## DC - 100 MHz DUAL DIGITAL VARIABLE GAIN AMPLIFIER with DRIVER

### Typical Applications

The HMC960LP4E is suitable for:

- Baseband I/Q Transceivers
- Direct Conversion & Low IF Transceivers
- Diversity Receivers
- ADC Drivers
- Adaptive Gain Control

### Features

- Low Noise: 6 dB NF
- High Linearity: Output IP3 +30 dBm
- Variable Gain: 0 to 40 dB
- High Bandwidth: DC to 100 MHz
- Precise Gain Accuracy: 0.5 dB Gain Step
- Excellent Magnitude and Phase Response
- Externally Controlled Common Mode Output Level
- Parallel or Serial Gain Control
- Read/Write Serial Port Interface (SPI)
- 24 Lead 4x4 mm SMT Package 16 mm<sup>2</sup>
- Programmable Input Impedance  
(400  $\Omega$  Differential or 100  $\Omega$  Differential)

### Functional Diagram

### General Description

The HMC960LP4E is a digitally programmable dual channel variable gain amplifier. It supports discrete gain steps from 0 to 40 dB in precise 0.5 dB steps. It features a glitch free architecture to provide exceptionally smooth gain transitions. The device has matched gain paths which provide excellent quadrature balance over a wide signal bandwidth.

The HMC960LP4E provides an SPI programmable input impedance of 100  $\Omega$  differential or 400  $\Omega$  differential (default).

Externally controlled common mode output feature enables the HMC960LP4E to provide a flexible output interface to other parts in the signal path.

Gain can be controlled via either a parallel interface (GC[6:0]) or via the read/write serial port (SPI).

Housed in a compact 4x4mm (LP4) SMT QFN package, the HMC960LP4E requires minimal external components and provides a low cost alternative to more complicated switched amplifier architectures.

[1] Sideband Rejection is only measured in dB, but relates to phase/magnitude channel imbalance as follows, for a mismatch of 1 degree phase and 0.1 dB magnitude:

$$\text{SBR} = -10\log\left[\frac{(1+A^2-2A\cos x)}{(1+A^2+2A\cos x)}\right]$$

where  $A = 10^{(0.1/20)}$  (linear magnitude) and  $x = 1^\circ \pi/180$  (radians)

[2] Output common mode voltage range is specified for worst case temperature, supply voltage, and bias settings with 2 V<sub>ppd</sub> signal amplitude. For 5 V supply and recommended biasing (op-amp bias =1 and driver bias=2), over 3.5 V is typical. See "Output IP3 vs. Common Mode Voltage vs. Driver Bias Setting[1]" in [Figure 12](#)

[3] Recommend bias setting (op-amp bias =1 and driver bias=2)

[4] Standard deviation = 15 mV

**Table 2. Test Conditions**

Unless otherwise specified, the following test conditions were used

Parameter	Condition
Temperature	+27 °C
Gain Setting	0 dB
Output Signal Level	2 V <sub>ppd</sub>
Input/Output Common Mode Level	2.5 V
Programmed Impedance	200 $\Omega$ per input (400 $\Omega$ differential)
Output Load	200 $\Omega$ per output (400 $\Omega$ differential)
Supplies	Analog: +5 V, Digital +5 V
Driver Bias Setting	'10'
Op-Amp Bias Setting	'01' (Standard Setting)

## DC - 100 MHz DUAL DIGITAL VARIABLE GAIN AMPLIFIER with DRIVER

### Evaluation PCB

The circuit board used in the application should use RF circuit design techniques. Signal lines should have 50 Ohms impedance while the package ground leads and exposed paddle should be connected directly to the ground plane similar to that shown. A sufficient number of via holes should be used to connect the top and bottom ground planes. The evaluation circuit board shown is available from Hittite upon request.

## DC - 100 MHz DUAL DIGITAL VARIABLE GAIN AMPLIFIER with DRIVER

### Evaluation Setup

### HMC960LP4E Application Information

The wide bandwidth, large dynamic range, and excellent noise-linearity trade-off make the HMC960LP4E ideal for Automatic Gain Control applications in the baseband section of a direct down-conversion receiver. Matched dual amplifier design provides excellent gain and phase balance between the two channels. Externally controlled common mode voltage, and SPI programmable input impedance simplify the interface between the HMC960LP4E and other components in the signal path. The HMC960LP4E can be cascaded with HMC900LP5E without the need of any matching circuitry. Together, these two components provide a complete baseband line-up that can directly drive ADC's such as the 12-bit, dual channel, 320 MSPS HMCAD1520.

