# 3 Terminology and guidelines

## 3.1 Definition: Operating requirement

An *operating requirement* is a specified value or range of values for a technical characteristic that you must guarantee during operation to avoid incorrect operation and possibly decreasing the useful life of the chip.

### 3.1.1 Example

This is an example of an operating requirement:

| Symbol | Description | Min. | Max. | Unit |
|---|---|---|---|---|
| $V_{DD}$ | 1.0 V core supply voltage | 0.9 | 1.1 | V |

## 3.2 Definition: Operating behavior

Unless otherwise specified, an *operating behavior* is a specified value or range of values for a technical characteristic that are guaranteed during operation if you meet the operating requirements and any other specified conditions.

### 3.2.1 Example

This is an example of an operating behavior:

| Symbol | Description | Min. | Max. | Unit |
|---|---|---|---|---|
| $I_{WP}$ | Digital I/O weak pullup/ pulldown current | 10 | 130 | µA |

## 3.3 Definition: Attribute

An *attribute* is a specified value or range of values for a technical characteristic that are guaranteed, regardless of whether you meet the operating requirements.

### 3.3.1 Example

This is an example of an attribute:

| Symbol | Description | Min. | Max. | Unit |
|---|---|---|---|---|
| CIN_D | Input capacitance: digital pins | — | 7 | pF |

## 3.4 Definition: Rating

A *rating* is a minimum or maximum value of a technical characteristic that, if exceeded, may cause permanent chip failure:

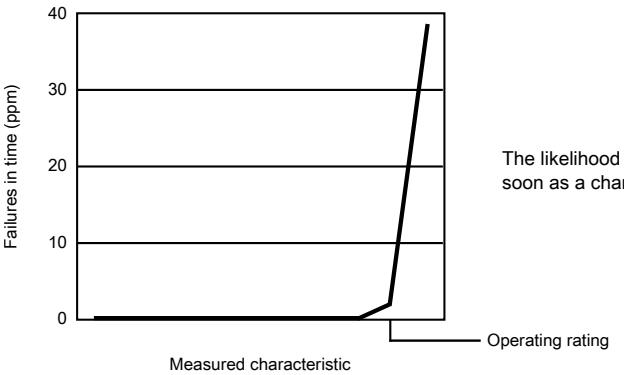
- *Operating ratings* apply during operation of the chip.
- *Handling ratings* apply when the chip is not powered.

### 3.4.1 Example

This is an example of an operating rating:

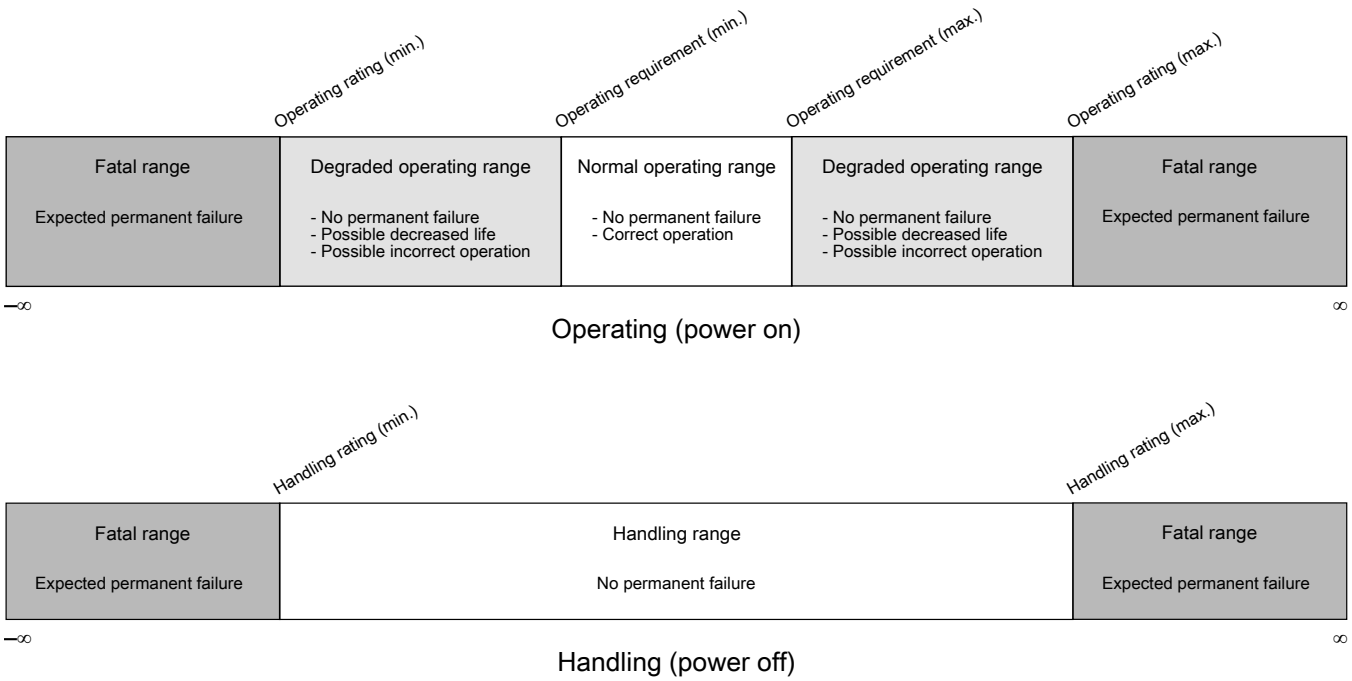
| Symbol | Description | Min. | Max. | Unit |
|---|---|---|---|---|
| $V_{DD}$ | 1.0 V core supply voltage | –0.3 | 1.2 | V |

