB2 FIR, HB3 FIR, and HB4 FIR in Figure 99) following the frequency translation stage. After the carrier of interest is tuned down to dc (carrier frequency $=0 \mathrm{~Hz}$ ), these filters efficiently lower the sample rate, while providing sufficient alias rejection from unwanted adjacent carriers around the bandwidth of interest.

HB1 FIR is always enabled and cannot be bypassed. The HB2, HB3, and HB4 FIR filters are optional and can be bypassed for higher output sample rates.

Table 17 shows the different bandwidths selectable by including different half-band filters. In all cases, the DDC filtering stage on the AD6674 provides $<-0.001 \mathrm{~dB}$ of pass-band ripple and $>100 \mathrm{~dB}$ of stop-band alias rejection.
Table 18 shows the amount of stop-band alias rejection for multiple pass-band ripple/cutoff points. The decimation ratio of the filtering stage of each DDC can be controlled individually through Bits[1:0] of the DDC control registers (Register 0x310, Register 0x330, Register 0x350, and Register 0x370).

Table 17. DDC Filter Characteristics

[^5]
## HALF-BAND FILTERS

The AD6674 offers four half-band filters to enable digital signal processing of the ADC converted data. These half-band filters are bypassable and can be individually selected.

## HB4 Filter

The first decimate by 2 , half-band, low-pass, FIR filter (HB4) uses an 11-tap, symmetrical, fixed coefficient filter implementation that is optimized for low power consumption. The HB4 filter is only used when complex outputs (decimate by 16) or real outputs (decimate by 8 ) are enabled; otherwise, it is bypassed. Table 19 and Figure 103 show the coefficients and response of the HB4 filter.

Table 19. HB4 Filter Coefficients

Figure 103. HB4 Filter Response

## HB3 Filter

The second decimate by 2 , half-band, low-pass, FIR filter (HB3) uses an 11-tap, symmetrical, fixed coefficient filter implementation that is optimized for low power consumption. The HB3 filter is only used when complex outputs (decimate by 8 or 16) or real outputs (decimate by 4 or 8 ) are enabled; otherwise, it is bypassed. Table 20 and Figure 104 show the coefficients and response of the HB3 filter.

Table 20. HB3 Filter Coefficients

Figure 104. HB3 Filter Response

## HB2 Filter

The third decimate by 2 , half-band, low-pass, FIR filter (HB2) uses a 19-tap, symmetrical, fixed coefficient filter implementation that is optimized for low power consumption.
The HB2 filter is only used when complex or real outputs (decimate by 4,8 , or 16 ) is enabled; otherwise, it is bypassed.

Table 21 and Figure 105 show the coefficients and response of the HB2 filter.

Table 21. HB2 Filter Coefficients

| HB2 Coefficient <br> Number | Normalized <br> Coefficient | Decimal <br> Coefficient (19-Bit) |

| C10 | 0.500000 | 131,072 |

Figure 105. HB2 Filter Response

## HB1 Filter

The fourth and final decimate by 2 , half-band, low-pass, FIR filter (HB1) uses a 55 -tap, symmetrical, fixed coefficient filter implementation that is optimized for low power consumption. The HB1 filter is always enabled and cannot be bypassed.
Table 22 and Figure 106 show the coefficients and response of the HB1 filter.

Figure 106. HB1 Filter Response

## DDC GAIN STAGE

Each DDC contains an independently controlled gain stage. The gain is selectable as either 0 dB or 6 dB . When mixing a real input signal down to baseband, it is recommended that the user enable the 6 dB of gain to recenter the dynamic range of the signal within the full scale of the output bits.
When mixing a complex input signal down to baseband, the mixer has already recentered the dynamic range of the signal within the full scale of the output bits, and no additional gain is necessary. However, the optional 6 dB gain compensates for low signal strengths. The downsample by 2 portion of the HB1 FIR filter is bypassed when using the complex to real conversion stage.

## DDC COMPLEX TO REAL CONVERSION

Each DDC contains an independently controlled complex to real conversion block. The complex to real conversion block reuses the last filter (HB1 FIR) in the filtering stage along with an $\mathrm{f}_{\mathrm{s}} / 4$ complex mixer to upconvert the signal. After upconverting the signal, the Q portion of the complex mixer is no longer needed and is dropped.
Figure 107 shows a simplified block diagram of the complex to real conversion.

Figure 107. Complex to Real Conversion Block

## DDC EXAMPLE CONFIGURATIONS

Table 23 describes the register settings for multiple DDC example configurations.

[^6]
## NOISE SHAPING REQUANTIZER (NSR)

When operating the AD6674 with the NSR enabled, a decimating half-band filter that is optimized at certain input frequency bands can also be enabled. This filter offers the user the flexibility in signal bandwidth process and image rejection. Careful frequency planning can offer advantages in analog filtering preceding the ADC. The filter can function either in high-pass or low-pass mode. On the AD6674-750 and AD6674-1000, this filter is nonbypassable when the NSR is enabled. The filter can be optionally enabled on the AD6674-500 when the NSR is enabled. When operating with NSR enabled, the decimating half-band filter mode (low pass or high pass) is selected by setting Bit 7 in Register 0x41E.

## DECIMATING HALF-BAND FILTER

The AD6674 decimating half-band filter reduces the input sample rate by a factor of 2 while rejecting aliases that fall into the band of interest. For an input sample clock of 1000 MHz , this reduces the output sample rate to 500 MSPS. This filter is designed to provide $>40 \mathrm{~dB}$ of alias protection for $39.5 \%$ of the output sample rate ( $79 \%$ of the Nyquist band). For an ADC sample rate of 1000 MSPS, the filter provides a maximum usable bandwidth of 197.5 MHz .

## Half-Band Filter Coefficients

The 19-tap, symmetrical, fixed coefficient half-band filter has low power consumption due to its polyphase implementation. Table 24 lists the coefficients of the half-band filter in low-pass mode. In high-pass mode, Coefficient C9 is multiplied by -1 . The normalized coefficients used in the implementation and the decimal equivalent values of the coefficients are listed. Coefficients not listed in Table 24 are 0s.

Table 24. Fixed Coefficients for Half-Band Filter

| Coefficient <br> Number | Normalized <br> Coefficient | Decimal Coefficient <br> (12-Bit) |
| :--- | :--- | :--- |
| 0 | 0.012207 | 25 |
| C2, C16 | -0.022949 | -47 |
| C4, C14 | 0.045410 | 93 |
| C6, C12 | -0.094726 | -194 |
| C8, C10 | 0.314453 | 644 |
| C9 | 0.500000 | 1024 |

## Half-Band Filter Features

The half-band decimating filter is designed to provide approximately $39.5 \%$ of the output sample rate in usable bandwidth ( $19.75 \%$ of the input sample clock). The filter provides $>40 \mathrm{~dB}$ of rejection. The response of the half-band filter in low-pass mode is shown in Figure 108 for an input sample clock of 1000 MHz . In low-pass mode, operation is allowed in the first Nyquist zone, which includes frequencies of up to $f_{s} / 2$, where $f_{s}$ is the decimated sample rate. For example, with an input clock of 1000 MHz , the output sample rate is 500 MSPS and $\mathrm{f}_{\mathrm{s}} / 2=$ 250 MHz .

Figure 108. Low-Pass Half-Band Filter Response
The half-band filter can also be utilized in high-pass mode. The usable bandwidth remains at $39.5 \%$ of the output sample rate ( $19.75 \%$ of the input sample clock), which is the same as in lowpass mode). Figure 109 shows the response of the half-band filter in high-pass mode with an input sample clock of 1000 MHz . In high-pass mode, operation is allowed in the second and third Nyquist zones, which includes frequencies from $f_{s} / 2$ to $3 f_{s} / 2$, where $f_{s}$ is the decimated sample rate. For example, with an input clock of 1000 MHz , the output sample rate is 500 MSPS, $\mathrm{f}_{\mathrm{s}} / 2=250 \mathrm{MHz}$, and $3 \mathrm{f}_{\mathrm{s}} / 2=750 \mathrm{MHz}$.

