

### FEATURES

- 14-bit/16-bit multiplying DAC
- Guaranteed monotonicity
- Output control on power-up and power-down internal or external control
- Versatile serial interface
- DAC clears to 0 V in both unipolar and bipolar output ranges

### APPLICATIONS

- Industrial process controls
- PC analog I/O boards
- Instrumentation

### FUNCTIONAL BLOCK DIAGRAM

Figure 1.

### GENERAL DESCRIPTION

The AD7849 is a 14-bit/16-bit serial input multiplying digital-to-analog converter (DAC). The DAC architecture ensures excellent differential linearity performance, and monotonicity is guaranteed to 14 bits for the A grade and to 16 bits for all other grades over the specified temperature ranges.

During power-up and power-down sequences (when the supply voltages are changing), the  $V_{OUT}$  pin is clamped to 0 V via a low impedance path. To prevent the output of A3 from being shorted to 0 V during this time, Transmission Gate G1 is also opened. These conditions are maintained until the power supplies stabilize, and a valid word is written to the DAC register. At this time, G2 opens and G1 closes. Both transmission gates are also externally controllable via the reset ( $\overline{RSTIN}$ ) control input. For instance, if the  $\overline{RSTIN}$  input is driven from a battery supervisor chip, then at power-off or during a brown out, the  $\overline{RSTIN}$  input is driven low to open G1 and close G2. The DAC must be reloaded, with  $\overline{RSTIN}$  high, to reenables the output. Conversely, the on-chip voltage detector output ( $\overline{RSTOUT}$ ) is also available to the user to control other parts of the system.

The AD7849 has a versatile serial interface structure and can be controlled over three lines to facilitate opto-isolator applications.  $\overline{SDOUT}$  is the output of the on-chip shift register and can be used in a daisy-chain fashion to program devices in the multi-channel system. The daisy-chain enable ( $\overline{DCEN}$ ) input controls this function.

The  $\overline{BIN/COMP}$  pin sets the DAC coding; with  $\overline{BIN/COMP}$  set to 0, the coding is straight binary; and with  $\overline{BIN/COMP}$  set to 1, the coding is two's complement. This allows the user to reset the DAC to 0 V in both the unipolar and bipolar output ranges.

The part is available in a 20-lead PDIP package and a 20-lead SOIC package.

<sup>3</sup> Sensitivity of gain error, offset error, and bipolar zero error to  $V_{DD}$ ,  $V_{SS}$  variations.

## RESET SPECIFICATIONS

These specifications apply when the device goes into reset mode during power-up or power-down sequence.  $V_{OUT}$  unloaded.

Table 2.

Parameter	All Versions	Unit	Test Conditions/Comments
$V_A$ , <sup>1</sup> Low Threshold Voltage for $V_{DD}$ , $V_{SS}$	1.2 0	V max V typ	This is the lower $V_{DD}/V_{SS}$ threshold voltage for the reset function. Above this, the reset is activated.
$V_B$ , High Threshold Voltage for $V_{DD}$ , $V_{SS}$	9.5 6.4	V max V min	This is the higher $V_{DD}/V_{SS}$ threshold voltage for the reset function. Below this, the reset is activated. Typically, 8 V.
$V_C$ , Low Threshold Voltage for $V_{CC}$	1 0	V max V typ	This is the lower $V_{CC}$ threshold voltage for the reset function. Above this, the reset is activated.
$V_D$ , High Threshold Voltage for $V_{CC}$	4 2.5	V max V min	This is the higher $V_{CC}$ threshold voltage for the reset function. Below this, the reset is activated. Typically, 3 V.
G2 $R_{ON}$	1	k $\Omega$ typ	On resistance of G2; $V_{DD} = 2 \text{ V}$ ; $V_{SS} = -2 \text{ V}$ ; $I_{G2} = 1 \text{ mA}$ .

<sup>1</sup> A pull-down resistor (65 k $\Omega$ ) on  $V_{OUT}$  maintains 0 V output when  $V_{DD}/V_{SS}$  is below  $V_A$ .

## AC PERFORMANCE CHARACTERISTICS

These characteristics are included for design guidance and are no subject to test.  $V_{REF+} = 5\text{ V}$ ;  $V_{DD} = 14.25\text{ V}$  to  $15.75\text{ V}$ ;  $V_{SS} = -14.25\text{ V}$  to  $-15.75\text{ V}$ ;  $V_{CC} = 4.75\text{ V}$  to  $5.25\text{ V}$ ;  $R_{OFS}$  connected to  $0\text{ V}$ .

