

NCP1060, NCP1063

High-Voltage Switcher for Low Power Offline SMPS

The NCP106X products integrate a fixed frequency current mode controller with a 700 V MOSFET. Available in a PDIP-7, SOIC-10 or SOIC-16 package, the NCP106X offer a high level of integration, including soft-start, frequency-jittering, short-circuit protection, skip-cycle, adjustable peak current set point, ramp compensation, and a Dynamic Self-Supply (eliminating the need for an auxiliary winding).

Unlike other monolithic solutions, the NCP106X is quiet by nature: during nominal load operation, the part switches at one of the available frequencies (60 kHz or 100 kHz). When the output power demand diminishes, the IC automatically enters frequency foldback mode and provides excellent efficiency at light loads. When the power demand reduces further, it enters into a skip mode to reduce the standby consumption down to a no load condition.

Protection features include: a timer to detect an overload or a short-circuit event, Overvoltage Protection with auto-recovery and AC input line voltage detection (A version).

The ON proprietary integrated Over Power Protection (OPP) lets you harness the maximum delivered power without affecting your standby performance simply via external resistors.

For improved standby performance, the connection of an auxiliary winding stops the DSS operation and helps to reduce input power consumption below 50 mW at high line.

NCP106x can be seamlessly used both in non-isolated and in isolated topologies.

Features

- Built-in 700 V MOSFET with $R_{DS(on)}$ of 34 Ω (NCP1060) and 11.4 Ω (NCP1063)
- Large Creepage Distance Between High-voltage Pins
- Current-Mode Fixed Frequency Operation – 60 kHz or 100 kHz (130 kHz on demand)
- Adjustable Peak Current: see below table
- Fixed Ramp Compensation
- Direct Feedback Connection for Non-isolated Converter
- Internal and Adjustable Over Power Protection (OPP) Circuit
- Skip-Cycle Operation at Low Peak Currents Only
- Dynamic Self-Supply: No Need for an Auxiliary Winding
- Internal 4 ms Soft-Start
- Auto-Recovery Output Short Circuit Protection with Timer-Based Detection
- Auto-Recovery Overvoltage Protection with Auxiliary Winding Operation
- Frequency Jittering for Better EMI Signature
- No Load Input Consumption < 50 mW

MARKING DIAGRAMS

x = Power Switch Circuit On-state Resistance
(0 = 34 Ω , 3 = 11.4 Ω)
f = Brown In (A = Yes, B = No)
yyy = Oscillator Frequency
(060 = 60 kHz, 100 = 100 kHz)
A = Assembly Location
L, WL = Wafer Lot
Y, YY = Year
W, WW = Work Week
G or ■ = Pb-Free Package

ORDERING INFORMATION

See detailed ordering and shipping information in the package dimensions section on page 26 of this data sheet.

- Frequency Foldback to Improve Efficiency at Light Load
- These are Pb-Free Devices

Typical Applications

- Auxiliary / Standby Isolated and Non-isolated Power Supplies
- Power Meter SMPS
- Wide Vin Low Power Industrial SMPS

NCP1060, NCP1063

PRODUCT INFORMATION & INDICATIVE MAXIMUM OUTPUT POWER

Product	R _{DS(on)}	I _{PK(0)}	230 Vac ± 15%		85 – 265 Vac	
			Adapter	Open Frame	Adapter	Open Frame
NCP1060 60 kHz	34 Ω	300 mA	3.3 W	8.3 W	1.9 W	4.7 W
NCP1063 100 kHz	11.4 Ω	780 mA	6.2 W	15.5 W	3.3 W	7.8 W

NOTE: Informative values only, with T_{amb} = 25°C, T_{case} = 100°C, PDIP-7 package, Self supply via Auxiliary winding and circuit mounted on minimum copper area as recommended.

Figure 1. Pin Connections

Table 1. PIN FUNCTION DESCRIPTION

Pin No			Pin Name	Function	Pin Description
PDIP 7	SOIC 10	SOIC 16			
1	1	1–4	GND	The IC Ground	
2	2	5	V _{CC}	Powers the internal circuitry	This pin is connected to an external capacitor. The V _{DD} includes an auto-recovery over voltage protection.
3	3	6	LIM/OPP	I _{peak} set / Over power limitation	The current drawn from the pin decreases I _{peak} of the primary winding. If resistive divider from the auxiliary winding is connected to this pin it sets the OPP compensation level (it diminishes the peak current.)
4	4	7	FB	Feedback signal input	This is the inverting input of the trans conductance error amplifier. It is normally connected to the switching power supply output through a resistor divider.
5	5	8	Comp	Compensation	The error amplifier output is available on this pin. The network connected between this pin and ground adjusts the regulation loop bandwidth. Also, by connecting an opto-coupler to this pin, the peak current set point is adjusted accordingly to the output power demand.
6		9–12			This un-connected pin ensures adequate creepage distance
7,8	6–10	13–16	Drain	Drain connection	The internal drain MOSFET connection

Application Information

Introduction

The NCP106X offers a complete current-mode control solution. The component integrates everything needed to build a rugged and cost effective Switch-Mode Power Supply (SMPS) featuring low standby power. The Quick Selection Table, Table 4, details the differences between references, mainly peak current setpoints, $R_{DS(on)}$ value and operating frequency.

