## MAX66240

## DeepCover Secure Authenticator with ISO 15693, SHA-256, and 4Kb User EEPROM

### General Description

DeepCover® embedded security solutions cloak sensitive data under multiple layers of advanced physical security to provide the most secure key storage possible.

The DeepCover Secure Authenticator (MAX66240) is a transponder IC that combines an ISO/IEC 15693 and ISO 18000-3 Mode 1-compatible RF front-end, a FIPS 180-based SHA-256 engine, and 4096 bits of user EEPROM in a single chip. A bidirectional security model enforces two-way authentication between a host system and the MAX66240. Each device has its own guaranteed unique 64-bit ROM ID that is factory programmed into the chip. This ROM ID is used as a fundamental input parameter for cryptographic operations and serves as an electronic serial number within the application.

### Features and Benefits

- Dedicated Hardware-Accelerated SHA Engine for Generating SHA-256 MACs
- Strong Authentication with a High Bit Count User-Programmable Secret and Input Challenge
- 4096 Bits of User EEPROM with User-Programmable R/W Protection Options Including OTP/EPROM Emulation Mode
- Unique Factory-Programmed 64-Bit Identification Number
- ISO/IEC 15693: Up to 26kbps
- ±2kV HBM ESD Protection for All Pins

### Applications

- Access Control
- Asset Tracking
- Printer Cartridge Configuration and Monitoring
- Medical Sensor Authentication and Calibration
- System Intellectual Property Protection

*Ordering Information appears at end of data sheet.*

### Typical Application Circuit

DeepCover is a registered trademark of Maxim Integrated Products, Inc.

# ABRIDGED DATA SHEET

MAX66240

DeepCover Secure Authenticator with  
ISO 15693, SHA-256, and 4Kb User EEPROM

## Absolute Maximum Ratings

Voltage Range on Any Pin Relative to GND ..... -0.5V to +4.0V  
 Maximum RMS Current, AC1 to AC2 ..... 30mA  
 Maximum Incident Magnetic Field Strength  
 (ISO/IEC 7810-compliant antenna) ..... 141.6dB $\mu$ A/m  
 Operating Temperature Range ..... -40°C to +85°C

Junction Temperature ..... +150°C  
 Storage Temperature Range ..... -55°C to +125°C  
 Lead Temperature (soldering, 10s) ..... +300°C  
 Soldering Temperature (reflow) ..... +260°C

*Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.*

## Package Thermal Characteristics (Note 1)

SO

Junction-to-Ambient Thermal Resistance ( $\theta_{JA}$ ) ..... 136°C/W  
 Junction-to-Case Thermal Resistance ( $\theta_{JC}$ ) ..... 38°C/W

TDFN

Junction-to-Ambient Thermal Resistance ( $\theta_{JA}$ ) ..... 60°C/W  
 Junction-to-Case Thermal Resistance ( $\theta_{JC}$ ) ..... 30°C/W

**Note 1:** Package thermal resistances were obtained using the method described in JEDEC specification JESD51-7, using a four-layer board. For detailed information on package thermal considerations, refer to [www.maximintegrated.com/thermal-tutorial](http://www.maximintegrated.com/thermal-tutorial).

## Electrical Characteristics

( $T_A = -40^\circ\text{C}$  to  $+85^\circ\text{C}$ , unless otherwise noted.) (Note 2)

| 100% Modulation Min Pulse Width | $t_1$ MAX | Refer to ISO 15693-2 Section 7.1 (Note 11)      |     |     | 9.44 | $\mu$ s |
| 100% Modulation Max Pulse Width | $t_2$ MIN | Refer to ISO 15693-2 Section 7.1 (Notes 11, 15) |     | 6.5 |      | $\mu$ s |
| 100% Modulation Max Low Time    | $t_2$ MAX | Refer to ISO 15693-2 Section 7.1 (Note 11)      |     |     | 9.44 | $\mu$ s |
| 100% Modulation Min Rise Time   | $t_3$ MIN | Refer to ISO 15693-2 Section 7.1 (Note 11)      | 0   |     |      | $\mu$ s |
| 100% Modulation Max Rise Time   | $t_3$ MAX | Refer to ISO 15693-2 Section 7.1 (Notes 11, 15) |     | 3.0 |      | $\mu$ s |

**Note 2:** Limits are 100% production tested at  $T_A$  = +25°C or  $T_A$  = +85°C. Limits over the operating temperature range and relevant supply voltage range are guaranteed by design and characterization. Typical values are at +25°C.

**Note 3:** For commands where the  $t_{CSHA}$  interval occurs see the applicable communication examples sections. For RF commands, the interval begins after the EOF of a valid request frame. The interval ends once the device's self-timed SHA-256 computation cycle is complete.