**Table 3.**

Parameter	A, B, C Versions	Unit	Test Conditions/Comments
<b>DYNAMIC PERFORMANCE</b>			
Output Settling Time <sup>1</sup>	7	$\mu\text{s typ}$	To 0.006% FSR. $V_{OUT}$ loaded. $V_{REF-} = 0\text{ V}$ .
	10	$\mu\text{s typ}$	To 0.003% FSR. $V_{OUT}$ loaded. $V_{REF-} = -5\text{ V}$ .
Slew Rate	4	$\text{V}/\mu\text{s typ}$	
Digital-to-Analog Glitch Impulse	250	$\text{nV}\cdot\text{sec typ}$	DAC alternatively loaded with 00 ... 00 and 111 ... 11. $V_{OUT}$ loaded. $\overline{\text{LDAC}}$ permanently low. $\overline{\text{BIN/COMP}}$ set to 1. $V_{REF-} = -5\text{ V}$ .
	150	$\text{nV}\cdot\text{sec typ}$	$\overline{\text{LDAC}}$ frequency = 100 kHz.
AC Feedthrough	1	$\text{mV p-p typ}$	$V_{REF-} = 0\text{ V}$ , $V_{REF+} = 1\text{ V rms}$ , 10 kHz sine wave. DAC loaded with all 0s. $\overline{\text{BIN/COMP}}$ set to 0.
Digital Feedthrough	5	$\text{nV}\cdot\text{sec typ}$	DAC alternatively loaded with all 1s and 0s. $\overline{\text{SYNC}}$ high.
Output Noise Voltage Density, 1 kHz to 100 kHz	80	$\text{nV}/\sqrt{\text{Hz typ}}$	Measured at $V_{OUT}$ . $V_{REF+} = V_{REF-} = 0\text{ V}$ . $\overline{\text{BIN/COMP}}$ set to 0.

<sup>1</sup>  $\overline{\text{LDAC}} = 0$ . Settling time does not include deglitching time of  $5\text{ }\mu\text{s}$  (typical).

## TIMING CHARACTERISTICS

$V_{DD} = 14.25\text{ V}$  to  $15.75\text{ V}$ ;  $V_{SS} = -14.25\text{ V}$  to  $-15.75\text{ V}$ ;  $V_{CC} = 4.75\text{ V}$  to  $5.25\text{ V}$ ;  $R_L = 2\text{ k}\Omega$ ,  $C_L = 200\text{ pF}$ . All specifications  $T_{MIN}$  to  $T_{MAX}$ , unless otherwise noted. Guaranteed by characterization. All input signals are specified  $t_r = t_f = 5\text{ ns}$  (10% to 90% of 5 V and timed from a voltage level of 1.6 V).

**Table 4.**

Parameter	Limit at 25°C (All Versions)	Limit at $T_{MIN}$ , $T_{MAX}$ (All Versions)	Unit	Test Conditions/Comments
$t_1$ <sup>1</sup>	200	200	ns min	SCLK cycle time
$t_2$	50	50	ns min	$\overline{\text{SYNC}}$ -to-SCLK setup time
$t_3$	70	70	ns min	$\overline{\text{SYNC}}$ -to-SCLK hold time
$t_4$	10	10	ns min	Data setup time
$t_5$	40	40	ns min	Data hold time
$t_6$ <sup>2</sup>	80	80	ns max	SCLK falling edge to SDO valid
$t_7$	80	80	ns min	$\overline{\text{LDAC}}$ , $\overline{\text{CLR}}$ pulse width
$t_r$	30	30	$\mu\text{s max}$	Digital input rise time
$t_f$	30	30	$\mu\text{s max}$	Digital input fall time

<sup>1</sup> SCLK mark/space ratio range is 40/60 to 60/40.

<sup>2</sup> SDO load capacitance is 50 pF.

## ABSOLUTE MAXIMUM RATINGS

$T_A = 25^\circ\text{C}$ , unless otherwise noted.

Table 5.

Parameter	Rating
$V_{DD}$ to DGND	-0.4 V to +17 V
$V_{CC}$ to DGND <sup>1</sup>	-0.4 V, $V_{DD} + 0.4$ V or +7 V (whichever is lower)
$V_{SS}$ to DGND	-0.4 V to -17 V
$V_{REF+}$ to DGND	$V_{DD} + 0.4$ V, $V_{SS} - 0.4$ V
$V_{REF-}$ to DGND	$V_{DD} + 0.4$ V, $V_{SS} - 0.4$ V
$V_{OUT}$ to DGND <sup>2</sup>	$V_{DD} + 0.4$ V, $V_{SS} - 0.4$ V or $\pm 10$ V (whichever is lower)
$R_{OFS}$ to DGND	$V_{DD} + 0.4$ V, $V_{SS} - 0.4$ V
Digital Input Voltage to DGND	-0.4 V to $V_{CC} + 0.4$ V
Input Current to any Pin Except Supplies <sup>3</sup>	$\pm 10$ mA
Operating Temperature Range	-40°C to +85°C
Storage Temperature Range	-65°C to +150°C
Junction Temperature	150°C
20-Lead PDIP	
Power Dissipation	875 mW
$\theta_{JA}$ Thermal Impedance	102°C/W
Lead Temperature (Soldering, 10 sec)	260°C
20-Lead SOIC	
Power Dissipation	875 mW
$\theta_{JA}$ Thermal Impedance	74°C/W
Lead Temperature, Soldering	
Vapor Phase (60 sec)	215°C
Infrared (15 sec)	220°C