- **Current-mode operation:** the controller uses current-mode control architecture.
- **700 V – Power MOSFET:** Due to ON Semiconductor Very High Voltage Integrated Circuit technology, the circuit hosts a high-voltage power MOSFET featuring a $34\ \Omega$ or $11.4\ \Omega$ $R_{DS(on)}$ – $T_j = 25^\circ\text{C}$. This value lets the designer build a power supply up to 7.8 W or 15.5 W operated on universal mains. An internal current source delivers the startup current, necessary to crank the power supply.
- **Dynamic Self-Supply:** Due to the internal high voltage current source, this device could be used in the application without the auxiliary winding to provide supply voltage.
- **Short circuit protection:** by permanently monitoring the COMP line activity, the IC is able to detect the presence of a short-circuit, immediately reducing the output power for a total system protection. A t_{SCP} timer is started as soon as the COMP current is below threshold, $I_{COMPfault}$, which indicates the maximum peak current. If at the end of this timer the fault is still present, then the device enters a safe, auto-recovery burst mode, affected by a fixed timer recurrence, $t_{recovery}$. Once the short has disappeared, the controller resumes and goes back to normal operation.
- **Built-in VCC Over Voltage Protection:** when the auxiliary winding is used to bias the V_{CC} pin (no DSS), an internal comparator is connected to V_{CC} pin. In case the voltage on the pin exceeds a level of V_{OVP} (18 V typically), the controller immediately stops switching and waits a full timer period ($t_{recovery}$) before attempting to restart. If the fault is gone, the controller resumes operation. If the fault is still there, e.g. a broken opto-coupler, the controller protects the load through a safe burst mode.
- **Line detection:** An internal comparator monitors the drain voltage as recovering from one of the following situations:
 - ◆ Short Circuit Protection,
 - ◆ V_{CC} OVP is confirmed,
 - ◆ UVLO,
 - ◆ TSD
- If the drain voltage is lower than the internal threshold ($V_{HV(EN)}$), the internal power switch is inhibited. This avoids operating at too low ac input. This is also called brown-in function in some fields. For applications not using standard AC mains (24 Vdc industrial bus for instance), the B version doesn't incorporate this line detection and let the device start as soon as voltage supply reaches $V_{start(min)}$.
- **Frequency jittering:** an internal low-frequency modulation signal varies the pace at which the oscillator frequency is modulated. This helps spreading out energy in conducted noise analysis. To improve the EMI signature at low power levels, the jittering remains active in frequency foldback mode.
- **Soft-Start:** a 4 ms soft-start ensures a smooth startup sequence, reducing output overshoots.
- **Frequency foldback capability:** a continuous flow of pulses is not compatible with no-load/light-load standby power requirements. To excel in this domain, the controller observes the COMP pin current information and when it reaches a level of $I_{COMPfold}$, the oscillator then starts to reduce its switching frequency as the feedback current continues to increase (the power demand continues to reduce). It can go down to 25 kHz (typical) reached for a feedback level of $I_{COMPfold(end)}$ (100 μA roughly). At this point, if the power continues to drop, the controller enters classical skip-cycle mode.
- **Skip:** if SMPS naturally exhibits a good efficiency at nominal load, it begins to be less efficient when the output power demand diminishes. By skipping un-needed switching cycles, the NCP106X drastically reduces the power wasted during light load conditions.
- **Ipeak set:** If current in range 26 μA and 285 μA is drawn from the pin, the peak current is proportionally reduced down to 40% of its original value. This feature enables to designer to set up the peak current to the value which is ideal for the application.

By routing a portion of the negative voltage present during the on-time on the auxiliary winding to the LIM/OPP pin, the user has a simple and non-dissipative means to alter the maximum peak current setpoint as the bulk voltage increases.

NCP1060, NCP1063

Application Information

Startup Sequence

When the power supply is first powered from the mains outlet, the internal current source (typically 8.0 mA) is biased and charges up the V_{CC} capacitor from the drain pin. Once the voltage on this V_{CC} capacitor reaches the $V_{CC(on)}$ level (typically 9.0 V), the current source turns off and

pulses are delivered by the output stage: the circuit is awake and activates the power MOSFET if the bulk voltage is above $V_{HV(EN)}$ level (87 V typically) for A version and if bulk voltage is above $V_{start(min)}$ (21 V dc) for B version. Figure 29 details the simplified internal circuitry.

