

## 20 V, 500 mA, Low Noise, CMOS LDO

Data Sheet ADP7104

#### **FEATURES**

Input voltage range: 3.3 V to 20 V Maximum output current: 500 mA

Low noise: 15  $\mu V$  rms for fixed output versions PSRR performance of 60 dB at 10 kHz,  $V_{OUT}$  = 3.3 V

**Reverse current protection** 

Low dropout voltage: 350 mV at 500 mA

Initial accuracy: ±0.8%

Accuracy over line, load, and temperature

-2% to +1%,  $T_J = -40$ °C to +125°C

-1.25% to +1%,  $T_J = 0$ °C to +85°C

Low quiescent current ( $V_{IN}$  = 5 V),  $I_{GND}$  = 900  $\mu$ A with 500 mA load Low shutdown current: <40  $\mu$ A at  $V_{IN}$  = 12 V, stable with small 1  $\mu$ F ceramic output capacitor

7 fixed output voltage options: 1.5 V, 1.8 V, 2.5 V, 3 V, 3.3 V,

5 V, and 9 V

Adjustable output from 1.22 V to  $V_{IN} - V_{DO}$ Foldback current limit and thermal overload protection

User programmable precision UVLO/enable

**Power-good indicator** 

8-lead LFCSP and 8-lead SOIC packages

#### **APPLICATIONS**

Regulation to noise sensitive applications: ADC, DAC circuits, precision amplifiers, high frequency oscillators, clocks, and PLLs

Communications and infrastructure Medical and healthcare Industrial and instrumentation

#### **GENERAL DESCRIPTION**

The ADP7104 is a CMOS, low dropout linear regulator that operates from 3.3 V to 20 V and provides up to 500 mA of output current. This high input voltage LDO is ideal for regulation of high performance analog and mixed signal circuits operating from 19 V to 1.22 V rails. Using an advanced proprietary architecture, it provides high power supply rejection, low noise, and achieves excellent line and load transient response with just a small 1  $\mu F$  ceramic output capacitor.

The ADP7104 is available in seven fixed output voltage options and an adjustable version, which allows output voltages that range from 1.22 V to  $V_{\rm IN}$  –  $V_{\rm DO}$  via an external feedback divider.

#### TYPICAL APPLICATION CIRCUITS

Figure 1. ADP7104 with Fixed Output Voltage, 5 V

Figure 2. ADP7104 with Adjustable Output Voltage, 5 V

The ADP7104 output noise voltage is 15  $\mu V$  rms and is independent of the output voltage. A digital power-good output allows power system monitors to check the health of the output voltage. A user programmable precision undervoltage lockout function facilitates sequencing of multiple power supplies.

The ADP7104 is available in 8-lead, 3 mm  $\times$  3 mm LFCSP and 8-lead SOIC packages. The LFCSP offers a very compact solution and also provides excellent thermal performance for applications requiring up to 500 mA of output current in a small, low-profile footprint.

Trademarks and registered trademarks are the property of their respective owners.

		10 kHz, $V_{IN} = 16 \text{ V}$ , $V_{OUT} = 15 \text{ V}$ , adjustable mode		80		dB

<sup>&</sup>lt;sup>1</sup> Based on an end-point calculation using 1 mA and 300 mA loads. See Figure 6 for typical load regulation performance for loads less than 1 mA.

#### INPUT AND OUTPUT CAPACITOR, RECOMMENDED SPECIFICATIONS

Table 2.

Parameter	Symbol	Conditions	Min	Тур	Max	Unit
Minimum Input and Output Capacitance <sup>1</sup>	C <sub>MIN</sub>	$T_A = -40^{\circ}\text{C to } +125^{\circ}\text{C}$	0.7			μF
Capacitor ESR	R <sub>ESR</sub>	$T_A = -40^{\circ}\text{C to } +125^{\circ}\text{C}$	0.001		0.2	Ω

<sup>&</sup>lt;sup>1</sup> The minimum input and output capacitance should be greater than 0.7 µF over the full range of operating conditions. The full range of operating conditions in the application must be considered during device selection to ensure that the minimum capacitance specification is met. X7R and X5R type capacitors are recommended; Y5V and Z5U capacitors are not recommended for use with any LDO.

<sup>&</sup>lt;sup>2</sup> Dropout voltage is defined as the input-to-output voltage differential when the input voltage is set to the nominal output voltage. This applies only for output voltages above 3.0 V.