## 3.5 Result of exceeding a rating



The likelihood of permanent chip failure increases rapidly as soon as a characteristic begins to exceed one of its operating ratings.

## 3.6 Relationship between ratings and operating requirements



## 3.7 Guidelines for ratings and operating requirements

Follow these guidelines for ratings and operating requirements:

- Never exceed any of the chip's ratings.
- During normal operation, don't exceed any of the chip's operating requirements.
- If you must exceed an operating requirement at times other than during normal operation (for example, during power sequencing), limit the duration as much as possible.

## 3.8 Definition: Typical value

A *typical value* is a specified value for a technical characteristic that:

- Lies within the range of values specified by the operating behavior
- Given the typical manufacturing process, is representative of that characteristic during operation when you meet the typical-value conditions or other specified conditions

Typical values are provided as design guidelines and are neither tested nor guaranteed.

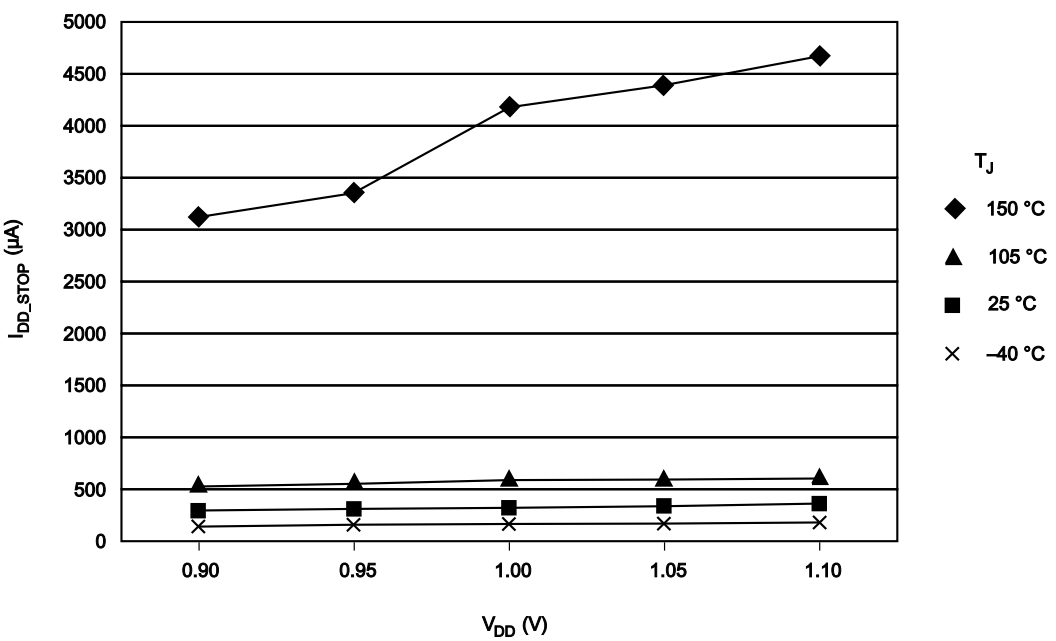
### 3.8.1 Example 1

This is an example of an operating behavior that includes a typical value:

| Symbol | Description | Min. | Typ. | Max. | Unit |
|---|---|---|---|---|---|
| $I_{WP}$ | Digital I/O weak pullup/pulldown current | 10 | 70 | 130 | µA |

### 3.8.2 Example 2

This is an example of a chart that shows typical values for various voltage and temperature conditions:



## 3.9 Typical Value Conditions

Typical values assume you meet the following conditions (or other conditions as specified):

| Symbol | Description | Value | Unit |
|---|---|---|---|
| $T_A$ | Ambient temperature | 25 | °C |
| $V_{DD}$ | 3.3 V supply voltage | 3.3 | V |

### 6.2.1.5 External NPN Ballast

The internal main regulator requires an external NPN ballast transistor to be connected as shown in the following figure as well as an external capacitance to be connected to the device in order to provide a stable 1.2V digital supply to the device. The HPREG design allows for collector voltage lower than VDDREG value. See AN4807 at www.nxp.com .

**NOTE**

To not overload BCTRL output, collector voltage should appear no later than VDDREG / VDD33 (3.3V).