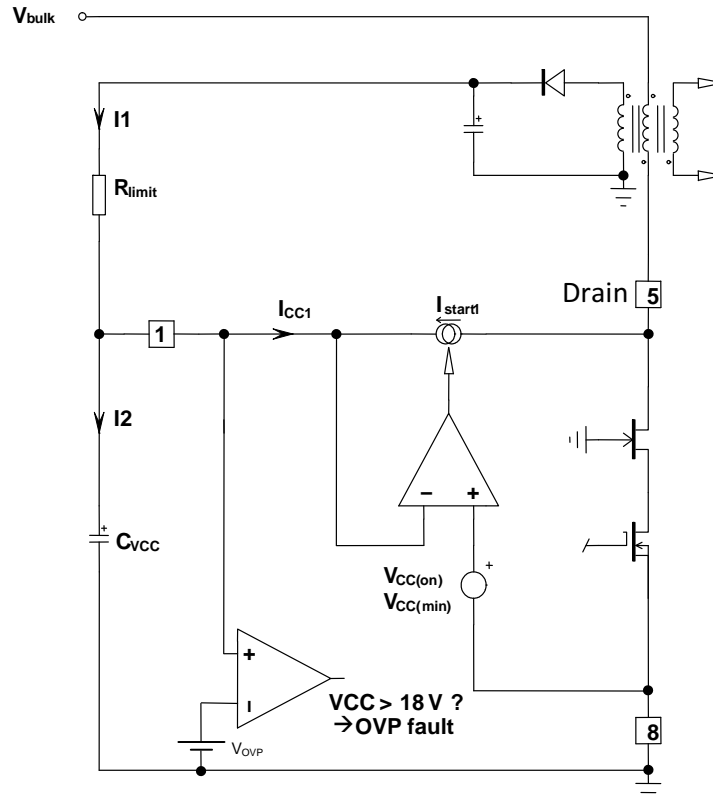

Figure 29. The Internal Arrangement of the Start-up Circuitry

Being loaded by the circuit consumption, the voltage on the V_{CC} capacitor goes down. When V_{CC} is below $V_{CC(min)}$ level (7.5 V typically), it activates the internal current source to bring V_{CC} toward $V_{CC(on)}$ level and stops again: a cycle takes place whose low frequency depends on the V_{CC}

capacitor and the IC consumption. A 1.5 V ripple takes place on the V_{CC} pin whose average value equals $(V_{CC(on)} + V_{CC(min)})/2$. Figure 30 portrays a typical operation of the DSS.

Figure 30. The Charge/Discharge Cycle Over a 1 μF V_{CC} Capacitor

As one can see, even if there is auxiliary winding to provide energy for V_{CC} , it happens that the device is still biased by DSS during start-up time or some fault mode when the voltage on auxiliary winding is not ready yet. The V_{CC} capacitor shall be dimensioned to avoid V_{CC} crosses $V_{\text{CC(off)}}$ level, which stops operation. The ΔV between $V_{\text{CC(min)}}$ and $V_{\text{CC(off)}}$ is 0.5 V. There is no current source to charge V_{CC} capacitor when driver is on, i.e. drain voltage is close to zero. Hence the V_{CC} capacitor can be calculated using

$$C_{V_{\text{CC}}} \geq \frac{I_{\text{CC1}} \cdot D_{\text{max}}}{f_{\text{OSC}} \cdot \Delta V} \quad (\text{eq. 1})$$

Take the 60 kHz device as an example. $C_{V_{\text{CC}}}$ should be above

$$\frac{0.8 \text{ m} \cdot 72\%}{54 \text{ kHz} \cdot 0.5} = 21 \text{ nF.}$$

A margin that covers the temperature drift and the voltage drop due to switching inside FET should be considered, and thus a capacitor above 0.1 μF is appropriate.

The V_{CC} capacitor has only a supply role and its value does not impact other parameters such as fault duration or the frequency sweep period for instance. As one can see on Figure 29, an internal OVP comparator, protects the switcher against lethal V_{CC} runaways. This situation can occur if the feedback loop optocoupler fails, for instance, and you would like to protect the converter against an over voltage event. In that case, the over voltage protection (OVP) circuit and immediately stops the output pulses for

t_{recovery} duration (400 ms typically). Then a new start-up attempt takes place to check whether the fault has disappeared or not. The OVP paragraph gives more design details on this particular section.