 $<sup>^3</sup>$  Start-up time is defined as the time between the rising edge of EN to VOUT being at 90% of its nominal value.

<sup>&</sup>lt;sup>4</sup> Current limit threshold is defined as the current at which the output voltage drops to 90% of the specified typical value. For example, the current limit for a 5.0 V output voltage is defined as the current that causes the output voltage to drop to 90% of 5.0 V, or 4.5 V.

## **ABSOLUTE MAXIMUM RATINGS**

Table 3.

Parameter	Rating
VIN to GND	-0.3 V to +22 V
VOUT to GND	-0.3 V to +20 V
EN/UVLO to GND	−0.3 V to VIN
PG to GND	−0.3 V to VIN
SENSE/ADJ to GND	−0.3 V to VOUT
Storage Temperature Range	−65°C to +150°C
Operating Junction Temperature Range	-40°C to +125°C
Soldering Conditions	JEDEC J-STD-020

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

#### THERMAL DATA

Absolute maximum ratings apply individually only, not in combination. The ADP7104 can be damaged when the junction temperature limit is exceeded. Monitoring ambient temperature does not guarantee that  $T_{\rm J}$  is within the specified temperature limits. In applications with high power dissipation and poor thermal resistance, the maximum ambient temperature may have to be derated.

In applications with moderate power dissipation and low PCB thermal resistance, the maximum ambient temperature can exceed the maximum limit as long as the junction temperature is within specification limits. The junction temperature ( $T_I$ ) of the device is dependent on the ambient temperature ( $T_A$ ), the power dissipation of the device ( $P_D$ ), and the junction-to-ambient thermal resistance of the package ( $\theta_{IA}$ ).

Maximum junction temperature ( $T_J$ ) is calculated from the ambient temperature ( $T_A$ ) and power dissipation ( $P_D$ ) using the formula

$$T_I = T_A + (P_D \times \theta_{IA})$$

Junction-to-ambient thermal resistance  $(\theta_{JA})$  of the package is based on modeling and calculation using a 4-layer board. The junction-to-ambient thermal resistance is highly dependent on the application and board layout. In applications where high maximum power dissipation exists, close attention to thermal board design is required. The value of  $\theta_{JA}$  may vary, depending

on PCB material, layout, and environmental conditions. The specified values of  $\theta_{IA}$  are based on a 4-layer, 4 in.  $\times$  3 in. circuit board. See JESD51-7 and JESD51-9 for detailed information on the board construction. For additional information, see the *AN-617 Application Note*.

 $\Psi_{JB}$  is the junction-to-board thermal characterization parameter with units of °C/W. The package's  $\Psi_{JB}$  is based on modeling and calculation using a 4-layer board. The JESD51-12, *Guidelines for Reporting and Using Electronic Package Thermal Information*, states that thermal characterization parameters are not the same as thermal resistances.  $\Psi_{JB}$  measures the component power flowing through multiple thermal paths rather than a single path as in thermal resistance,  $\theta_{JB}$ . Therefore,  $\Psi_{JB}$  thermal paths include convection from the top of the package as well as radiation from the package, factors that make  $\Psi_{JB}$  more useful in real-world applications. Maximum junction temperature  $(T_J)$  is calculated from the board temperature  $(T_B)$  and power dissipation  $(P_D)$  using the formula

$$T_I = T_B + (P_D \times \Psi_{IB})$$

See JESD51-8 and JESD51-12 for more detailed information about  $\Psi_{\text{IB}}.$ 

#### THERMAL RESISTANCE

 $\theta_{JA}$  and  $\Psi_{JB}$  are specified for the worst-case conditions, that is, a device soldered in a circuit board for surface-mount packages.  $\theta_{JC}$  is a parameter for surface-mount packages with top mounted heatsinks.  $\theta_{IC}$  is presented here for reference only.

**Table 4. Thermal Resistance** 

Package Type	<b>Ө</b> ЈА	<b>Ө</b> лс	$\Psi_{JB}$	Unit
8-Lead LFCSP	40.1	27.1	17.2	°C/W
8-Lead SOIC	48.5	58.4	31.3	°C/W

#### **ESD CAUTION**

**ESD** (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

## PIN CONFIGURATIONS AND FUNCTION DESCRIPTIONS

#### NOTES

- 1. NC = NO CONNECT. DO NOT CONNECT TO THIS PIN.
- EXPOSED PAD ON THE BOTTOM OF THE PACKAGE BE CONNECTED TO THE GROUND PLANE ON THE BOARD.

