OUTLINE

The R3114x series are CMOS-based voltage detector ICs with high detector threshold accuracy and ultra-low supply current, which can be operated at an extremely low voltage and is used for system reset as an example.

TIMING CHART

DEFINITION OF OUTPUT DELAY TIME

Output Delay Time (t_{PLH}) is defined as follows:

1. In the case of Nch Open Drain Output:

Under the condition of the output pin (OUT) is pulled up through a resistor of 470k Ω to 5V, the time interval between the rising edge of V_{DD} pulse from 0.55V to $(-V_{DET})+2.0V$ or the time interval of 6.0V pulse voltage is supplied, the becoming of the output voltage to 2.5V.

2. In the case of CMOS Output:

The time interval between the rising edge of V_{DD} pulse from 0.55V to $(-V_{DET})+2.0V$ or the time interval of 6.0V pulse voltage is supplied, the becoming of the output voltage to $((-V_{DET})+2.0V)/2$ or 3.0V.

*Note2) 1. In the case of CMOS output type:

When the voltage is forced from 0.55V to (-V_{DET})+2.0V or a 6.0V pulse voltage is added to V_{DD}, time interval that the output voltage reaches ((-V_{DET})+2.0V)/2 or a 3.0V.

2. In the case of Nch Open Drain output type:

The output pin is pulled up to 5.0V through 470k Ω , and when the voltage is forced from 0.55V to (-V_{DET})+2.0V or a 6.0V pulse voltage is added to V_{DD}, time interval that the output voltage reaches 2.5V.

OPERATION

• Operation of R3114xxx1A

Block Diagram (R3114xxx1A)

Operation Diagram

• Explanation of operation

Step 1. The output voltage is equal to the pull-up voltage.

Step 2. At Point "A", $V_{ref} \geq V_{DD} \times (R_b + R_c) / (R_a + R_b + R_c)$ is true, as a result, the output of comparator is reversed from "L" to "H", therefore the output voltage becomes the GND level. The voltage level of Point A means a detector threshold voltage ($-V_{DET}$).

Step 3. When the supply voltage is lower than the minimum operating voltage, the operation of the output transistor becomes indefinite. The output voltage is equal to the pull-up voltage.

Step 4. The output voltage is equal to the GND level.

Step 5. At Point "B", $V_{ref} \leq V_{DD} \times R_b / (R_a + R_b)$ is true, as a result, the output of comparator is reversed from "H" to "L", then the output voltage is equal to the pull-up voltage. The voltage level of Point B means a released voltage ($+V_{DET}$).

*) The difference between a released voltage and a detector threshold voltage is a detector threshold hysteresis.

Block Diagram (R3114xxx1C)

• Explanation of operation

- Step 1. The output voltage is equal to the supply voltage (V_{DD}).
- Step 2. At Point "A", $V_{ref} \geq V_{DD} \times (Rb+Rc)/(Ra+Rb+Rc)$ is true, as a result, the output of comparator is reversed from "L" to "H", therefore the output voltage becomes the GND level. The voltage level of Point A means a detector threshold voltage ($-V_{DET}$).
- Step 3. When the supply voltage is lower than the minimum operating voltage, the operation of the output transistor becomes indefinite.
- Step 4. The output voltage is equal to the GND level.
- Step 5. At Point "B", $V_{ref} \leq V_{DD} \times Rb/(Ra+Rb)$ is true, as a result, the output of comparator is reversed from "H" to "L", then the output voltage is equal to the supply voltage (V_{DD}). The voltage level of Point B means a released voltage ($+V_{DET}$).
- *) The difference between a released voltage and a detector threshold voltage is a detector threshold hysteresis.

Detector Operation vs. glitch input voltage to the V_{DD} pin

When the R3114x is at released, if the pulse voltage which the detector threshold or lower voltage, the graph below means that the relation between pulse width and the amplitude of the swing to keep the released state for the R3114x.

V_{DD} Input Waveform

This graph shows the maximum pulse conditions to keep the released voltage. If the pulse with larger amplitude or wider width than the graph above, is input to V_{DD} pin, the reset signal may be output.

TECHNICAL NOTES

When connecting resistors to the device's input pin

When connecting a resistor (R1) to an input of this device, the input voltage decreases by [Device's Consumption Current] x [Resistance Value] only. And, the cross conduction current^{*1}, which occurs when changing from the detecting state to the release state, is decreased the input voltage by [Cross Conduction Current] x [Resistance Value] only. And then, this device will enter the re-detecting state if the input voltage reduction is larger than the difference between the detector voltage and the released voltage.

When the input resistance value is large and the VDD is gone up at mildly in the vicinity of the released voltage, repeating the above operation may result in the occurrence of output.

As shown in Figure A/B, set R1 to become 100 kΩ or less as a guide, and connect C_{IN} of 0.1 μF and more to between the input pin and GND. Besides, make evaluations including temperature properties under the actual usage condition, with using the evaluation board like this way. As a result, make sure that the cross conduction current has no problem.