Figure 1. Typical Receive Path Block Diagram Showing HMC960LP4E

## DC - 100 MHz DUAL DIGITAL VARIABLE GAIN AMPLIFIER with DRIVER

### Theory of Operation

The HMC960LP4E consists of the following functional blocks

1. Input Match & Gain Stage
2. Second Gain Stage
3. Output Driver & Gain Stage
4. Bias Circuit
5. Serial Port Interface
6. Parallel Port Interface

### Input Match & Gain Stage

The HMC960LP4E input stage consists of a user selectable  $100\ \Omega$  or  $400\ \Omega$  differential input impedance and a programmable gain of 0, 10 or 20 dB. A block diagram showing input impedance of the I channel is presented below, Q channel is similar.

NOTE:

[1]  $R_{in}$  is selectable VIA SPI  $50\ \Omega$  OR  $200\ \Omega$

[2]  $R = R_{in}$  or  $3.162R_{in}$  or  $10R_{in}$  depending on selected gain

Figure 2. Input Stage Block Diagram

### Second Gain Stage

The HMC960LP4E second stage consists of a series of carefully scaled resistors to generate up to 10 dB of gain in 0.5 dB steps. The gain step is fully determined by resistor ratios and as such the gain precision is relatively independent of both temperature and process variation.

## DC - 100 MHz DUAL DIGITAL VARIABLE GAIN AMPLIFIER with DRIVER

### Output Driver & Gain Stage

The HMC960LP4E output driver consists of a differential class AB driver which is designed to drive typical ADC loads directly or can drive up to  $200\ \Omega$  in parallel with  $50\ \text{pF}$  to AC ground per differential output. The stage provides a programmable 0 dB or 10 dB gain via switched resistors. Note that the output common mode of the driver is controlled directly via an input pin and can be set as per ["Table 1. Electrical Specifications"](#).

Figure 3. Output Driver Block Diagram

## DC - 100 MHz DUAL DIGITAL VARIABLE GAIN AMPLIFIER with DRIVER

### Gain Decode Logic

The decode logic automatically allocates gain to the three stages so as to minimize output noise and optimize noise figure. Without using decode logic gain can be allocated arbitrarily, as shown in [Table 11](#). Decode logic gain allocation, shown in Figure 4, can be controlled via the parallel port or the SPI, and reflects gain control shown in [Table 10](#).

Figure 4. Decode Logic Gain Allocation

### Bias Circuit

A band gap reference circuit generates the reference currents used by the different sections. The bias circuit is enabled or disabled as required with the I or Q channel as appropriate.

**DC - 100 MHz DUAL DIGITAL  
VARIABLE GAIN AMPLIFIER with DRIVER****Serial Port Interface**

The HMC960LP4E features a four wire serial port for simple communication with the host controller. Typical serial port operation can be run with SCK at speeds up to 30 MHz.

The details of SPI access for the HMC960LP4E is provided in the following sections. Note that the READ operation below is always preceded by a WRITE operation to Register 0 to define the register to be queried. Also note that every READ cycle is also a WRITE cycle in that data sent to the SPI while reading the data will also be stored by the HMC960LP4E when SEN goes high. If this is not desired then it is suggested to write to Register 0 during the READ operation so that the status of the device will be unaffected.

**Power on Reset and Soft Reset**

The HMC960LP4E has a built in Power On Reset (POR) and a serial port accessible Soft Reset (SR). POR is accomplished when power is cycled for the HMC960LP4E while SR is accomplished via the SPI by writing 20h to Reg 0h followed by writing 00h to Reg 0h. All chip registers will be reset to default states approximately 250 us after power up.

**Serial Port WRITE Operation**

The host changes the data on the falling edge of SCK and the HMC960LP4E reads the data on the rising edge.

A typical WRITE cycle is shown in [Figure 5](#). It is 32 clock cycles long.

1. The host both asserts SEN (active low Serial Port Enable) and places the MSB of the data on SDI followed by a rising edge on SCK.
2. HMC960LP4E reads SDI (the MSB) on the 1st rising edge of SCK after SEN.
3. HMC960LP4E registers the data bits, D23:D0, in the next 23 rising edges of SCK (total of 24 data bits).
4. Host places the 5 register address bits, A4:A0, on the next 5 falling edges of SCK (MSB to LSB) while the HMC960LP4E reads the address bits on the corresponding rising edge of SCK.
5. Host places the 3 chip address bits, CA2:CA0=[110], on the next 3 falling edges of SCK (MSB to LSB). Note the HMC960LP4E chip address is fixed as "6d" or "110b".
6. SEN goes from low to high after the 32th rising edge of SCK. This completes the WRITE cycle.
7. HMC960LP4E also exports data back on the SDO line. For details see the section on READ operation.