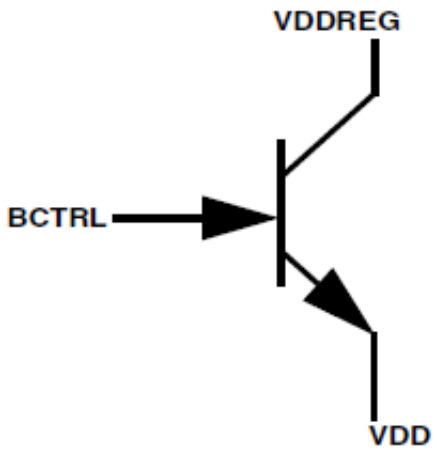

**Figure 3. External NPN Ballast connections**

**Table 6. BCTRL OUTPUT specification**

| Parameter | Value | Comments |
|---|---|---|
| BCTRL OUTPUT specification | 20mA | BCTRL driver can not drive more than 20mA current |
| Maximum pin voltage | VDDREG-0.5V | For Example, VDDREG =3.0V BCTRL should not exceed 2.5V. |

**Table 7. Assumptions For calculations**

| Parameter | Value |
|---|---|
| VDDREG | 3.0V to 3.6V with typical value of 3.3V |
| Max DC Collector current | 0.85A @85 °C |
| Emitter voltage | 1.2V to 1.25V |
| Collector voltage | Equal to VDDREG |

**Table 8. General guidelines for selection of NPN ballast**

| Symbol | Parameters | Value | Unit | Comments |
|---|---|---|---|---|
| Hfe | Minimum DC current gain (Beta) | 42.5 | | As BCTRL pin can not drive more than 20mA Minimum value of beta for a collector current of 0.85A comes out to be 42.5. |
| PD (Junction to ambient) | Minimum power dissipation @ TA=85 °C | 2.04 | W | Assuming 0.85A collector current with Collector voltage of Ballast 3.6V(max) we get VCE= 3.6V-1.2V=2.4V So power dissipated is 2.4V*0.85A=2.04W . This should be met for junction to ambient power dissipation spec of ballast |
| IcmaxDC peak | Maximum peak DC collector current | 0.85 | A | 1.2A and above capacity device preferable |
| VBE | Maximum voltage that BCTRL pin can drive | 1.25V for 0.85A @ 85 °C | V | For a VDDREG of 3.0 V (min.), BCTRL pin can drive voltage up to VDDREG - 0.5 V = 2.5 V. Since emitter of ballast is fixed at 1.25 V (max) if chosen ballast can supply 0.85 A collector current @ 85 °C with a base-to-emitter voltage of 1.25 V or lower, it is suitable for application. |
| Ft | Unity current gain Frequency of Ballast | 50 | MHz | |

Reducing the collector-to-emitter voltage drop lowers the ballast transistor heat dissipation. This can be implemented in two ways:

1. By introducing series resistor or diode(s) between the collector and VDDREG (placed far enough from the transistor for proper cooling)
2. By connecting the collector to a separate lower-voltage supply

In both of the above cases the transistor has to stay away from the deep saturation region; otherwise, due to significant Hfe degradation, its base current exceeds the BCTRL output maximum value.

In general, the transistor must be selected such that its Vce saturation voltage is lower than the expected minimum Collector-Emitter voltage, and at the same time, the base current is less than 20 mA for the maximum expected collector current. More information can be found in collateral documentation at http://www.nxp.com

1. Power sequencing of USB0_VBUS is independent of any other power supply.
2. Power sequencing of USB1_VBUS is independent of any other power supply.

**NOTE**

NA stands for no sequencing needs, for example, the supply can come in any order.

**NOTE**

All supplies grouped together e.g. 1,2, others. These have no power sequencing restriction in between them.

**NOTE**

If none of the SDRAMC pins are connected on the board, the SDRAMC supply could be left floating.

**NOTE**

At power up, 1.2V supply will follow 3.3V supply. At power down, it should be checked that 1.2V falls before 3.3V.

**NOTE**

The standby current on USBx_VBUS is 300 - 500 uA. This is well below the 2.5 mA limit set by the USB 2.0 specification.

This supply will be ON for applications that need to monitor the USB bus during standby. This supply can be turned-off during standby in applications that cannot tolerate the standby current and do not monitor the USB bus.

