

MAX11156

18-Bit, 500ksps, $\pm 5V$ SAR ADC with Internal Reference in TDFN

General Description

The MAX11156 18-bit, 500ksps, SAR ADC offers excellent AC and DC performance with true bipolar input range, small size, and internal reference. The MAX11156 measures a $\pm 5V$ ($10V_{P-P}$) input range while operating from a single 5V supply. A patented charge-pump architecture allows direct sampling of high-impedance sources. The MAX11156 integrates an optional 6ppm/ $^{\circ}C$ reference with internal buffer, saving the cost and space of an external reference.

The MAX11156 produces 94.6dB SNR and -105dB THD (typ). The MAX11156 guarantees 18-bit no-missing codes.

The MAX11156 communicates using an SPI-compatible serial interface at 2.5V, 3V, 3.3V, or 5V logic. The serial interface can be used to daisy-chain multiple ADCs in parallel for multichannel applications and provides a busy indicator option for simplified system synchronization and timing.

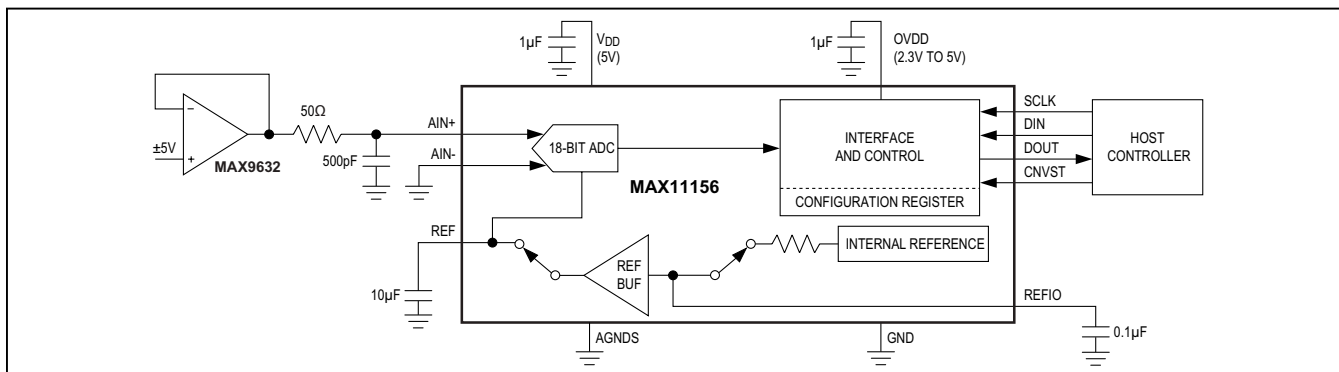

The MAX11156 is offered in a 12-pin, 3mm x 3mm, TDFN package and is specified over the $-40^{\circ}C$ to $+85^{\circ}C$ temperature range.

Applications

- Data Acquisition Systems
- Industrial Control Systems/Process Control
- Medical Instrumentation
- Automatic Test Equipment

Selector Guide and **Ordering Information** appear at end of data sheet.

Typical Operating Circuit

Benefits and Features

- High DC/AC Accuracy Improves Measurement Quality
 - 18-Bit Resolution with No Missing Codes
 - 500ksps Throughput Rate Without Pipeline Delay/Latency
 - 94.6dB SNR and -105dB THD at 10kHz
 - 1.7 LSB_{RMS} Transition Noise
 - ± 0.4 LSB DNL (typ) and ± 2.5 LSB INL (typ)
- Highly Integrated ADC Saves Cost and Space
 - 6ppm/ $^{\circ}C$ (typ) Internal Reference and Reference Buffer
 - $\pm 5V$ Bipolar Analog Input Range
- Wide Supply Range and Low Power Simplify Power-Supply Design
 - 5V Analog Supply
 - 2.3V to 5V Digital Supply
 - 26.5mW Power Consumption at 500ksps
 - 10 μA in Shutdown Mode
- Multi-Industry Standard Serial Interface and Small Package Reduce Size
 - SPI/QSPI™/MICROWIRE®/DSP-Compatible Serial Interface
 - 3mm x 3mm Tiny 12-Pin TDFN Package

Absolute Maximum Ratings

V_{DD} to GND -0.3V to +6V
 OV_{DD} to GND -0.3V to the lower of ($V_{DD} + 0.3V$) and +6V
 A_{IN+} to GND $\pm 7V$
 A_{IN-} , REF, REFIO, AGNDS
to GND -0.3V to the lower of ($V_{DD} + 0.3V$) and +6V
SCLK, DIN, DOUT, CNVST
to GND -0.3V to the lower of ($V_{DD} + 0.3V$) and +6V
Maximum Current into Any Pin 50mA

Continuous Power Dissipation ($T_A = +70^\circ C$)
TDFN (derate 18.2mW/ $^\circ C$ above $+70^\circ C$) 1349mW
Operating Temperature Range $-40^\circ C$ to $+85^\circ C$
Junction Temperature $+150^\circ C$
Storage Temperature Range $-65^\circ C$ to $+150^\circ C$
Lead Temperature (soldering, 10s) $+300^\circ C$
Soldering Temperature (reflow) $+260^\circ C$

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Package Thermal Characteristics (Note 1)

TDFN

Junction-to-Ambient Thermal Resistance (θ_{JA}) $59.3^\circ C/W$

Junction-to-Case Thermal Resistance (θ_{JC}) $22.5^\circ C/W$

Note 1: Package thermal resistances were obtained using the method described in JEDEC specification JESD51-7, using a four-layer board. For detailed information on package thermal considerations, refer to www.maximintegrated.com/thermal-tutorial.

Electrical Characteristics (continued)

(V_{DD} = 4.75V to 5.25V, V_{OVDD} = 2.3V to 5.25V, f_{SAMPLE} = 500kHz, V_{REF} = 4.096V, Reference Mode 3; T_A = T_{MIN} to T_{MAX} , unless otherwise noted. Typical values are at T_A = +25°C.) (Note 2)

Note 2: Maximum and minimum limits are fully production tested over specified supply voltage range and at a temperature of +25°C and +85°C. Limits below +25°C are guaranteed by design and device characterization. Typical values are not guaranteed.

Note 3: See the [Analog Inputs](#) and [Overvoltage Input Clamps](#) sections.

Note 4: See the [Definitions](#) section.

Note 5: Defined as the change in positive full-scale code transition caused by a $\pm 5\%$ variation in the V_{DD} supply voltage.

Note 6: 10kHz sine wave input, -0.1dB below full scale.

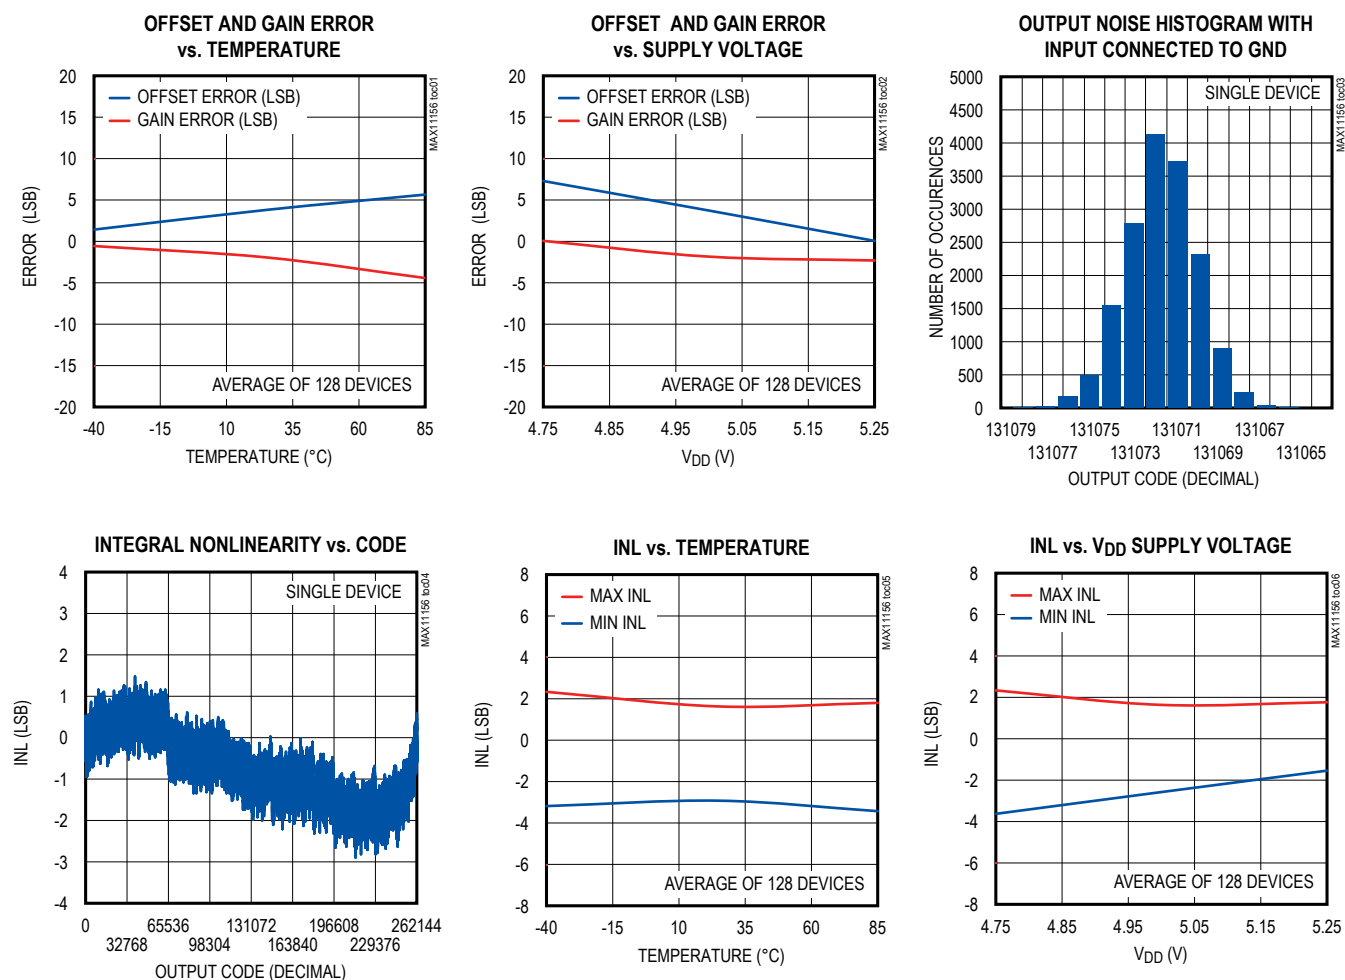

Note 7: See [Table 4](#) for definition of the reference modes.