**Note 4:** For commands where the  $t_{PROG}$  interval occurs see the applicable communication examples sections. For RF commands, the interval begins after the EOF of a valid request frame. The interval ends once the device's self-timed EEPROM write cycle is complete.

**Note 5:** Write-cycle endurance is tested in compliance with JESD47G.

**Note 6:** Not 100% production tested; guaranteed by reliability qualification.

**Note 7:** Data retention is tested in compliance with JESD47G.

**Note 8:** Guaranteed by 100% production test at elevated temperature for a shorter time; equivalence of this production test to the data sheet limit at operating temperature range is established by reliability testing.

**Note 9:** EEPROM writes can become nonfunctional after the data-retention time is exceeded. Long-term storage at elevated temperatures is not recommended.

**Note 10:** System requirement.

**Note 11:** Guaranteed by design and/or characterization only. Not production tested.

**Note 12:** Characterized in accordance with ISO/IEC 10373-7.

**Note 13:** Applies to Read/Write Scratchpad (writing), Write Memory, Compute and Read Page MAC, Set Protection, Authenticated Write Memory RF Setup, Authenticated Write Memory RF Execute, Authenticated Set Protection RF Setup, and Authenticated Set Protection RF Execute commands.

**Note 14:** Field strength between 350mA/m and 3A/m.

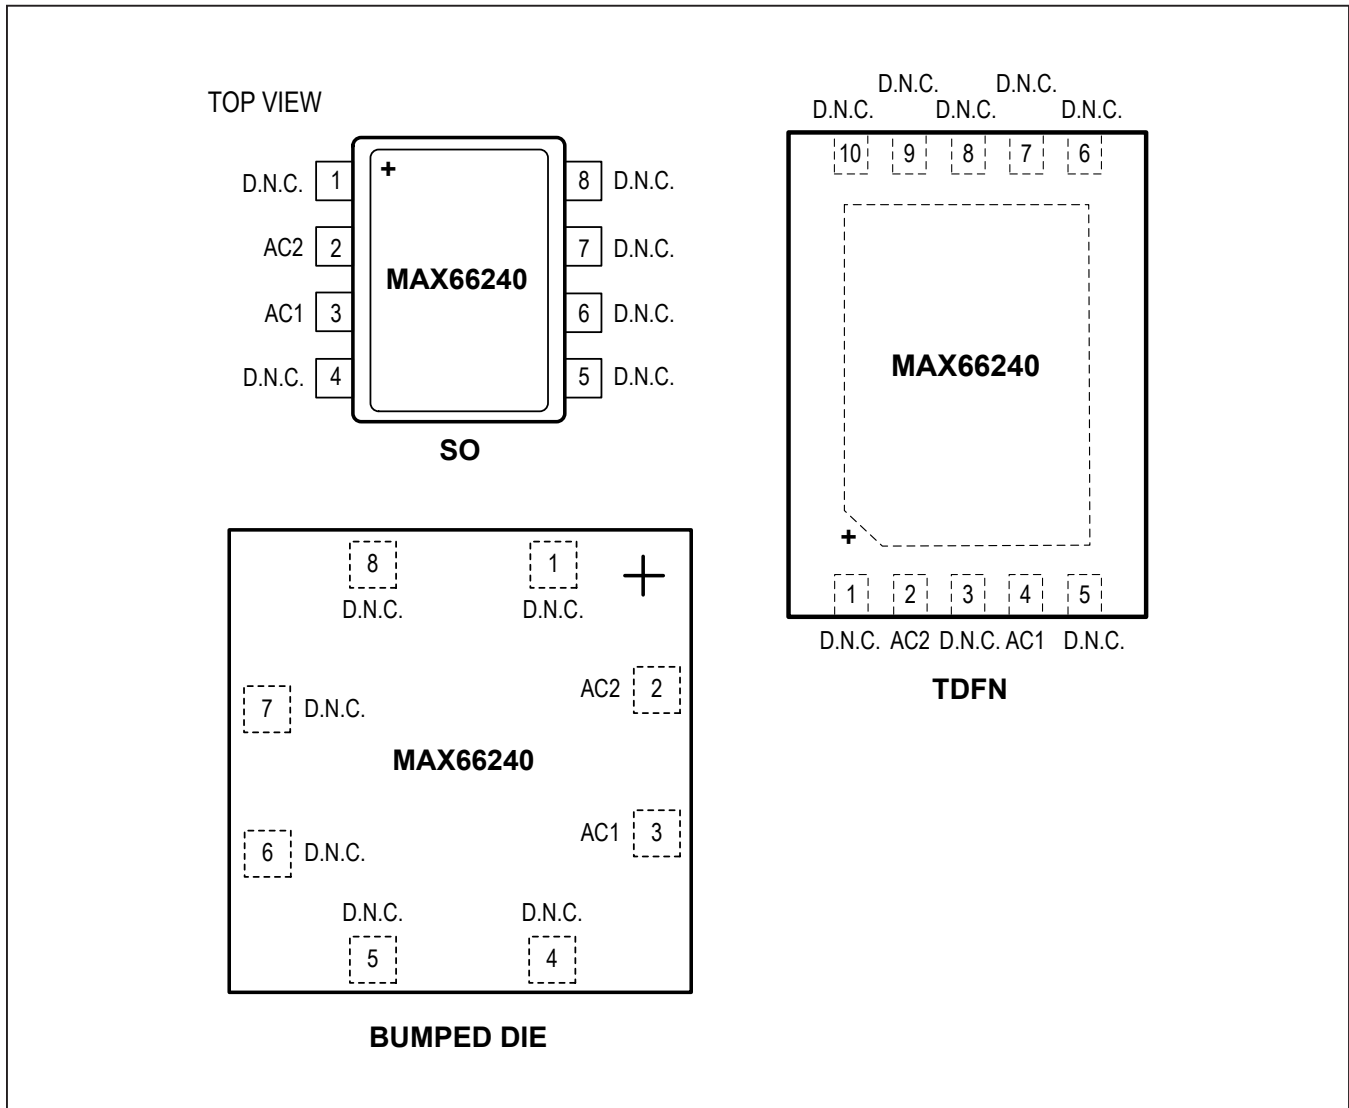

**Note 15:** Field strength between 350mA/m and 5A/m.

# ABRIDGED DATA SHEET

MAX66240

DeepCover Secure Authenticator with  
ISO 15693, SHA-256, and 4Kb User EEPROM

## Detailed Description

The MAX66240 transponder combines an ISO 15693 RF front-end, a SHA-256 engine, 4096 bits of user EEPROM organized as 16 256-bit pages, protection control, status memory, and a 64-bit ROM ID in a single chip. A 256-bit scratchpad assists when installing a new secret or stores the challenge when computing a page MAC.

It is common for a secure authentication IC to be attacked using a variety of sophisticated die-level methods to extract secure data, reverse device settings, etc., in an effort to compromise a system security implementation. To provide the highest affordable protection against this inevitable malicious attack, the MAX66240 employs proprietary die-level physical techniques, circuits, and crypto methods to protect sensitive data, control signals, and control settings.