## 8.2 Power supply

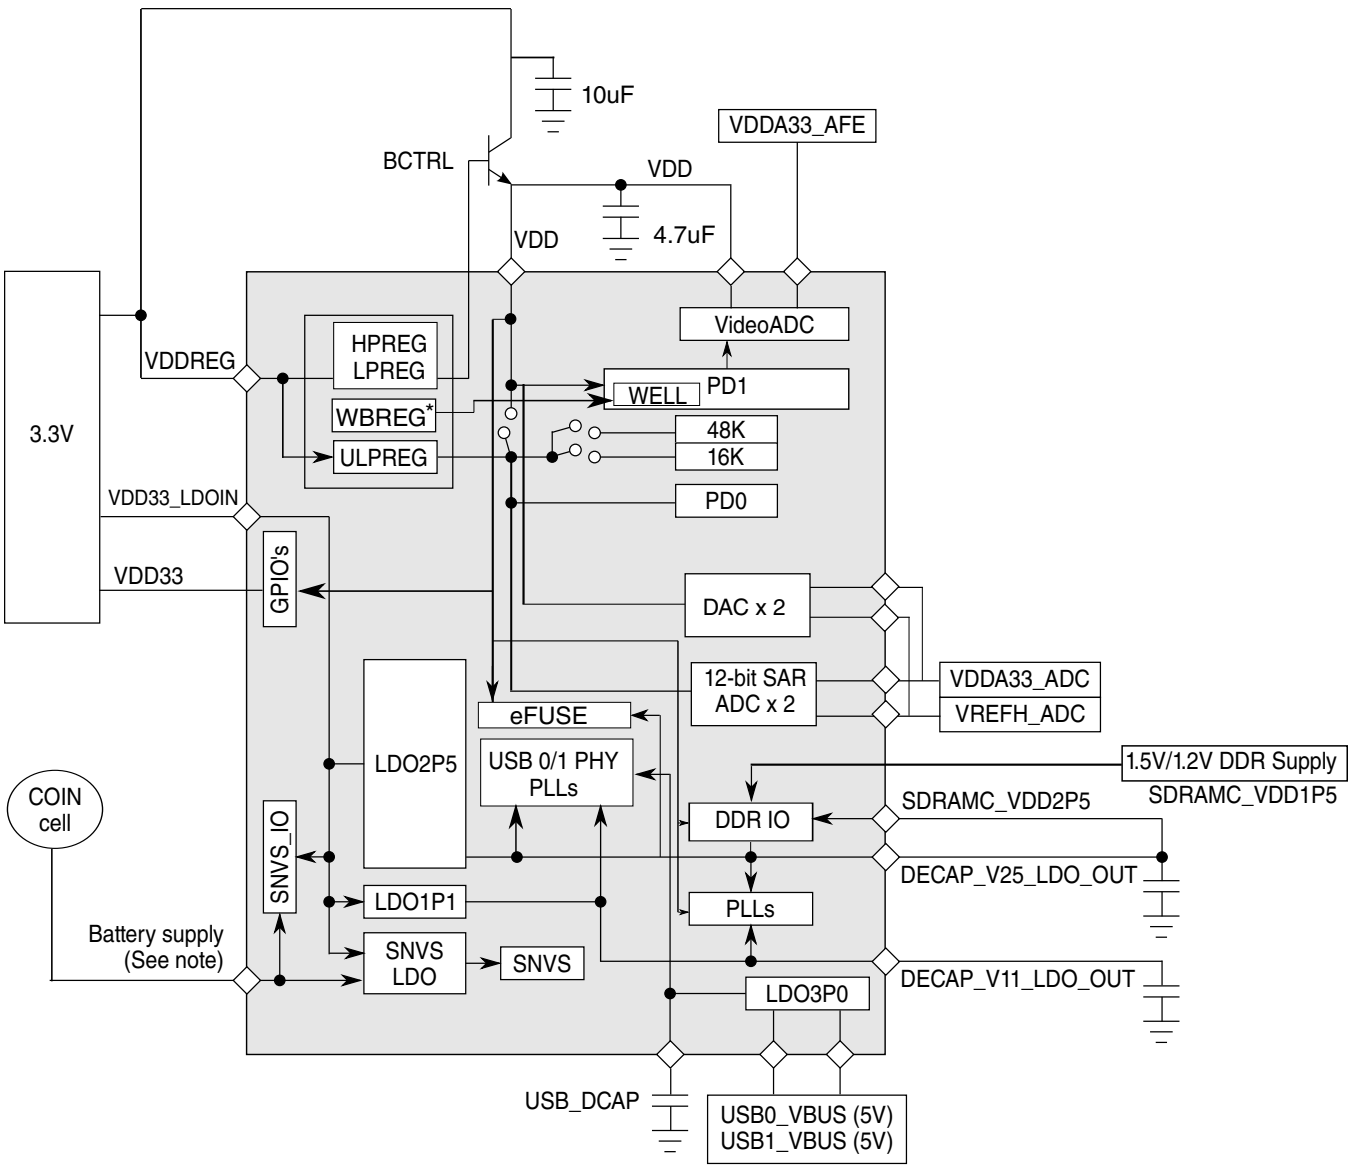

**Figure 4. Power supply**

### NOTE

VBAT is the battery supply. If not required, then VBAT should be tied to VDDREG.

**NOTE**

WBREG is the Well Bias Regulator. Supplies PD1 WELL during well bias modes.

## 8.5 Recommended Connections for Unused Analog Interfaces

**NOTE**

There are two options to handle unused power pins:

1. Connect all unused supplies to their respective voltage. To save the power, do not enable the module and/or do not enable clock gate to the module.
2. Keep all unused supplies floating.