Note 8: f_{IN1} = 9.4kHz, f_{IN2} = 10.7kHz, Each tone at -6.1dB below full scale.

Note 9: C_{LOAD} = 65pF on DOUT.

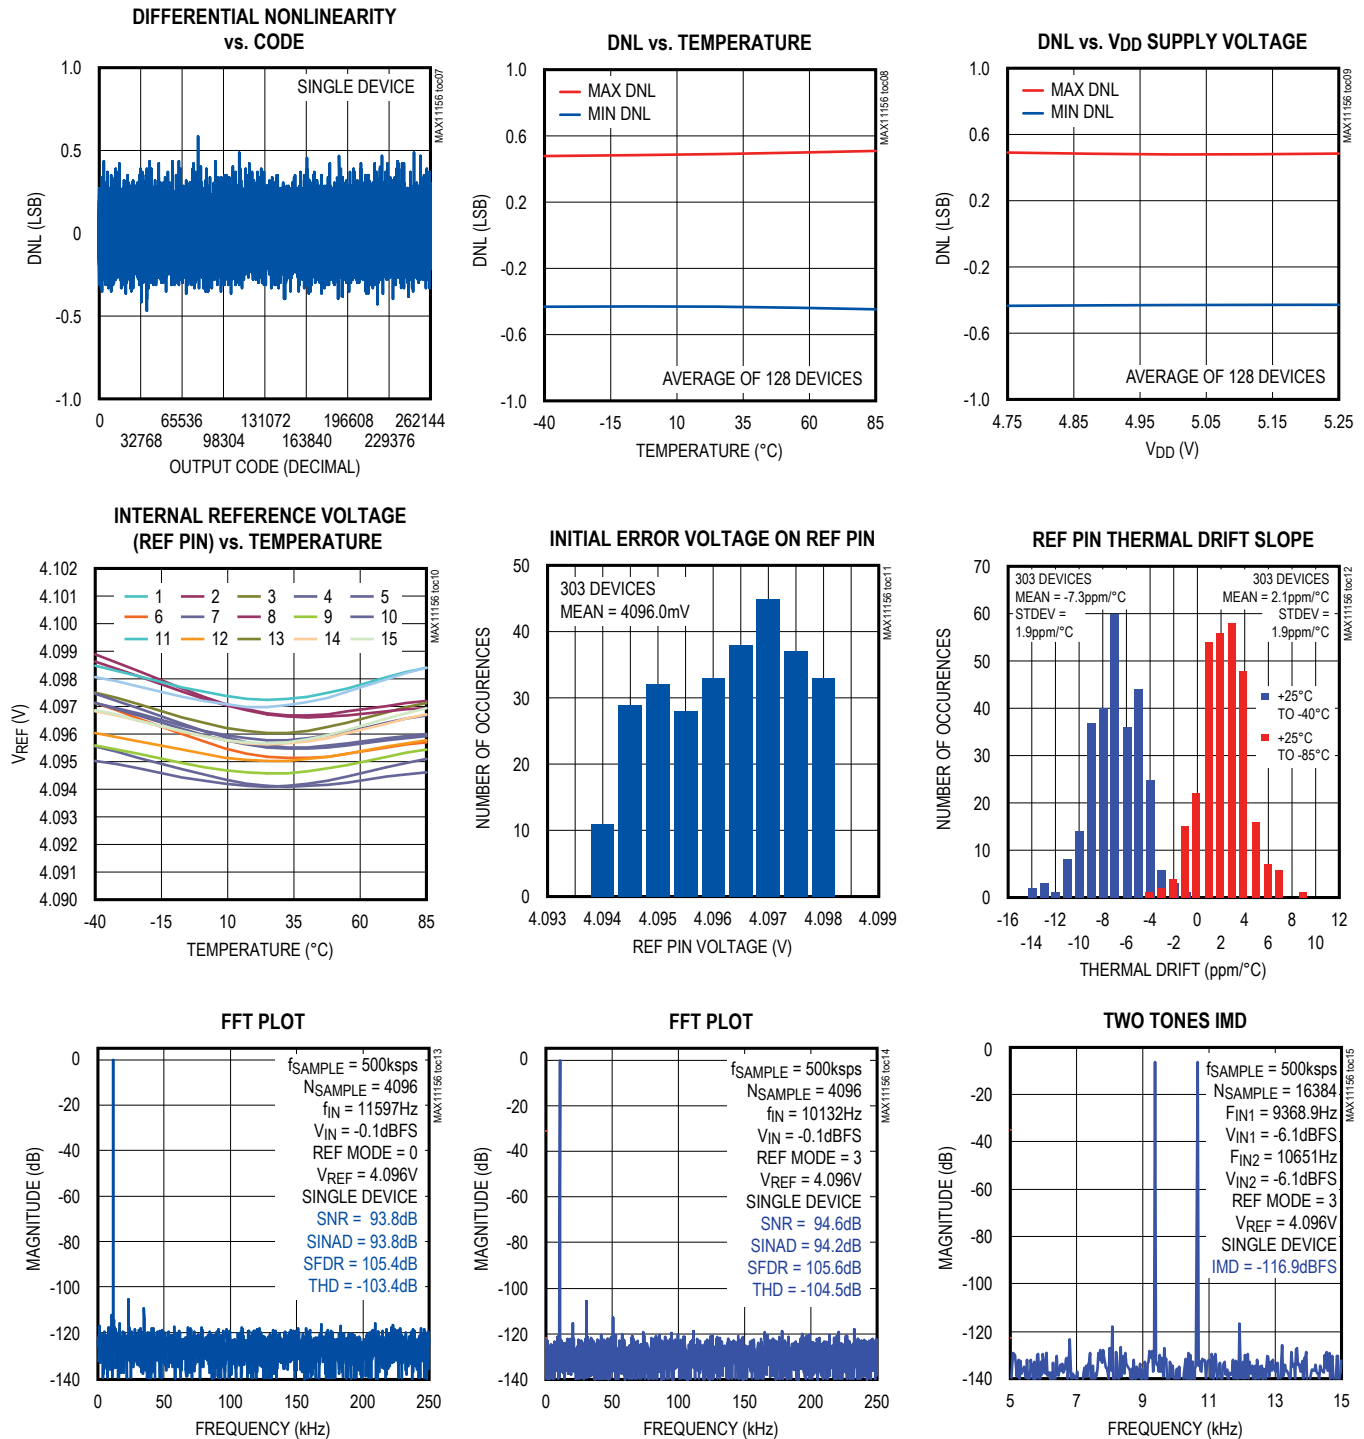

Typical Operating Characteristics

(V_{DD} = 5V, V_{OVDD} = 3.3V, f_{SAMPLE} = 500kHz, V_{REF} = 4.096V, Reference Mode 3, T_A = +25°C, unless otherwise noted.)