<sup>1</sup>  $V_{CC}$  must not exceed  $V_{DD}$  by more than 0.4 V. If it is possible for this to happen during power-up or power-down (for example, if  $V_{CC}$  is greater than 0.4 V while  $V_{DD}$  is still 0 V), the following diode protection scheme ensures protection.

<sup>2</sup>  $V_{OUT}$  can be shorted to DGND, +10 V, -10 V, provided that the power dissipation of the package is not exceeded.

<sup>3</sup> Transient currents of up to 100 mA do not cause SCR latch-up.

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

### ESD CAUTION

**ESD (electrostatic discharge) sensitive device.** Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

## PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

Figure 2. Pin Configuration

Table 6. Pin Function Descriptions

Pin No.	Mnemonic	Description
1	$V_{REF+}$	$V_{REF+}$ Input. The DAC is specified for $V_{REF+}$ of 5 V. The DAC is fully multiplying so that the $V_{REF+}$ range is +5 V to -5 V.
2	$V_{REF-}$	$V_{REF-}$ Input. The DAC is specified for $V_{REF-}$ of -5 V. The DAC is fully multiplying so that the $V_{REF-}$ range is -5 V to +5 V.
3	$V_{SS}$	Negative supply for the analog circuitry. This is nominally -15 V.
4	$\overline{SYNC}$	Data Synchronization Logic Input. When it goes low, the internal logic is initialized in readiness for a new data-word.
5	SCLK	Serial Clock Logic Input. Data is clocked into the input register on each SCLK falling edge.
6	$V_{CC}$	Positive supply for the digital circuitry. This is nominally 5 V.
7	SDOUT	Serial Data Output. With DCEN at Logic 1, this output is enabled, and the serial data in the input shift register is clocked out on each rising edge of SCLK.
8	DCEN	Daisy-Chain Enable Logic Input. Connect this pin high if a daisy-chain interface is being used; otherwise, this pin must be connected low.
9	$\overline{BIN/COMP}$	Logic Input. This input selects the data format to be either binary or twos complement. In the unipolar output range, natural binary format is selected by connecting the input to Logic 0. In the bipolar output range, offset binary is selected by connecting this input to Logic 0, and twos complement is selected by connecting it to a Logic 1.
10	DGND	Digital Ground. Ground reference point for the on-chip digital circuitry.
11	$\overline{LDAC}$	Load DAC Logic Input. This input updates the DAC output. The DAC output is updated on the falling edge of this signal, or alternatively, if this input is permanently low, an automatic update mode is selected where the DAC is updated on the 16th falling SCLK edge.
12	SDIN	Serial Data Input. The 16-bit serial data-word is applied to this input.
13	$\overline{CLR}$	Clear Logic Input. Taking this input low sets $V_{OUT}$ to 0 V in both the unipolar output range and the bipolar twos complement output range. It sets $V_{OUT}$ to $V_{REF-}$ in the offset binary bipolar output range.
14	$\overline{RSTIN}$	Reset Logic Input. This input allows external access to the internal reset logic. Applying Logic 0 to this input, resets the DAC output to 0 V. In normal operation, it should be tied to Logic 1.
15	$\overline{RSTOUT}$	Reset Logic Output. This is the output from the on-chip voltage monitor used in the reset circuit. It can be used to control other system components, if desired.
16	AGND	This is the analog ground for the device. It is the point to which the output gets shorted in reset mode.
17	$V_{DD}$	Positive Supply for the Analog Circuitry. This is 15 V nominal.
18	NC	No Connect. Leave unconnected.
19	$V_{OUT}$	DAC Output Voltage Pin.
20	ROFS	Input to Summing Resistor of DAC Output Amplifier. This is used to select the output voltage ranges. Also, see Figure 20 to Figure 23 in the Applying the AD7849 section.

## TERMINOLOGY

### Least Significant Bit

This is the analog weighting of 1 bit of the digital word in a DAC. For the B version and the C versions,  $1 \text{ LSB} = (V_{\text{REF}+} - V_{\text{REF}-})/2^{16}$ . For the A version,  $1 \text{ LSB} = (V_{\text{REF}+} - V_{\text{REF}-})/2^{14}$ .