There are multiple programmable options for the 4Kb user array including unrestricted read/write and four protection modes: read protection, write protection, EPROM emulation mode, and authentication protection. Read protection prevents user read-access to the memory, which effectively extends the secret into the protected memory. The data remains accessible only for the SHA-256 engine. Write protection prevents changes to the memory data. EPROM emulation mode logically ANDs memory data with incoming new data, which allows changing bits from 1 to 0, but not vice versa. By changing one bit at a time, this mode could be used to create a nonvolatile, nonresettable counter. EPROM emulation mode requires that the memory is not write protected. Authentication protection, if activated, requires that the host prove itself as authentic (i.e., knows the MAX66240 secret) to modify the memory by supplying a correct MAC that is based on the device secret, its ROM ID, memory data, and the new data to be copied to EEPROM. If the authentication hurdle is passed, the write protection and EPROM emulation mode

protections still determine the effect of the write access. Any protection, if activated, applies to individual memory pages. As a factory default, none of the protections is activated. Once authentication protection is activated, the reader must authenticate itself for memory writes as well as for additional changes to the memory protection.

In addition to its important use as a unique data value in cryptographic SHA-256 computations, the device's 64-bit ROM ID can be used to electronically identify the object to which the MAX66240 is associated. Applications of the MAX66240 include, access control, asset tracking, printer cartridge configuration and monitoring, medical sensor authentication and calibration, and system intellectual property protection.

## Overview

The block diagram in [Figure 1](#) shows the relationships between the major control and memory sections of the MAX66240. The device has six main data components: 16 256-bit pages of user EEPROM, a 256-bit secret, protection control/status memory, 512-bit SHA-256 engine, 64-bit ROM ID, and a 256-bit scratchpad.

[Figure 2](#) shows the applicable commands and the affected data fields. The network function commands allow the reader to identify all transponders in its range and to change their state, e.g., to select one for further communication. The protocol required for these network function commands is described in the [Network Function Commands](#) section. The memory and control functions fall into five categories: ISO 15693 generic commands, secret installation, memory access, protection setting, and MAC computation. The protocol for these commands is described in the [Memory and Control Function Commands](#) section. All data is read and written least significant bit (LSb) first, starting with the least significant byte (LSB).

## Parasite Power

The MAX66240 receives all energy necessary for its operation from the surrounding RF field, which needs to have a minimum strength as specified in the [Electrical Characteristics](#) table.