Fault Condition – Short-circuit on V_{CC}

In some fault situations, a short-circuit can purposely occur between V_{CC} and GND. In high line conditions ($V_{\text{HV}} = 370 \text{ V}_{\text{DC}}$) the current delivered by the startup device will seriously increase the junction temperature. For instance, since I_{start1} equals 5 mA (the min corresponds to the highest T_j), the device would dissipate $370 \times 5 \text{ m} = 1.85 \text{ W}$. To avoid this situation, the controller includes a novel circuitry made of two startup levels, I_{start1} and I_{start2} . At power-up, as long as V_{CC} is below a 1.4 V level, the source delivers I_{start2} (around 500 μA typical), then, when V_{CC} reaches 1.4 V, the source smoothly transitions to I_{start1} and delivers its nominal value. As a result, in case of short-circuit between V_{CC} and GND, the power dissipation will drop to $370 \times 500 \mu = 185 \text{ mW}$. Figure 30 portrays this particular behavior.

The first startup period is calculated by the formula $C \times V = I \times t$, which implies a $1 \mu \times 1.4 / 500 \mu = 2.8 \text{ ms}$ startup time for the first sequence. The second sequence is obtained by toggling the source to 8 mA with a delta V of $V_{\text{CC(on)}} - V_{\text{CCTH}} = 9.0 - 1.4 = 7.6 \text{ V}$, which finally leads to a second startup time of $1 \mu \times 7.6 / 8 \text{ m} = 0.95 \text{ ms}$. The total startup time becomes $2.8 \text{ m} + 0.95 \text{ m} = 3.75 \text{ ms}$. Please note that this calculation is approximated by the presence of the knee in the vicinity of the transition.

Fault Condition – Output Short-circuit

As soon as V_{CC} reaches $V_{CC(on)}$, drive pulses are internally enabled. If everything is correct, the auxiliary winding increases the voltage on the V_{CC} pin as the output voltage rises. During the start-sequence, the controller smoothly ramps up the peak drain current to maximum setting, i.e. I_{PK} , which is reached after a typical period of 4 ms. When the output voltage is not regulated, the current coming through COMP pin is below $I_{COMPfault}$ level (40 μ A typically), which is not only during the startup period but also anytime an overload occurs, an internal error flag is

asserted, I_{pflag} , indicating that the system has reached its maximum current limit set point. The assertion of this flag triggers a fault counter t_{SCP} (48 ms typically). If at counter completion, I_{pflag} remains asserted, all driving pulses are stopped and the part stays off in $t_{recovery}$ duration (about 400 ms). A new attempt to re-start occurs and will last 48 ms providing the fault is still present. If the fault still affects the output, a safe burst mode is entered, affected by a low duty-cycle operation (11%). When the fault disappears, the power supply quickly resumes operation. Figure 31 depicts this particular mode:

Figure 31. In case of short-circuit or overload, the NCP106X protects itself and the power supply via a low frequency burst mode. The V_{CC} is maintained by the current source and self-supplies the controller.

Auto-recovery Over Voltage Protection

The particular NCP106X arrangement offers a simple way to prevent output voltage runaway when the optocoupler fails. As Figure 32 shows, a comparator monitors the V_{CC} pin. If the auxiliary pushes too much voltage into the C_{VCC} capacitor, then the controller considers an OVP situation and stops the internal drivers. When an OVP occurs, all switching pulses are permanently disabled. After $t_{recovery}$ delay, it resumes the internal drivers. If the failure symptom still exists, e.g. feedback opto-coupler fails, the device keeps the auto-recovery OVP mode. It is recommended insertion of a resistor (R_{limit}) between the auxiliary dc level and the V_{CC} pin to protect the

IC against high voltage spikes, which can damage the IC, and to filter out the V_{cc} line to avoid undesired OVP activation. R_{limit} should be carefully selected to avoid triggering the OVP as we discussed, but also to avoid disturbing the V_{CC} in low / light load conditions.

Self-supplying controllers in extremely low standby applications often puzzles the designer. Actually, if a SMPS operated at nominal load can deliver an auxiliary voltage of an arbitrary 16 V (V_{nom}), this voltage can drop below 10 V (V_{stby}) when entering standby. This is because the recurrence of the switching pulses expands so much that the low frequency re-fueling rate of the V_{CC} capacitor is not enough to keep a proper auxiliary voltage.

NCP1060, NCP1063

Figure 32. A more detailed view of the NCP106X offers better insight on how to properly wire an auxiliary winding

Figure 33. describes the main signal variations when the part operates in auto-recovery OVP:

Figure 33: If the VCC current exceeds a certain threshold, an auto-recovery protection is activated.

Soft-start

The NCP106X features a 4 ms soft-start which reduces the power-on stress but also contributes to lower the output overshoot. Figure 34 shows a typical operating waveform. The NCP106X features a novel patented structure which offers a better soft-start ramp, almost ignoring the start-up pedestal inherent to traditional current-mode supplies.