Figure 109. High-Pass Half-Band Filter Response

## NSR OVERVIEW

The AD6674 features an NSR to allow higher than 9-bit SNR to be maintained in a subset of the Nyquist band. The harmonic performance of the receiver is unaffected by the NSR feature. When enabled, the NSR contributes an additional 3.0 dB of loss to the input signal, such that a 0 dBFS input is reduced to -3.0 dBFS at the output pins. This loss does not degrade the SNR performance of the AD6674.
The NSR feature can be independently controlled per channel via the SPI.

Two different bandwidth modes are provided; select the mode from the SPI port. In each of the two modes, the center frequency of the band can be tuned such that IFs can be placed anywhere in the Nyquist band. The NSR feature is enabled by default on the AD6674. The bandwidth and mode of the NSR operation are selected by setting the appropriate bits in Register 0x420 and Register 0x422. By selecting the appropriate profile and mode bits in these two registers, the NSR feature can be enabled for the desired mode of operation.

## $\mathbf{2 1 \%}$ BW Mode (>75 MHz at 375 MSPS)

The first NSR mode offers excellent noise performance across a bandwidth that is $21 \%$ of the ADC output sample rate ( $42 \%$ of the Nyquist band) and can be centered by setting the NSR mode bits in the NSR mode register (Address 0x420) to 000. In this mode, set the useful frequency range using the 6-bit tuning word in the NSR tuning register (Address 0x422). There are 59 possible tuning words (TW), from 0 to 58 ; each step is $0.5 \%$ of the ADC sample rate.

$$
f_{0}=f_{A D C} \times 0.005 \times T W
$$

where:
$f_{0}$ is the left band edge.
$f_{A D C}$ is the ADC sample rate.
$T W$ is the tuning word.

$$
f_{\text {CENTER }}=f_{0}+0.105 \times f_{A D C}
$$

where $f_{\text {CENTER }}$ is the channel center.

$$
f_{1}=f_{0}+0.21 \times f_{A D C}
$$

where $f_{1}$ is the right band edge.
Figure 110 to Figure 112 show the typical spectrum that can be expected from the AD6674 in the $21 \%$ BW mode for three different tuning words.

Figure 110. $A D 6674-750, f_{C L O C K}=750 \mathrm{MHz}, f_{s}=375 \mathrm{MSPS}, f_{I N}=10.3 \mathrm{MHz}$, 21\% BW Mode, Tuning Word $=0$

Figure 111. AD6674-750, $f_{C L O C K}=750 \mathrm{MHz}, f_{s}=375 \mathrm{MSPS}, f_{i N}=90.3 \mathrm{MHz}$, $21 \%$ BW Mode, Tuning Word $=26$ ( $f_{s} / 4$ Tuning)

Figure 112. AD6674-750, $f_{C L O C K}=750 \mathrm{MHz}, f_{S}=375 \mathrm{MSPS}, f_{I N}=140.3 \mathrm{MHz}$, $21 \%$ BW Mode, Tuning Word $=58$

## 28\% BW Mode (>100 MHz at 375 MSPS)

The second NSR mode offers excellent noise performance across a bandwidth that is $28 \%$ of the ADC output sample rate ( $56 \%$ of the Nyquist band) and can be centered by setting the NSR mode bits in the NSR mode register (Address 0x420) to 001. In this mode, the useful frequency range can be set using the 6-bit tuning word in the NSR tuning register (Address 0x422). There are 44 possible tuning words (TW, from 0 to 43 ); each step is $0.5 \%$ of the ADC sample rate.

$$
f_{0}=f_{A D C} \times 0.005 \times T W
$$

where:
$f_{0}$ is the left band edge.
$f_{A D C}$ is the ADC sample rate.
$T W$ is the tuning word.

$$
f_{\text {CENTER }}=f_{0}+0.14 \times f_{A D C}
$$

where $f_{\text {CENTER }}$ is the channel center.

$$
f_{1}=f_{0}+0.28 \times f_{A D C}
$$

where $f_{1}$ is the right band edge.

Figure 113 to Figure 115 show the typical spectrum that can be expected from the AD6674 in the $28 \%$ BW mode for three different tuning words.

Figure 113. $A D 6674-750, f_{C L O C K}=750 \mathrm{MHz}, f_{S}=375 \mathrm{MSPS}, f_{I N}=10.3 \mathrm{MHz}$, $28 \%$ BW Mode, Tuning Word $=0$

## VARIABLE DYNAMIC RANGE (VDR)

The AD6674 features a VDR digital processing block to allow up to a 14-bit dynamic range to be maintained in a subset of the Nyquist band. Across the full Nyquist band, a minimum 9-bit dynamic range is available at all times. This operation is suitable for applications such as DPD processing. The harmonic performance of the receiver is unaffected by this feature. When enabled, VDR does not contribute loss to the input signal but operates by effectively changing the output resolution at the output pins. This feature can be independently controlled per channel via the SPI.

The VDR block operates in either complex or real mode. In complex mode, VDR has selectable bandwidths of $25 \%$ and $43 \%$ of the output sample rate. In real mode, the bandwidth of operation is limited to $25 \%$ of the output sample rate. The bandwidth and mode of the VDR operation are selected by setting the appropriate bits in Register 0x430.
When the VDR block is enabled, input signals that violate a defined mask (signified by gray shaded areas in Figure 116) result in the reduction of the output resolution of the AD6674. The VDR block analyzes the peak value of the aggregate signal level in the disallowed zones to determine the reduction of the output resolution. To indicate that the AD6674 is reducing output, the resolution VDR punish bits and/or a VDR high/low resolution bit can optionally be inserted into the output data stream as control bits by programming the appropriate value into Register 0x559 and Register 0x55A. Up to two control bits can be used without the need to change the converter resolution parameter, N. Up to three control bits can be used, but if using three, the converter resolution parameter, N, must be changed to 13 . The VDR high/low resolution bit can be programmed into either of the three available control bits and simply indicates if VDR is reducing output resolution (bit value is a 1 ), or if full resolution is available (bit value is a 0 ). Enable the two punish bits to give a clearer indication of the available resolution of the sample. To decode these two bits, see Table 25.

Table 25. VDR Reduced Output Resolution Values

| VDR Punish Bits[1:0] | Output Resolution (Bits) |
| :--- | :--- |
| 00 | 14 |
| 01 | 13 |
| 10 | 12 or 11 |
| 11 | 10 or 9 |

The frequency zones of the mask are defined by the bandwidth mode selected in Register 0x430. The upper amplitude limit for input signals located in these frequency zones is -30 dBFS . If the input signal level in the disallowed frequency zones goes above an amplitude level of -30 dBFS (into the gray shaded areas), the VDR block triggers a reduction in the output resolution, as shown in Figure 116. The VDR block engages and begins limiting output resolution gradually as the signal amplitudes increase in the mask regions. As the signal amplitude level increases into the mask regions, the output resolution is gradually lowered. For every 6 dB increase in signal level above -30 dBFS , one bit of output resolution is discarded from the output data by the VDR block, as shown in Table 26. These zones can be tuned within the Nyquist band by setting Bits[3:0] in Register 0x434 to determine the VDR center frequency ( $\mathrm{f}_{\mathrm{VDR}}$ ). The VDR center frequency in complex mode can be adjusted from $1 / 16 \mathrm{f}_{\mathrm{s}}$ to $15 / 16 \mathrm{fs}$ in $1 / 16 \mathrm{fs}$ steps. In real mode, $\mathrm{f}_{\text {VDR }}$ can be adjusted from $1 / 8 \mathrm{f}_{\mathrm{s}}$ to $3 / 8 \mathrm{f}_{\mathrm{S}}$ in $1 / 16 \mathrm{f}_{\mathrm{S}}$ steps.