Figure 3. LFCSP Package

#### NOTES

- 1. NC = NO CONNECT. DO NOT CONNECT TO THIS PIN.
- 2. IT IS HIGHLY RECOMMENDED THAT THE EXPOSED PAD ON THE BOTTOM OF THE PACKAGE BE CONNECTED TO THE GROUND PLANE ON THE BOARD.

Figure 4. Narrow Body SOIC Package

**Table 5. Pin Function Descriptions** 

Pin No.	Mnemonic	Description
1	VOUT	Regulated Output Voltage. Bypass VOUT to GND with a 1 µF or greater capacitor.
2	SENSE/ADJ	Sense (SENSE). Measures the actual output voltage at the load and feeds it to the error amplifier. Connect SENSE as close as possible to the load to minimize the effect of IR drop between the regulator output and the load. This function applies to fixed voltages only.  Adjust Input (ADJ). An external resistor divider sets the output voltage. This function applies to adjustable voltages only.
3	GND	Ground.
4	NC	Do Not Connect to this Pin.
5	EN/UVLO	Enable Input (EN). Drive EN high to turn on the regulator; drive EN low to turn off the regulator. For automatic startup, connect EN to VIN.  Programmable Undervoltage Lockout (UVLO). When the programmable UVLO function is used, the upper and lower thresholds are determined by the programming resistors.
6	GND	Ground.
7	PG	Power Good. This open-drain output requires an external pull-up resistor to VIN or VOUT. If the part is in shutdown, current limit, thermal shutdown, or falls below 90% of the nominal output voltage, PG immediately transitions low. If the power-good function is not used, the pin may be left open or connected to ground.
8	VIN	Regulator Input Supply. Bypass VIN to GND with a 1 $\mu F$ or greater capacitor.
	EPAD	Exposed Pad. Exposed paddle on the bottom of the package. The EPAD enhances thermal performance and is electrically connected to GND inside the package. It is highly recommended that the EPAD be connected to the ground plane on the board.

## TYPICAL PERFORMANCE CHARACTERISTICS

 $V_{IN} = 7.5 \text{ V}$ ,  $V_{OUT} = 5 \text{ V}$ ,  $I_{OUT} = 10 \text{ mA}$ ,  $C_{IN} = C_{OUT} = 1 \mu\text{F}$ ,  $T_A = 25^{\circ}\text{C}$ , unless otherwise noted.

### THEORY OF OPERATION

The ADP7104 is a low quiescent current, low-dropout linear regulator that operates from 3.3 V to 20 V and provides up to 500 mA of output current. Drawing a low 1 mA of quiescent current (typical) at full load makes the ADP7104 ideal for battery-operated portable equipment. Typical shutdown current consumption is 40  $\mu A$  at room temperature.

Optimized for use with small 1  $\mu$ F ceramic capacitors, the ADP7104 provides excellent transient performance.

Figure 59. Fixed Output Voltage Internal Block Diagram

Figure 60. Adjustable Output Voltage Internal Block Diagram

Internally, the ADP7104 consists of a reference, an error amplifier, a feedback voltage divider, and a PMOS pass transistor. Output current is delivered via the PMOS pass device, which is controlled by the error amplifier. The error amplifier compares the reference voltage with the feedback voltage from the output and amplifies the difference. If the feedback voltage is lower than the reference voltage, the gate of the PMOS device is pulled lower, allowing more current to pass and increasing the output voltage. If the

feedback voltage is higher than the reference voltage, the gate of the PMOS device is pulled higher, allowing less current to pass and decreasing the output voltage.

The ADP7104 is available in seven fixed output voltage options, ranging from 1.5 V to 9 V and in an adjustable version with an output voltage that can be set to between 1.22 V and 19 V by an external voltage divider. The output voltage can be set according to the following equation:

Figure 61. Typical Adjustable Output Voltage Application Schematic

The value of R2 should be less than 200 k $\Omega$  to minimize errors in the output voltage caused by the ADJ pin input current. For example, when R1 and R2 each equal 200 k $\Omega$ , the output voltage is 2.44 V. The output voltage error introduced by the ADJ pin input current is 2 mV or 0.08%, assuming a typical ADJ pin input current of 10 nA at 25°C.