NCP1060, NCP1063

Figure 34. The 4 ms Soft-start Sequence

Jittering

Frequency jittering is a method used to soften the EMI signature by spreading the energy in the vicinity of the main switching component. The NCP106X offers a $\pm 6\%$ deviation of the nominal switching frequency. The sweep

sawtooth is internally generated and modulates the clock up and down with a fixed frequency of 300 Hz. Figure 35 shows the relationship between the jitter ramp and the frequency deviation. It is not possible to externally disable the jitter.

Figure 35. Modulation Effects on the Clock Signal by the Jittering Sawtooth

Line Detection (for A version only)

An internal comparator monitors the drain voltage as recovering from one of the following situations:

- Short Circuit Protection,
- V_{CC} OVP is confirmed,

- UVLO
- TSD

If the drain voltage is lower than the internal threshold $V_{HV(EN)}$ (87 Vdc typically), the internal power switch is inhibited. This avoids operating at too low ac input.

NCP1060, NCP1063

Frequency Foldback

The reduction of no-load standby power associated with the need for improving the efficiency, requires to change the traditional fixed-frequency type of operation. This device implements a switching frequency foldback when the COMP current passes above a certain level, $I_{COMPfold}$, set around $68 \mu A$. At this point, the oscillator enters frequency foldback and reduces its switching frequency.

The internal peak current set-point is following the COMP current information until its level reaches I_{Freeze} .

Below this value, the peak current setpoint is frozen to 30% of the $I_{PK(0)}$. The only way to further reduce the transmitted power is to diminish the operating frequency down to F_{min} (25 kHz typically). This value is reached at a COMP current level of $I_{COMPfold(end)}$ ($100 \mu A$ typically). Below this point, if the output power continues to decrease, the part enters skip cycle for the best noise-free performance in no-load conditions. Figure 36 and Figure 37 depict the adopted scheme for the part.

Figure 36. By observing the current on the COMP pin, the controller reduces its switching frequency for an improved performance at light load.

Figure 37. Ipk set-point is frozen at lower power demand.

NCP1060, NCP1063

Figure 38. I_{pk} set–point is frozen at lower power demand ($I_{LMOP} \geq 285 \mu A$)

Feedback and Skip

Figure 39 depicts the relationship between COMP pin voltage and current. The COMP pin operates linearly as the absolute value of COMP current (I_{COMP}) is above $40 \mu A$. In

this linear operating range, the dynamic resistance is $17.7 k\Omega$ typically ($R_{COMP(up)}$) and the effective pull up voltage is $2.7 V$ typically ($V_{COMP(REF)}$). When I_{COMP} is decreases, the COMP voltage will increase to $3.2 V$.

Figure 39. COMP Pin Voltage vs. Current

Figure 40 depicts the skip mode block diagram. When the COMP current information reaches $I_{COMPskip}$, the internal clock setting the flip–flop is blanked and the internal consumption of the controller is decreased. The hysteresis of

internal skip comparator is minimized to lower the ripple of the auxiliary voltage for V_{CC} pin and V_{OUT} of power supply during skip mode. It eases the design of V_{CC} over load range.

NCP1060, NCP1063

Figure 40. Skip Cycle Schematic

Limit and OPP Function

The function makes the integrated circuit more flexible. The current drawn out of LIM/OPP pin defines the current set point.

Figure 41. Ipk set-point dependence on I_{LMOP} current

There are several known ways to implement Over Power Protection (OPP), all suffering from particular problems. These problems range from the added consumption burden on the converter or the skip-cycle disturbance brought by the current-sense offset. A way to reduce the power capability at high line is to capitalize on the negative voltage swing present on the auxiliary diode anode. During the power switch on-time, this point dips to $-N V_{in}$, N being the turns ratio between the primary winding and the auxiliary winding. The negative plateau on auxiliary winding will have an amplitude dependant on the input voltage. Resistors

R_{OPPU} and R_{OPPL} (Figure 42) define current drawn from LIM/OPP and the negative voltage on auxiliary winding. The negative voltage is tied up with bulk voltage, so the higher the bulk voltage is, the deeper is the negative voltage on auxiliary winding, the higher current is drawn from LIM/OPP pin and the lower the peak current is. During the internal MOSFET off period, voltage on auxiliary winding is positive, but the IC ignores the LIM/OPP current. The positive LIM/OPP current has no influence on proper IC function.

NCP1060, NCP1063

Figure 42. The OPP Circuitry Affects the Maximum Peak Current Set Point

Ramp Compensation and I_{pk} Set-point

In order to allow the NCP106X to operate in CCM with a duty cycle above 50%, a fixed slope compensation is internally applied to the current-mode control.

Here we got a table of the ramp compensation, the initial current set point, and the final current set-point of different versions of switcher.