Table 26. VDR Reduced Output Resolution Values

| Signal Amplitude Violating Defined <br> VDR Mask | Output Resolution <br> (Bits) |
| :--- | :--- |
| Amplitude $\leq-30 \mathrm{dBFS}$ | 14 |
| $-30 \mathrm{dBFS}<$ amplitude $\leq-24 \mathrm{dBFS}$ | 13 |
| $-24 \mathrm{dBFS}<$ amplitude $\leq-18 \mathrm{dBFS}$ | 12 |
| $-18 \mathrm{dBFS}<$ amplitude $\leq-12 \mathrm{dBFS}$ | 11 |
| $-12 \mathrm{dBFS}<$ amplitude $\leq-6 \mathrm{dBFS}$ | 10 |
| $-6 \mathrm{dBFS}<$ amplitude $\leq 0 \mathrm{dBFS}$ | 9 |

INTERMODULATION PRODUCTS <-30dBFS

## VDR REAL MODE

The real mode of VDR works over a bandwidth of $25 \%$ of the sample rate ( $50 \%$ of the Nyquist band). The output bandwidth of the AD6674 can be $25 \%$ only when operating in real mode. Figure 117 shows the frequency zones for the $25 \%$ bandwidth real output VDR mode tuned to a center frequency ( $f_{\text {VDR }}$ ) of $f_{s} / 4$ (tuning word $=0 \times 04$ ). The frequency zones where the amplitude may not exceed -30 dBFS are the upper and lower portions of the Nyquist band signified by the red shaded areas.

Figure 117.25\% VDR Bandwidth, Real Mode
The center frequency ( $\mathrm{f}_{\mathrm{VDR}}$ ) of the VDR function can be tuned within the Nyquist band from $1 / 8 \mathrm{f}_{\mathrm{s}}$ to $3 / 8 \mathrm{f}_{\mathrm{s}}$ in $1 / 16 \mathrm{f}_{\mathrm{s}}$ steps. In real mode, Tuning Word $2(0 x 02)$ through Tuning Word 6 (0x06) are valid. Table 27 shows the relative frequency values, and Table 28 shows the absolute frequency values based on a sample rate of 737.28 MSPS.

Table 27. VDR Tuning Words and Relative Frequency Values, 25\% BW, Real Mode

| Tuning Word | Lower Band Edge | Center Frequency | Upper Band Edge |
| :---: | :---: | :---: | :---: |
| 2 (0x02) | 0 | 1/8 fs | 1/4 fs |
| 3 (0x03) | $1 / 16 \mathrm{fs}$ | $3 / 16 \mathrm{fs}$ | $5 / 16 \mathrm{fs}$ |
| 4 (0x04) | $1 / 8 \mathrm{f}_{5}$ | 1/4 fs | $3 / 8 \mathrm{fs}$ |
| 5 (0x05) | $3 / 16 \mathrm{fs}$ | $5 / 16 \mathrm{fs}_{5}$ | $7 / 16 \mathrm{f}_{5}$ |
| 6 (0x06) | $1 / 4 \mathrm{f}_{\mathrm{s}}$ | $3 / 8 \mathrm{fs}$ | $1 / 2 \mathrm{fs}$ |
| Table 28. VDR Tuning Words and Absolute Frequency Values, 25\% BW, Real Mode with $\mathrm{f}_{\mathrm{S}}=$ 737.28 MSPS |  |  |  |

| 2 (0x02) | 0 | 92.16 | 184.32 |
| 3 (0x03) | 46.08 | 138.24 | 230.40 |
| 4 (0x04) | 92.16 | 184.32 | 276.48 |
| 5 (0x05) | 138.24 | 230.40 | 322.56 |
| 6 (0x06) | 184.32 | 276.48 | 368.64 |

## VDR COMPLEX MODE

The complex mode of VDR works with selectable bandwidths of $25 \%$ of the sample rate ( $50 \%$ of the Nyquist band) and $43 \%$ of the sample rate ( $86 \%$ of the Nyquist band). Figure 118 and Figure 119 show the frequency zones for VDR in the complex mode. When operating VDR in complex mode, place I input signal data on Channel A and place Q input signal data on Channel B.

Figure 118 shows the frequency zones for the $25 \%$ bandwidth VDR mode with a center frequency of $\mathrm{f}_{\mathrm{s}} / 4$ (tuning word $=$ $0 x 04)$. The frequency zones where the amplitude may not exceed - 30 dBFS are the upper and lower portions of the Nyquist band extending into the complex domain.

Figure 118. 25\% VDR Bandwidth, Complex Mode
The center frequency ( $\mathrm{f}_{\mathrm{VDR}}$ ) of the VDR function can be tuned within the Nyquist band from 0 to $15 / 16 \mathrm{f}_{\mathrm{s}}$ in $1 / 16 \mathrm{f}_{\mathrm{s}}$ steps. In complex mode, Tuning Word 0 (0x00) through Tuning Word 15 ( 0 x 0 F ) are valid. Table 29 and Table 30 show the tuning words and frequency values for the $25 \%$ complex mode. Table 29 shows the relative frequency values, and Table 30 shows the absolute frequency values based on a sample rate of 737.28 MSPS.

Table 29. VDR Tuning Words and Relative Frequency Values, 25\% BW, Complex Mode

| Tuning Word | Lower Band Edge | Center Frequency | Upper Band Edge |
| :---: | :---: | :---: | :---: |
| 0 (0x00) | $-1 / 8 \mathrm{f}_{5}$ | 0 | 1/8 f |
| 1 (0x01) | $-1 / 16$ fs | 1/16 fs | 3/16 fs |
| 2 (0x02) | 0 | $1 / 8 \mathrm{f}_{5}$ | $1 / 4 \mathrm{fs}$ |
| 3 (0x03) | 1/16 fs | 3/16 fs | $5 / 16 \mathrm{f}_{5}$ |
| 4 (0x04) | $1 / 8 \mathrm{ff}$ | $1 / 4 \mathrm{f}_{5}$ | $3 / 8 \mathrm{f}_{\mathrm{s}}$ |
| 5 (0x05) | $3 / 16 \mathrm{f}_{5}$ | $5 / 16 \mathrm{f}_{\mathrm{s}}$ | $7 / 16 \mathrm{f}_{5}$ |

## DIGITAL OUTPUTS

## INTRODUCTION TO JESD204B INTERFACE

The AD6674 digital outputs are designed to the JEDEC Standard No. JESD204B serial interface for data converters. JESD204B is a protocol to link the AD6674 to a digital processing device over a serial interface with lane rates of up to 12.5 Gbps . The benefits of the JESD204B interface over LVDS include a reduction in required board area for data interface routing, and enabling smaller packages for converter and logic devices.

## JESD204B OVERVIEW

The JESD204B data transmit block assembles the parallel data from the ADC into frames and uses $8 \mathrm{~B} / 10 \mathrm{~B}$ encoding as well as optional scrambling to form serial output data. Lane synchronization is supported through the use of special control characters during the initial establishment of the link. Additional control characters are embedded in the data stream to maintain synchronization thereafter. A JESD204B receiver is required to complete the serial link. For additional details on the JESD204B interface, users are encouraged to refer to the JESD204B standard.
The AD6674 JESD204B data transmit block maps up to two physical ADCs or up to eight virtual converters (when DDCs are enabled) over a link. A link can be configured to use one, two, or four JESD204B lanes. The JESD204B specification refers to a number of parameters to define the link and these parameters must match between the JESD204B transmitter (AD6674 output) and receiver (logic device input).
The JESD204B link is described according to the following parameters:

- $\quad \mathrm{L}$ is the number of lanes per converter device (lanes per link) $($ AD6674 value $=1,2$, or 4$)$
- $\quad \mathrm{M}$ is the number of converters per converter device (virtual converters per link) (AD6674 value $=1,2,4$, or 8$)$
- $\quad \mathrm{F}$ is the number of octets per frame $(\mathrm{AD} 6674$ value $=1,2$, 4,8 , or 16 )
- $\quad \mathrm{N}^{\prime}$ is the number of bits per sample (JESD204B word size) (AD6674 value $=8$ or 16)
- $\quad \mathrm{N}$ is the converter resolution $(\operatorname{AD6674}$ value $=7$ to 16$)$
- CS is the number of control bits per sample (AD6674 value $=0,1,2$, or 3 )
- K is the number of frames per multiframe $(\mathrm{AD} 6674$ value $=4,8,12,16,20,24,28$, or 32$)$
- $\quad$ S is the number of samples transmitted per single converter per frame cycle (AD6674 value $=$ set automatically based on $\mathrm{L}, \mathrm{M}, \mathrm{F}$, and $\mathrm{N}^{\prime}$ )
- HD is high density mode (AD6674 = set automatically based on $\mathrm{L}, \mathrm{M}, \mathrm{F}$, and $\mathrm{N}^{\prime}$ )
- CF is the number of control words per frame clock cycle per converter device $(\operatorname{AD6674}$ value $=0)$