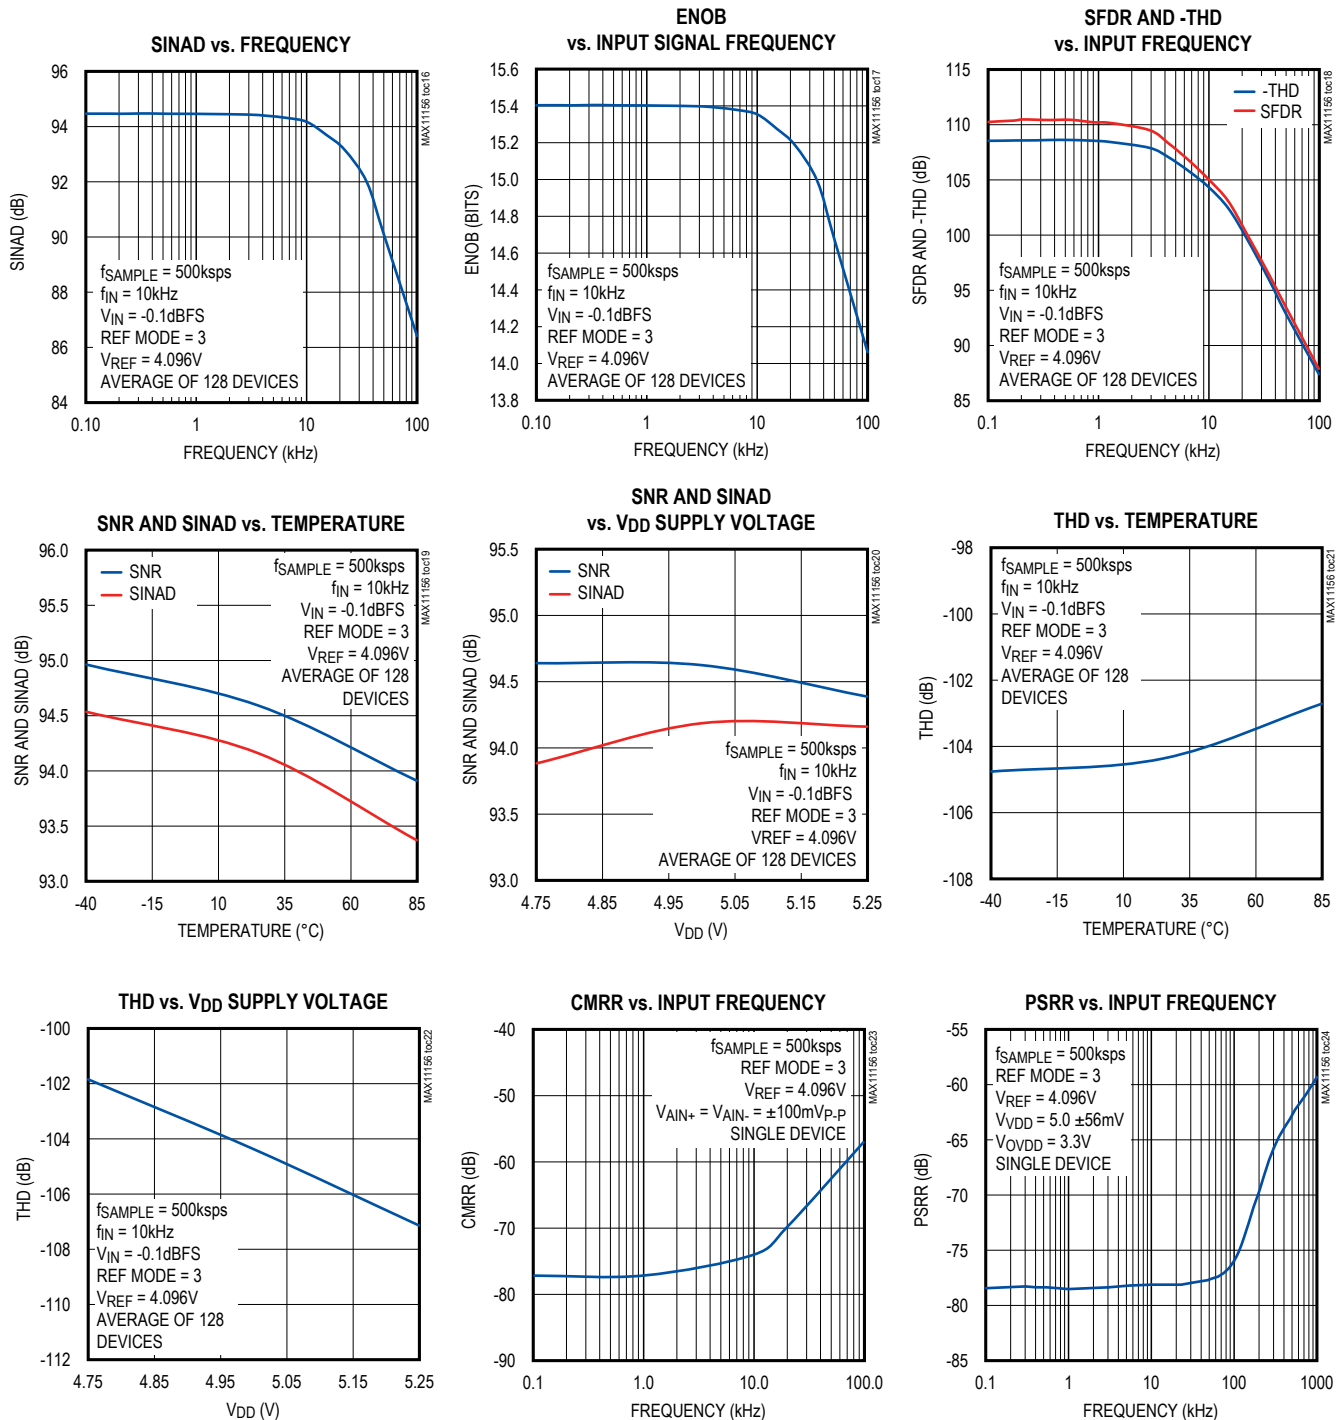

Typical Operating Characteristics (continued)

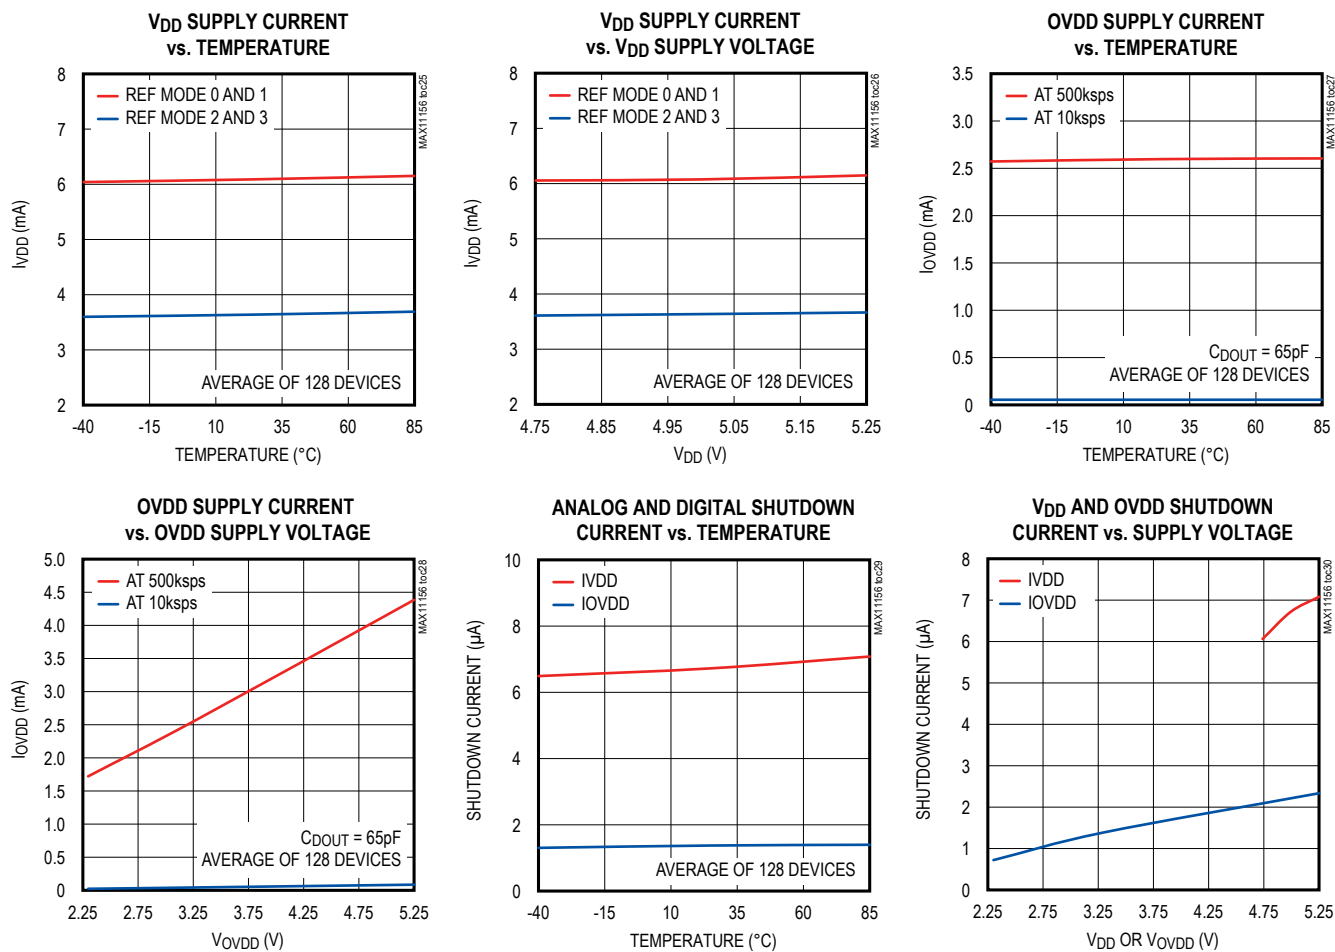

($V_{DD} = 5V$, $V_{OVDD} = 3.3V$, $f_{SAMPLE} = 500kHz$, $V_{REF} = 4.096V$, Reference Mode 3, $T_A = +25^\circ C$, unless otherwise noted.)

Typical Operating Characteristics (continued)

(V_{DD} = 5V, V_{OVD} = 3.3V, f_{SAMPLE} = 500kHz, V_{REF} = 4.096V, Reference Mode 3, T_A = +25°C, unless otherwise noted.)

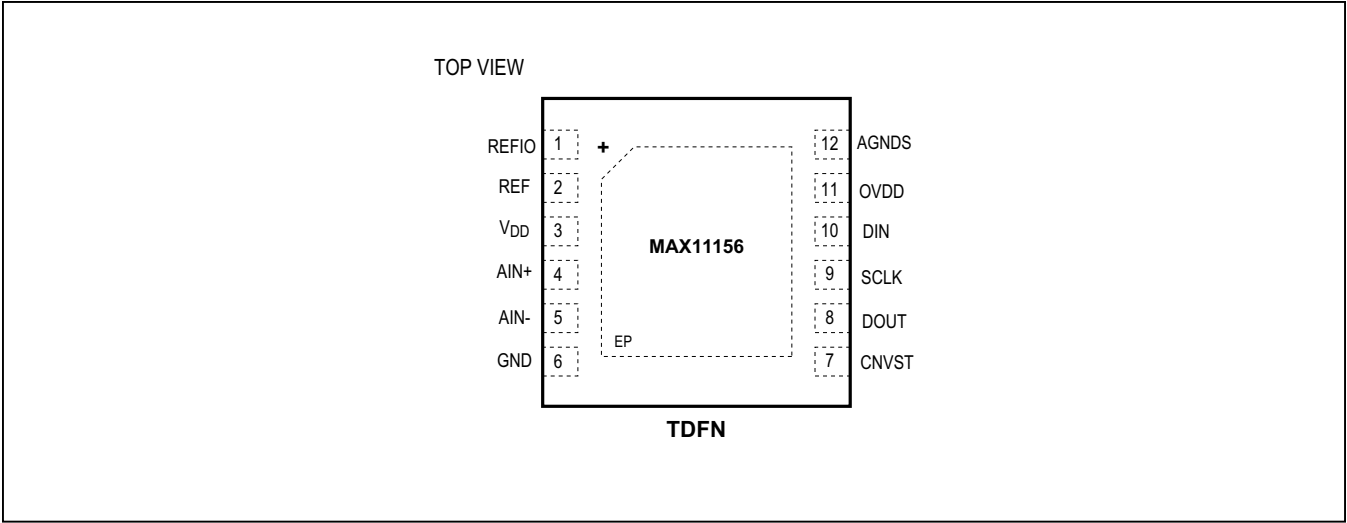

Typical Operating Characteristics (continued)

(V_{DD} = 5V, V_{OVD} = 3.3V, f_{SAMPLE} = 500kHz, V_{REF} = 4.096V, Reference Mode 3, T_A = +25°C, unless otherwise noted.)