	NCP1060		NCP1063	
	60 kHz	100 kHz	60 kHz	100 kHz
f_{sw}	60 kHz	100 kHz	60 kHz	100 kHz
S_a	8.4 mA/ μ s	14 mA/ μ s	15.6 mA/ μ s	26 mA/ μ s
$I_{pk}(\text{Duty}=50\%)$	250 mA		650 mA	
$I_{pk(0)}$	300 mA		780 mA	

Figure 43 depicts the variation of I_{PK} set-point vs. the power switcher duty ratio, which is caused by the internal ramp compensation.

Figure 43. I_{PK} set-point varies with power switch on time, which is caused by the ramp compensation.

FB Pin Function

The FB pin is used in non isolated SMPS application only. Portion of the output voltage is connected into the pin. The voltage is compared with internal V_{REF} (3.3 V) using Operation Transconductance Amplifier (Figure 44). The OTAs output is connected to COMP pin. The OTA output is accessible through the COMP pin and is used for the loop compensation, usually an RC network. The current capability of OTA is limited to -150μ A typically. The

positive current is defined by internal $R_{COMP(up)}$ resistor and $V_{COMP(ref)}$ voltage. If FB path loop is broken (i.e. the FB pin is disconnected), an internal current I_{FB} (1μ A typ.) will pull up the FB pin and the IC stops switching to avoid uncontrolled output voltage increasing.

In isolated topology, the FB pin should be connected to GND pin. In this configuration no current flows from OTA to COMP pin (OTA is disabled) so the OTA has no influence on regulation at all.

NCP1060, NCP1063

Figure 44. FB Pin Connection

Design Procedure

The design of an SMPS around a monolithic device does not differ from that of a standard circuit using a controller and a MOSFET. However, one needs to be aware of certain characteristics specific of monolithic devices. Let us follow the steps:

$V_{in \text{ min}} = 90 \text{ Vac}$ or 127 Vdc once rectified, assuming a low bulk ripple

$V_{in \text{ max}} = 265 \text{ Vac}$ or 375 Vdc

$V_{out} = 12 \text{ V}$

$P_{out} = 5 \text{ W}$

Operating mode is CCM

$\eta = 0.8$

1. The lateral MOSFET body-diode shall never be forward biased, either during start-up (because of a large leakage inductance) or in normal operation as shown in Figure 45. This condition sets the maximum voltage that can be reflected during toff. As a result, the Flyback voltage which is reflected on the drain at the switch opening cannot be larger than the input voltage. When selecting components, you thus must adopt a turn ratio which adheres to the following equation:

$$N \cdot (V_{out} + V_f) < V_{in, \text{min}} \quad (\text{eq. 2})$$

2. In our case, since we operate from a 127 V DC rail while delivering 12 V , we can select a reflected voltage of 120 V dc maximum. Therefore, the turn ratio $N_p:N_s$ must be smaller than

$$\frac{V_{\text{reflect}}}{V_{out} + V_f} = \frac{120}{12 + 0.5} = 9.6 \text{ or } N_p : N_s < 9.6.$$

Here we choose $N = 8$ in this case. We will see later on how it affects the calculation.

Figure 45. The Drain-Source Wave Shall Always be Positive

Figure 46. Primary Inductance Current Evolution in CCM

3. Lateral MOSFETs have a poorly doped body-diode which naturally limits their ability to sustain the avalanche. A traditional RCD clamping network shall thus be installed to protect the MOSFET. In some low power applications, a simple capacitor can also be used since

$$V_{\text{drain,max}} = V_{\text{in}} + N \cdot (V_{\text{out}} + V_f) + I_{\text{peak}} \cdot \sqrt{\frac{L_f}{C_{\text{tot}}}} \quad (\text{eq. 3})$$

where L_f is the leakage inductance, C_{tot} the total capacitance at the drain node (which is increased by the capacitor you will wire between drain and source), N the $N_p:N_s$ turn ratio, V_{out} the output voltage, V_f the secondary diode forward drop and finally, I_{peak} the maximum peak current. Worst case occurs when the SMPS is very close to regulation, e.g. the V_{out} target is almost reached and I_{peak} is still pushed to the maximum. For this design, we have selected our maximum voltage around 650 V (at $V_{\text{in}} = 375$ Vdc). This voltage is given by the RCD clamp installed from the drain to the bulk voltage. We will see how to calculate it later on.

4. Calculate the maximum operating duty-cycle for this flyback converter operated in CCM:

$$\begin{aligned} d_{\text{max}} &= \frac{N \cdot (V_{\text{out}} \cdot V_f)}{N \cdot (V_{\text{out}} \cdot V_f) + V_{\text{in,min}}} \\ &= \frac{1}{1 + \frac{V_{\text{in,min}}}{N \cdot (V_{\text{out}} \cdot V_f)}} = 0.44 \end{aligned} \quad (\text{eq. 4})$$

5. To obtain the primary inductance, we have the choice between two equations:

$$L = \frac{(V_{\text{in}} \cdot d)^2}{f_{\text{sw}} \cdot K \cdot P_{\text{in}}} \quad (\text{eq. 5})$$

$$\text{where } K = \frac{\Delta I_L}{I_{\text{Lavg}}}$$

and defines the amount of ripple we want in CCM (see Figure 46).