**Serial Port READ Operation**

The SPI can read from the internal registers in the chip. The data is available on SDO pin. This pin itself is tri-stated when the device is not being addressed. However when the device is active and has been addressed by the SPI master, the HMC960LP4E controls the SDO pin and exports data on this pin during the next SPI cycle.

HMC960LP4E changes the data to the host on the rising edge of SCK and the host reads the data from HMC960LP4E on the falling edge.

A typical READ cycle is shown in [Figure 5](#). Read cycle is 32 clock cycles long. To specifically read a register, **the address of that register must be written to dedicated Reg 0h**. This requires two full cycles, one to write the required address, and a 2nd to retrieve the data. A read cycle can then be initiated as follows;

1. The host asserts SEN (active low Serial Port Enable) followed by a rising edge SCK.
2. HMC960LP4E reads SDI (the MSB) on the 1<sup>st</sup> rising edge of SCK after SEN.
3. HMC960LP4E registers the data bits in the next 23 rising edges of SCK (total of 24 data bits). **The LSBs of the data bits represent the address of the register that is intended to be read.**
4. Host places the 5 register address bits on the next 5 falling edges of SCK (MSB to LSB) while the HMC960LP4E reads the address bits on the corresponding rising edge of SCK. **For a read operation this is "00000".**

# DC - 100 MHz DUAL DIGITAL VARIABLE GAIN AMPLIFIER with DRIVER

5. Host places the 3 chip address bits <110> on the next 3 falling edges of SCK (MSB to LSB). Note the HMC960LP4E chip address is fixed as "6d" or "110b".
6. SEN goes from low to high after the 32<sup>nd</sup> rising edge of SCK. This completes the first portion of the READ cycle.
7. The host asserts SEN (active low Serial Port Enable) followed by a rising edge SCK.
8. HMC960LP4E places the 24 data bits, 5 address bits, and 3 chip id bits, on the SDO, on each rising edge of the SCK, commencing with the first rising edge beginning with MSB.
9. The host de-asserts SEN (i.e. sets SEN high) after reading the 32 bits from the SDO output. The 32 bits consists of 24 data bits, 5 address bits, and the 3 chip id bits. This completes the read cycle.

Note that the data sent to the SPI during this portion of the READ operation is stored in the SPI when SEN is de-asserted. This can potentially change the state of the HMC960LP4E. If this is undesired it is recommended that during the second phase of the READ operation that Reg 0h is addressed with either the same address or the address of another register to be read during the next cycle.

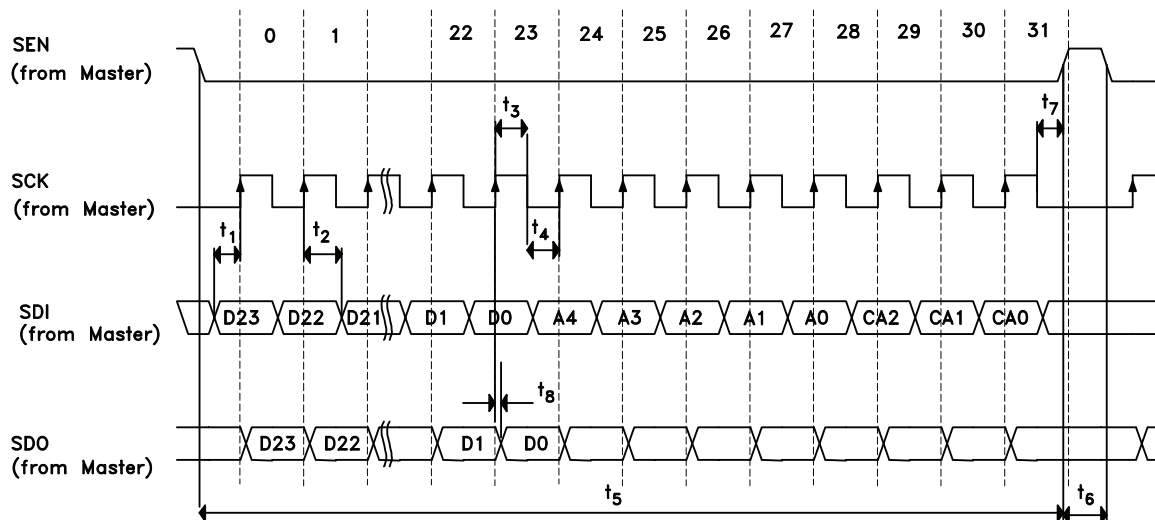

Figure 5. SPI Timing Diagram

## DC - 100 MHz DUAL DIGITAL VARIABLE GAIN AMPLIFIER with DRIVER

DVDD = 5 V  $\pm$ 10%, GND = 0 V

**Table 6. Main SPI Timing Characteristics**

Parameter	Conditions	Min	Typ	Max	Units
$t_1$	SDI to SCK Setup Time	8			nsec
$t_2$	SDI to SCK Hold Time	8			nsec
$t_3$	SCK High Duration <sup>[1]</sup>	10			nsec
$t_4$	SCK Low Duration	10			nsec
$t_5$	SEN Low Duration	20			nsec
$t_6$	SEN High Duration	20			nsec
$t_7$	SCK to SEN <sup>[2]</sup>	8			nsec
$t_8$	SCK to SDO out <sup>[3]</sup>			8	nsec