The ADP7104 uses the EN/UVLO pin to enable and disable the VOUT pin under normal operating conditions. When EN/UVLO is high, VOUT turns on, when EN is low, VOUT turns off. For automatic startup, EN/UVLO can be tied to VIN.

The ADP7104 incorporates reverse current protections circuitry that prevents current flow backwards through the pass element when the output voltage is greater than the input voltage. A comparator senses the difference between the input and output voltages. When the difference between the input voltage and output voltage exceeds 55 mV, the body of the PFET is switched to  $V_{\text{OUT}}$  and turned off or opened. In other words, the gate is connected to VOUT.

### APPLICATIONS INFORMATION

#### **CAPACITOR SELECTION**

#### **Output Capacitor**

The ADP7104 is designed for operation with small, space-saving ceramic capacitors but functions with most commonly used capacitors as long as care is taken with regard to the effective series resistance (ESR) value. The ESR of the output capacitor affects the stability of the LDO control loop. A minimum of 1  $\mu F$  capacitance with an ESR of 1  $\Omega$  or less is recommended to ensure the stability of the ADP7104. Transient response to changes in load current is also affected by output capacitance. Using a larger value of output capacitance improves the transient response of the ADP7104 to large changes in load current. Figure 62 shows the transient responses for an output capacitance value of 1  $\mu F$ .

Figure 62. Output Transient Response,  $V_{OUT} = 1.8 \text{ V}$ ,  $C_{OUT} = 1 \mu\text{F}$ 

#### **Input Bypass Capacitor**

Connecting a 1  $\mu$ F capacitor from VIN to GND reduces the circuit sensitivity to printed circuit board (PCB) layout, especially when long input traces or high source impedance are encountered. If greater than 1  $\mu$ F of output capacitance is required, the input capacitor should be increased to match it.

#### **Input and Output Capacitor Properties**

Any good quality ceramic capacitors can be used with the ADP7104, as long as they meet the minimum capacitance and maximum ESR requirements. Ceramic capacitors are manufactured with a variety of dielectrics, each with different behavior over temperature and applied voltage. Capacitors must have a dielectric adequate to ensure the minimum capacitance over the necessary temperature range and dc bias conditions. X5R or X7R dielectrics with a voltage rating of 6.3 V to 25 V are recommended. Y5V and Z5U dielectrics are not recommended, due to their poor temperature and dc bias characteristics.

Figure 63 depicts the capacitance vs. voltage bias characteristic of an 0402, 1  $\mu$ F, 10 V, X5R capacitor. The voltage stability of a capacitor is strongly influenced by the capacitor size and voltage rating. In general, a capacitor in a larger package or higher voltage rating exhibits better stability. The temperature variation of the X5R dielectric is ~ $\pm$ 15% over the  $-40^{\circ}$ C to  $+85^{\circ}$ C temperature range and is not a function of package or voltage rating.

Figure 63. Capacitance vs. Voltage Characteristic

Use Equation 1 to determine the worst-case capacitance accounting for capacitor variation over temperature, component tolerance, and voltage.

$$C_{EFF} = C_{BIAS} \times (1 - TEMPCO) \times (1 - TOL) \tag{1}$$

where

*C<sub>BIAS</sub>* is the effective capacitance at the operating voltage. *TEMPCO* is the worst-case capacitor temperature coefficient. *TOL* is the worst-case component tolerance.

In this example, the worst-case temperature coefficient (TEMPCO) over  $-40^{\circ}$ C to  $+85^{\circ}$ C is assumed to be 15% for an X5R dielectric. The tolerance of the capacitor (TOL) is assumed to be 10%, and C<sub>BIAS</sub> is  $0.94~\mu\text{F}$  at 1.8~V, as shown in Figure 63.

Substituting these values in Equation 1 yields

$$C_{EFF} = 0.94 \,\mu\text{F} \times (1 - 0.15) \times (1 - 0.1) = 0.719 \,\mu\text{F}$$

Therefore, the capacitor chosen in this example meets the minimum capacitance requirement of the LDO overtemperature and tolerance at the chosen output voltage.

To guarantee the performance of the ADP7104, it is imperative that the effects of dc bias, temperature, and tolerances on the behavior of the capacitors be evaluated for each application.