## Unique Identification Number (UID)

Each MAX66240 contains a factory-programmed and locked identification number that is 64 bits long (Figure 3). The lower 28 bits are the serial number of the chip. The upper 36 bits are fixed at E02B00800h. The code in bit locations 49 to 56 identifies the chip manufacturer, according to ISO/IEC 7816-6/AM1. This code is 2Bh for Maxim. The UID is read accessible through the Inventory and Get System Information commands.

## ROM ID

The read-only ROM ID is similar to the UID (Figure 4). The first 8 bits are a family code, which is E0h. The next 28 bits are a unique serial number. The next 20 bits are fixed at 2B000h. The last 8 bits are a cyclic redundancy check (CRC) of the first 56 bits. The CRC is generated using the polynomial  $X^8 + X^5 + X^4 + 1$  (Figure 5). Additional information about this CRC is available in Application Note 27: [Understanding and Using Cyclic Redundancy Checks with Maxim iButton® Products](#). The ROM ID is part of the input data to the SHA-256 engine. It is read accessible through the command Get 1-Wire ROM ID.

ISO 15693, SHA-256, and 4Kb User EEPROM

## Memory Resources

The memory of the MAX66240 consists of user EEPROM, secret memory, an SRAM scratchpad, personality registers, ROM ID, and two ISO 15693-specific bytes. [Table 1](#) shows the size, access mode, and purpose of the various memory areas. Brackets around an access mode indicate possible restrictions, such as write protection or read protection.

The user memory is organized as 16 pages of 32 bytes each ([Figure 6](#)). A page is divided into 8 page blocks of 32 bits each. With the MAX66240, the page protection applies to individual memory pages. The user memory is written in page blocks. If not read protected, the memory can be read starting at any page block of any page. The protocol allows reading multiple page blocks and pages up to the end of the memory in a single read command flow.

The secret is either directly written (loaded) or computed. This write access always encompasses the entire 32-byte secret. To protect against transmission errors, the new secret (loading) or a partial secret (computing) is first written to the scratchpad from where it can be read for verification. As the name implies, the secret memory is not user readable. To protect a secret from changes, it must be write protected (locked).

Page protection control is activated through the Write Page Protection command. Besides write protection, read protection and EPROM emulation mode, the MAX66240 supports authentication protection. If authentication protection is activated, changes to the page protection settings as well as writing to the protected user memory require that the reader provide a valid MAC for the operation. Once a protection is activated, it cannot be reversed. The protection settings as well as the personality registers are read accessible through the Read Status command. See the [Memory and Control Function Commands](#) section for command flow details.

Depending on the command, the ROM ID may be required in the MAC computations. This makes the MAC generated by a MAX66240 or written to the MAX66240 (if authentication protection is activated) device-specific, even if the values of all other data elements are identical. Instead of requiring the reader to derive the ROM ID from the UID, the MAX66240 supports a special command to read the ROM ID directly.

Note that the ISO 15693 standard commands Read Single Block and Read Multiple Blocks do not address the user memory by page number and page block number. Instead, they use absolute block numbers counting from 0 to 127. [Figure 7](#) shows how these absolute numbers map to the user memory.

**Table 1. Memory Resources**

| NAME                                   | SIZE (BYTES) | ACCESS MODE                       | PURPOSE  |
|--|--------------|-----------------------------------|--|
| User Memory (EEPROM)                   | 512          | (Read), (Write), Internal Read    | Application-specific data storage; also used for MAC computations.   |
| Secret Memory (EEPROM)                 | 32           | (Write), (Compute), Internal Read | Storage of the secret that is used for MAC computations.   |
| Scratchpad (SRAM)                      | 32           | Read, Write, Internal Read        | Intermediate data storage when installing a secret; also used to store the challenge for a MAC computation.                              |
| Personality Registers                  | 4            | Read, Internal Read               | Lock status indicator for the secret and read access to the device's manufacturer ID (factory preprogrammed parts).                      |
| ROM ID                                 | 8            | Read, Internal Read               | Used for MAC computations.   |
| Application Family Identifier (AFI)    | 1            | Read, (Write)                     | Can be used during the inventory phase to narrow the number of transponders that participate in the discovery or anti-collision process. |
| Data Storage Format Identifier (DSFID) | 1            | Read, (Write)                     | User byte that can provide details on how the data in the user memory is structured.   |

## ISO/IEC 15693 Interface

The communication between an HF reader and MAX66240 (transponder) is a master-transponder type transaction, and is based on the exchange of data packets. The reader initiates every transaction; only one side (reader or transponder) transmits information at any time. Each data packet begins with a start-of-frame (SOF) pattern and ends with an end-of-frame (EOF) pattern. A data packet delimited by an SOF and an EOF is called a frame

(Figure 8). The last 2 bytes of an ISO 15693 frame are an inverted 16-bit CRC of the preceding data generated according to the CRC-16-CCITT polynomial  $X^{16} + X^{12} + X^5 + 1$  (Figure 9). This CRC is transmitted with the LSB first. For more details on the CRC-16-CCITT, refer to ISO 15693-3, Annex C. Frame information is modulated on a 13.56MHz carrier. The subsequent paragraphs are a concise description of the required modulation, coding, and basic timing.