[1] The SPI is relatively insensitive to the duty cycle of SCK.

[2] SEN must rise after the 32<sup>nd</sup> falling edge of SCK but before the next rising SCK edge. If SCK is shared amongst several devices this timing must be respected.

[3] Typical load to SDO is 10 pF, maximum 20 pF

### Parallel Port Interface

The HMC960LP4E features a seven bit parallel port to aid in real time gain selection. The dynamic performance of the parallel port is specified below.

**Table 7. Gain Control Parallel Port Timing Characteristics**

Parameter	Conditions	Min.	Typ.	Max.	Units
$f_{SSP}$	Gain control switching rate			20	MHz
$t_{SSP}$	Allowable skew between GC[6:0] input transitions			10	nsec

**Table 11. Reg 03h - Gain Control Register, WHEN NOT using decode logic [3][4]**

Bit	Name	Width	Default	Description
[8:0]	gain[8:0]	9	000000000	gain[8:0] define the VGA I and Q channel gain when Reg 02h[5] = 1 and Reg 02h[6] = 1 (i.e. SPI gain control and gain decode bypassed)  Generally the first 4 bits control the 1st and 3rd stage while the last 5 bits control the 2nd stage gain. x001nnnnn - 1st stage set to 0 dB x010nnnnn - 1st stage set to 10 dB x100nnnnn - 1st stage set to 20 dB  0xxxxnnnnn - 3rd stage set to 0 dB 1xxxxnnnnn - 3rd stage set to 10 dB  xxxnnnnnn - 2nd stage set as follows: nnnnn = 00000 - set to 0 dB nnnnn = 00001 - set to 0.5 dB nnnnn = 10011 - set to 9.5 dB nnnnn = 10100 - set to 10 dB
[23:9]	unused			

[1] Reg 03h bit assignment depends on the setting of bits 5 and 6 in Reg 02h. If Reg 02h[5]=0, then all Reg 03h bits are ignored (parallel port selected)

[2] For Reg 02h[5]=1 and Reg 02h[6]=0, gain control is via an SPI register with decode, and Reg 03h[6:0] are used as follows.

[3] Note that the Parallel Port gain logic always uses the gain decode logic, and therefore the bit encoding is the same as Reg 03h - Gain Control Register WHEN USING decode logic.

[4] For Reg 02h[5]=1 and Reg 02h[6]=1, gain control is via an SPI register without decode, and Reg 03h[6:0] are used as follows.

Компания «ЭлектроПласт» предлагает заключение долгосрочных отношений при поставках импортных электронных компонентов на взаимовыгодных условиях!

Наши преимущества:

- Оперативные поставки широкого спектра электронных компонентов отечественного и импортного производства напрямую от производителей и с крупнейших мировых складов;
- Поставка более 17-ти миллионов наименований электронных компонентов;
- Поставка сложных, дефицитных, либо снятых с производства позиций;
- Оперативные сроки поставки под заказ (от 5 рабочих дней);
- Экспресс доставка в любую точку России;
- Техническая поддержка проекта, помощь в подборе аналогов, поставка прототипов;
- Система менеджмента качества сертифицирована по Международному стандарту ISO 9001;
- Лицензия ФСБ на осуществление работ с использованием сведений, составляющих государственную тайну;
- Поставка специализированных компонентов (Xilinx, Altera, Analog Devices, Intersil, Interpoint, Microsemi, Aeroflex, Peregrine, Syfer, Eurofarad, Texas Instrument, Miteq, Cobham, E2V, MA-COM, Hittite, Mini-Circuits, General Dynamics и др.);

Помимо этого, одним из направлений компании «ЭлектроПласт» является направление «Источники питания». Мы предлагаем Вам помощь Конструкторского отдела:

- Подбор оптимального решения, техническое обоснование при выборе компонента;
- Подбор аналогов;
- Консультации по применению компонента;
- Поставка образцов и прототипов;
- Техническая поддержка проекта;
- Защита от снятия компонента с производства.