If pin is shared by several peripheral, then all peripherals connected to multiplexer have to be powered. For example: if pin is shared by GPIO and ADC input and GPIO functionality is used, then ADC has to be powered due to internal structure of the multiplexer. Keep unused input signals grounded if power pins are powered. Keep unused input signals floating if power pins are floating. Keep unused output signals floating.

**NOTE**

VideoADC 3.3V and 1.2V power supply pins should be decoupled to their respective grounds using low-ESR 100nF capacitors

**NOTE**

If possible, avoid using switched voltage regulators for the AFE power domains. Use linear voltage regulators instead.

**NOTE**

The 3.3V and 1.2V power domains should be separated from other circuitry on the board by inductors/beads to filter out high frequency noise.

## 9.2 Display and Video interfaces

### 9.2.1 DCU Switching Specifications

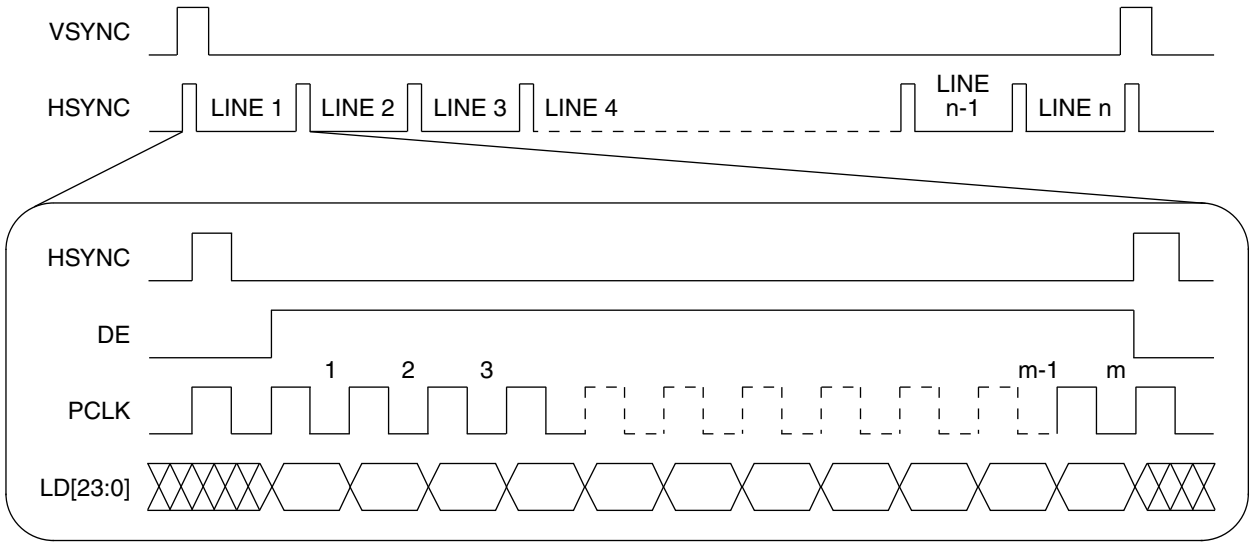
#### 9.2.1.1 Interface to TFT panels (DCU0/1)

This section provides the LCD interface timing for a generic active matrix color TFT panel. In the figure below, signals are shown with positive polarity. The sequence of events for active matrix interface timing:

- PCLK latches data into the panel on its positive edge (when positive polarity is selected). In active mode, PCLK runs continuously. This signal frequency could be from 5 to 66 MHz depending on the panel type.
- HSYNC causes the panel to start a new line. It always encompasses at least one PCLK pulse.
- VSYNC causes the panel to start a new frame. It always encompasses at least one HSYNC pulse.
- DE acts like an output enable signal to the LCD panel. This output enables the data to be shifted onto the display. When disabled, the data is invalid and the trace is off.

**Figure 14. TFT LCD interface timing overview[1]**

1. In the figure, LD[23:0]" signal is "line data," an aggregation of the DCU's RGB signals—R[0:7], G[0:7] and B[0:7].



### 9.2.1.2 Interface to TFT LCD Panels—Pixel Level Timings

This section provides the horizontal timing (timing of one line), including both the horizontal sync pulse and data. All parameters shown in the figure below are programmable. This timing diagram corresponds to positive polarity of the PCLK signal (meaning the data and sync signals change on the rising edge) and active-high polarity of the HSYNC, VSYNC and DE signals. The user can select the polarity of the HSYNC and VSYNC signals via the SYN_POL register, whether active-high or active-low. The default is active-high. The DE signal is always active-high. Pixel clock inversion and a flexible programmable pixel clock delay are also supported. They are programmed via the clock divide . The DELTA_X and DELTA_Y parameters are programmed via the DISP_SIZE register. The PW_H, BP_H and FP_H parameters are programmed via the HSYN PARA register. The PW_V, BP_V and FP_V parameters are programmed via the VSYN_PARA register.