### Relative Accuracy

Relative accuracy or endpoint nonlinearity is a measure of the maximum deviation from a straight line passing through the endpoints of the DAC transfer function. It is measured after adjusting for both endpoints (that is, offset and gain errors are adjusted out) and is normally expressed in least significant bits or as a percentage of full-scale range.

### Differential Nonlinearity

Differential nonlinearity is the difference between the measured change and the ideal change between any two adjacent codes. A specified differential nonlinearity of less than  $\pm 1$  LSB over the operating temperature range ensures monotonicity.

### Gain Error

Gain error is a measure of the output error between an ideal DAC and the actual device output with all 1s loaded after offset error has been adjusted out. Gain error is adjustable to zero with an external potentiometer.

### Offset Error

This is the error present at the device output with all 0s loaded in the DAC. It is due to the op amp input offset voltage and bias current and the DAC leakage current.

### Bipolar Zero Error

When the AD7849 is connected for bipolar output and (100 ... 000) is loaded to the DAC, the deviation of the analog output from the ideal midscale of 0 V is called the bipolar zero error.

### Digital-to-Analog Glitch Impulse

This is the amount of charge injected from the digital inputs to the analog output when the inputs change state. Normally, this is specified as the area of the glitch in nV-secs.

### Multiplying Feedthrough Error

This is an ac error due to capacitive feedthrough from either of the  $V_{\text{REF}}$  terminals to  $V_{\text{OUT}}$  when the DAC is loaded with all 0s.

### Digital Feedthrough

When the DAC is not selected ( $\overline{\text{SYNC}}$  is held high), high frequency logic activity on the digital inputs is capacitively coupled through the device to show up as noise on the  $V_{\text{OUT}}$  pin. This noise is digital feedthrough.

## CIRCUIT DESCRIPTION

### DIGITAL-TO-ANALOG CONVERSION

Figure 15 shows the digital-to-analog section of the AD7849. There are three on-chip DACs, each of which has its own buffer amplifier. DAC1 and DAC2 are 4-bit DACs. They share a 16-resistor string, but they have their own analog multiplexers. The voltage reference is applied to the resistor string. DAC3 is a 12-bit voltage mode DAC with its own output stage.

The four MSBs of the 16-bit digital input code drive DAC1 and DAC2, while the 12 LSBs control DAC3. Using DAC1 and DAC2, the MSBs select a pair of adjacent nodes on the resistor string and present that voltage to the positive and negative inputs of DAC3. This DAC interpolates between these two voltages to produce the analog output voltage.

To prevent nonmonotonicity in the DAC due to amplifier offset voltages, DAC1 and DAC2 leap-frog along the resistor string. For example, when switching from Segment 1 to Segment 2, DAC1 switches from the bottom of Segment 1 to the top of Segment 2 while DAC 2 remains connected to the top of Segment 1. The code driving DAC3 is automatically complemented to compensate for the inversion of its inputs. This means that any linearity effects due to amplifier offset voltages remain unchanged when switching from one segment to the next, and 16-bit monotonicity is ensured if DAC3 is monotonic. Therefore, 12-bit resistor matching in DAC3 guarantees overall 16-bit monotonicity. This is much more achievable than the 16-bit matching that a conventional R-2R structure would need.

### Output Stage

The output stage of the AD7849 is shown in Figure 14. It is capable of driving a 2 k $\Omega$  load in parallel with 200 pF. The feedback and offset resistors allow the output stage to be configured for gains of 1 or 2. Additionally, the offset resistor can be used to shift the output range. The AD7849 has a special feature to ensure output stability during power-up and power-down sequences. This feature is available for control applications where actuators must not be allowed to move in an uncontrolled fashion.

Figure 14. Output Stage

When the supply voltages are changing, the  $V_{OUT}$  pin is clamped to 0 V via a low impedance path. To prevent the output of A3 from being shorted to 0 V during this time, Transmission Gate G1 is opened. These conditions are maintained until the power supplies stabilize, and a valid word is written to the DAC register. At this time, G2 opens and G1 closes. Both transmission gates are also externally controllable via the reset in ( $\overline{RSTIN}$ ) control input. For instance, if the  $\overline{RSTIN}$  input is driven from a battery supervisor chip, then at power-off or during a brownout, the  $\overline{RSTIN}$  input will be driven low to open G1 and close G2. The DAC has to be reloaded, with  $\overline{RSTIN}$  high, to reenble the output. Conversely, the on-chip voltage detector output ( $\overline{RSTOUT}$ ) is also available to the user to control other parts of the system.

The AD7849 output buffer is configured as a track-and-hold amplifier. Although normally tracking its input, this amplifier is placed in hold mode for approximately 5  $\mu$ s after the leading edge of  $\overline{LDAC}$ . This short state keeps the DAC output at its previous voltage while the AD7849 is internally changing to its new value. therefore, any glitches that occur in the transition are not seen at the output. In systems where  $\overline{LDAC}$  is permanently low, deglitching is not in operation.