MAX11156

18-Bit, 500ksps, ±5V SAR ADC
with Internal Reference in TDFN

Pin Configuration

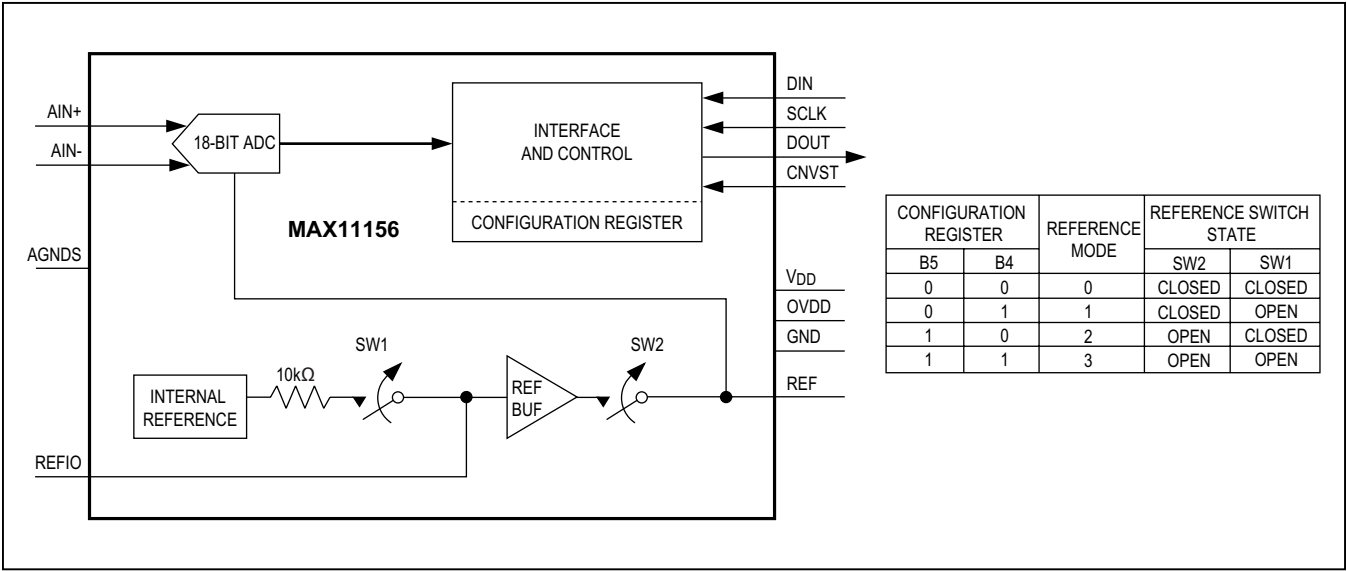

Pin Description

PIN	NAME	I/O	FUNCTION
1	REFIO	I/O	External Reference Input/Internal Reference Output. Place a 0.1μF capacitor from REFIO to AGNDS.
2	REF	I/O	External Reference Input/Reference Buffer Decoupling. Bypass to AGNDS in close proximity with a X5R or X7R 10μF 16V chip. See the <i>Layout, Grounding, and Bypassing</i> section.
3	V _{DD}	I	Analog Power Supply. Bypass to GND with a 0.1μF capacitor for each device and one 10μF per PCB.
4	AIN+	I	Positive Analog Input
5	AIN-	I	Negative Analog Input. Connect AIN- to the analog ground plane or to a remote-sense ground.
6	GND	I	Power-Supply Ground
7	CNVST	I	Convert Start Input. The rising edge of CNVST initiates conversions. The falling edge of CNVST with SCLK high enables the serial interface.
8	DOUT	O	Serial Data Output. DOUT will change stated on the falling edge of SCLK.
9	SCLK	I	Serial Clock Input. Clocks data out of the serial interface when the device is selected.
10	DIN	I	Serial Data Input. DIN data is latched into the serial interface on the rising edge of SCLK.
11	OVDD	I	Digital Power Supply. Bypass to GND with a 0.1μF capacitor for each device and one 10μF per PCB.
12	AGNDS	I	Analog Ground Sense. Zero current reference for the on-board DAC and reference source. Reference for REFIO and REF.
—	EP	—	Exposed Pad. EP is connected internally to GND. Connect to PCB GND.

MAX11156

18-Bit, 500ksps, ±5V SAR ADC
with Internal Reference in TDFN

Functional Diagram

Detailed Description

The MAX11156 is an 18-bit single-channel, pseudo-differential ADC with a maximum throughput rates of 500ksps. This ADC includes a precision internal reference that allows for measuring a bipolar input voltage range of ±5V. An external reference can also be applied for input ranges between ±3.05V and ±5.19V. Both inputs (AIN+ and AIN-) are sampled with a pseudo-differential on-chip track-and-hold exhibiting no pipeline delay or latency, making these ADCs ideal for multiplexed applications.

The MAX11156 measures a true bipolar voltage of ±5V (10V_{P-P}) and the inputs are protected for up to ±20mA of overrange current. This ADC is powered from a 4.75V to 5.25V analog supply (V_{DD}) and a separate 2.3V to 5.25V digital supply (OVDD). The MAX11156 requires 500ns to acquire the input sample on an internal track-and-hold and then convert the sampled signal to 18 bits of accuracy using an internally clocked converter.

Analog Inputs

The MAX11156 ADC consists of a true sampling pseudo-differential input stage with high-impedance, capacitive inputs. The internal T/H circuitry feature a small-signal bandwidth of about 6MHz to provide 18-bit accurate sampling in 500ns. This allows for accurate sampling of

a number of scanned channels through an external multiplexer.

The MAX11156 can thus convert input signals on AIN+ in the range of $-(K \times V_{REF} + AIN-)$ to $+(K \times V_{REF} + AIN-)$ where $K = 5.000/4.096$. AIN+ should also be limited to $\pm(V_{DD} + 0.1V)$ for accurate conversions. AIN- has an input range of -0.1V to +0.1V and should be connected to the ground reference of the input signal source. The MAX11156 performs a true differential sample on inputs between AIN+ and AIN- with good common-mode rejection (see the [Typical Operating Circuit](#)). This allows for improved sampling of remote transducer inputs.

Many traditional ADCs with single supplies that measure bipolar input signals use resistive divider networks directly on the analog inputs. These networks increase the complexity of the input signal conditioning. However, the MAX11156 includes a patented input switch architecture which allows direct sampling onto the input sample and hold capacitor without the use of scaling resistor networks. This results in zero source loading errors when the sample and hold is allowed to fully settle. This architecture requires a minimum sample rate of 10Hz to maintain accurate conversions over the designed temperature and supply ranges.

Overvoltage Input Clamps

The MAX11156 includes an input clamping circuit that activates when the input voltage at AIN+ is above ($V_{DD} + 300mV$) or below $-(V_{DD} + 300mV)$. The clamp circuit remains high impedance while the input signal is within the range of $\pm(V_{DD} + 100mV)$ and draws little to no current. However, when the input signal exceeds this range the clamps begin to turn on. Consequently, to obtain the highest accuracy, ensure that the input voltage does not exceed the range of $\pm(V_{DD} + 100mV)$.

To make use of the input clamps, connect a resistor (R_S) between the AIN+ input and the voltage source to limit the voltage at the analog input and to ensure the fault current into the devices does not exceed $\pm 20mA$. Note that the voltage at the AIN+ input pin limits to approximately 7V during a fault condition so the following equation can be used to calculate the value of R_S :

$$R_S = \frac{V_{FAULT\ MAX} - 7V}{20mA}$$

where $V_{FAULT\ MAX}$ is the maximum voltage that the source produces during a fault condition.

Figure 1 and Figure 2 illustrate the clamp circuit voltage current characteristics for a source impedance $R_S = 1280\Omega$. While the input voltage is within the $\pm(V_{DD} + 300mV)$ range, no current flows in the input clamps. Once the input voltage goes beyond this voltage range, the clamps turn on and limit the voltage at the input pin.

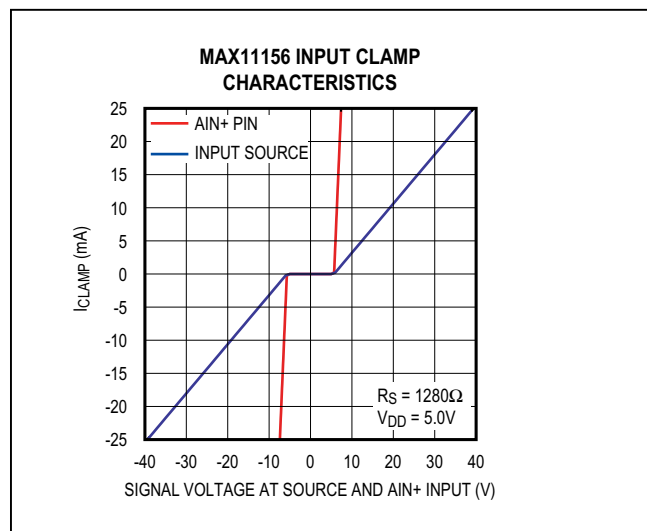

Figure 1. Input Clamp Characteristics

Internal/External Reference (REFIO) Configuration

The MAX11156 includes a standard SPI interface that selects internal or external reference modes of operation through an input configuration register (see the [Input Configuration Interface](#) section). The MAX11156 features an internal bandgap reference circuit ($V_{REFIO} = 4.096V$) that is buffered with an internal reference buffer that drives the REF pin. The MAX11156 configure register allows four combinations of reference configuration. These reference mode are:

Reference Mode 00: ADC reference is provided by the internal bandgap feed out the REFIO pin, noise filtered with an external capacitor on the REFIO pin, then buffered by the internal reference buffer and decoupled with an external capacitor on the REF pin. In this mode the ADC requires no external reference source.

Reference Mode 01: ADC reference is provided externally and feeds into the REFIO pin, buffered with the internal reference buffer and decoupled with an external capacitor on the REF pin. This mode is typically used when a common reference source is needed for more than one MAX11156.

Reference Mode 10: The internal bandgap is used as a reference source output and feed out to the REFIO pin. However, the internal reference buffer is in a shutdown state and the REF pin is high impedance. This state would typically be used to provide a common reference source to a set of external reference buffers for several MAX11156.

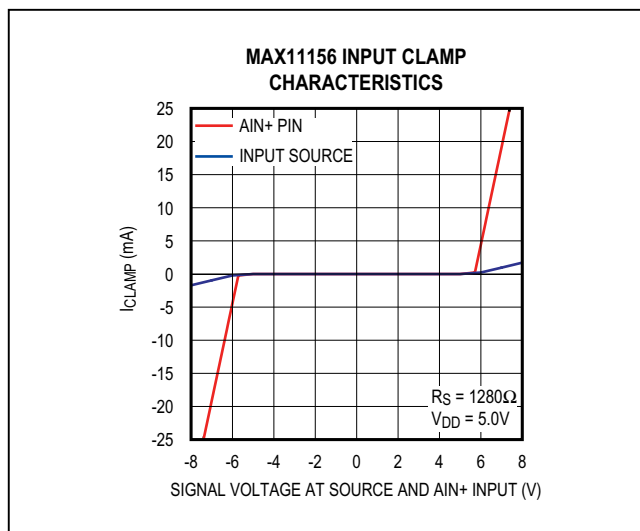

Figure 2. Input Clamp Characteristics (Zoom In)

Reference Mode 11: The internal bandgap reference source as well as the internal reference buffer are both in a shutdown state. The REF pin is in a high-impedance state. This mode would typically be used when an external reference source and external reference buffer is used to drive all MAX11156 parts in a system.

Regardless of the reference mode used, the MAX11156 requires a low-impedance reference source on the REF pin to support 18-bit accuracy. When using the internal reference buffer, externally bypass the reference buffer output using at least a $10\mu F$, low-inductance, low-ESR capacitor placed as close as possible to the REF pin, thus minimizing additional PCB inductance. When using the internal bandgap reference source, bypass the REFIO pin with a $0.1\mu F$ capacitor to ground. If providing an external reference and using the internal reference buffer, drive the REFIO pin directly with an external reference source in the range of 3.0V to 4.25V. Finally, if disabling the MAX11156 internal bandgap reference source and internal reference buffer, drive the REF pin with a reference voltage in the range of 2.5V to 4.25V and place at least a $10\mu F$, low-inductance, low-ESR capacitor placed as close as possible to the REF pin.

When using the MAX11156 in external reference mode, it is recommended that an external reference buffer be used. For bypass capacitors on the REF pin, X7R or X5R ceramic capacitors in a 1210 case size or smaller have been found to provide adequate bypass performance. Y5U or Z5U ceramic capacitors are not recommended due to their high voltage and temperature coefficients.