Figure 120 shows a simplified block diagram of the AD6674 JESD204B link. By default, the AD6674 is configured to use two converters and four lanes. Converter A data is output to SERDOUT $0 \pm /$ SERDOUT $1 \pm$, and Converter B is output to SERDOUT $2 \pm /$ SERDOUT3 $\pm$. The AD6674 allows other configurations such as combining the outputs of both converters onto a single lane or changing the mapping of the A and B digital output paths. These modes are set up through a quick configuration register in the SPI register map, along with additional customizable options.
By default in the AD6674, the 14-bit converter word from each converter is broken into two octets (eight bits of data). Bit 13 (MSB) through Bit 6 are in the first octet. The second octet contains Bit 5 through Bit 0 (LSB) and two tail bits. The tail bits can be configured as zeros or a pseudorandom number (PN) sequence. The tail bits can also be replaced with control bits indicating an overrange, SYSREF $\pm$, signal monitor output, or fast detect output.
The two resulting octets can be scrambled. Scrambling is optional; however, it is recommended to avoid spectral peaks when transmitting similar digital data patterns. The scrambler uses a self synchronizing, polynomial-based algorithm defined by the equation $1+\mathrm{x}^{14}+\mathrm{x}^{15}$. The descrambler in the receiver must be a self synchronizing version of the scrambler polynomial.
The two octets are then encoded with an $8 B / 10 B$ encoder. The 8B/10B encoder works by taking eight bits of data (an octet) and encoding them into a 10 -bit symbol. Figure 121 shows how the 14 -bit data is transferred from the ADC, the tail bits are added, the two octets are scrambled, and the octets are encoded into two 10-bit symbols. Figure 121 illustrates the default data format.

## AD6674

Figure 120. Transmit Link Simplified Block Diagram Showing Full Bandwidth Mode (Register 0x200=0x07)

Figure 121. ADC Output Datapath Showing Data Framing

Figure 122. Data Flow

## FUNCTIONAL OVERVIEW

The block diagram in Figure 122 shows the flow of data through the JESD204B hardware from the sample input to the physical output. The processing can be divided into layers that are derived from the open-source initiative (OSI) model that is widely used to describe the abstractions layers of communications systems. These are the transport layer, data link layer, and physical layer (serializer and output driver).

## Transport Layer

The transport layer packs the data (consisting of samples and optional control bits) into JESD204B frames, which are mapped to 8 -bit octets that are sent to the data link layer. The transport layer mapping is controlled by rules derived from the link parameters. Tail bits are added to fill gaps where required. Use the following equation to determine the number of tail bits within a sample (JESD204B word):

$$
T=N^{\prime}-N-C S
$$

## Data Link Layer

The data link layer is responsible for the low level functions of passing data across the link. These include optionally scrambling the data, inserting control characters for multichip synchronization/lane alignment/monitoring, and encoding 8 -bit octets into 10 -bit symbols. The data link layer is also responsible for sending the ILAS, which contains the link configuration data, used by the receiver to verify the settings in the transport layer.

## Physical Layer

The physical layer consists of the high speed circuitry clocked at the serial clock rate. In this section, parallel data is converted into one, two, or four lanes of high speed differential serial data.

## JESD204B LINK ESTABLISHMENT

The AD6674 JESD204B Tx interface operates in Subclass 1 as defined in the JEDEC Standard No. 204B (July 2011) specification. The link establishment process is divided into the following steps: code group synchronization, ILAS, and user data.

## Code Group Synchronization (CGS) and SYNCINB $\pm$

Code group synchronization (CGS) is the process by which the JESD204B receiver finds the boundaries between the 10 -bit symbols in the stream of data. During the CGS phase, the JESD204B transmit block transmits /K28.5/ characters. The receiver must locate /K28.5/ characters in its input data stream using clock and data recovery (CDR) techniques.
The receiver issues a synchronization request by asserting the SYNCINB $\pm$ pin of the AD6674 low. The JESD204B Tx begins sending /K/ characters. After the receiver has synchronized, it waits for the correct reception of at least four consecutive /K/ symbols. It then deasserts SYNCINB $\pm$. The AD6674 then transmits an ILAS on the following LMFC boundary.

For more information on the CGS phase, refer to the JEDEC Standard No. 204B (July 2011), Section 5.3.3.1.
The SYNCINB $\pm$ pin operation can also be controlled by the SPI. The SYNCINB $\pm$ signal is a differential LVDS mode signal by default, but it can also be driven single-ended. For more information on configuring the SYNCINB $\pm$ pin operation, refer to Register $0 \times 572$. The SYNCINB $\pm$ pin can also be configured to run in CMOS (single-ended) mode by setting Bit 4 in Register 0x572. When running SYNCINB $\pm$ in CMOS mode, connect the CMOS SYNCINB signal to Pin 21 (SYNCINB+) and leave Pin 20 (SYNCINB-) floating.

## Initial Lane Alignment Sequence (ILAS)

The ILAS phase follows the CGS phase and begins on the next LMFC boundary. The ILAS consists of four multiframes, with an /R/ character marking the beginning and an /A/ character marking the end. The ILAS begins by sending an /R/ character followed by 0 to 255 ramp data for one multiframe. On the second multiframe the link configuration data is sent, starting with the third character. The second character is a /Q/ character to confirm that the link configuration data follows. All undefined data slots are filled with ramp data. The ILAS sequence is never scrambled.

The ILAS sequence construction is shown in Figure 123. The four multiframes include the following:

- Multiframe 1: Begins with an /R/ character [K28.0] and ends with an /A/ character (K28.3).
- Multiframe 2: Begins with an /R/ character followed by a /Q/ (K28.4) character, followed by link configuration parameters over 14 configuration octets (see Table 33), and ends with an /A/ character. Many of the parameter values are of the value - 1 notation.
- Multiframe 3: Begins with an /R/ character (K28.0) and ends with an /A/ character (K28.3).
- Multiframe 4: Begins with an /R/ character (K28.0) and ends with an /A/ character (K28.3).

## User Data and Error Detection

After the ILAS is complete, the user data is sent. Normally, in a frame all characters are user data. However, to monitor the frame clock and multiframe clock synchronization, there is a mechanism for replacing characters with /F/ or /A/ alignment characters when the data meets certain conditions. These conditions are different for unscrambled and scrambled data. The scrambling operation is enabled by default but can be disabled using the SPI.

For scrambled data, any 0 xFC character at the end of a frame is replaced by an $/ \mathrm{F} /$ and any $0 \times 7 \mathrm{C}$ character at the end of a multiframe is replaced with an /A/. The JESD204B Rx checks for /F/ and /A/ characters in the received data stream and verifies that they only occur in the expected locations. If an unexpected /F/ or /A/ character is found, the receiver handles the situation by using dynamic realignment or asserting the SYNCINB $\pm$ signal for more than four frames to initiate a resynchronization. For unscrambled data, if the final character of two subsequent frames is equal, the second character is replaced with an /F/ if it is at the end of a frame, and an $/ \mathrm{A} /$ if it is at the end of a multiframe.

Insertion of alignment characters can be modified using the SPI. The frame alignment character insertion is enabled by default. For more information on the link controls, see Register 0x571 in the Memory Map section.