# PROGRAMMABLE UNDERVOLTAGE LOCKOUT (UVLO)

The ADP7104 uses the EN/UVLO pin to enable and disable the VOUT pin under normal operating conditions. As shown in Figure 64, when a rising voltage on EN crosses the upper threshold, VOUT turns on. When a falling voltage on EN/UVLO crosses the lower threshold, VOUT turns off. The hysteresis of the EN/UVLO threshold is determined by the Thevenin equivalent resistance in series with the EN/UVLO pin.

Figure 64. Typical VOUT Response to EN Pin Operation

The upper and lower thresholds are user programmable and can be set using two resistors. When the EN/UVLO pin voltage is below 1.22 V, the LDO is disabled. When the EN/UVLO pin voltage transitions above 1.22 V, the LDO is enabled and 10  $\mu A$  hysteresis current is sourced out the pin raising the voltage, thus providing threshold hysteresis. Typically, two external resistors program the minimum operational voltage for the LDO. The resistance values, R1 and R2 can be determined from:

$$R1 = V_{HYS}/10 \mu A$$
  
 $R2 = 1.22 \text{ V} \times R1/(V_{IN} - 1.22 \text{ V})$ 

where:

 $V_{IN}$  is the desired turn-on voltage.  $V_{HYS}$  is the desired EN/UVLO hysteresis level.

Hysteresis can also be achieved by connecting a resistor in series with EN/UVLO pin. For the example shown in Figure 65, the enable threshold is 2.44 V with a hysteresis of 1 V.

Figure 65. Typical EN Pin Voltage Divider

Figure 64 shows the typical hysteresis of the EN/UVLO pin. This prevents on/off oscillations that can occur due to noise on the EN pin as it passes through the threshold points.

The ADP7104 uses an internal soft-start to limit the inrush current when the output is enabled. The start-up time for the 3.3 V option is approximately 580  $\mu s$  from the time the EN active threshold is crossed to when the output reaches 90% of its final value. As shown in Figure 66, the start-up time is dependent on the output voltage setting.

Figure 66. Typical Start-Up Behavior

#### **POWER-GOOD FEATURE**

The ADP7104 provides a power-good pin (PG) to indicate the status of the output. This open-drain output requires an external pull-up resistor to VIN or VOUT. If the part is in shutdown mode, current-limit mode, or thermal shutdown, or if it falls below 90% of the nominal output voltage, the power-good pin (PG) immediately transitions low. During soft-start, the rising threshold of the power-good signal is 93.5% of the nominal output voltage.

The open-drain output is held low when the ADP7104 has sufficient input voltage to turn on the internal PG transistor. The PG transistor is terminated via a pull-up resistor to VOUT or VIN.

Power-good accuracy is 93.5% of the nominal regulator output voltage when this voltage is rising, with a 90% trip point when this voltage is falling. Regulator input voltage brownouts or glitches trigger power no good signals if  $V_{\rm OUT}$  falls below 90%.

A normal power-down causes the power-good signal to go low when  $V_{\text{OUT}}$  drops below 90%.

Figure 67 and Figure 68 show the typical power-good rising and falling threshold over temperature.

Figure 67. Typical Power-Good Threshold vs. Temperature,  $V_{OUT}$  Rising

Figure 68. Typical Power-Good Threshold vs. Temperature, V<sub>OUT</sub> Falling

#### NOISE REDUCTION OF THE ADJUSTABLE ADP7104

The ultralow output noise of the fixed output ADP7104 is achieved by keeping the LDO error amplifier in unity gain and setting the reference voltage equal to the output voltage. This architecture does not work for an adjustable output voltage LDO. The adjustable output ADP7104 uses the more conventional architecture where the reference voltage is fixed and the error amplifier gain is a function of the output voltage. The disadvantage of the conventional LDO architecture is that the output voltage noise is proportional to the output voltage.

The adjustable LDO circuit may be modified slightly to reduce the output voltage noise to levels close to that of the fixed output ADP7104. The circuit shown in Figure 69 adds two additional components to the output voltage setting resistor divider.  $C_{NR}$  and  $R_{NR}$  are added in parallel with  $R_{FB1}$  to reduce the ac gain of the error amplifier.  $R_{NR}$  is chosen to be equal to  $R_{FB2}$ , this limits the ac gain of the error amplifier to approximately 6 dB. The actual gain is the parallel combination of  $R_{NR}$  and  $R_{FB1}$  divided by  $R_{FB2}$ . This ensures that the error amplifier always operates at greater than unity gain.