Maxim offers a wide range of precision references ideal for 18-bit accuracy. [Table 1](#) lists some of the options recommended.

Input Amplifier

The conversion results are accurate when the ADC acquires the input signal for an interval longer than the input signal's settling time. The ADC input sampling

capacitor charges during the acquisition period. During this acquisition period, the settling of the sampled voltage is affected by the source resistance and the input sampling capacitance. Sampling error can be estimated by modeling the time constant of the total input capacitance and the driving source impedance.

Although the MAX11156 is easy to drive, an amplifier buffer is recommended if the source impedance is such that when driving a switch capacitor of $\sim 20pF$ a significant settling error in the desired sampling period will occur. If this is the case, it is recommended that a configuration shown in the [Typical Operating Circuit](#) is used where at least a $500pF$ capacitor is attached to the AIN+ pin. This capacitance reduces the size of the transient at the start of the acquisition period, which in some buffers will cause an input signal dependent offsets.

Regardless of whether an external buffer amp is used or not, the time constant, $R_{SOURCE} \times C_{LOAD}$, of the input should not exceed $t_{ACQ}/13$, where R_{SOURCE} is the total signal source impedance, C_{LOAD} is the total capacitance at the ADC input (external and internal) and t_{ACQ} is the acquisition period. Thus to obtain accurate sampling in a 500ns acquisition time a source impedance of less than 1042Ω should be used if driving the ADC directly. When driving the ADC from a buffer, it is recommended a series resistance (5Ω to 50Ω typical) between the amplifier and the external input capacitance as shown in the [Typical Operating Circuit](#).

We report some amplifier features to select the ADC driver.

- 1) Fast settling time: For multichannel multiplexed applications the driving operational amplifier must be able to settle to 18-bit resolution when a full-scale step is applied during the minimum acquisition time.
- 2) Low noise: It is important to ensure that the driver amplifier has a low average noise density appropriate for the desired bandwidth of the application. When the MAX11156 is used with its full bandwidth of 6MHz, it

Table 1. MAX11156 External Reference Recommendations

PART	V _{OUT} (V)	TEMPERATURE COEFFICIENT (MAX)	INITIAL ACCURACY (%)	NOISE (0.1Hz TO 10Hz) (μV_{P-P})	PACKAGE
MAX6126	2.5, 3, 4.096, 5.0	3 (A), 5 (B)	0.06	1.35	μ MAX-8 SO-8
MAX6325	2.5	1	0.04	1.5	SO-8
MAX6341	4.096	1	0.02	2.4	SO-8

is preferable to use an amplifier that will produce an output noise spectral density of less than 6nV/√Hz, to ensure the overall SNR is not degraded significantly. It is recommended to insert an external RC filter at the MAX11156 AIN+ input to attenuate out-of-band input noise and preserve the ADC's SNR. The effective RMS noise at the MAX11156 AIN+ input is 65μV, thus additional noise from a buffer circuit should be significantly lower in order to achieve the maximum SNR performance.

- 3) THD performance: The input buffer amplifier used should have a comparable THD performance with that of the MAX11156 to ensure the THD of the digitized signal is not degraded.

Table 2 summarizes the operational amplifiers that are compatible with the MAX11156. The MAX9632 has sufficient bandwidth, low enough noise and distortion to support the full performance of the MAX11156. The MAX9633 is a dual amp and can support buffering for true pseudo-differential sampling.

Transfer Function

The ideal transfer characteristic for the MAX11156 is shown in Figure 3. The precise location of various points on the transfer function are given in Table 3.

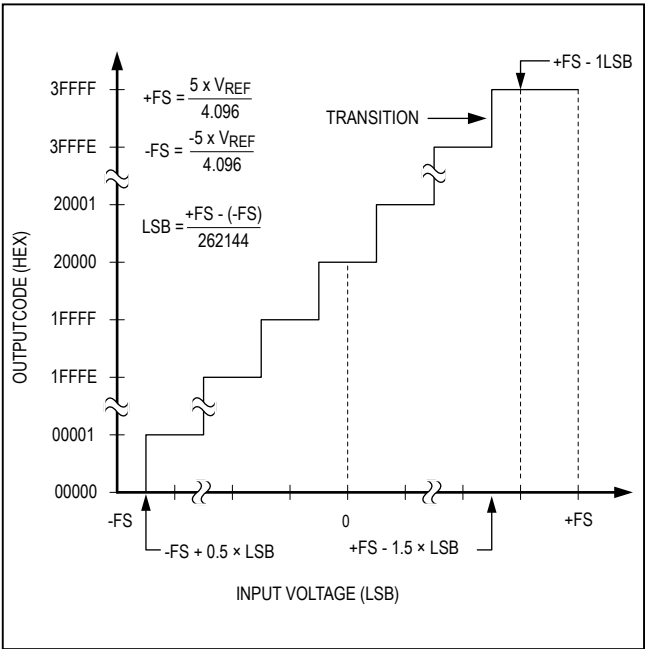

Figure 3. Bipolar Transfer Function

Table 2. List of Recommended ADC Driver Op Amps for MAX11156

AMPLIFIER	INPUT-NOISE DENSITY (nV/√Hz)	SMALL-SIGNAL BANDWIDTH (MHz)	SLEW RATE (V/μs)	THD (dB)	I _{CC} (mA)	COMMENTS
MAX9632	1	55	30	-128	3.9	Single amp, low noise, low THD
MAX9633	3	27	18	-128	3.5	Dual amp, low noise, low THD

Table 3. Transfer Function Example

CODE TRANSITION	BIPOLAR INPUT (V)	DIGITAL OUTPUT CODE (HEX)
+FS - 1.5 LSB	+4.999943	3FFFE - 3FFFF
Midscale + 0.5 LSB	+0.000019	20000 - 20001
Midscale	0	20000
Midscale - 0.5 LSB	-0.000019	1FFFF - 20000
-FS + 0.5 LSB	-4.999981	00000 - 00001

Input Configuration Interface

An SPI interface clocked at up to 50MHz controls the MAX11156. Input configuration data is clocked into the configuration register on the falling edge of SCLK through the DIN pin. The data on DIN is used to program the ADC configuration register. The construct of this register is illustrated in Table 4. The configuration register defines the output interface mode, the reference mode, and the power-down state of the MAX11156.

Configuring in CS Mode

Figure 4 details the timing for loading the input configuration register when the MAX11156 is connected in CS mode (see Figure 6 and Figure 8 for hardware connections). The load process is enabled on the falling edge of CNVST when SCLK is held high. The configuration data is clocked into the configuration register through DIN on the next 8 SCLK falling edges. Pull CNVST high to complete the input configuration register load process. DIN should idle high outside an input configuration register read.

Table 4. ADC Configuration Register

BIT NAME	BIT	DEFAULT STATE	LOGIC STATE	FUNCTION
MODE	7:6	00	00	CS Mode, No-Busy Indicator
			01	CS Mode, with Busy Indicator
			10	Daisy-Chain Mode, No-Busy Indicator
			11	Daisy-Chain Mode, with Busy Indicator
REF	5:4	00	00	Reference Mode 0. Internal reference and reference buffer are both powered on.
			01	Reference Mode 1. Internal reference is turned off, but internal reference buffer powered on. Apply the external reference voltage at REFIO.
			10	Reference Mode 2. Internal reference is powered on, but the internal reference buffer is powered off. This mode allows for internal reference to be used with an external reference buffer.
			11	Reference Mode 3. Internal reference and reference buffer are both powered off. Apply an external reference voltage at REF.
SHDN	3	0	0	Normal Mode. All circuitry is fully powered up at all times.
			1	Static Shutdown. All circuitry is powered down.
Reserved	2:0	0	0	Reserved, Set to 0

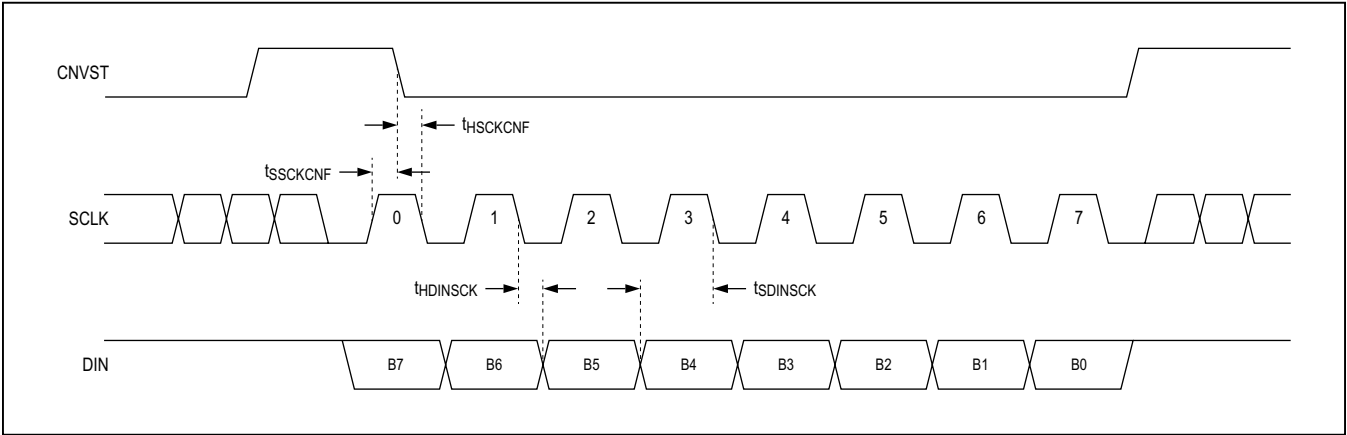

Figure 4. Input Configuration Timing in CS Mode

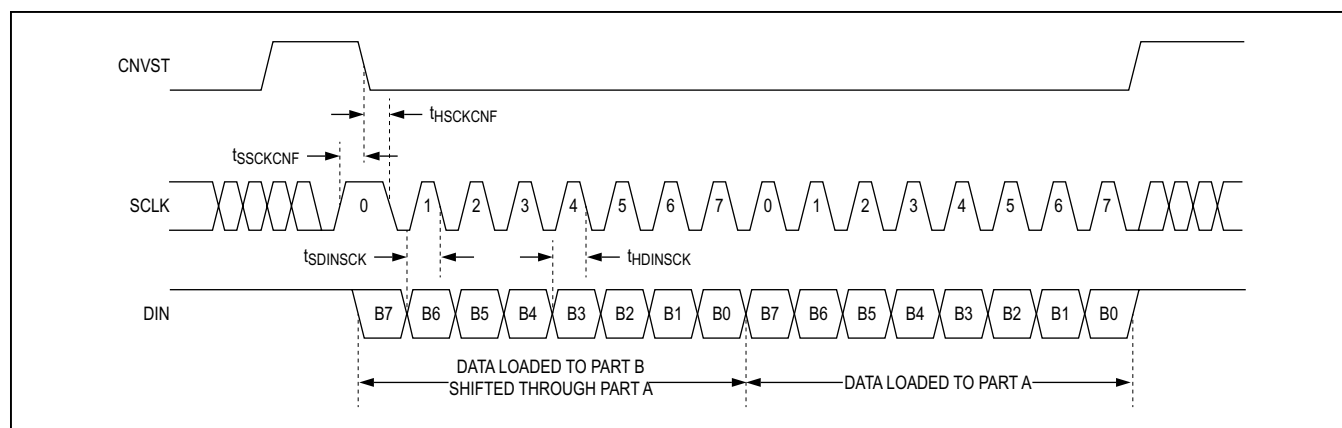

Figure 5. Input Configuration Timing in Daisy-Chain Mode

Configuring in Daisy-Chain Mode

Figure 5 details the configuration register load process when the MAX11156 is connected in a daisy-chain configuration (see Figure 12 and Figure 14 for hardware connections). The load process is enabled on the falling edge of CNVST when SCLK is held high. In daisy-chain mode, the input configuration registers are chained together through DOUT to DIN. Device A's DOUT will drive device B's DIN. The input configuration register is an 8-bit, first-in first-out shift register. The configuration data is clocked in N times through $8 \times N$ falling SCLK edges. After the MAX11156 ADC in the chain is loaded with the configuration byte, pull CNVST high to complete the configuration register loading process. Figure 5 illustrates a configuration sequence for loading two devices in a chain.