Figure 123. Initial Lane Alignment Sequence
Table 33. AD6674 Control Characters Used in JESD204B

| Abbreviation | Control Symbol | 8-Bit Value | 10-Bit Value, RD $^{\mathbf{1}}=\mathbf{- 1}$ | 10-Bit Value, $\mathbf{R D}^{\mathbf{1}}=\boldsymbol{+ 1}$ | Description |
| :--- | :--- | :--- | :--- | :--- | :--- |
| /R/ | K28.0 | 00011100 | 0011110100 | 1100001011 | Start of multiframe |
| /A/ | K28.3 | 01111100 | 0011110011 | 1100001100 | Lane alignment |
| /Q/ | K28.4 | 10011100 | 0011110010 | 1100001101 | Start of link configuration data |
| /K/ | K28.5 | 10111100 | 0011111010 | 1100000101 | Group synchronization |
| /F/ | K28.7 | 11111100 | 0011111000 | 1100000111 | Frame alignment |

${ }^{1} \mathrm{RD}$ is running disparity.

## 8B/10B Encoder

The 8B/10B encoder converts 8-bit octets into 10-bit symbols and inserts control characters into the stream when needed. The control characters used in JESD204B are shown in Table 33. The $8 \mathrm{~B} / 10 \mathrm{~B}$ encoding ensures that the signal is dc balanced by using the same number of ones and zeros across multiple symbols.
The 8B/10B interface has options that can be controlled via the SPI. These operations include bypass and invert. These options are intended to be a troubleshooting tool for the verification of the digital front end (DFE). Refer to the Memory Map section, Register $0 \times 572$ [2:1], for information on configuring the $8 \mathrm{~B} / 10 \mathrm{~B}$ encoder.

## PHYSICAL LAYER (DRIVER) OUTPUTS

## Digital Outputs, Timing and Controls

The AD6674 physical layer consists of drivers that are defined in the JEDEC Standard No. 204B (July 2011). The differential digital outputs are powered up by default. The drivers use a dynamic $100 \Omega$ internal termination to reduce unwanted reflections.

Place a $100 \Omega$ differential termination resistor at each receiver input, which results in a nominal 300 mV p-p swing at the receiver (see Figure 124). Alternatively, single-ended $50 \Omega$ termination resistors can be used. When single-ended termination is used, the termination voltage is DRVDD/2; otherwise, $0.1 \mu \mathrm{~F}$ ac coupling capacitors can be used to terminate to any single-ended voltage.

Figure 124. AC-Coupled Digital Output Termination Example

The AD6674 digital outputs can interface with custom ASICs and FPGA receivers, providing superior switching performance in noisy environments. Single point-to-point network topologies are recommended with a single differential $100 \Omega$ termination resistor placed as close to the receiver inputs as possible. The common mode of the digital output automatically biases itself to half the DRVDD supply of $1.2 \mathrm{~V}\left(\mathrm{~V}_{\mathrm{CM}}=0.6 \mathrm{~V}\right)$. See Figure 125 for an example of dc coupling the outputs to the receiver logic.

Figure 125. DC-Coupled Digital Output Termination Example
If there is no far-end receiver termination, or if there is poor differential trace routing, timing errors may result. To avoid such timing errors, it is recommended that the trace length be less than six inches, and that the differential output traces be close together and at equal lengths.
Figure 126 to Figure 128, Figure 129 to Figure 131, and Figure 132 to Figure 134 show examples of the digital output data eye, time interval error (TIE) jitter histogram, and bathtub curve for one AD6674 lane running at $10 \mathrm{Gbps}, 7.37 \mathrm{Gbps}$, and 6 Gbps , respectively. The format of the output data is twos complement by default. To change the output data format, see the Memory Map section (Register 0x561 in Table 45).

## De-Emphasis

De-emphasis enables the receiver eye diagram mask to be met in conditions where the interconnect insertion loss does not meet the JESD204B specification. Use the de-emphasis feature only when the receiver is unable to recover the clock due to excessive insertion loss. Under normal conditions, it is disabled to conserve power. Additionally, enabling and setting too high a de-emphasis value on a short link may cause the receiver eye diagram to fail. Use the de-emphasis setting with caution because it may increase EMI. See the Memory Map section (Register 0x5C1 to Register 0x5C5 in Table 45) for more information.

## PLL

The PLL is used to generate the serializer clock, which operates at the JESD204B lane rate. The JESD204B lane rate control bit (Register 0x56E[4]) must be set to correspond with the lane rate.

Figure 135. DDCs and Virtual Converter Mapping

## JESD204B Tx CONVERTER MAPPING

To support the different chip operating modes, the AD6674 design treats each sample stream (real or I/Q) as originating from separate virtual converters. The I/Q samples are always mapped in pairs with the I samples mapped to the first virtual converter, and the Q samples mapped to the second virtual converter. With this transport layer mapping, the number of virtual converters are the same whether a single real converter is used along with a DDC block producing I/Q outputs, or an analog downconversion is used with two real converters producing I/Q outputs.
Figure 136 shows a block diagram of the two scenarios described for I/Q transport layer mapping.

Figure 136. I/Q Transport Layer Mapping
The JESD204B Tx block for AD6674 supports up to four digital DDC blocks. Each DDC block outputs either two sample streams (I/Q) for the complex data components (real + imaginary) or one sample stream for real (I) data. The JESD204B interface can be configured to use up to eight virtual converters depending on the DDC configuration. Figure 135 shows the virtual converters and their relationship to DDC outputs when complex outputs are used. Table 34 shows the virtual converter mapping for each chip operating mode when channel swapping is disabled.

## CONFIGURING THE JESD204B LINK

The AD6674 has one JESD204B link. It offers an easy way to set up the JESD204B link through the quick configuration register (Register 0x570). The serial outputs (SERDOUT0 $\pm$ to SERDOUT3 $\pm$ ) are considered to be part of one JESD204B link. The basic parameters that determine the link setup are

- Number of lanes per link (L)
- Number of converters per link (M)
- Number of octets per frame (F)

If the internal DDCs are used for on-chip digital processing, the M value represents the number of virtual converters. The virtual converter mapping setup is shown in Figure 135.
The maximum lane rate allowed by the JESD204B specification is 12.5 Gbps . The lane rate is related to the JESD204B parameters using the following equation:

$$
\text { Lane Line Rate }=\frac{\left(M \times N^{\prime} \times\left(\frac{10}{8}\right) \times f_{\text {OUT }}\right)}{L}
$$

where:

$$
f_{\text {OUT }}=\frac{f_{\text {ADC_сLOCK }}}{\text { Decimation Ratio }}
$$

The decimation ratio (DCM) is the parameter programmed in Register 0x201.

Use the following steps to configure the output:

1. Power down the link.
2. Select the quick configuration options.
3. Configure detailed options.
4. Set output lane mapping (optional).
5. Set additional driver configuration options (optional).
6. Power up the link.

If the lane rate calculated is less than 6.25 Gbps , select the low lane rate option by programming a value of $0 \times 10$ to Register $0 \times 56 \mathrm{E}$.

Table 35 and Table 36 show the JESD204B output configurations supported for both $\mathrm{N}^{\prime}=16$ and $\mathrm{N}^{\prime}=8$, respectively, for a given number of virtual converters. Take care to ensure that the serial lane rate for a given configuration is within the supported range of 3.125 Gbps to 12.5 Gbps .

See the Example 1: ADC with DDC Option (Two ADCs + Four DDCs) section and the Example 2: ADC with NSR Option (Two ADCs + NSR) section for two examples describing which JESD204B transport layer settings are valid for a given chip mode.

## Example 1: ADC with DDC Option (Two ADCs + Four DDCs)

The chip application mode is four-DDC mode (see Figure 137) with the following characteristics:

- Two 14-bit converters at 1 GSPS
- Four DDCs application layer mode with complex outputs (I/Q)
- Chip decimation ratio $=16$
- $\quad \mathrm{DDC}$ decimation ratio $=16($ see Table 15)

The JESD204B output configuration is as follows:

- Virtual converters required $=8$ (see Table 35)
- Output sample rate (fout) $=1000 / 16=62.5$ MSPS

Supported JESD204B output configurations (see Table 35) include

- $\mathrm{N}^{\prime}=16$ bits
- $\mathrm{N}=14$ bits
- $\mathrm{L}=1, \mathrm{M}=8$, and $\mathrm{F}=16$; or $\mathrm{L}=2, \mathrm{M}=8$, and $\mathrm{F}=8$ (quick configuration $=0 \times 1 \mathrm{C}$ or $0 \times 5 \mathrm{~B}$ )
- $\mathrm{CS}=0$ to 1
- $\mathrm{K}=32$
- Output serial lane rate $=10 \mathrm{Gbps}$ per lane $(\mathrm{L}=1)$ or 5 Gbps per lane ( $L=2$ )
- For $\mathrm{L}=1$, low lane rate mode disabled
- For $\mathrm{L}=2$, low lane rate mode enabled

Example 1 shows the flexibility in the digital and lane configurations for the AD6674. The sample rate is 1 GSPS, but the outputs are all combined into either one or two lanes depending on the I/O speed capability of the receiving device.