## DIGITAL INTERFACE

The AD7849 contains an input serial-to-parallel shift register and a DAC latch. A simplified diagram of the input loading circuitry is shown in Figure 16. Serial data on the SDIN input is loaded to the input register under control of DCEN, SYNC and SCLK. When a complete word is held in the shift register, it can then be loaded into the DAC latch under control of LDAC. Only the data in the DAC latch determines the analog output on the AD7849.

The daisy-chain enable (DCEN) input is used to select either the standalone mode or the daisy-chain mode. The loading format is slightly different depending on which mode is selected.

### Serial Data Loading Format (Standalone Mode)

When DCEN is at Logic 0, standalone mode is selected. In this mode, a low SYNC input provides the frame synchronization signal that tells the AD7849 that valid serial data on the SDIN input is available for the next 16 falling edges of SCLK. An internal counter/decoder circuit provides a low gating signal so that only 16 data bits are clocked into the input shift register. After 16 SCLK pulses, the internal gating signal goes inactive (high), thus locking out any further clock pulses. Therefore, either a continuous clock or a burst clock source can be used to clock in data.

The SYNC input is taken high after the complete 16-bit word is loaded in.

The B version and C version are 16-bit resolution DACs and have a straight 16-bit load format, with the MSB (DB15) being loaded first. The A version is a 14-bit DAC; however, the loading structure is still 16 bit. The MSB (DB13) is loaded first, and the final two bits of the 16-bit stream must be 0s.

The DAC latch, and hence the analog output, can be updated in two ways. The status of the LDAC input is examined after SYNC is taken low. Depending on its status, one of two update modes is selected.

If LDAC = 0, then automatic update mode is selected. In this mode, the DAC latch and analog output are updated automatically when the last bit in the serial data stream is clocked in. The update thus takes place on the 16th falling SCLK edge.

If LDAC = 1, then automatic update mode is disabled. The DAC latch update and output update are now separate. The DAC latch is updated on the falling edge of LDAC. However, the output update is delayed for a further 5  $\mu$ s by means of an internal track-and-hold amplifier in the output stage. This function results in a lower digital-to-analog glitch impulse at the DAC output. Note that the LDAC input must be taken back high again before the next data transfer is initiated.

Figure 17. Simplified Loading Structure

NOTES  
1. DCEN IS TIED PERMANENTLY HIGH.

01008-019

Figure 18. Timing Diagram (Daisy-Chain Mode)

**Serial Data Loading Format (Daisy-Chain Mode)**

By connecting DCEN high, daisy-chain mode is enabled. This mode of operation is designed for multiDAC systems where several AD7849s can be connected in cascade. In this mode, the internal gating circuitry on SCLK is disabled, and a serial data output facility is enabled. The internal gating signal is permanently active (low) so that the SCLK signal is continuously applied to the input shift register when SYNC is low. The data is clocked into the register on each falling SCLK edge after SYNC goes low. If more than 16 clock pulses are applied, the data ripples out of the shift register and appears on the SDOUT line. By connecting this line to the SDIN input on the next AD7849 in the chain, a multiDAC interface can be constructed. Sixteen SCLK pulses are required for each DAC in the system. Therefore, the total number of clock cycles must equal  $16 \times N$ , where N is the total number of devices in the chain. When the serial transfer to all devices is complete, SYNC is taken high, which prevents any further data from being clocked into the input register.

A continuous SCLK source can be used if SYNC is held low for the correct number of clock cycles. Alternatively, a burst clock containing the exact number of clock cycles can be used and SYNC taken high some time later.

When the transfer to all input registers is complete, a common LDAC signal updates all DAC latches with the data in each input register. All analog outputs are therefore updated simultaneously, 5 μs after the falling edge of LDAC.

**Clear Function (CLR)**

The clear function bypasses the input shift register and loads the DAC latch with all 0s. It is activated by taking CLR low. In all ranges, except the offset binary bipolar range (-5 V to +5 V), the output voltage is reset to 0 V. In the offset binary bipolar range, the output is set to  $V_{REF-}$ . This clear function is distinct and separate from the automatic power-on reset feature of the device.

**APPLYING THE AD7849**

**Power Supply Sequencing and Decoupling**

In the AD7849,  $V_{CC}$  should not exceed  $V_{DD}$  by more than 0.4 V. If this happens, then an internal diode is turned on, and it produces latch-up in the device. Care should be taken to employ the following power supply sequence:  $V_{DD}$ ,  $V_{SS}$ , and then  $V_{CC}$ . In systems where it is possible to have an incorrect power sequence (for example, if  $V_{CC}$  is greater than 0.4 V while  $V_{DD}$  is still 0 V), the circuit shown in Figure 19 can be used to ensure that the Absolute Maximum Ratings are not exceeded.