Data loaded into the configuration register alters the state of the MAX11156 on the next conversion cycle after the register is loaded. However, powering up the internal reference buffer or stabilizing the REFIO pin voltage will take several milliseconds to settle to 18-bit accuracy.

Shutdown Mode

The SHDN bit in the configuration register forces the MAX11156 into and out of shutdown. Set SHDN to 0 for normal operation. Set SHDN to 1 to shut down all internal circuitry and reset all registers to their default state.

Output Interface

The MAX11156 can be programmed into one of four output modes; \overline{CS} modes with and without busy indicator and daisy-chain modes with and without busy indicator. When operating without busy indication, the user must externally timeout the maximum ADC conversion time before commencing readback. When operating in one of the two

busy indication modes, the user can connect the DOUT output of the MAX11156 to an interrupt input on the digital host and use this interrupt to trigger the output data read.

Regardless of the output interface mode used, digital activity should be limited to the first half of the conversion phase. Having SCLK or DIN transitions near the sampling instance can also corrupt the input sample accuracy. Therefore, keep the digital inputs quiet for approximately 25ns before and 10ns after the rising edge of CNVST. These times are denoted as t_{SQ} and t_{HQ} in all subsequent timing diagrams.

In all interface modes, the data on DOUT is valid on both SCLK edges. However, the input setup time into the receiving digital host will be maximized when data is clocked into that digital host on the falling SCLK edge. Doing so will allow for higher data transfer rates between the MAX11156 and the digital host and consequently higher converter throughput.

In all interface modes, it is recommended that the SCLK be idled low to avoid triggering an input configuration write on the falling edge of CNVST. If at anytime the device detects a high SCLK state on a falling edge of CNVST, it will enter the input configuration write mode and will write the state of DIN on the next 8 falling SCLK edges to the input configuration register.

In all interface modes, all data bits from a previous conversion must be read before reading bits from a new conversion. When reading out conversion data, if too few SCLK falling edges are provided and all data bits are not read out, only the remaining unread data bits will be outputted during the next readout cycle. In such an event, the output data in every other readout cycle will appear to have been truncated as only the leftover bits from the previous readout cycle are outputted.

This is an indication to the user that there are insufficient SCLK falling edges in a given readout cycle. [Table 5](#) provides a guide to aid in the selection of the appropriate output interface mode for a given application.

CS No-Busy Indicator Mode

The $\overline{\text{CS}}$ no-busy indicator mode is ideally suited for maximum throughput when a single MAX11156 is connected to a SPI-compatible digital host. The connection diagram is shown in [Figure 6](#), and the corresponding timing is provided in [Figure 7](#).

A rising edge on CNVST completes the acquisition, initiates the conversion, and forces DOUT to high impedance. The conversion continues to completion irrespective of the state of CNVST allowing CNVST to be used as a select line for other devices on the board. If CNVST is brought low during a conversion and held low throughout the maximum conversion time, the MSB will be output at the end of the conversion.

When the conversion is complete, the MAX11156 enters the acquisition phase. Drive CNVST low to output the MSB onto DOUT. The remaining data bits are then clocked by subsequent SCLK falling edges. DOUT returns to high impedance after the 18th SCLK falling edge, or when CNVST goes high.

Table 5. ADC Output Interface Mode Selector Guide

MODE	TYPICAL APPLICATION AND BENEFITS
$\overline{\text{CS}}$ Mode, No-Busy Indicator	Single or multiple ADCs connected to SPI-compatible digital host. Ideally suited for maximum throughput.
$\overline{\text{CS}}$ Mode, With Busy Indicator	Single ADC connected to SPI-compatible digital host with interrupt input. Ideally suited for maximum throughput.
Daisy-Chain Mode, No-Busy Indicator	Multiple ADCs connected to a SPI-compatible digital host. Ideally suited for multichannel simultaneous sampled isolated applications.
Daisy-Chain Mode, With Busy Indicator	Multiple ADCs connected to a SPI-compatible digital host with interrupt input. Ideally suited for multichannel simultaneous sampled isolated applications.

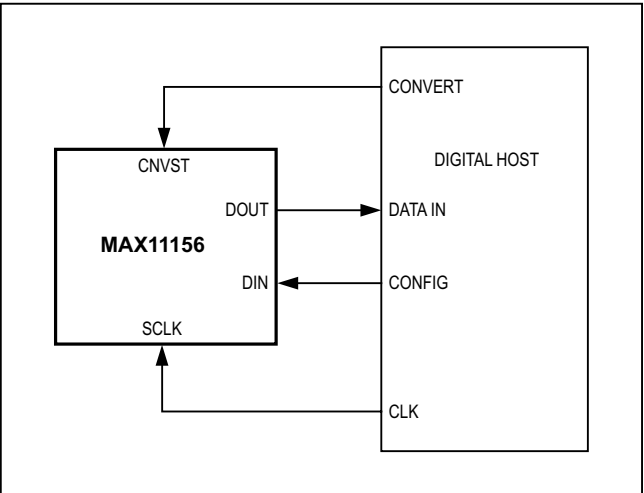

Figure 6. $\overline{\text{CS}}$ No-Busy Indicator Mode Connection Diagram

$\overline{\text{CS}}$ with Busy Indicator Mode

The $\overline{\text{CS}}$ with busy indicator mode is shown in [Figure 8](#) where a single ADC is connected to a SPI-compatible digital host with interrupt input. The corresponding timing is given in [Figure 9](#).

A rising edge on CNVST completes the acquisition, initiates the conversion and forces DOUT to high impedance. The conversion continues to completion irrespective of the state of CNVST allowing CNVST to be used as a select line for other devices on the board.