## Reader to Transponder Communication

The communication from reader to transponder uses amplitude modulation (Figure 10); the modulation index can be either in the range of 10% to 30% or 100% (ISO 15693-2, Section 7.1). The standard defines two pulse-position data coding modes. The “1 out of 256” data coding mode transmits one 1 byte in 4.833ms, equivalent to a data rate of 1655bps (Figure 11). The location of a modulation pause during the 4.833ms conveys the value of the byte. The “1 out of 4” data coding mode transmits 2 bits in 75.52μs, equivalent to a data rate of 26,484bps (Figure 12). The location of a modulation pause during

the 75.52μs conveys the value of the 2 bits. A byte is transmitted as a concatenation of four 2-bit transmissions, with the least significant 2 bits of the byte being transmitted first. The transmission of the SOF pattern also takes 75.52μs. The SOF pattern has two modulation pauses. The position of the second pause determines whether the frame uses the “1 out of 256” or “1 out of 4” data coding mode (Figure 13 and Figure 14, respectively). The transmission of the EOF pattern takes 37.76μs; the EOF is the same for both coding modes and has one modulation pause (Figure 15). For full details, refer to ISO 15693-2, Sections 7 and 8.

## Transponder to Reader Communication

The Subcarrier\_flag bit in the request data frame specifies the use of one or two subcarrier in the response frame. For the one subcarrier case, the subcarrier frequency is 423.75kHz. For the two subcarrier case, the subcarrier frequencies are 423.75kHz and 484.28kHz. The Data\_rate\_flag bit in the request data frame specifies the response frame data rate. Low data rate is approximately 6,600bps, and high data rate is approximately 26,500bps. The data rate varies slightly depending on the use of one or two subcarriers. The LSB is transmitted first.

In the single subcarrier high data rate case, one bit is transmitted in 37.76 $\mu$ s. For a logic 0, the transponder modulates for 16 cycles then does not modulate for 16 cycles, which is repeated 8 times. This is followed by 256 cycles of no modulation. For a logic 1, the transponder does not modulate for 256 cycles. It then modulates for 16 cycles then does not modulate for 16 cycles, which is repeated 8 times. An SOF or EOF is transmitted in approximately 151 $\mu$ s. For an SOF, the transponder does not modulate for 768 cycles. It then modulates for 16 cycles then does not modulate for 16 cycles, which is repeated 24 times. This is followed by a logic 1. For an EOF, the transponder sends a logic 0. It then modulates for 16 cycles then does not modulate for 16 cycles, which

is repeated 24 times. This is followed by no modulation for 768 cycles. See [Figure 16](#) and [Figure 18](#) for more details. For low data rate, multiply all cycle counts and times by 4.

In the two subcarrier low data rate case, one bit is transmitted in 37.46 $\mu$ s. For a logic 0, the transponder modulates for 16 cycles then does not modulate for 16 cycles, which is repeated 8 times. Next, the transponder modulates for 14 cycles then does not modulate for 14 cycles, which is repeated 9 times. For a logic 1, the transponder modulates for 14 cycles then does not modulate for 14 cycles, which is repeated 9 times. Next, the transponder modulates for 16 cycles then does not modulate for 16 cycles, which is repeated 8 times. An SOF or EOF is transmitted in approximately 149.8 $\mu$ s. For an SOF, the transponder modulates for 14 cycles then does not modulate for 14 cycles, which is repeated 27 times. Next, the transponder modulates for 16 cycles then does not modulate for 16 cycles, which is repeated 24 times. This is followed by a logic 1. For an EOF, the transponder sends a logic 0. It then modulates for 16 cycles then does not modulate for 16 cycles, which is repeated 24 times. Next, the transponder modulates for 14 cycles then does not modulate for 14 cycles, which is repeated 27 times. See [Figure 17](#) and [Figure 19](#) for more details. For low data rate, multiply all cycle counts and times by 4.

## ISO 15693 Transponder States and State Transitions

ISO 15693 defines four transponder states and three address modes. The states are power-off, ready, quiet, and selected. The address modes are nonaddressed, addressed, and select. The addressed mode requires that the reader include the transponder's UID in the request. [Figure 20](#) shows how the Reset to Ready, Stay Quiet, and Select commands respond when changing the transponder's state. [Table 2](#) shows how other commands respond depending on address mode and the transponder's state. Note that Stay Quiet never generates a response. For full details, refer to ISO 15693-2, Section 7.