Figure 19. Power Supply Protection

01008-020

## Unipolar Configuration

Figure 20 shows the AD7849 in the unipolar binary circuit configuration. The DAC is driven by the AD586, 5 V reference. Because  $R_{OFS}$  is tied to 0 V, the output amplifier has a gain of  $\times 2$ , and the output range is 0 V to 10 V. If a 0 V to 5 V range is required,  $R_{OFS}$  should be tied to  $V_{OUT}$ , configuring the output stage for a gain of  $\times 1$ . Table 7 gives the code table for the circuit shown in Figure 20.

\*ADDITIONAL PINS OMITTED FOR CLARITY.

Figure 20. Unipolar Binary Operation

Table 7. Code Table for Figure 20

Binary Number in DAC Latch	Analog Output ( $V_{OUT}$ )
MSB	LSB
1111 1111 1111 1111	10 (65,535/65,536) V
1000 0000 0000 0000	10 (32,768/65,536) V
0000 0000 0000 0001	10 (1/65,536) V
0000 0000 0000 0000	0 V

Table 7 assumes a 16-bit resolution;  $1 \text{ LSB} = 10 \text{ V}/2^{16} = 10 \text{ V}/65,536 = 152 \mu\text{V}$ .

Offset and gain can be adjusted in Figure 20 as follows:

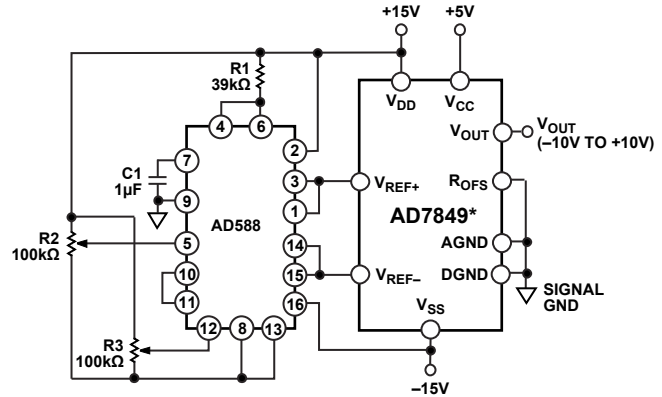

- To adjust offset, disconnect the  $V_{REF-}$  input from 0 V, load the DAC with all 0s, and adjust the  $V_{REF-}$  voltage until  $V_{OUT} = 0 \text{ V}$ .
- To adjust gain, load the AD7849 with all 1s and adjust R1 until  $V_{OUT} = 10 (65,535/65,536) = 9.9998474 \text{ V}$  for the 16-bit, B and C versions. For the 14-bit A version,  $V_{OUT}$  should be  $10 (16,383/16,384) = 9.9993896 \text{ V}$ .

If a simple resistor divider is used to vary the  $V_{REF-}$  voltage, it is important that the temperature coefficients of these resistors match that of the DAC input resistance ( $-300 \text{ ppm}/^\circ\text{C}$ ). Otherwise, extra offset errors will be introduced over temperature. Many circuits do not require these offset and gain adjustments. In these circuits, R1 can be omitted. Pin 5 of the AD586 may be left open circuit, and Pin 2 ( $V_{REF-}$ ) of the AD7849 tied to 0 V.

## Bipolar Configuration

Figure 21 shows the AD7849 set up for  $\pm 10 \text{ V}$  bipolar operation. The AD588 provides precision  $\pm 5 \text{ V}$  tracking outputs that are fed to the  $V_{REF+}$  and  $V_{REF-}$  inputs of the AD7849. The code table for the circuit shown in Figure 21 is shown in Table 8.

Full-scale and bipolar-zero adjustment are provided by varying the gain and balance on the AD588. R2 varies the gain on the AD588, while R3 adjusts the +5 V and -5 V outputs together with respect to ground.

\*ADDITIONAL PINS OMITTED FOR CLARITY

Figure 21. Bipolar  $\pm 10 \text{ V}$  Operation

Table 8. Code Table for Figure 21

Binary Number in DAC Latch	Analog Output ( $V_{OUT}$ )
MSB	LSB
1111 1111 1111 1111	+10 (32,767/32,768) V
1000 0000 0000 0001	+10 (1/32,768) V
1000 0000 0000 0000	0 V
0111 1111 1111 1111	-10 (1/32,768) V
0000 0000 0000 0000	-10 (32,768/32,768) V

Table 8 assumes a 16-bit resolution;  $1 \text{ LSB} = 20 \text{ V}/2^{16} = 305 \mu\text{V}$ .