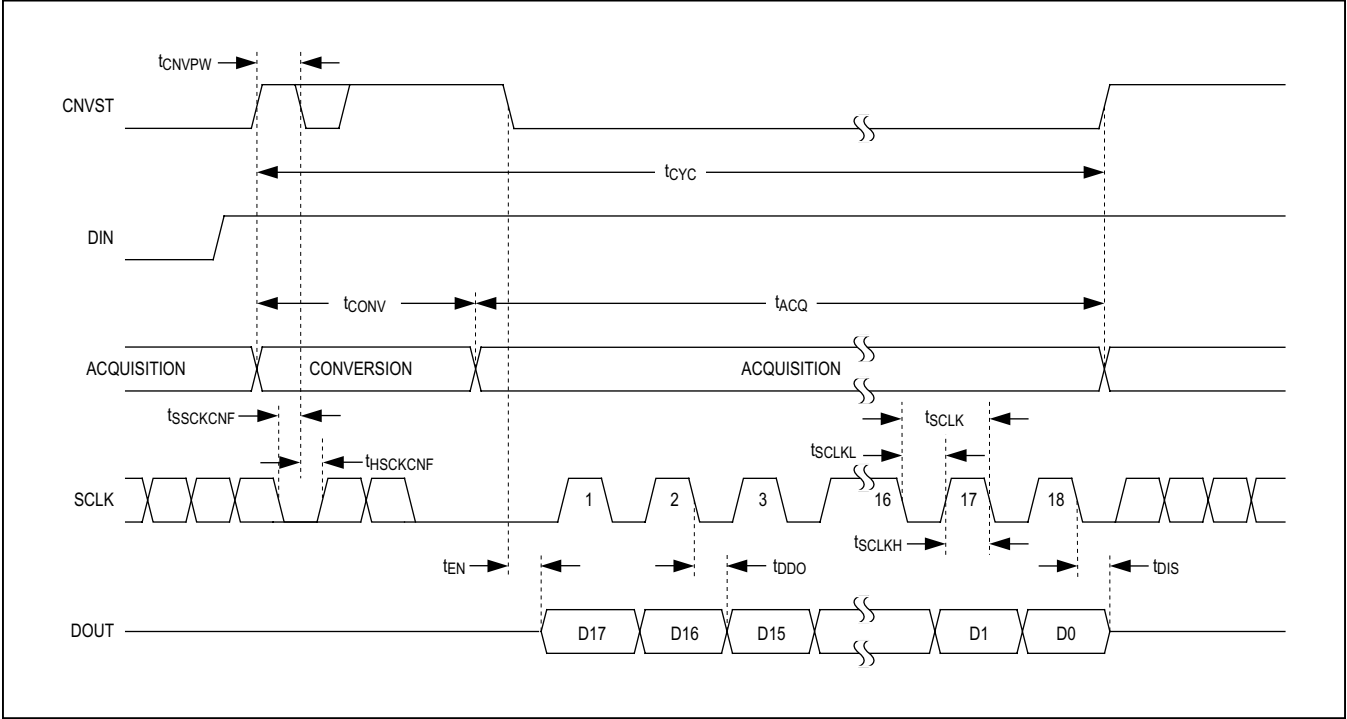

Figure 7. $\overline{\text{CS}}$ No Busy Indicator Mode Timing

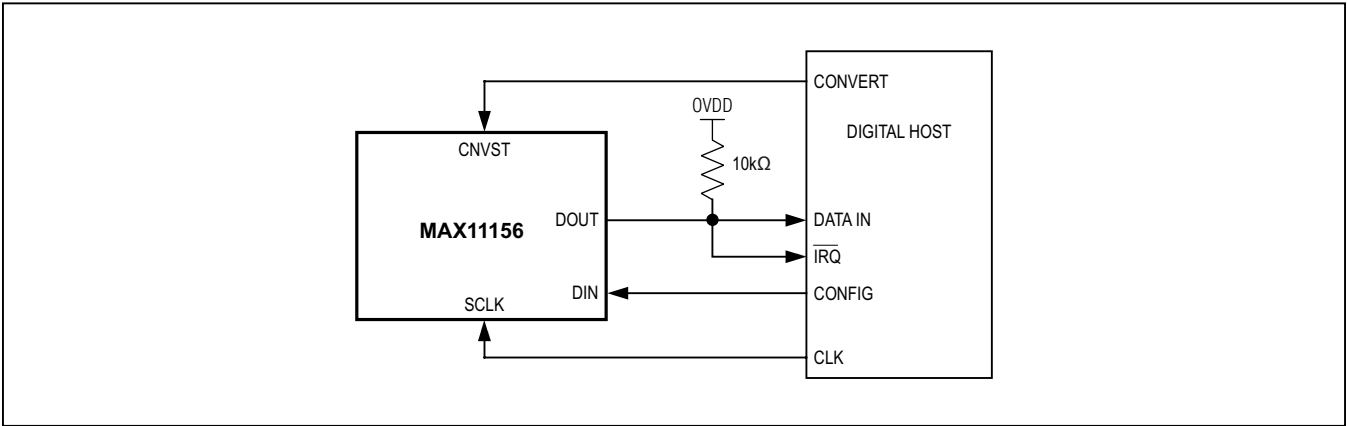

Figure 8. $\overline{\text{CS}}$ With Busy Indicator Mode Connection Diagram

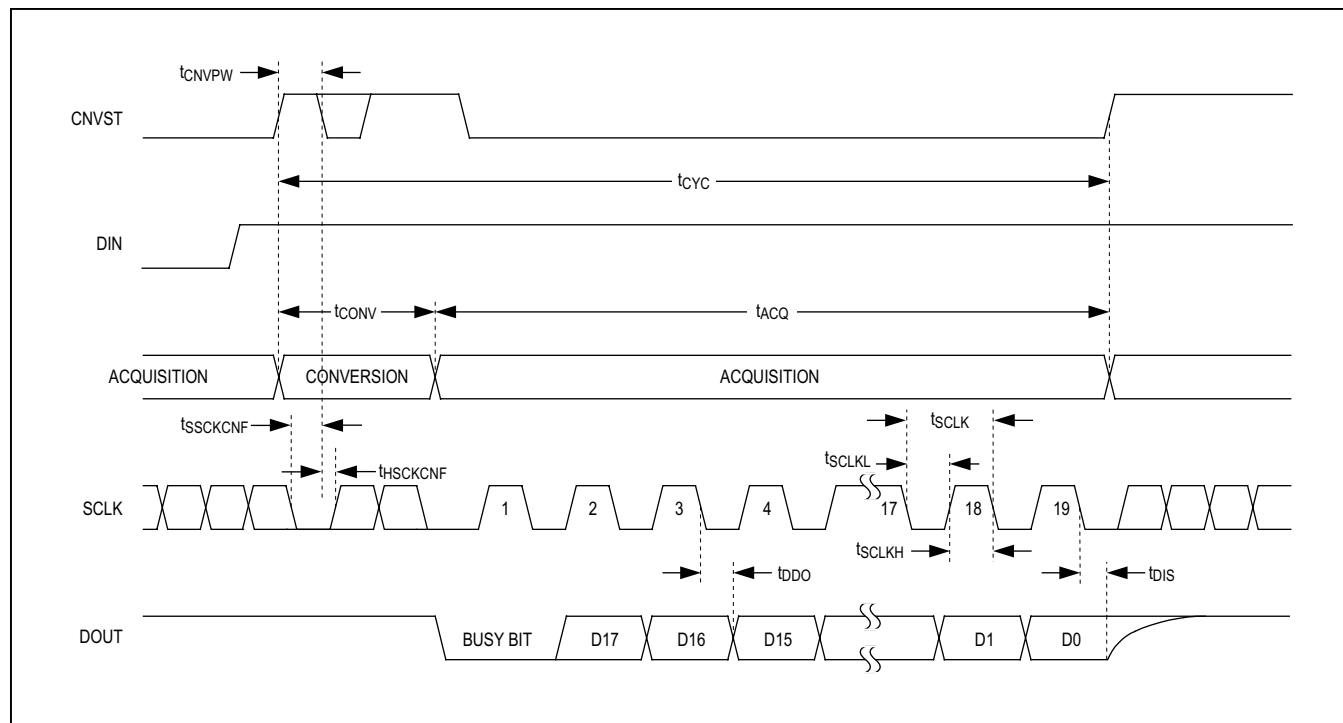

Figure 9. \overline{CS} With Busy Indicator Mode Timing

When the conversion is complete, DOUT transitions from high impedance to a low logic level, signaling to the digital host through the interrupt input that data readback can commence. The MAX11156 then enters the acquisition phase. The data bits are then clocked out, MSB first, by

subsequent SCLK falling edges. DOUT returns to high impedance after the 19th SCLK falling edge or when CNVST goes high, and is then pulled to OVDD through the external pullup resistor.

**Multichannel \overline{CS} Configuration,
Asynchronous or Simultaneous Sampling**

The multichannel \overline{CS} configuration is generally used when multiple MAX11156 ADCs are connected to an SPI-compatible digital host. [Figure 10](#) shows the connection diagram example using two MAX11156 devices. [Figure 11](#) shows the corresponding timing.

Asynchronous or simultaneous sampling is possible by controlling the $\overline{CS1}$ and $\overline{CS2}$ edges. In [Figure 10](#), the DOUT bus is shared with the digital host limiting the throughput rate. However, maximum throughput is possible if the host accommodates each ADC's DOUT pin independently.

A rising edge on CNVST completes the acquisition, initiates the conversion and forces DOUT to high impedance. The conversion continues to completion

irrespective of the state of CNVST allowing CNVST to be used as a select line for other devices on the board. However, CNVST must be returned high before the minimum conversion time for proper operation so that another conversion is not initiated with insufficient acquisition time and data correctly read out of the device.

When the conversion is complete, the MAX11156 enters the acquisition phase. Each ADC result can be read by bringing its CNVST input low, which consequently outputs the MSB onto DOUT. The remaining data bits are then clocked by subsequent SCLK falling edges. For each device, its DOUT will return to a high-impedance state after the 18th SCLK falling edge or when CNVST goes high. This control allows multiple devices to share the same DOUT bus.

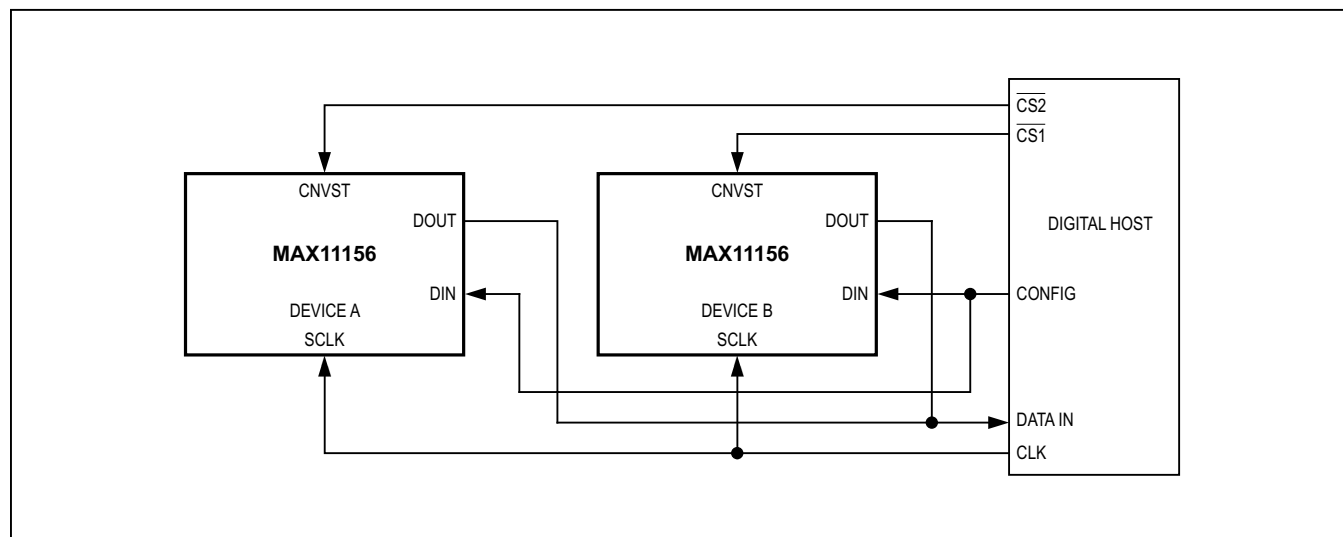

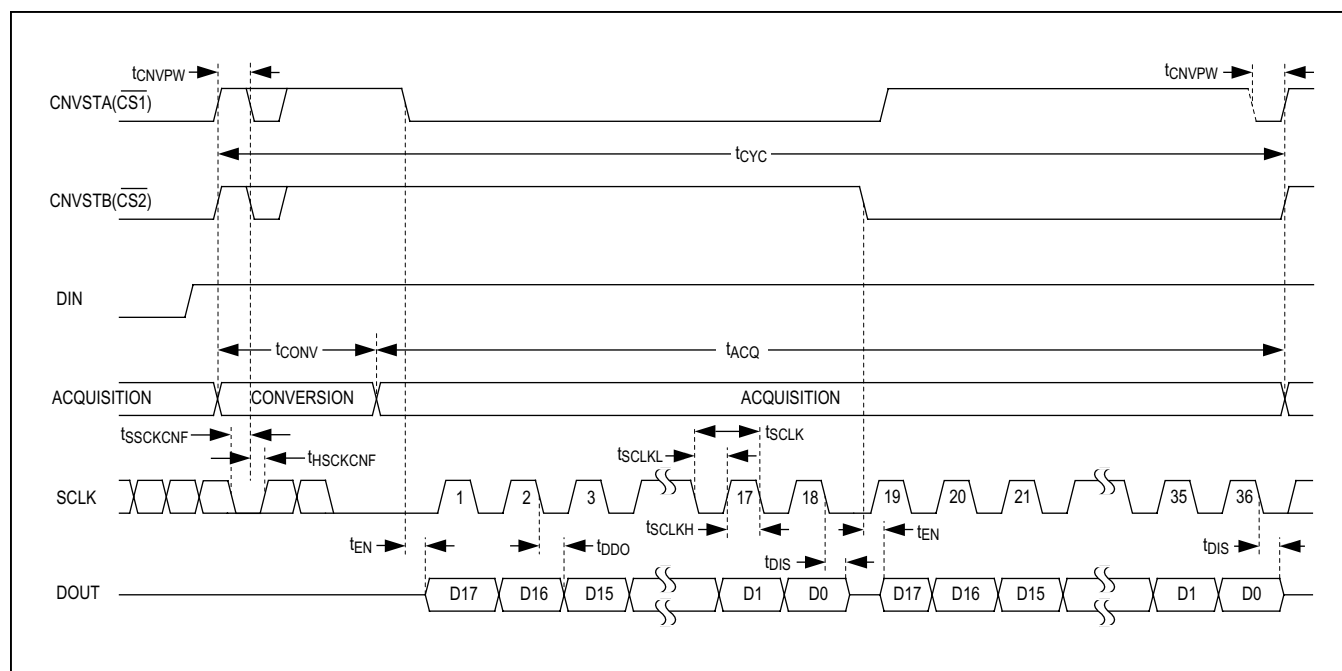

Figure 10. Multichannel \overline{CS} Configuration Diagram

Figure 11. Multichannel \overline{CS} Configuration Timing

Daisy-Chain, No-Busy Indicator Mode

The daisy-chain mode with no-busy indicator is ideally suited for multichannel isolated applications that require minimal wiring complexity. Simultaneous sampling of multiple ADC channels is realized on the serial interface where data readback is analogous to clocking a shift register. Figure 12 shows a connection diagram of two MAX11156s configured in a daisy chain. The corresponding timing is given in Figure 13.