- Small K : deep CCM, implying a large primary inductance, a low bandwidth and a large leakage inductance.
- Large K : approaching DCM where the RMS losses are worse, but smaller inductance, leading to a better leakage inductance.

From Equation 6, a K factor of 1 (50% ripple), gives an inductance of:

$$L = \frac{(127 \cdot 0.44)^2}{60\text{k} \cdot 1 \cdot 5} = 10.04 \text{ mH}$$

$$\Delta I_L = \frac{V_{\text{in}} \cdot d}{L \cdot f_{\text{sw}}} = \frac{127 \cdot 0.44}{10.04\text{m} \cdot 60\text{k}} = 92.8 \text{ mA peak to peak}$$

The peak current can be evaluated to be:

$$I_{\text{peak}} = \frac{I_{\text{avg}}}{d} + \frac{\Delta I_L}{2} = \frac{49.2 \text{ m}}{0.44} + \frac{92.8 \text{ m}}{2} = 158 \text{ mA}$$

On I_L , I_{Lavg} can also be calculated:

$$I_{\text{Lavg}} = I_{\text{peak}} - \frac{\Delta I_L}{2} = 158\text{m} - \frac{92.8\text{m}}{2} = 111.6 \text{ mA}$$

6. Based on the above numbers, we can now evaluate the conduction losses:

$$\begin{aligned} I_{\text{d,rms}} &= \sqrt{d \cdot \left(I_{\text{peak}}^2 - I_{\text{peak}} \cdot \Delta I_L + \frac{\Delta I_L^2}{3} \right)} \\ &= \sqrt{0.44 \cdot \left(0.158^2 - 0.158 \cdot 0.0928 + \frac{0.0928^2}{3} \right)} \\ &= 57 \text{ mA} \end{aligned}$$

If we take the maximum $R_{\text{DS(on)}}$ for a 125°C junction temperature, i.e. 34 Ω, then conduction losses worse case are:

$$P_{\text{cond}} = I_{\text{d,rms}}^2 \cdot R_{\text{DS(on)}} = 110 \text{ mW}$$

7. Off-time and on-time switching losses can be estimated based on the following calculations:

$$\begin{aligned} P_{\text{off}} &= \frac{I_{\text{peak}} \cdot (V_{\text{bulk}} + V_{\text{clamp}}) \cdot t_{\text{off}}}{2T_{\text{SW}}} \quad (\text{eq. 6}) \\ &= \frac{0.158 \cdot (127 + 100 \cdot 2) \cdot 10\text{n}}{2 \cdot 16.7 \mu} \\ &= 15.5 \text{ mW} \end{aligned}$$

Where, assume the V_{clamp} is equal to 2 times of reflected voltage.

$$P_{on} = \frac{I_{valley} \cdot (V_{bulk} + N \cdot (V_{out} + V_f)) \cdot t_{on}}{6 \cdot T_{SW}} \quad (\text{eq. 7})$$

$$= \frac{0.0464 \cdot (127 + 100) \cdot 10 \text{ n}}{6 \cdot 16.7 \mu}$$

$$= 2.1 \text{ mW}$$

It is noted that the overlap of voltage and current seen on MOSFET during turning on and off duration is dependent on the snubber and parasitic capacitance seen from drain pin. Therefore the t_{off} and t_{on} in Equation 7 and Equation 8 have to be modified after measuring on the bench.

8. The theoretical total power is then
 $117 + 15.5 + 2.1 = 127.6 \text{ mW}$

9. If the NCP106X operates at DSS mode, then the losses caused by DSS mode should be counted as losses of this device on the following calculation:

$$P_{DSS} = I_{CC1} \cdot V_{in,max} = 0.8 \text{ m} \cdot 375 = 300 \text{ mW} \quad (\text{eq. 8})$$

MOSFET Protection

As in any Flyback design, it is important to limit the drain excursion to a safe value, e.g. below the MOSFET BV_{dss} which is 700 V. Figure 47 a–b–c present possible implementations:

Figure 47. a, b, c : Different Options to Clamp the Leakage Spike

Figure 47a: the simple capacitor limits the voltage according to the lateral MOSFET body–diode shall never be forward biased, either during start–up (because of a large leakage inductance) or in normal operation as shown by Figure 45. This condition sets the maximum voltage that can be reflected during t_{off} . As a result, the flyback voltage which is reflected on the drain at the switch opening cannot be larger than the input voltage. When selecting components, you must adopt a turn ratio which adheres to the following Equation 3. This option is only valid for low power applications, e.g. below 5 W, otherwise chances exist to destroy the MOSFET. After evaluating the leakage inductance, you can compute C with (Equation 4). Typical values are between 100 pF and up to 470 pF. Large capacitors increase capacitive losses...