 $C_{NR}$  is chosen by setting the reactance of  $C_{NR}$  equal to  $R_{FB1} - R_{NR}$  at a frequency between 50 Hz and 100 Hz. This sets the frequency where the ac gain of the error amplifier is 3 dB down from its dc gain.

Figure 69. Noise Reduction Modification to Adjustable LDO

The noise of the adjustable LDO is can be found by using the formula below assuming the noise of a fixed output LDO is approximately 15  $\mu$ V.

$$15 \,\mu\text{V} \times \sqrt{1 + \left( \left( \frac{1}{1/13 \,k\Omega + 1/40.2 \,k\Omega} \right) / 13 \,k\Omega \right)}$$

Based on the component values shown in Figure 69, the ADP7104 has the following characteristics:

- DC gain of 4.09 (12.2 dB)
- 3 dB roll off frequency of 59 Hz
- High frequency ac gain of 1.76 (4.89 dB)
- Noise reduction factor of 1.33 (2.59 dB)
- RMS noise of the adjustable LDO without noise reduction of 27.8  $\mu V$  rms
- RMS noise of the adjustable LDO with noise reduction (assuming 15  $\mu V$  rms for fixed voltage option) of 19.95  $\mu V$  rms

9507-064

## CURRENT LIMIT AND THERMAL OVERLOAD PROTECTION

The ADP7104 is protected against damage due to excessive power dissipation by current and thermal overload protection circuits. The ADP7104 is designed to current limit when the output load reaches 600 mA (typical). When the output load exceeds 600 mA, the output voltage is reduced to maintain a constant current limit.

Thermal overload protection is included, which limits the junction temperature to a maximum of 150°C (typical). Under extreme conditions (that is, high ambient temperature and/or high power dissipation) when the junction temperature starts to rise above 150°C, the output is turned off, reducing the output current to zero. When the junction temperature drops below 135°C, the output is turned on again, and output current is restored to its operating value.

Consider the case where a hard short from VOUT to ground occurs. At first, the ADP7104 current limits, so that only 600 mA is conducted into the short. If self heating of the junction is great enough to cause its temperature to rise above 150°C, thermal shutdown activates, turning off the output and reducing the output current to zero. As the junction temperature cools and drops below 135°C, the output turns on and conducts 600 mA into the short, again causing the junction temperature to rise above 150°C. This thermal oscillation between 135°C and 150°C causes a current oscillation between 600 mA and 0 mA that continues as long as the short remains at the output.

Current and thermal limit protections are intended to protect the device against accidental overload conditions. For reliable operation, device power dissipation must be externally limited so the junction temperature does not exceed 125°C.

#### THERMAL CONSIDERATIONS

In applications with low input-to-output voltage differential, the ADP7104 does not dissipate much heat. However, in applications with high ambient temperature and/or high input voltage, the heat dissipated in the package may become large enough that it causes the junction temperature of the die to exceed the maximum junction temperature of 125°C.

When the junction temperature exceeds 150°C, the converter enters thermal shutdown. It recovers only after the junction temperature has decreased below 135°C to prevent any permanent damage. Therefore, thermal analysis for the chosen application is very important to guarantee reliable performance over all conditions. The junction temperature of the die is the sum of the ambient temperature of the environment and the temperature rise of the package due to the power dissipation, as shown in Equation 2.

To guarantee reliable operation, the junction temperature of the ADP7104 must not exceed 125°C. To ensure that the junction temperature stays below this maximum value, the user must be aware of the parameters that contribute to junction temperature changes. These parameters include ambient temperature, power dissipation in the power device, and thermal resistances between the junction and ambient air ( $\theta_{JA}$ ). The  $\theta_{JA}$  number is dependent on the package assembly compounds that are used and the amount of copper used to solder the package GND pins to the PCB.

Table 6 shows typical  $\theta_{JA}$  values of the 8-lead SOIC and 8-lead LFCSP packages for various PCB copper sizes. Table 7 shows the typical  $\Psi_{IB}$  values of the 8-lead SOIC and 8-lead LFCSP.

Table 6. Typical  $\theta_{JA}$  Values

		θ <sub>JA</sub> (°C/W)		
Copper Size (mm²)	LFCSP	SOIC		
25 <sup>1</sup>	165.1	167.8		
100	125.8	111		
500	68.1	65.9		
1000	56.4	56.1		
6400	42.1	45.8		

<sup>&</sup>lt;sup>1</sup> Device soldered to minimum size pin traces.