A rising edge on CNVST completes the acquisition and initiates the conversion. Once a conversion is initiated, it continues to completion irrespective of the state of CNVST. When a conversion is complete, the MSB is presented onto DOUT and the MAX11156 returns to the acquisition phase. The remaining data bits are stored within an internal shift register. To read these bits out, CNVST is brought low and each bit is shifted out on subsequent SCLK falling edge. The DIN input of each ADC in the chain is used to transfer conversion data from the previous ADC into the internal shift register of the next ADC, thus allowing for data to be clocked through the multichip chain on each SCLK falling edge. Each ADC in the chain outputs its MSB data first requiring $18 \times N$ clocks to read back N ADCs.

In daisy-chain mode, the maximum conversion rate is reduced due to the increased readback time. For instance, with a 5ns digital host setup time and 3V interface, up to four MAX11156 devices running at a conversion rate of 279ksps can be daisy-chained.

Daisy-Chain with Busy Indicator Mode

The daisy-chain mode with busy indicator is ideally suited for multichannel isolated applications that require minimal wiring complexity while providing a conversion complete indication that can be used to interrupt a host processor to read data.

Simultaneous sampling of multiple ADC channels is realized on the serial interface where data readback is analogous to clocking a shift register. The daisy-chain mode with busy indicator is shown in Figure 14 where three MAX11156s are connected to a SPI-compatible digital host with corresponding timing given in Figure 15.

A rising edge on CNVST completes the acquisition and initiates the conversion. Once a conversion is initiated, it continues to completion irrespective of the state of CNVST. When a conversion is complete, the busy indicator is presented onto each DOUT and the MAX11156 returns to the acquisition phase. The busy indicator for the last ADC in

the chain can be connected to an interrupt input on the digital host. The digital host should insert a 50ns delay from the receipt of this interrupt before reading out data from all ADCs to ensure that all devices in the chain have completed conversion.

The conversion data is stored within an internal shift register. To read these bits out, CNVST is brought low and each bit is shifted out on subsequent SCLK falling edge. The DIN input of each ADC in the chain is used to transfer conversion data from the previous ADC into the internal shift register of the next ADC, thus allowing for data to be

clocked through the multichip chain on each SCLK falling edge. The total of number of falling SCLKs needed to read back all data from N ADCs is $18 \times N + 1$ edges, the one additional SCLK falling edge required to clock out the busy mode bit from the host side ADC.

In daisy-chain mode, the maximum conversion rate is reduced due to the increased readback time. For instance, with a 5ns digital host setup time and 3V interface, up to four MAX11156 devices running at a conversion rate of 276ksps can be daisy-chained on a 3-wire port.

Layout, Grounding, and Bypassing

For best performance, use PCBs with ground planes. Ensure that digital and analog signal lines are separated from each other. Do not run analog and digital lines parallel to one another (especially clock lines), and avoid running digital lines underneath the ADC package. A single solid GND plane configuration with digital signals routed from one direction and analog signals from the other provides the best performance. Connect the GND and AGND pins on the MAX11156 to this ground plane. Keep the ground return to the power-supply low impedance and as short as possible for noise-free operation.

A 500pF C0G (or NPO) ceramic chip capacitor should be placed between AIN+ and the ground plane as close as possible to the MAX11156. This capacitor reduces the inductance seen by the sampling circuitry and reduces the voltage transient seen by the input source circuit.

For best performance, connect the REF output to the ground plane with a 16V, 10 μ F ceramic chip capacitor with a X5R or X7R dielectric in a 1210 or smaller case size. Ensure that all bypass capacitors are connected directly into the ground plane with an independent via.

Bypass VDD and OVDD to the ground plane with 0.1 μ F ceramic chip capacitors on each pin as close as possible to the device to minimize parasitic inductance. Add at least one bulk 10 μ F decoupling capacitor to VDD and OVDD per PCB. For best performance, bring a VDD power plane in on the analog interface side of the MAX11156 and a OVDD power plane from the digital interface side of the device.

Definitions

Integral Nonlinearity

Integral nonlinearity (INL) is the deviation of the values on an actual transfer function from a straight line. For these devices, this straight line is a line drawn between the end points of the transfer function, once offset and gain errors have been nullified.

Differential Nonlinearity

Differential nonlinearity (DNL) is the difference between an actual step width and the ideal value of 1 LSB. For these devices, the DNL of each digital output code is measured and the worst-case value is reported in the [Electrical Characteristics](#) table. A DNL error specification of less than ± 1 LSB guarantees no missing codes and a monotonic transfer function.

Offset Error

For the MAX11156, the offset error is defined at the center of code 0x2000. The center of code 0x2000 should occur with an analog input voltage of exactly 0V. The offset error is defined as the deviation between the actual analog input voltage required to produce the center of code 0x2000 and the ideal analog input of 0V, expressed in LSBs.

Gain Error

Gain error is defined as the difference between the change in analog input voltage required to produce a top code transition minus a bottom code transition, subtracted from the ideal change in analog input voltage on $(5.0V/4.096V) \times V_{REF} \times (262142/262144)$. For the MAX11156, top code transition is 0x3FFFE to 0x3FFFF. The bottom code transition is 0x00000 and 0x00001. For the MAX11156, the analog input voltage to produce these code transitions is measured and then the gain error is computed by subtracting $2.0 \times (5.0V/4.096V) \times V_{REF} \times (262142/262144)$ from this measurement.

Signal-to-Noise Ratio

For a waveform perfectly reconstructed from digital samples, signal-to-noise ratio (SNR) is the ratio of the full-scale analog input power to the RMS quantization error (residual error). The ideal, theoretical minimum analog-to-digital noise is caused by quantization noise error only and results directly from the ADC's resolution (N bits):

$$SNR = (6.02 \times N + 1.76)dB$$

In reality, there are other noise sources besides quantization noise: thermal noise, reference noise, clock jitter, etc. SNR is computed by taking the ratio of the power signal to the power noise, which includes all spectral components not including the fundamental, the first five harmonics, and the DC offset.

Signal-to-Noise Plus Distortion

Signal-to-noise plus distortion (SINAD) is the ratio of the fundamental input frequency's power to the power of all the other ADC output signals:

$$SINAD(dB) = 10 \times \log \left[\frac{\text{Signal}}{(\text{Noise} + \text{Distortion})} \right]$$

Effective Number of Bits

The effective number of bits (ENOB) indicates the global accuracy of an ADC at a specific input frequency and sampling rate. An ideal ADC's error consists of quantization noise only. With an input range equal to the full-scale range of the ADC, calculate the ENOB as follows:

$$\text{ENOB} = \frac{\text{SINAD} - 1.76}{6.02}$$

Total Harmonic Distortion

Total harmonic distortion (THD) is the ratio of the power contained in the first five harmonics of the converted data to the power of the fundamental. This is expressed as:

$$\text{THD} = 10 \times \log \frac{(P_2^2 + P_3^2 + P_4^2 + P_5^2)}{P_1^2}$$

where P_1 is the fundamental power and P_2 through P_5 is the power of the 2nd- through 5th-order harmonics.

Spurious-Free Dynamic Range

Spurious-free dynamic range (SFDR) is the ratio of the power of the fundamental (maximum signal component) to the power of the next-largest frequency component.

Aperture Delay

Aperture delay (t_{AD}) is the time delay from the sampling clock edge to the instant when an actual sample is taken.

Aperture Jitter

Aperture jitter (t_{AJ}) is the sample-to-sample variation in aperture delay.

Small-Signal Bandwidth

A small -20dBFS analog input signal is applied to an ADC in a manner that ensures that the signal's slew rate does not limit the ADC's performance. The input frequency is then swept up to the point where the amplitude of the digitized conversion result has decreased 3dB.

Full-Power Bandwidth

A large -0.5dBFS analog input signal is applied to an ADC, and the input frequency is swept up to the point where the amplitude of the digitized conversion result has decreased by 3dB. This point is defined as full-power input bandwidth frequency.

Компания «ЭлектроПласт» предлагает заключение долгосрочных отношений при поставках импортных электронных компонентов на взаимовыгодных условиях!

Наши преимущества:

- Оперативные поставки широкого спектра электронных компонентов отечественного и импортного производства напрямую от производителей и с крупнейших мировых складов;
- Поставка более 17-ти миллионов наименований электронных компонентов;
- Поставка сложных, дефицитных, либо снятых с производства позиций;
- Оперативные сроки поставки под заказ (от 5 рабочих дней);
- Экспресс доставка в любую точку России;
- Техническая поддержка проекта, помощь в подборе аналогов, поставка прототипов;
- Система менеджмента качества сертифицирована по Международному стандарту ISO 9001;
- Лицензия ФСБ на осуществление работ с использованием сведений, составляющих государственную тайну;
- Поставка специализированных компонентов (Xilinx, Altera, Analog Devices, Intersil, Interpoint, Microsemi, Aeroflex, Peregrine, Syfer, Eurofarad, Texas Instrument, Miteq, Cobham, E2V, MA-COM, Hittite, Mini-Circuits, General Dynamics и др.);

Помимо этого, одним из направлений компании «ЭлектроПласт» является направление «Источники питания». Мы предлагаем Вам помощь Конструкторского отдела:

- Подбор оптимального решения, техническое обоснование при выборе компонента;
- Подбор аналогов;
- Консультации по применению компонента;
- Поставка образцов и прототипов;
- Техническая поддержка проекта;
- Защита от снятия компонента с производства.