### Power-Off State

This state applies if the transponder is outside the reader's RF field. A transponder transitions to the power-off state when leaving the power-delivering RF field. When entering the RF field, the transponder automatically transitions to the ready state.

### Ready State

In this state, a transponder has enough power to perform any of its functions. The purpose of the ready state is to have the transponder population ready to process the inventory command as well as other commands sent in the addressed or nonaddressed mode. A transponder can exit the ready state and transition to the quiet or the selected state upon receiving the Stay Quiet or Select command sent in addressed mode.

### Quiet State

In this state, a transponder has enough power to perform any of its functions. The purpose of the quiet state is to silence transponders with which the reader does not want to communicate. Only commands sent with the addressed mode are processed. This way the reader can use the

nonaddressed mode for communication with remaining transponders in the ready state. A transponder can exit the quiet state and transition to the ready state upon receiving the Reset to Ready command in addressed or nonaddressed mode. It can also transition to the selected state upon receiving Select commands sent in addressed mode.

### Selected State

In this state, a transponder has enough power to perform any of its functions. The purpose of the selected state is to isolate the transponder with which the reader wants to communicate. Commands are processed regardless of the address mode in which they are sent, including the Inventory command. With multiple transponders in the RF field, the reader can put one transponder in the selected state, leaving all others in the ready state. For a transponder in the selected state, the reader can use the selected mode, which keeps the request data packets as short as with the nonaddressed mode. A new transponder entering the RF field will not disturb communication since it powers up in the ready state. A transponder can exit the selected state and transition to the ready state upon receiving the Reset to Ready command sent in nonaddressed or addressed mode. It can also transition to the quiet state upon receiving the Stay Quiet command sent in the addressed mode. A transponder also transitions from selected to ready upon receiving a Select command if the UID in the request is different from the transponder's own UID. In this case, the reader's intention is to transition another transponder with the matching UID to the selected state. If the transponder already in the selected state does not recognize the command, e.g., due to a bit error, two transponders could be in the selected state. To prevent this from happening, the reader should use the Reset to Ready or the Stay Quiet command to transition a transponder out of the selected state.

**Table 2. Command Response vs. Transponder State and Address Mode Combinations**

| TRANSPONDER STATES | ADDRESS MODES   |  |   |

## Wait Times

ISO 15693 defines several standard wait times. For full details, refer to ISO 15693-2, Section 9.

The wait time from request frame EOF to response frame SOF is  $t_1$ .  $t_1$  min is 318.6 $\mu$ s (4320 cycles),  $t_1$  nom is 320.9 $\mu$ s (4352 cycles), and  $t_1$  max is 323.3 $\mu$ s (4384 cycles). Commands that perform MAC calculations or write memory will extend  $t_1$  by a command specific combination of  $t_{RFAIP}$ ,  $t_{CSHA}$ , and  $t_{PROG}$ . If a 100% modulation pulse is detected during  $t_1$ , the transponder must restart its  $t_1$  counter.

The 10% modulation ignore time after a request frame EOF is received is  $t_{MIT}$ .  $t_{MIT}$  min is 323.3 $\mu$ s (4384 cycles) +  $t_{NRT}$ , where  $t_{NRT}$  is the nominal response frame length.

The wait time between a response frame and a subsequent request frame is  $t_2$ .  $t_2$  min is 309.2 $\mu$ s (4192 cycles).

The wait time between slot EOFs in an Inventory command where  $Nb\_slots\_flag$  is  $t_3$ . For 100% modulation,  $t_{3MIN}$  is 323.3 $\mu$ s (4384 cycles) +  $t_{SOF}$ , where  $t_{SOF}$  is the time requires to transmit a request frame SOF. For 10% modulation,  $t_3$  min is 323.3 $\mu$ s (4384 cycles) +  $t_{NRT}$  +  $t_{2MIN}$ , where  $t_{NRT}$  is the nominal response frame length.

## Network Function Commands

The ISO 15693 standard defines four network function commands: Inventory, Stay Quiet, Select, and Reset to Ready. Their purpose is to identify the UIDs of all transponders in the field (to Inventory) and to manage access to these transponders. [Figure 20](#) shows how the network function commands are used to transition a transponder from one state to another.

## Network Function Command Errors

Various error conditions can occur. If an error occurs, and the request is sent in addressed mode with matching UID or in select mode with the transponder in the Selected state, the transponder will transmit an error response. In any other mode/state combination, an error will result in no response. In case of an error response, the response begins with response flags of 01h, followed by a single-byte error code. [Table 5](#) shows a matrix of commands, errors, and error codes.