## Example 2: ADC with NSR Option (Two ADCs + NSR)

The chip application mode is NSR mode (see Figure 138) with the following characteristics:

- Two 14 -bit converters at 500 MSPS
- NSR blocks enabled for each channel
- Chip decimation ratio $=1$

The JESD204B output configuration is as follows:

- Virtual converters required $=2$ (see Table 35)
- Output sample rate $\left(f_{\text {fout }}\right)=500$ MSPS

Supported JESD204B output configurations (see Table 35) include

- $\mathrm{N}^{\prime}=16$ bits
- $\mathrm{N}=9$ bits
- $\mathrm{L}=2, \mathrm{M}=2$, and $\mathrm{F}=2 ; \mathrm{L}=4, \mathrm{M}=2$, and $\mathrm{F}=1$ (quick configuration $=0 \times 49$ or $0 \times 88$ )
- $\mathrm{CS}=0$ to 2
- $\mathrm{K}=32$
- Output serial lane rate $=10 \mathrm{Gbps}$ per lane $(\mathrm{L}=2)$ or 5 Gbps per lane $(\mathrm{L}=4)$
- For $\mathrm{L}=2$, low lane rate mode disabled
- For $\mathrm{L}=4$, low lane rate mode enabled

Example 2 shows the flexibility in the digital and lane configurations for the AD6674. The sample rate is 500 MSPS, but the outputs are all combined into either two or four lanes depending on the I/O speed capability of the receiving device.

Figure 138. Two-ADC + NSR Mode

## MULTICHIP SYNCHRONIZATION

The AD6674 has a SYSREF $\pm$ input that allows the user flexible options for synchronizing the internal blocks. The SYSREF $\pm$ input is a source synchronous system reference signal that enables multichip synchronization. The input clock divider, DDCs, signal monitor block, and JESD204B link can be synchronized using the SYSREF $\pm$ input. For the highest level of timing accuracy, SYSREF $\pm$ must meet setup and hold requirements relative to the $\mathrm{CLK} \pm$ input.
The flowchart in Figure 139 describes the internal mechanism by which multichip synchronization can be achieved in the

AD6674. The AD6674 supports several features that aid users in meeting the requirements for capturing a SYSREF $\pm$ signal. The SYSREF $\pm$ sample event is defined as either a synchronous low to high transition or a synchronous high to low transition. Additionally, the AD6674 allows the SYSREF $\pm$ signal to be sampled using either the rising edge or falling edge of the CLK $\pm$ input. The AD6674 also has the ability to ignore a programmable number (up to 16) of SYSREF $\pm$ events. The SYSREF $\pm$ control options can be selected using Register 0x120 and Register 0x121.

Figure 139. Multichip Synchronization

## AD6674

## SYSREF $\pm$ SETUP/HOLD WINDOW MONITOR

To assist in ensuring a valid SYSREF $\pm$ capture, the AD6674 has a SYSREF $\pm$ setup and hold window monitor. This feature allows the system designer to determine the location of the SYSREF $\pm$ signals relative to the CLK $\pm$ signals by reading back the amount of setup/hold margin on the interface through the memory map. Figure 140 and Figure 141 show both the setup and hold
status values for different phases of SYSREF $\pm$. The setup detector returns the status of the SYSREF $\pm$ signal before the CLK $\pm$ edge and the hold detector returns the status of the SYSREF $\pm$ signal after the CLK $\pm$ edge. Register 0x128 stores the status of SYSREF $\pm$ and lets the user know if the SYSREF $\pm$ signal was successfully captured by the ADC.

Figure 140. SYSREF $\pm$ Setup Detector

Figure 141. SYSREF $\pm$ Hold Detector

Table 37 shows the description of the contents of Register 0x128 and how to interpret them.
Table 37. SYSREF $\pm$ Setup/Hold Monitor, Register 0x128

| Register 0x128[7:4] Hold <br> Status | Register 0x128[3:0] Setup <br> Status | Description |
| :--- | :--- | :--- |
| $0 \times 0$ | $0 \times 0$ to 0x7 | Possible setup error; the smaller this number, the smaller the setup margin |
| $0 \times 0$ to $0 \times 8$ | $0 \times 8$ | No setup or hold error (best hold margin) |
| $0 \times 8$ | $0 \times 9$ to $0 \times F$ | No setup or hold error (best setup and hold margin) |
| $0 \times 8$ | $0 \times 0$ | No setup or hold error (best setup margin) |
| $0 \times 9$ to $0 \times F$ | $0 \times 0$ | Possible hold error; the larger this number, the smaller the hold margin |
| $0 \times 0$ | $0 \times 0$ | Possible setup or hold error |

## TEST MODES <br> ADC TEST MODES

The AD6674 has various test options that aid in the system level implementation. The AD6674 has ADC test modes that are available in Register 0x550. These test modes are described in Table 38. When an output test mode is enabled, the analog section of the ADC is disconnected from the digital back-end blocks and the test pattern is run through the output formatting block. Some of the test patterns are subject to output formatting, and some are not. The PN generators from the PN sequence tests can be reset by setting Bit 4 or Bit 5 of Register 0x550. These tests can be performed with or without an analog signal (if present, the analog signal is ignored), but they do require an encode clock. For more information, see the AN-877 Application Note, Interfacing to High Speed ADCs via SPI.

## JESD204B BLOCK TEST MODES

In addition to the ADC test modes, the AD6674 also has flexible test modes in the JESD204B block. These test modes are listed in Register 0x573 and Register 0x574. These test patterns can be inserted at various points along the output data path. These test
insertion points are shown in Figure 121. Table 39 describes the various test modes available in the JESD204B block. For the AD6674, a transition from the test modes (Register 0x573 $\neq$ $0 \times 00)$ to normal mode $(0 \times 573=0 \times 00)$ require a SPI soft reset. This is done by writing $0 \times 81$ to Register 0x00 (self cleared).

## Transport Layer Sample Test Mode

The transport layer samples are implemented in the AD6674 as defined by Section 5.1.6.3 in the JEDEC JESD204B specification. These tests are enabled via Register 0x571[5]. The test pattern is equivalent to the raw samples from the ADC.

## Interface Test Modes

The interface test modes are described in Register 0x573, Bits[3:0]. These test modes are also explained in Table 39. The interface tests can be inserted at various points along the data. See Figure 121 for more information on the test insertion points. Register 0x573, Bits[5:4], show where these tests are inserted.

Table 38. ADC Test Modes

| Output Test Mode <br> Bit Sequence | Pattern Name | Expression | Default/Seed <br> Value | Sample (N, N + 1, N + 2, ...) |
| :--- | :--- | :--- | :--- | :--- |

Table 39. JESD204B Interface Test Modes

| Output Test Mode <br> Bit Sequence | Pattern Name | Expression | Default |
| :--- | :--- | :--- | :--- |
| 0000 | Off (default) | Not applicable | Not applicable |
| 0001 | Alternating checker board | $0 \times 5555,0 \times A A A A, 0 \times 5555 \ldots$ | Not applicable |
| 0010 | $1 / 0$ word toggle | $0 \times 0000,0 \times F F F F, 0 \times 0000 \ldots$ | Not applicable |
| 0011 | 31 -bit PN sequence | $x^{31}+x^{28}+1$ | $0 x 0003 A F F F$ |
| 0100 | 23-bit PN sequence | $x^{23}+x^{18}+1$ | $0 x 003 A F F$ |
| 0101 | 15-bit PN sequence | $x^{15}+x^{14}+1$ | $0 \times 03 A F$ |
| 0110 | 9-bit PN sequence | $x^{9}+x^{5}+1$ | $0 \times 092$ |
| 0111 | 7-bit PN sequence | $x^{7}+x^{6}+1$ | $0 \times 07$ |
| 1000 | Ramp output | $(x) \% 2^{16}$ | Ramp size depends on test insertion point |
| 1110 | Continuous/repeat user test | Register 0x551 to Register 0x558 | User Pattern 1 to User Pattern 4, then repeat |
| 1111 | Register 0x551 to Register 0x558 | User Pattern 1 to User Pattern 4, then zeros |  |

Table 40, Table 41, and Table 42 show examples of some of the test modes when inserted at the JESD204B sample input, physical layer (PHY) 10-bit input, and scrambler 8-bit input. UP in the Table 40 to Table 42 represent the user pattern control bits from the memory map register table (see Table 45).