## 9.4.3 SAI/I²S Switching Specifications

This section provides the AC timings for the SAI in master (clocks driven) and slave modes (clocks input). If the polarity of the clock and/or the frame sync have been inverted, all the timings remain valid by inverting the clock signal (SAI_BCLK) and/or the frame sync (SAI_FS) shown in the figures below.

## 9.5.1 QuadSPI timing

- All data is based on a negative edge data launch from the device and a negative edge data capture, as shown in the timing diagrams in this section. This corresponds to the N/1 sample point as shown in the reference manual QSPI section "Internal Sampling of Serial Flash Input Data."
- Measurements are with a load of 35 pF on output pins. I/P Slew : 1ns
- Timings assume a setting of 0x0000_000x for QSPI_SMPR register (see the reference manual for details).

**NOTE**

- Tcss and Tcsh are set by QuadSPI_FLSCH register, the minimum values of 3 shown are the register default values, refer to Reference Manual for further details.
- The timing in the datasheet is based on default values for the QuadSPI-SMPR register and is the recommended setting for highest SCK frequency in SDR mode.
- A negative time indicates the actual capture edge inside the device is earlier than clock appearing at pad.
- Frequency calculator guideline (Max read frequency): Tck > (Flash access time)max + (Tis)max
- A negative input hold time has no bearing on the maximum achievable operating frequency.

## DDR Mode

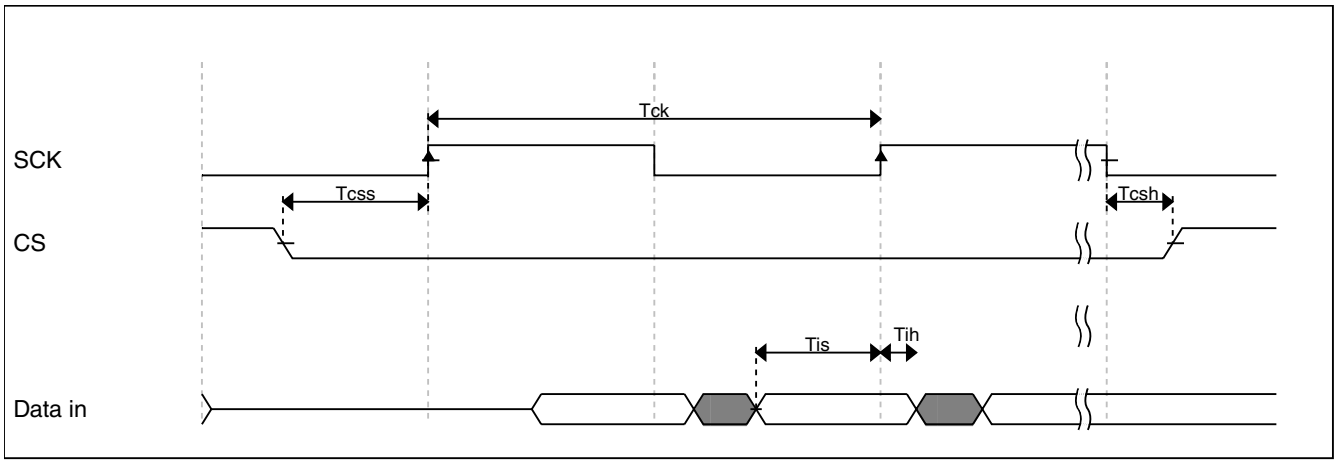

**Figure 32. QuadSPI Input/Read timing (DDR mode)**

## NOTE

- The numbers are for a setting of 0x1 in register QuadSPI_SMPR[DDRSMP]
- Read frequency calculations should be: Tck/2 > (flash access time) + Setup (Tis) - (QuadSPI_SMPR[DDRSMP])x Tck/4
- Frequency calculator guideline (Max read frequency): Tck/2 > (Flash access time)max + (Tis)max - (QuadSPI_SMPR[DDRSMP]) x Tck/4
- Hold timing: flash_access (min) + flash_data_valid (min) > Tck/2 + HOLD(Tih) + (QuadSPI_SMPR[DDRSMP])Tck/4

## 9.5.3 FlexBus timing specifications

This section provides FlexBus timing parameters. All processor bus timings are synchronous; input setup/hold and output delay are given in respect to the rising edge of a reference clock, FB_CLK. The FB_CLK frequency may be the same as the internal system bus frequency.

The following timing numbers indicate when data is latched or driven onto the external bus, relative to the FlexBus output clock (FB_CLK). All other timing relationships can be derived from these values.