**Table 5. Network Function Command Error Code Matrix**

| ERROR EXPLANATION      | Invalid Request Packet | Option Flag Set |
|------------------------|------------------------|-----------------|
| ERROR CODE             | 02h                    | 03h             |
| <b>FAILING COMMAND</b> |                        |                 |
| Reset to Ready         | ✓                      | ✓               |
| Select                 | ✓                      | ✓               |

## Detailed Command Descriptions

### Inventory

This command allows the reader to learn the UIDs and DSFIDs of all transponders in its RF field in an iterative process.

The AFI\_flag determines if the AFI byte must be included in the request frame. The AFI byte is compared to the transponders AFI. The parameter byte determines the length of the mask. The LSb of the mask aligns with the LSb of the transponder's UID. The mask is compared to the transponder's UID. The Nb\_slots\_flag determines if a slot counter is concatenated with the mask for comparison to the transponder's UID. The slot counter starts at 0000b after the Inventory request frame is transmitted, and increments during the course of the Inventory command with every subsequent EOF sent by the reader. The AFI byte (if used) must match the transponder's AFI or be 00h, and the mask concatenated with the slot counter (if used) must match the transponder's UID for a response to be generated. This allows the reader to select transponders to respond to the Inventory command. The processing of an Inventory command ends if the transponder receives an SOF of a new request frame.

If a transponder meets all conditions to respond, it transmits a response frame. If multiple transponders meet the conditions, the response frames collide and may not be readable. The reader must eliminate the collision.

To identify all transponders in the RF field, the reader could begin with a mask length of 0 and activate the slot counter (Nb\_slots\_flag = 0). By using this method and going through all 16 slots, the reader has a chance to receive clean responses (i.e., the transponder is identified) as well as colliding responses. To prevent a transponder that has been identified from further participating in the collision management sequence, the reader transitions it to the quiet state. Next, the reader issues another Inventory command where the slot number that previously generated a collision is now used as a 4-bit mask, and runs again through all 16 slots. If a collision is found, another Inventory command is issued, this time with a mask that is extended at the higher bits by the slot counter value that produced the collision. This process is repeated until all transponders are identified. For a full description of the Inventory command processing by the transponder and the timing specifications, refer to ISO 15693 Part 3, Sections 8 to 9.

| Inventory                                  |  |
|--|--|
| Command Code                               | 01h  |
| Parameter Byte                             | Mask Length (Table 6)  |
| Conditions, Restrictions                   | The command is ignored unless the transponder is in the Ready or Selected state.   |
| Protocol Variations                        | <ul style="list-style-type: none"> <li>• Nb_slot_flag = 0, AFI_flag = 0, mask length = 0</li> <li>• Nb_slot_flag = 0, AFI_flag = 0, mask length ≠ 0</li> <li>• Nb_slot_flag = 0, AFI_flag = 1, mask length = 0</li> <li>• Nb_slot_flag = 0, AFI_flag = 1, mask length ≠ 0</li> <li>• Nb_slot_flag = 1, AFI_flag = 0, mask length = 0</li> <li>• Nb_slot_flag = 1, AFI_flag = 0, mask length ≠ 0</li> <li>• Nb_slot_flag = 1, AFI_flag = 1, mask length = 0</li> <li>• Nb_slot_flag = 1, AFI_flag = 1, mask length ≠ 0</li> </ul> |
| Other Notes                                | For the setting of the request flags (RQF), see Table 4.<br>The mask pattern is transmitted only if the mask length is ≠ 0.<br>The AFI is transmitted only if the AFI_flag bit in the request flags is set to 1.   |
| Error Conditions (Error Response)          | An error will result in no response.   |
| t1 (Request Frame to Response Frame Delay) | 318.6µs to 323.3µs   |

**Table 6. Parameter Byte Bitmap**

| Bit 7 | Bit 6 | Bit 5 | Bit 4 | Bit 3 | Bit 2 | Bit 1 | Bit 0 |
|-------|-------|-------|-------|-------|-------|-------|-------|
| MLEN  |       |       |       |       |       |       |       |

**Bits [7:0]: Mask Length (MLEN).** These bits specify the length of the mask. The mask (MASK) is transmitted only if MLEN is  $\neq 0$ . The maximum mask length is 60 (3Ch, if Nb\_slots\_flag = 0) or 64 (40h, if Nb\_slots\_flag = 1).