## Data Link Layer Test Modes

The data link layer test modes are implemented in the AD6674 as defined by Section 5.3.3.8.2 in the JEDEC JESD204B specification. These tests are shown in Register 0x574, Bits[2:0]. Test patterns inserted at this point are useful for verifying the functionality of the data link layer. When the data link layer test modes are enabled, disable SYNCINB $\pm$ by writing $0 \mathrm{xC0}$ to Register 0x572.

## SERIAL PORT INTERFACE (SPI)

The AD6674 SPI allows the user to configure the converter for specific functions or operations through a structured register space provided inside the ADC. The SPI gives the user added flexibility and customization, depending on the application. Addresses are accessed via the serial port and can be written to or read from via the serial port. Memory is organized into bytes that can be further divided into fields. These fields are documented in the Memory Map section. For detailed operational information, see the Serial Control Interface Standard.

## CONFIGURATION USING THE SPI

Three pins define the SPI of this ADC: the SCLK pin, the SDIO pin, and the CSB pin (see Table 43). The SCLK (serial clock) pin is used to synchronize the read and write data presented from/to the ADC. The SDIO (serial data input/output) pin is a dual-purpose pin that allows data to be sent and read from the internal ADC memory map registers. The CSB (chip select bar) pin is an active low control that enables or disables the read and write cycles.

Table 43. Serial Port Interface Pins

| Pin | Function |
| :--- | :--- |
| SCLK | Serial clock. The serial shift clock input, which is used to <br> synchronize serial interface reads and writes. |
| SDIO | Serial data input/output. A dual-purpose pin that <br> typically serves as an input or an output, depending on <br> the instruction being sent and the relative position in the <br> timing frame. <br> Chip select bar. An active low control that gates the read <br> and write cycles. |

The falling edge of CSB, in conjunction with the rising edge of SCLK, determines the start of the framing. See Figure 4 and Table 5 for an example of the serial timing and its definitions.

Other modes involving the CSB pin are available. The CSB pin can be held low indefinitely, which permanently enables the device; this is called streaming. The CSB can stall high between bytes to allow additional external timing. When CSB is tied high, SPI functions are placed in a high impedance mode. This mode turns on any SPI pin secondary functions.
All data is composed of 8 -bit words. The first bit of each individual byte of serial data indicates whether a read or write
command is issued. This bit allows the SDIO pin to change direction from an input to an output.
In addition to word length, the instruction phase determines whether the serial frame is a read or write operation, allowing the serial port to be used both to program the chip and to read the contents of the on-chip memory. If the instruction is a readback operation, performing a readback causes the SDIO pin to change direction from an input to an output at the appropriate point in the serial frame.
Data can be sent in MSB first mode or in LSB first mode. MSB first is the default on power-up and can be changed via the SPI port configuration register. For more information about this and other features, see the Serial Control Interface Standard.

## HARDWARE INTERFACE

The pins described in Table 43 comprise the physical interface between the user programming device and the serial port of the AD6674. The SCLK pin and the CSB pin function as inputs when using the SPI. The SDIO pin is bidirectional, functioning as an input during write phases and as an output during readback.

The SPI interface is flexible enough to be controlled by either FPGAs or microcontrollers. One method for SPI configuration is described in detail in the AN-812 Application Note, Microcontroller-Based Serial Port Interface (SPI) Boot Circuit.
Do not activate the SPI port during periods when the full dynamic performance of the converter is required. Because the SCLK signal, the CSB signal, and the SDIO signal are typically asynchronous to the ADC clock, noise from these signals can degrade converter performance. If the on-board SPI bus is used for other devices, it may be necessary to provide buffers between this bus and the AD6674 to prevent these signals from transitioning at the converter inputs during critical sampling periods.

## SPI ACCESSIBLE FEATURES

Table 44 provides a brief description of the general features that are accessible via the SPI. These features are described in detail in the Serial Control Interface Standard. The AD6674 device specific features are described in the Memory Map section.

Table 44. Features Accessible Using the SPI

| Feature Name | Description |
| :--- | :--- |
| Mode | Allows the user to set either power-down mode or standby mode |
| Clock | Allows the user to access the clock divider via the SPI |
| Test I/O | Allows the user to set test modes to have known data on output bits |
| Output Mode | Allows the user to set up outputs |
| Serializer/Deserializer (SERDES) Output Setup | Allows the user to vary SERDES settings, including swing and emphasis |

## MEMORY MAP

## READING THE MEMORY MAP REGISTER TABLE

Each row in the memory map register table has eight bit locations. The memory map is roughly divided into seven sections: the Analog Devices SPI registers, the analog input buffer control registers, ADC function registers, the DDC function registers, NSR decimate by 2 and noise shaping requantizer registers, variable dynamic range registers, and the digital outputs and test modes registers.

Table 45 (see the Memory Map Register Table section) documents the default hexadecimal value for each hexadecimal address shown. The column with the heading Bit 7 (MSB) is the start of the default hexadecimal value given. For example, Address 0x561, the output mode register, has a hexadecimal default value of $0 \times 01$. This means that $\operatorname{Bit} 0=1$, and the remaining bits are 0 s . This setting is the default output format value, which is twos complement. For more information on this function and others, see the Table 45.

## Open and Reserved Locations

All address and bit locations that are not included in Table 45 are not currently supported for this device. Write unused bits of a valid address location with 0 s unless the default value is set otherwise. Writing to these locations is required only when part of an address location is open (for example, Address 0x561). If the entire address location is open (for example, Address 0x013), do not write to this address location.

## Default Values

After the AD6674 is reset, critical registers are loaded with default values. The default values for the registers are given in the memory map register table, Table 45.

## Logic Levels

An explanation of logic level terminology follows:

- "Bit is set" is synonymous with "bit is set to Logic 1" or "writing Logic 1 for the bit."
- "Clear a bit" is synonymous with "bit is set to Logic 0 " or "writing Logic 0 for the bit."
- "X" denotes a "don't care".

## Channel Specific Registers

Some channel setup functions such as buffer input termination (Register 0x016) can be programmed to a different value for each channel. In these cases, channel address locations are internally duplicated for each channel. These registers and bits are designated in Table 45 as local. These local registers and bits can be accessed by setting the appropriate Channel A or Channel B bits in Register 0x008. If both bits are set, the subsequent write affects the registers of both channels. In a read cycle, set only Channel A or Channel B to read one of the two registers. If both bits are set during an SPI read cycle, the device returns the value for Channel A. Registers and bits designated as global in Table 45 affect the entire device and the channel features for which independent settings are not allowed between channels. The settings in Register 0x008 do not affect the global registers and bits.

## SPI Soft Reset

After issuing a soft reset by programming $0 \times 81$ to Register $0 \times 000$, the AD6674 requires 5 ms to recover. Therefore, when programming the AD6674 for application setup, ensure that an adequate delay is programmed into the firmware after asserting the soft reset and before starting the device setup.