Figure 47b: the most standard circuitry is called the RCD network. You calculate R_{clamp} and C_{clamp} using the following formulae:

$$R_{clamp} = \frac{2 \cdot V_{clamp} \cdot (V_{clamp} + N \cdot (V_{out} + V_f))}{L_{leak} \cdot I_{leak}^2 \cdot f_{sw}} \quad (\text{eq. 9})$$

$$C_{clamp} = \frac{V_{clamp}}{V_{ripple} \cdot f_{sw} \cdot R_{clamp}}$$

V_{clamp} is usually selected 50–80 V above the reflected value $N \times (V_{out} + V_f)$. The diode needs to be a fast one and

a MUR160 represents a good choice. One major drawback of the RCD network lies in its dependency upon the peak current. Worse case occurs when I_{peak} and V_{in} are maximum and V_{out} is close to reach the steady–state value.

Figure 47c: this option is probably the most expensive of all three but it offers the best protection degree. If you need a very precise clamping level, you must implement a zener diode or a TVS. There are little technology differences behind a standard zener diode and a TVS. However, the die area is far bigger for a transient suppressor than that of zener. A 5 W zener diode like the 1N5388B will accept 180 W peak power if it lasts less than 8.3 ms. If the peak current in the worse case (e.g. when the PWM circuit maximum current limit works) multiplied by the nominal zener voltage exceeds these 180 W, then the diode will be destroyed when the supply experiences overloads. A transient suppressor like the P6KE200 still dissipates 5 W of continuous power but is able to accept surges up to 600 W @ 1 ms. Select the zener or TVS clamping level between 40 to 80 volts above the reflected output voltage when the supply is heavily loaded.

As a good design practice, it is recommended to implement one of this protection to make sure Drain pin voltage doesn't go above 650 V (to have some margin between Drain pin voltage and BV_{dss}) during most stringent operating conditions (high V_{in} and peak power).

NCP1060, NCP1063

Power Dissipation and Heatsinking

The NCP106X welcomes two dissipating terms, the DSS current-source (when active) and the MOSFET. Thus, $P_{tot} = P_{DSS} + P_{MOSFET}$. It is mandatory to properly manage the heat generated by losses. If no precaution is taken, risks exist to trigger the internal thermal shutdown (TSD). To help dissipating the heat, the PCB designer must foresee large copper areas around the package. Take the PDIP-7 package as an example, when surrounded by a surface approximately 200 mm^2 of $35 \mu\text{m}$ copper, the maximum power the device can thus evacuate is:

$$P_{max} = \frac{T_{Jmax} - T_{ambmax}}{R_{\theta JA}} \quad (\text{eq. 10})$$

which gives around 870 mW for an ambient of 50°C and a maximum junction of 150°C . If the surface is not large enough, the $R_{\theta JA}$ is growing and the maximum power the device can evacuate decreases. Figure 48 gives a possible layout to help drop the thermal resistance.

Компания «ЭлектроПласт» предлагает заключение долгосрочных отношений при поставках импортных электронных компонентов на взаимовыгодных условиях!

Наши преимущества:

- Оперативные поставки широкого спектра электронных компонентов отечественного и импортного производства напрямую от производителей и с крупнейших мировых складов;
- Поставка более 17-ти миллионов наименований электронных компонентов;
- Поставка сложных, дефицитных, либо снятых с производства позиций;
- Оперативные сроки поставки под заказ (от 5 рабочих дней);
- Экспресс доставка в любую точку России;
- Техническая поддержка проекта, помощь в подборе аналогов, поставка прототипов;
- Система менеджмента качества сертифицирована по Международному стандарту ISO 9001;
- Лицензия ФСБ на осуществление работ с использованием сведений, составляющих государственную тайну;
- Поставка специализированных компонентов (Xilinx, Altera, Analog Devices, Intersil, Interpoint, Microsemi, Aeroflex, Peregrine, Syfer, Eurofarad, Texas Instrument, Miteq, Cobham, E2V, MA-COM, Hittite, Mini-Circuits, General Dynamics и др.);

Помимо этого, одним из направлений компании «ЭлектроПласт» является направление «Источники питания». Мы предлагаем Вам помощь Конструкторского отдела:

- Подбор оптимального решения, техническое обоснование при выборе компонента;
- Подбор аналогов;
- Консультации по применению компонента;
- Поставка образцов и прототипов;
- Техническая поддержка проекта;
- Защита от снятия компонента с производства.