Table 7. Typical Ψ<sub>IB</sub> Values

Model	Ψ <sub>JB</sub> (°C/W)
LFCSP	15.1
SOIC	31.3

The junction temperature of the ADP7104 is calculated from the following equation:

$$T_J = T_A + (P_D \times \theta_{JA}) \tag{2}$$

where:

 $T_A$  is the ambient temperature.

 $P_D$  is the power dissipation in the die, given by

$$P_D = [(V_{IN} - V_{OUT}) \times I_{LOAD}] + (V_{IN} \times I_{GND})$$
(3)

where:

 $I_{LOAD}$  is the load current.

 $I_{GND}$  is the ground current.

 $V_{IN}$  and  $V_{OUT}$  are input and output voltages, respectively.

Power dissipation due to ground current is quite small and can be ignored. Therefore, the junction temperature equation simplifies to the following:

$$T_{I} = T_{A} + \{ [(V_{IN} - V_{OUT}) \times I_{LOAD}] \times \theta_{JA} \}$$

$$\tag{4}$$

As shown in Equation 4, for a given ambient temperature, input-to-output voltage differential, and continuous load current, there exists a minimum copper size requirement for the PCB to ensure that the junction temperature does not rise above 125°C. Figure 70 to Figure 77 show junction temperature calculations for different ambient temperatures, power dissipation, and areas of PCB copper.

Figure 70. LFCSP,  $T_A = 25^{\circ}C$ 

Figure 72. LFCSP,  $T_A = 85^{\circ}C$ 

Figure 73. SOIC,  $T_A = 25^{\circ}C$ 

Figure 74. SOIC,  $T_A = 50^{\circ}$ C

Figure 75. SOIC,  $T_A = 85^{\circ}C$ 

In the case where the board temperature is known, use the thermal characterization parameter,  $\Psi_{JB}$ , to estimate the junction temperature rise (see Figure 76 and Figure 77). Maximum junction temperature  $(T_J)$  is calculated from the board temperature  $(T_B)$  and power dissipation  $(P_D)$  using the following formula:

$$T_J = T_B + (P_D \times \Psi_{JB}) \tag{5}$$

The typical value of  $\Psi_{JB}$  is 15.1°C/W for the 8-lead LFCSP package and 31.3°C/W for the 8-lead SOIC package.

## PRINTED CIRCUIT BOARD LAYOUT CONSIDERATIONS

Heat dissipation from the package can be improved by increasing the amount of copper attached to the pins of the ADP7104. However, as listed in Table 6, a point of diminishing returns is eventually reached, beyond which an increase in the copper size does not yield significant heat dissipation benefits.

Place the input capacitor as close as possible to the VIN and GND pins. Place the output capacitor as close as possible to the VOUT and GND pins. Use of 0805 or 0603 size capacitors and resistors achieves the smallest possible footprint solution on boards where area is limited.

Компания «ЭлектроПласт» предлагает заключение долгосрочных отношений при поставках импортных электронных компонентов на взаимовыгодных условиях!

#### Наши преимущества:

- Оперативные поставки широкого спектра электронных компонентов отечественного и импортного производства напрямую от производителей и с крупнейших мировых складов:
- Поставка более 17-ти миллионов наименований электронных компонентов;
- Поставка сложных, дефицитных, либо снятых с производства позиций;
- Оперативные сроки поставки под заказ (от 5 рабочих дней);
- Экспресс доставка в любую точку России;
- Техническая поддержка проекта, помощь в подборе аналогов, поставка прототипов;
- Система менеджмента качества сертифицирована по Международному стандарту ISO 9001:
- Лицензия ФСБ на осуществление работ с использованием сведений, составляющих государственную тайну;
- Поставка специализированных компонентов (Xilinx, Altera, Analog Devices, Intersil, Interpoint, Microsemi, Aeroflex, Peregrine, Syfer, Eurofarad, Texas Instrument, Miteq, Cobham, E2V, MA-COM, Hittite, Mini-Circuits, General Dynamics и др.);

Помимо этого, одним из направлений компании «ЭлектроПласт» является направление «Источники питания». Мы предлагаем Вам помощь Конструкторского отдела:

- Подбор оптимального решения, техническое обоснование при выборе компонента;
- Подбор аналогов;
- Консультации по применению компонента;
- Поставка образцов и прототипов;
- Техническая поддержка проекта;
- Защита от снятия компонента с производства.