All FlexBus signals use pad type pad_fsr. The following timing specifications assume a pad slew rate setting of 11 and a load of 50 pF[3]

**Table 53. FlexBus timing specifications**

| Num | Characteristic | Min | Max | Unit |
|---|---|---|---|---|
| | Frequency of operation | — | 83[1] (with Wait state) | MHz |
| | | | 57[2] without Wait state [-1] | |
| FB1 | Clock Period | 12 | — | ns |
| FB4 | Input setup | 10.6 | — | ns |
| FB5 | Input hold | 0 | — | ns |
| FB2 | Output valid | — | 6.4 | ns |
| FB3 | Output hold | 0 | — | ns |

1. Freq = 1000/(11+ access time of external memory+ trace delay for clk and data)
2. Freq = 1000/(17+access time of external memory)

3. These timing parameters are specified assuming maximum operating frequency and the fastest pad slew rate setting (11).

| No. | Parameter | Min. | Max. | Unit |
|---|---|---|---|---|

| 8 | Stop condition setup time | 2 | — | PER_CLKCycle |

1. I2C input timing is valid for Automotive and TTL inputs levels, hysteresis enabled, and an input edge rate no slower than 1 ns (10% – 90%).
2. PER_CLK is the IPG Clock which drives the I2C BIU and module clock inputs. Typically this is 66 MHz. See the Clocking Overview chapter in the device reference manual for more details.

## Table 62. I2C output timing specifications — SCL and SDA [1, 2, 3, 4]

| No. | Parameter | Min | Max | Unit |
|---|---|---|---|---|
| 1 | Start condition hold time | 6 | — | PER_CLK Cycle[5] |
| 2 | Clock low time | 10 | — | PER_CLK Cycle |

| 7 | Start condition setup time (for repeated start condition only) | 20 | — | PER_CLK Cycle |
| 8 | Stop condition setup time | 10 | — | PER_CLK Cycle |

1. All output timing is worst case and includes the mismatching of rise and fall times of the output pads.
2. Output parameters are valid for CL = 25 pF, where CL is the external load to the device (lumped). The internal package capacitance is accounted for, and does not need to be subtracted from the 25 pF value.
3. Timing is guaranteed to same drive capabilities for all signals, mixing of pad drives may reduce operating speedsand may cause incorrect operation.
4. Programming the IBFD register (I2C bus Frequency Divider) with the maximum frequency results in the minimum output timings listed. The I2C interface is designed to scale the data transition time, moving it to the middle of the SCL low period. The actual position is affected by the pre-scale and division values programmed in the IBC field of the IBFD register.
5. PER_CLK is the IPG Clock which drives the I2C BIU and module clock inputs. Typically this is 66 MHz. See the Clocking Overview chapter in the device reference manual for more details.

# 9.7 Clocks and PLL Specifications

## 9.7.1 24 MHz Oscillator Specifications

The system crystal oscillator consists of a Pierce-type structure running off the digital supply. A straight forward biased-inverter implementation is used. The crystal must be rated for a drive level of 250 µW or higher. An ESR (equivalent series resistance) of 80 Ω or less is recommended to achieve a gain margin of 5.

**Table 64. 24MHz external oscillator electrical characteristics**

| Symbol | Parameter | Condition | Value | | | Unit |
|---|---|---|---|---|---|---|
| | | | Min | Typ | Max | |
| $f_{osc}$ | Crystal oscillator range | — | — | 24 | — | MHz |
| $I_{osc}$ | Startup current | — | — | < 5 | — | mA |
| $t_{uposc}$ | Oscillator startup time | — | — | < 5 | — | ms |
| $C_{IN}$ | Input Capacitance | EXTAL and XTAL pins | — | 9 | — | pF |
| VIH | XTAL pin input high voltage | — | 0.8 x Vdd[1] | — | Vdd +0.3 | V |
| VIL | XTAL pin input low voltage | — | Vss -0.3 | — | 0.2 x Vdd | V |

1. $V_{DD}$ =1.1 V ± 10%, TA = -40 to +85 °C, unless otherwise specified.

## 9.7.2 32 KHz Oscillator Specifications

This block implements an amplifier that when combined with a suitable quartz crystal and external load capacitors implements a low power oscillator. It also implements a power mux such that it can be powered from either a ~3 V backup battery or VDDIO such as the oscillator consumes power from VDDIO when that supply is available and transitions to the back up battery when VDDIO is lost.

In addition, if the clock monitor determines that the OSC32K is not present, then the source of the 32 K will automatically switch to the 128kHz internal RC clock divided by 4.

The OSC32k runs from vdd_rtc supply, generated inside OSC32k itself from VDDIO/ VBAT. The target battery is a ~3 V coin cell. Proper choice of coin cell type is necessary for chosen VDDIO range. Appropriate series resistor (Rs) must be used when connecting the coin cell. Rs depends on the charge current limit that depends on the chosen coin cell.