## MEMORY MAP REGISTER TABLE

All address and bit locations that are not included in Table 45 are not currently supported for this device.
Table 45. Memory Map Registers

| Reg. Addr. (Hex) | Register Name | Bit 7 <br> (MSB) | Bit 6 | Bit 5 | Bit 4 | Bit 3 | Bit 2 | Bit 1 | Bit 0 (LSB) | Default | Notes |

## APPLICATIONS INFORMATION

## POWER SUPPLY RECOMMENDATIONS

The AD6674 must be powered by the following seven supplies: AVDD1 $=1.25 \mathrm{~V}$, AVDD2 $=2.5 \mathrm{~V}$, AVDD3 $=3.3 \mathrm{~V}$, AVDD1_SR $=1.25 \mathrm{~V}, \mathrm{DVDD}=1.25 \mathrm{~V}, \mathrm{DRVDD}=1.25 \mathrm{~V}, \mathrm{SPIVDD}=1.8 \mathrm{~V}$. For applications requiring an optimal high power efficiency and low noise performance, it is recommended that the ADP2164 and ADP2370 switching regulators be used to convert the 3.3 V , 5.0 V , or 12 V input rails to an intermediate rail ( 1.8 V and 3.8 V ). These intermediate rails are then postregulated by very low noise, low dropout (LDO) regulators (ADP1741, ADM7172, and ADP125). Figure 142 shows the recommended method. For more detailed information on the recommended power solution, refer to the AD6674 evaluation board documentation.

Figure 142. High Efficiency, Low Noise Power Solution for the AD6674
It is not necessary to split all of these power domains in all cases. The recommended solution shown in Figure 142 provides the lowest noise, highest efficiency power delivery system for the AD6674. If only one 1.25 V supply is available, it must be routed to AVDD1 first and then tapped off and isolated with a ferrite bead or a filter choke preceded by decoupling capacitors for AVDD1_SR, DVDD, and DRVDD, in that order. The user can use several different decoupling capacitors to cover both high and low frequencies. These must be located close to the point of entry at the PCB level and close to the devices, with minimal trace lengths.

## EXPOSED PAD THERMAL HEAT SLUG RECOMMENDATIONS

It is required that the exposed pad on the underside of the ADC be connected to ground to achieve the best electrical and
thermal performance of the AD6674. Connect an exposed continuous copper plane on the PCB to the AD6674 exposed pad, Pin 0 . The copper plane must have several vias to achieve the lowest possible resistive thermal path for heat dissipation to flow through the bottom of the PCB. These vias must be solder filled or plugged. The number of vias and the fill determine the resultant $\theta_{\mathrm{JA}}$ measured on the board.
To maximize the coverage and adhesion between the ADC and PCB , partition the continuous copper plane by overlaying a silkscreen on the PCB into several uniform sections. This provides several tie points between the ADC and PCB during the reflow process, whereas using one continuous plane with no partitions only guarantees one tie point. See Figure 143 for a PCB layout example. For detailed information on packaging and the PCB layout of chip scale packages, see the AN-772 Application Note, A Design and Manufacturing Guide for the Lead Frame Chip Scale Package (LFCSP).

Figure 143. Recommended PCB Layout of Exposed Pad for the AD6674

## AVDD1_SR (PIN 57) AND AGND (PIN 56, PIN 60)

AVDD1_SR (Pin 57) and AGND (Pin 56 and Pin 60) can be used to provide a separate power supply node to the SYSREF $\pm$ circuits of the AD6674. If running in Subclass 1, the AD6674 can support periodic one-shot or gapped signals. To minimize the coupling of this supply into the AVDD1 supply node, adequate supply bypassing is needed.

${ }^{1} \mathrm{Z}=$ RoHS Compliant Part.
${ }^{2}$ The AD6674-500EBZ, AD6674-750EBZ, and AD6674-1000EBZ evaluation boards are optimized for the full analog input frequency range.

Компания «ЭлектроПласт» предлагает заключение долгосрочных отношений при поставках импортных электронных компонентов на взаимовыгодных условиях!

Наши преимущества:

- Оперативные поставки широкого спектра электронных компонентов отечественного и импортного производства напрямую от производителей и с крупнейших мировых складов;
- Поставка более 17-ти миллионов наименований электронных компонентов;
- Поставка сложных, дефицитных, либо снятых с производства позиций;
- Оперативные сроки поставки под заказ (от 5 рабочих дней);
- Экспресс доставка в любую точку России;
- Техническая поддержка проекта, помощь в подборе аналогов, поставка прототипов;
- Система менеджмента качества сертифицирована по Международному стандарту ISO 9001;
- Лицензия ФСБ на осуществление работ с использованием сведений, составляющих государственную тайну;
- Поставка специализированных компонентов (Xilinx, Altera, Analog Devices, Intersil, Interpoint, Microsemi, Aeroflex, Peregrine, Syfer, Eurofarad, Texas Instrument, Miteq, Cobham, E2V, MA-COM, Hittite, Mini-Circuits,General Dynamics и др.);

Помимо этого, одним из направлений компании «ЭлектроПласт» является направление «Источники питания». Мы предлагаем Вам помощь Конструкторского отдела:

- Подбор оптимального решения, техническое обоснование при выборе компонента;
- Подбор аналогов;
- Консультации по применению компонента;
- Поставка образцов и прототипов;
- Техническая поддержка проекта;
- Защита от снятия компонента с производства.

[^0]:    ${ }^{1}$ See the AN-835 Application Note, Understanding High Speed ADC Testing and Evaluation, for definitions and for details on how these tests were completed.
    ${ }^{2}$ Noise density is measured at low analog input frequency ( 30 MHz ).
    ${ }^{3}$ See Table 10 for recommended device settings to achieve stated typical performance.
    ${ }^{4}$ When NSR is activated on the AD6674-750 and AD6674-1000, the decimating half-band filter is also enabled.
    ${ }^{5}$ Crosstalk is measured at 185 MHz with -1.0 dBFS analog input on one channel and no input on the adjacent channel.

[^1]:    ${ }^{1}$ Differential and common-mode return loss is measured from 100 MHz to $0.75 \times$ baud rate.

[^2]:    ${ }^{1}$ To ensure proper ADC operation, connect AVDD1_SR and AGND separately from the AVDD1 and EPAD connection. For more information, see the Applications Information section.

[^3]:    ${ }^{1}$ The input termination can be changed to accommodate the application with little or no impact to ac performance.
    ${ }^{2}$ The input capacitance can be set to 1.5 pF to achieve wider input bandwidth but results in slightly lower linearity and noise performance.

[^4]:    ${ }^{1}$ DCM = decimation.

[^5]:    ${ }^{1}$ fout $=A D C$ input sample rate $\div D D C$ decimation.

[^6]:    ${ }^{1} \mathrm{f}_{\mathrm{s}}$ is the ADC sample rate. Bandwidths listed are $<-0.001 \mathrm{~dB}$ of pass-band ripple and $>100 \mathrm{~dB}$ of stop-band alias rejection.
    ${ }^{2}$ The NCOs must be synchronized either through the SPI or through the SYSREF $\pm$ pin after all writes to the FTW or POW registers have completed. This is necessary to ensure the proper operation of the NCO. See the NCO Synchronization section for more information.

[^7]:    ${ }^{1}$ fout is the output sample rate. fout $=A D C$ sample rate/chip decimation. The JESD204B serial lane rate must be $\geq 3.125 \mathrm{Gbps}$ and $\leq 12.5 \mathrm{Gbps}$; when the serial lane rate is $\leq 12.5 \mathrm{Gbps}$ and $\geq 6.25 \mathrm{Gbps}$, the low lane rate mode must be disabled (set Bit 4 to $0 \times 0$ in Register $0 \times 56 \mathrm{E}$ ). When the serial lane rate is $<6.25 \mathrm{Gbps}$ and $\geq 3.125 \mathrm{Gbps}$, the low lane rate mode must be enabled (set Bit 4 to $0 \times 1$ in Register 0x56E).
    ${ }^{2}$ JESD204B transport layer descriptions are as described in the JESD204B Overview section.
    ${ }^{3}$ For $F=1, K=20,24,28$, and 32 . $\operatorname{For} F=2, K=12,16,20,24,28$, and 32 . For $F=4, K=8,12,16,20,24,28$, and 32 . $\operatorname{For} F=8$ and $F=16, K=4,8,12,16,20,24,28$, and 32 .