## Stay Quiet

This command addresses an individual transponder and transitions it to the Quiet state. The transponder does not send a response.

| <b>Stay Quiet</b>                          |   |
|--|---|
| Command Code                               | 02h   |
| Parameter Byte                             | N/A   |
| Conditions, Restrictions                   | To transition to the Quiet state, the request must be sent in addressed mode with matching UID. |
| Protocol Variations                        | None  |
| Other Notes                                | For the setting of the request flags (RQF), see Table 3.  |
| Error Conditions (Error Response)          | An error will result in no response.  |
| t1 (Request Frame to Response Frame Delay) | None  |

## Select

This command addresses an individual transponder and transitions it to the Selected state. The transponder transitioning to the Selected state sends a response. If there was a transponder with a different UID in the Selected state, then that transponder transitions to the Ready state without sending a response.

| <b>Select</b>                              |   |
|--|---|
| Command Code                               | 25h   |
| Parameter Byte                             | N/A   |
| Conditions, Restrictions                   | To transition to the Selected state, the request must be sent in addressed mode with matching UID.  |
| Protocol Variations                        | None  |
| Other Notes                                | For the setting of the request flags (RQF), see Table 3.  |
| Error Conditions (Error Response)          | <ul style="list-style-type: none"> <li>• Request data format error (response error code = 02h)</li> <li>• The Option_flag is set (response error code = 03h)</li> </ul> |
| t1 (Request Frame to Response Frame Delay) | 318.6 $\mu$ s to 323.3 $\mu$ s  |

## Reset to Ready

This command addresses an individual transponder and transitions it to the Ready state. The transponder transitioning to the Ready state sends a response.

| Reset to Ready                                |   |
|---|---|
| Command Code                                  | 26h   |
| Parameter Byte                                | N/A   |
| Conditions, Restrictions                      | To transition from the Quiet state to the Ready state, the request must be sent in nonaddressed mode or in addressed mode with matching UID. To transition from the Selected state to the Ready state, the request must be sent in select mode. |
| Protocol Variations                           | <ul style="list-style-type: none"><li>If the transponder is in the Selected state, and the request is sent in addressed mode with nonmatching UID, the transponder transitions to the Ready state, but will not respond.</li></ul>              |
| Other Notes                                   | For the setting of the request flags (RQF), see Table 3.  |
| Error Conditions<br>(Error Response)          | <ul style="list-style-type: none"><li>Request data format error (response error code = 02h)</li><li>The Option_flag is set (response error code = 03h)</li></ul>  |
| t1 (Request Frame to<br>Response Frame Delay) | 318.6μs to 323.3μs  |

## Errata

ISO 15693-3 Section 9.1 specifies that if the VICC detects a carrier modulation during time  $t_1$ , it shall reset its  $t_1$  timer and wait for a further time  $t_1$  before starting to transmit its response to a VCD request or to switch to the next slot when in an inventory process. **The MAX66240 is not compliant with this specification.**

ISO15693-3 Section 9.4.2 specifies that during an inventory process, when the VCD has received no VICC response, it shall wait a time  $t_3$  before sending a subsequent EOF to switch to the next slot. If the VCD sends a 100% modulated EOF, the minimum value of  $t_3$  is  $4384/f_c$  ( $323.3\mu s$ ) +  $t_{sof}$ . The MAX66240 is not compliant with this specification. The MAX66240 requires a minimum  $t_3 = 4384/f_c$  ( $323.3\mu s$ ) +  $t_{nr}$  +  $t_{2min}$ , where  $t_{sof}$  is the time duration for a VICC to transmit an SOF to the VCD, and  $t_{nr}$  is the nominal response time of a VICC.  $t_{nr}$  and  $t_{sof}$  are dependent on the VICC-to-VCD data rate and subcarrier modulation mode.

Компания «ЭлектроПласт» предлагает заключение долгосрочных отношений при поставках импортных электронных компонентов на взаимовыгодных условиях!

Наши преимущества:

- Оперативные поставки широкого спектра электронных компонентов отечественного и импортного производства напрямую от производителей и с крупнейших мировых складов;
- Поставка более 17-ти миллионов наименований электронных компонентов;
- Поставка сложных, дефицитных, либо снятых с производства позиций;
- Оперативные сроки поставки под заказ (от 5 рабочих дней);
- Экспресс доставка в любую точку России;
- Техническая поддержка проекта, помощь в подборе аналогов, поставка прототипов;
- Система менеджмента качества сертифицирована по Международному стандарту ISO 9001;
- Лицензия ФСБ на осуществление работ с использованием сведений, составляющих государственную тайну;
- Поставка специализированных компонентов (Xilinx, Altera, Analog Devices, Intersil, Interpoint, Microsemi, Aeroflex, Peregrine, Syfer, Eurofarad, Texas Instrument, Miteq, Cobham, E2V, MA-COM, Hittite, Mini-Circuits, General Dynamics и др.);

Помимо этого, одним из направлений компании «ЭлектроПласт» является направление «Источники питания». Мы предлагаем Вам помощь Конструкторского отдела:

- Подбор оптимального решения, техническое обоснование при выборе компонента;
- Подбор аналогов;
- Консультации по применению компонента;
- Поставка образцов и прототипов;
- Техническая поддержка проекта;
- Защита от снятия компонента с производства.