For bipolar-zero adjustment on the AD7849, load the DAC with 100 ... 000 and adjust R3 until  $V_{OUT} = 0 \text{ V}$ . Full scale is adjusted by loading the DAC with all 1s and adjusting R2 until  $V_{OUT} = 9.999694 \text{ V}$ .

When bipolar-zero and full-scale adjustment are not needed, omit R2 and R3, connect Pin 11 to Pin 12 on the AD588 and leave Pin 5 on the AD588 floating.

If a  $\pm 5 \text{ V}$  output range is desired with the circuit shown in Figure 21, tie Pin 20 ( $R_{OFS}$ ) to Pin 19 ( $V_{OUT}$ ), thus reducing the output gain stage to unity and giving an output range of  $\pm 5 \text{ V}$ .

**Other Output Voltage Ranges**

In some cases, users may require output voltage ranges other than those already mentioned. One example is systems that need the output voltage to be a whole number of millivolts (that is, 1 mV or 2 mV). If the circuit shown in Figure 22 is used, then the LSB size is 125  $\mu$ V. This makes it possible to program whole millivolt values at the output. Table 9 shows the code table for the circuit shown in Figure 22.

\*ADDITIONAL PINS OMITTED FOR CLARITY.

Figure 22. 0 V to 8.192 V Output Range

**Table 9. Code Table for Figure 22**

Binary Number in DAC Latch	Analog Output ( $V_{out}$ )
MSB	LSB
1111 1111 1111 1111	$8.192\text{ V} (65,535/65,536) = 8.1919\text{ V}$
1000 0000 0000 0000	$8.192\text{ V} (32,768/65,536) = 4.096\text{ V}$
0000 0000 0000 1000	$8.192\text{ V} (8/65,536) = 0.001\text{ V}$
0000 0000 0000 0100	$8.192\text{ V} (4/65,536) = 0.0005\text{ V}$
0000 0000 0000 0010	$8.192\text{ V} (2/65,536) = 0.00025\text{ V}$
0000 0000 0000 0001	$8.192\text{ V} (1/65,536) = 0.000125\text{ V}$

Table 9 assumes a 16-bit resolution; 1 LSB =  $8.192\text{ V}/2^{16} = 125\ \mu\text{V}$ .

**Generating a  $\pm 5\text{ V}$  Output Range from a Single +5 V Reference**

Figure 23 shows how to generate a  $\pm 5\text{ V}$  output range when using a single +5 V reference.  $V_{REF-}$  is connected to 0 V, and  $R_{OFS}$  is connected to  $V_{REF+}$ . The 5 V reference input is applied to these pins. With all 0s loaded to the DAC, the noninverting terminal of the output stage amplifier is at 0 V, and  $V_{OUT}$  is the inverse of  $V_{REF+}$ . With all 1s loaded to the DAC, the noninverting terminal of the output stage amplifier is 5 V and, therefore,  $V_{OUT}$  is also 5 V.

\*ADDITIONAL PINS OMITTED FOR CLARITY.

Figure 23. Generating a  $\pm 5\text{ V}$  Output Range from a Single +5 V

**MICROPROCESSOR INTERFACING**

Microprocessor interfacing to the AD7849 is via a serial bus that uses standard protocol compatible with DSP processors and microcontrollers. The communications channel requires a 3-wire interface consisting of a clock signal, a data signal, and a synchronization signal. The AD7849 requires a 16-bit data-word with data valid on the falling edge of SCLK. For all the interfaces, the DAC update can be done automatically when all data is clocked in, or it can be done under control of  $\overline{\text{LDAC}}$ .

Figure 24 through Figure 27 show the AD7849 configured for interfacing to a number of popular DSP processors and microcontrollers.

**AD7849-to-DSP56000 Interface**

A serial interface between the AD7849 and the DSP56000 is shown in Figure 24. The DSP56000 is configured for normal mode asynchronous operation with a gated clock. It is also setup for a 16-bit word with SCK and SC2 as outputs and the FSL control bit set to 0. SCK is internally generated on the DSP56000 and applied to the AD7849 SCLK input. Data from the DSP56000 is valid on the falling edge of SCK. The SC2 output provides the framing pulse for valid data. This line must be inverted before being applied to the  $\overline{\text{SYNC}}$  input of the AD7849.

In this interface, an  $\overline{\text{LDAC}}$  pulse generated from an external timer is used to update the outputs of the DAC. This update can also be produced using a bit programmable control line from the DSP56000.

\*ADDITIONAL PINS OMITTED FOR CLARITY.

Figure 24. AD7849-to-DSP56000 Interface

# AD7849

## AD7849-to-TMS320C2x Interface

Figure 25 shows a serial interface between the AD7849 and the TMS320C2x DSP processor. In this interface, the CLKX and FSX signals for the TMS320C2x should be generated using external clock/timer circuitry. The FSX pin of the TMS320C2x must be configured as an input. Data from the TMS320C2x is valid on the falling edge of CLKX.