For example:

- Average Discharge Voltage is 2.5 V
- Maximum Charge Current is 0.6 mA

For a charge voltage of 3.2 V, Rs = (3.2-2.5)/0.6 m = 1.17 k

**Table 65. OSC32K Main Characteristics**

| | Notes | Min | Typ | Max |
|---|---|---|---|---|
| $F_{OSC}$ | This frequency is nominal and determined mainly by the crystal selected. 32.0 K would work as well. | | 32.768 KHz | |
| Current consumption | The 4 µA is the consumption of the oscillator alone (OSC32k). Total supply consumption will depend on what the digital portion of the RTC consumes. The ring oscillator consumes 1 µA when ring oscillator is inactive, 20 µA when the ring oscillator is running. Another 1.5 µA is drawn from vdd_rtc in the power_detect block. So, the total current is 6.5 µA on vdd_rtc when the ring oscillator is not running. | | 4 µA | |
| Bias resistor | This the integrated bias resistor that sets the amplifier into a high gain state. Any leakage through the ESD network, external board leakage, or even a scope probe that is significant relative to this value will debias the amp. The debiasing will result in low gain, and will impact the circuit's ability to start up and maintain oscillations. | | 14 MΩ | |
| Crystal Properties | | | | |
| Cload | Usually crystals can be purchased tuned for different Cloads. This Cload value is typically 1/2 of the capacitances realized on the PCB on either side of the quartz. A higher Cload will decrease oscillation margin, but increases current oscillating through the crystal | | 12.5 pF | |
| ESR | Equivalent series resistance of the crystal. Choosing a crystal with a higher value will decrease the oscillating margin. | | 50 kΩ | |

## 12.2 Pinout diagrams

**NOTE**

The 176 LQFP parts are not pin compatible between the F and R series families devices.

**NOTE**

If tamper detection is not required, the tamper pins must be tied to ground.

## 12.2.2 Special Signal

**Table 76. Special Signal Considerations**

| Special Signal | Comments |
|---|---|
| DDR_VREF | When using DDR_VREF with DDR I/O, the nominal reference voltage must be half of the SDRAMC_VDD1P5 supply. The user must tie DDR_VREF to a precision external resistor divider. Shunt each resistor with a closely-mounted 0.1 µF capacitor. |
| DDR_ZQ | DRAM calibration resistor 240 Ω 1% used as reference during DRAM output buffer driver calibration should be connected between this pad and GND |
| DECAP_V25_LDO_OUT | DCAP_V25_LDO_OUT can be tied to SDRAMC_VDD2P5 to provide the predriver supply for the DDR I/O segment. SDRAMC_VDD1P5 requires an external regulated supply. If SDRAMC_VDD2P5 uses an external 2.5V supply, do NOT tie it to DCAP_V25_LDO_OUT. |
| EXT_POR, TEST | Factory use only, tie to ground.. |
| EXT_TAMPER0, EXT_TAMPER1, EXT_TAMPER2, EXT_TAMPER3, EXT_TAMPER4, EXT_TAMPER5 | Security related tamper detection inputs, if not in use they must be tied to ground. |
| FA_VDD | Factory use only, tie to VDD. |

## Table 76. Special Signal Considerations (continued)

| Special Signal | Comments |
|---|---|
| JTCLK, JTDI, JTDO, JTMS | For JTAG the use of external resistors is unnecessary. However, if external resistors are used, the user must ensure that the on-chip pull-up/down configuration is matched. For example, do not use an external pull down on an input that has on-chip pull-up. JTDO is configured with a keeper circuit such that the floating condition is eliminated if an external pull resistor is not present. An external pull resistor on JTDO is detrimental and should be avoided. |
| LVDS0N, LVDS0P | Not recommended for application use, intended for clock observation purposes during debug only. |
| RESETB/RESET_OUT | Active low input used to generate a system wide reset (except the SRTC). A glitch filter is include to help prevent unexpected resets, a minimum pulse width of 125 nsecs is required to guarantee a reset is detected. |
| XTAL, EXTAL | A 24.0 MHz fundamental mode crystal should be connected between XTAL and EXTAL. The crystal must be rated for a drive level of 250 µW or higher. An ESR (equivalent series resistance) of 80 Ω or less is recommended. This clock is used as a reference for USB, so there are strict frequency tolerance and jitter requirements. The crystal can be eliminated if an external 24 MHz oscillator is available in the system. In this case, XTAL must be directly driven by the external oscillator and EXTAL floated. The XTAL signal level must swing from ~0.8 x DECAP_V11_ LDO_OUT to ~0.2 V. |
| XTAL32, EXTAL32 | If the user wishes to configure XTAL32 and EXTAL32 as an RTC oscillator, a 32.768 kHz crystal, (≤50 kΩ ESR, 10 pF load) should be connected between XTAL32 and EXTAL32. Keep in mind the capacitors implemented on either side of the crystal are about twice the crystal load capacitor. To hit the exact oscillation frequency, the board capacitors need to be reduced to account for board and chip parasitics. The integrated oscillation amplifier is self biasing, but relatively weak. Care must be taken to limit parasitic leakage from XTAL32 and EXTAL32 to either power or ground (>100 MΩ). This will debias the amplifier and cause a reduction of startup margin. Typically XTAL32 and EXTAL32 should bias to approximately 0.5 V. If it is desired to feed an external low frequency clock into XTAL32 the EXTAL32 pin should be left floating or driven with a complimentary signal. The logic level of this forcing clock should not exceed DECAP_V11_ LDO_OUT level and the frequency should be <100 kHz under typical conditions. In the case where the SIRC is used, it is recommended to connect XTAL32 to ground and leave EXTAL32 floating. |