Figure 25. AD7849-to-TMS320C2x Interface

The clock/timer circuitry generates the  $\overline{\text{LDAC}}$  signal for the AD7849 to synchronize the update of the output with the serial transmission. Alternatively, the automatic update mode can be selected by connecting  $\overline{\text{LDAC}}$  to DGND.

## AD7849-to-68HC11 Interface

Figure 26 shows a serial interface between the AD7849 and the 68HC11 microcontroller. SCK of the 68HC11 drives SCLK of the AD7849, while the MOSI output drives the serial data line of the AD7849. The  $\overline{\text{SYNC}}$  signal is derived from a port line (PC0 shown).

For correct operation of this interface, the 68HC11 should be configured such that its CPOL bit is a 0 and its CPHA bit is a 1. When data is transmitted to the part, PC0 is taken low. When the 68HC11 is configured like this, data on MOSI is valid on the falling edge of SCK. The 68HC11 transmits its serial data in 8-bit bytes with only eight falling clock edges occurring in the transmit cycle. To load data to the AD7849, PC0 is left low after the first eight bits are transferred, and a second byte of data is then transferred serially to the AD7849. When the second serial transfer is complete, the PC0 line is taken high.

Figure 26 shows the  $\overline{\text{LDAC}}$  input of the AD7849 being driven from another bit programmable port line (PC1). As a result, the DAC can be updated by taking  $\overline{\text{LDAC}}$  low after the DAC input register has been loaded.

Figure 26. AD7849-to-68HC11 Interface

## AD7849-to-87C51 Interface

A serial interface between the AD7849 and the 87C51 microcontroller is shown in Figure 27. TXD of the 87C51 drives SCLK of the AD7849, while RXD drives the serial data line of the part. The  $\overline{\text{SYNC}}$  signal is derived from the P3.3 port line, and the  $\overline{\text{LDAC}}$  line is driven from the P3.2 port line.

The 87C51 provides the LSB of its SBUF register as the first bit in the serial data stream. Therefore, ensure that the data in the SBUF register is arranged correctly so that the most significant bits are the first to be transmitted to the AD7849, and the last bit to be sent is the LSB of the word to be loaded to the AD7849. When data is transmitted to the part, P3.3 is taken low. Data on RXD is valid on the falling edge of TXD. The 87C51 transmits its serial data in 8-bit bytes, with only eight falling clock edges occurring in the transmit cycle. To load data to the AD7849, P3.3 is left low after the first eight bits are transferred, and a second byte of data is then transferred serially to the AD7849. When the second serial transfer is complete, the P3.3 line is taken high.

Figure 27 shows the  $\overline{\text{LDAC}}$  input of the AD7849 driven from the bit programmable P3.2 port line. As a result, the DAC output can be updated by taking the  $\overline{\text{LDAC}}$  line low following the completion of the write cycle. Alternatively,  $\overline{\text{LDAC}}$  can be hardwired low, and the analog output is updated on the 16th falling edge of TXD after the  $\overline{\text{SYNC}}$  signal for the DAC goes low.

**NOTES**

Компания «ЭлектроПласт» предлагает заключение долгосрочных отношений при поставках импортных электронных компонентов на взаимовыгодных условиях!

Наши преимущества:

- Оперативные поставки широкого спектра электронных компонентов отечественного и импортного производства напрямую от производителей и с крупнейших мировых складов;
- Поставка более 17-ти миллионов наименований электронных компонентов;
- Поставка сложных, дефицитных, либо снятых с производства позиций;
- Оперативные сроки поставки под заказ (от 5 рабочих дней);
- Экспресс доставка в любую точку России;
- Техническая поддержка проекта, помощь в подборе аналогов, поставка прототипов;
- Система менеджмента качества сертифицирована по Международному стандарту ISO 9001;
- Лицензия ФСБ на осуществление работ с использованием сведений, составляющих государственную тайну;
- Поставка специализированных компонентов (Xilinx, Altera, Analog Devices, Intersil, Interpoint, Microsemi, Aeroflex, Peregrine, Syfer, Eurofarad, Texas Instrument, Miteq, Cobham, E2V, MA-COM, Hittite, Mini-Circuits, General Dynamics и др.);

Помимо этого, одним из направлений компании «ЭлектроПласт» является направление «Источники питания». Мы предлагаем Вам помощь Конструкторского отдела:

- Подбор оптимального решения, техническое обоснование при выборе компонента;
- Подбор аналогов;
- Консультации по применению компонента;
- Поставка образцов и прототипов;
- Техническая поддержка проекта;
- Защита от снятия компонента с производства.
